

# CHEMISTRY

The background of the cover is a complex, three-dimensional molecular structure. It features a series of interconnected hexagonal rings, similar to a carbon nanotube or a honeycomb lattice, rendered in a translucent, glowing style. The structure is composed of white and grey spheres (atoms) connected by lines (bonds). The overall color palette is dominated by cool blues and purples, with bright, fiery orange and yellow highlights that suggest energy or chemical reactions. The perspective is dynamic, with the structure appearing to curve and recede into the distance.

## ABOUT THE AUTHOR

**NIVALDO TRO** is a professor of chemistry at Westmont College in Santa Barbara, California, where he has been a faculty member since 1990. He received his Ph.D. in chemistry from Stanford University for work on developing and using optical techniques to study the adsorption and desorption of molecules to and from surfaces in ultrahigh vacuum. He then went on to the University of California at Berkeley, where he did postdoctoral research on ultrafast reaction dynamics in solution. Since coming to Westmont, Professor Tro has been awarded grants from the American Chemical Society Petroleum Research Fund, from Research Corporation, and from the National Science Foundation to study the dynamics of various processes occurring in thin adlayer films adsorbed on dielectric surfaces. He has been honored as Westmont's outstanding teacher of the year three times and has also received the college's outstanding researcher of the year award. Professor Tro lives in Santa Barbara with his wife, Ann, and their four children, Michael, Ali, Kyle, and Kaden.

TO MICHAEL, ALI, KYLE, AND KADEN

# BRIEF CONTENTS

<b>1</b>	Matter, Measurement, and Problem Solving	ii
<b>2</b>	Atoms and Elements	44
<b>3</b>	Molecules, Compounds, and Chemical Equations	86
<b>4</b>	Chemical Quantities and Aqueous Reactions	138
<b>5</b>	Gases	196
<b>6</b>	Thermochemistry	248
<b>7</b>	The Quantum-Mechanical Model of the Atom	296
<b>8</b>	Periodic Properties of the Elements	336
<b>9</b>	Chemical Bonding I: The Lewis Model	382
<b>10</b>	Chemical Bonding II: Molecular Shapes, Valence Bond Theory, and Molecular Orbital Theory	426
<b>11</b>	Liquids, Solids, and Intermolecular Forces	484
<b>12</b>	Solids and Modern Materials	532
<b>13</b>	Solutions	570
<b>14</b>	Chemical Kinetics	622
<b>15</b>	Chemical Equilibrium	674
<b>16</b>	Acids and Bases	722
<b>17</b>	Aqueous Ionic Equilibrium	778
<b>18</b>	Free Energy and Thermodynamics	838
<b>19</b>	Electrochemistry	888
<b>20</b>	Radioactivity and Nuclear Chemistry	938
<b>21</b>	Organic Chemistry	978
<b>22</b>	Biochemistry	1028
<b>23</b>	Chemistry of the Nonmetals	1062
<b>24</b>	Metals and Metallurgy	1100
<b>25</b>	Transition Metals and Coordination Compounds	1126
<b>Appendix I</b> Common Mathematical Operations in Chemistry		A-1
<b>Appendix II</b> Useful Data		A-5
<b>Appendix III</b> Answers to Selected Exercises		A-15
<b>Appendix IV</b> Answers to In-Chapter Practice Problems		A-54

# INTERACTIVE MEDIA CONTENTS

**Interactive Worked Examples (IWEs)** [https://media.pearsoncmg.com/ph/esm/esm\\_tro\\_chemistry\\_4/media/index.html](https://media.pearsoncmg.com/ph/esm/esm_tro_chemistry_4/media/index.html)

- 1.5** Determining the Number of Significant Figures in a Number
- 1.6** Significant Figures in Calculations
- 1.8** Unit Conversion
- 1.9** Unit Conversions Involving Units Raised to a Power
- 1.10** Density as a Conversion Factor
- 1.12** Problems with Equations
- 2.3** Atomic Numbers, Mass Numbers, and Isotope Symbols
- 2.5** Atomic Mass
- 2.8** The Mole Concept—Converting between Mass and Number of Atoms
- 2.9** The Mole Concept
- 3.3** Writing Formulas for Ionic Compounds
- 3.11** Using the Nomenclature Flow Chart to Name Compounds
- 3.13** The Mole Concept—Converting between Mass and Number of Molecules
- 3.16** Chemical Formulas as Conversion Factors
- 3.18** Obtaining an Empirical Formula from Experimental Data
- 3.21** Determining an Empirical Formula from Combustion Analysis
- 3.23** Balancing Chemical Equations
- 4.1** Stoichiometry
- 4.3** Limiting Reactant and Theoretical Yield
- 4.5** Calculating Solution Concentration
- 4.6** Using Molarity in Calculations
- 4.8** Solution Stoichiometry
- 4.10** Writing Equations for Precipitation Reactions
- 5.5** Ideal Gas Law I
- 5.7** Density
- 5.8** Molar Mass of a Gas
- 5.12** Gases in Chemical Reactions
- 5.15** Graham's Law of Effusion
- 6.2** Temperature Changes and Heat Capacity
- 6.3** Thermal Energy Transfer
- 6.5** Measuring  $\Delta E_{\text{rxn}}$  in a Bomb Calorimeter
- 6.7** Stoichiometry Involving  $\Delta H$
- 6.8** Measuring  $\Delta H_{\text{rxn}}$  in a Coffee-Cup Calorimeter
- 6.11**  $\Delta H_{\text{rxn}}^\circ$  and the Standard Enthalpies of Formation
- 7.2** Photon Energy
- 7.3** Wavelength, Energy, and Frequency
- 7.5** Quantum Numbers I
- 7.7** Wavelength of Light for a Transition in the Hydrogen Atom
- 8.4** Writing Electron Configurations from the Periodic Table
- 8.5** Atomic Size
- 8.6** Electron Configurations and Magnetic Properties for Ions
- 8.8** First Ionization Energy
- 9.4** Writing Lewis Structures
- 9.6** Writing Lewis Structures for Polyatomic Ions
- 9.7** Writing Resonance Structures
- 9.8** Assigning Formal Charges
- 9.10** Writing Lewis Structures for Compounds Having Expanded Octets
- 9.11** Calculating  $\Delta H_{\text{rxn}}$  from Bond Energies
- 10.2** Predicting Molecular Geometries
- 10.4** Predicting the Shape of Larger Molecules
- 10.5** Determining Whether a Molecule Is Polar
- 10.8** Hybridization and Bonding Scheme
- 10.10** Molecular Orbital Theory
- 11.1** Dipole–Dipole Forces
- 11.2** Hydrogen Bonding
- 11.3** Using the Heat of Vaporization in Calculations
- 11.5** Using the Two-Point Form of the Clausius–Clapeyron Equation to Predict the Vapor Pressure at a Given Temperature
- 12.4** Relating Density to Crystal Structure
- 13.3** Using Parts by Mass in Calculations
- 13.4** Calculating Concentrations
- 13.5** Converting between Concentration Units
- 13.6** Calculating the Vapor Pressure of a Solution Containing a Nonelectrolyte and Nonvolatile Solute
- 13.9** Boiling Point Elevation
- 14.2** Determining the Order and Rate Constant of a Reaction
- 14.4** The First-Order Integrated Rate Law: Determining the Concentration of a Reactant at a Given Time
- 14.8** Using the Two-Point Form of the Arrhenius Equation
- 14.9** Reaction Mechanisms
- 15.1** Expressing Equilibrium Constants for Chemical Equations
- 15.5** Finding Equilibrium Constants from Experimental Concentration Measurements
- 15.8** Finding Equilibrium Concentrations When You Know the Equilibrium Constant and All but One of the Equilibrium Concentrations of the Reactants and Products
- 15.9** Finding Equilibrium Concentrations from Initial Concentrations and the Equilibrium Constant
- 15.12** Finding Equilibrium Concentrations from Initial Concentrations in Cases with a Small Equilibrium Constant
- 15.14** The Effect of a Concentration Change on Equilibrium
- 16.1** Identifying Brønsted–Lowry Acids and Bases and Their Conjugates

- 16.3** Calculating pH from  $[\text{H}_3\text{O}^+]$  or  $[\text{OH}^-]$
- 16.5** Finding the  $[\text{H}_3\text{O}^+]$  of a Weak Acid Solution
- 16.7** Finding the pH of a Weak Acid Solution in Cases Where the  $x$  is *small* Approximation Does Not Work
- 16.8** Finding the Equilibrium Constant from pH
- 16.9** Finding the Percent Ionization of a Weak Acid
- 16.12** Finding the  $[\text{OH}^-]$  and pH of a Weak Base Solution
- 16.14** Determining the pH of a Solution Containing an Anion Acting as a Base
- 17.2** Calculating the pH of a Buffer Solution as an Equilibrium Problem and with the Henderson–Hasselbalch Equation
- 17.3** Calculating the pH Change in a Buffer Solution after the Addition of a Small Amount of Strong Acid or Base
- 17.4** Using the Henderson–Hasselbalch Equation to Calculate the pH of a Buffer Solution Composed of a Weak Base and Its Conjugate Acid
- 17.6** Strong Acid–Strong Base Titration pH Curve
- 17.7** Weak Acid–Strong Base Titration pH Curve
- 17.8** Calculating Molar Solubility from  $K_{\text{sp}}$
- 18.4** Calculating Gibbs Free Energy Changes and Predicting Spontaneity from  $\Delta H$  and  $\Delta S$
- 18.5** Calculating Standard Entropy Changes ( $\Delta S_{\text{rxn}}^\circ$ )
- 18.6** Calculating the Standard Change in Free Energy for a Reaction Using  $\Delta G_{\text{rxn}}^\circ = \Delta H_{\text{rxn}}^\circ - T\Delta S_{\text{rxn}}^\circ$
- 18.10** Calculating  $\Delta G_{\text{rxn}}$  under Nonstandard Conditions
- 18.11** The Equilibrium Constant and  $\Delta G_{\text{rxn}}^\circ$
- 19.2** Half-Reaction Method of Balancing Aqueous Redox Equations in Acidic Solution
- 19.3** Balancing Redox Reactions Occurring in Basic Solution
- 19.4** Calculating Standard Potentials for Electrochemical Cells from Standard Electrode Potentials of the Half-Reactions
- 19.6** Relating  $\Delta G^\circ$  and  $E_{\text{cell}}^\circ$
- 20.1** Writing Nuclear Equations for Alpha Decay
- 20.2** Writing Nuclear Equations for Beta Decay, Positron Emission, and Electron Capture
- 20.4** Radioactive Decay Kinetics
- 20.5** Radiocarbon Dating
- 21.3** Naming Alkanes

### Key Concept Videos (KCVs) [https://media.pearsoncmg.com/ph/esm/esm\\_tro\\_chemistry\\_4/media/index.html](https://media.pearsoncmg.com/ph/esm/esm_tro_chemistry_4/media/index.html)

- 1.1** Atoms and Molecules
- 1.3** Classifying Matter
- 1.8** Solving Chemical Problems
- 2.3** Atomic Theory
- 2.6** Subatomic Particles and Isotope Symbols
- 2.9** The Mole Concept
- 3.5** Naming Ionic Compounds
- 3.6** Naming Molecular Compounds
- 3.11** Writing and Balancing Chemical Equations
- 4.2** Reaction Stoichiometry
- 4.3** Limiting Reactant, Theoretical Yield, and Percent Yield
- 4.6** Reactions in Solution
- 5.3** Simple Gas Laws and Ideal Gas Law
- 5.4** Simple Gas Laws and Ideal Gas Law
- 5.6** Mixtures of Gases and Partial Pressures
- 5.8** Kinetic Molecular Theory
- 6.3** The First Law of Thermodynamics
- 6.4** Heat Capacity
- 6.6** The Change in Enthalpy for a Chemical Reaction
- 7.2** The Nature of Light
- 7.4** The Wave Nature of Matter
- 7.5** Quantum Mechanics and the Atom: Orbitals and Quantum Numbers
- 8.3** Electron Configurations
- 8.4** Writing an Electron Configuration based on an Element's Position on the Periodic Table
- 8.6** Periodic Trends in the Size of Atomic Effective Nuclear Charge
- 9.5** The Lewis Model for Chemical Bonding
- 9.7** Writing Lewis Structures for Molecular Compounds
- 9.8** Resonance and Formal Charge
- 10.2** VSEPR Theory
- 10.3** VSEPR Theory: The Effect of Lone Pairs
- 10.6** Valence Bond Theory
- 10.7** Valence Bond Theory: Hybridization
- 11.3** Intermolecular Forces
- 11.5** Vaporization and Vapor Pressure
- 11.7** Heating Curve for Water
- 11.8** Phase Diagrams
- 12.3** Unit Cells: Simple Cubic, Body-Centered Cubic, and Face-Centered Cubic
- 13.4** Solution Equilibrium and the Factors Affecting Solubility
- 13.5** Solution Concentration: Molarity, Molality, Parts by Mass and Volume, Mole Fraction
- 13.6** Colligative Properties
- 14.3** The Rate Law for a Chemical Reaction
- 14.4** The Integrated Rate Law
- 14.5** The Effect of Temperature on Reaction Rate
- 15.3** The Equilibrium Constant
- 15.8** Finding Equilibrium Concentrations from Initial Concentrations
- 15.9** Le Châtelier's Principle
- 16.3** Definitions of Acids and Bases
- 16.6** Finding the  $[\text{H}_3\text{O}^+]$  and pH of Strong and Weak Acid Solutions
- 16.8** The Acid–Base Properties of Ions and Salts
- 17.2** Buffers
- 17.2** Finding pH and pH Changes in Buffer Solutions
- 17.4** The Titration of a Weak Acid and a Strong Base
- 18.3** Entropy and the Second Law of Thermodynamics
- 18.6** The Effect of  $\Delta H$ ,  $\Delta S$ , and  $T$  on Reaction Spontaneity
- 18.7** Standard Molar Entropies
- 19.4** Standard Electrode Potentials
- 19.5** Cell Potential, Free Energy, and the Equilibrium Constant
- 20.3** Types of Radioactivity

# CONTENTS

PREFACE xxii

## 1 Matter, Measurement, and Problem Solving xxxiv

- 1.1 Atoms and Molecules 1
- 1.2 The Scientific Approach to Knowledge 3
  - The Nature of Science** Thomas S. Kuhn and Scientific Revolutions 5
- 1.3 The Classification of Matter 5
  - The States of Matter: Solid, Liquid, and Gas 6
  - Classifying Matter according to Its Composition: Elements, Compounds, and Mixtures 7
  - Separating Mixtures 8
- 1.4 Physical and Chemical Changes and Physical and Chemical Properties 9
- 1.5 Energy: A Fundamental Part of Physical and Chemical Change 12
- 1.6 The Units of Measurement 13
  - Standard Units 13 The Meter: A Measure of Length 14 The Kilogram: A Measure of Mass 14 The Second: A Measure of Time 14 The Kelvin: A Measure of Temperature 15
  - Prefix Multipliers 17 Derived Units: Volume and Density 17 Calculating Density 19
  - Chemistry and Medicine** Bone Density 20
- 1.7 The Reliability of a Measurement 20
  - Counting Significant Figures 22 Exact Numbers 22 Significant Figures in Calculations 23 Precision and Accuracy 25
  - Chemistry in Your Day** Integrity in Data Gathering 26
- 1.8 Solving Chemical Problems 26
  - Converting from One Unit to Another 26 General Problem-Solving Strategy 28 Units Raised to a Power 30 Order-of-Magnitude Estimations 31
  - Problems Involving an Equation 32
- CHAPTER IN REVIEW** Self-Assessment Quiz 33 Key Terms 34 Key Concepts 35 Key Equations and Relationships 35 Key Learning Outcomes 36
- EXERCISES** Review Questions 36 Problems by Topic 36 Cumulative Problems 40 Challenge Problems 41 Conceptual Problems 42 Questions for Group Work 42 Data Interpretation and Analysis 43 Answers to Conceptual Connections 43

## 2 Atoms and Elements 44

- 2.1 Brownian Motion: Atoms Confirmed 45
- 2.2 Early Ideas About the Building Blocks of Matter 47
- 2.3 Modern Atomic Theory and the Laws That Led to It 47
  - The Law of Conservation of Mass 47 The Law of Definite Proportions 48 The Law of Multiple Proportions 49 John Dalton and the Atomic Theory 50
  - Chemistry in Your Day** Atoms and Humans 50
- 2.4 The Discovery of the Electron 51
  - Cathode Rays 51 Millikan's Oil Drop Experiment: The Charge of the Electron 52
- 2.5 The Structure of the Atom 53
- 2.6 Subatomic Particles: Protons, Neutrons, and Electrons in Atoms 55
  - Elements: Defined by Their Numbers of Protons 56
  - Isotopes: When the Number of Neutrons Varies 57
  - Ions: Losing and Gaining Electrons 59
  - Chemistry in Your Day** Where Did Elements Come From? 60
- 2.7 Finding Patterns: The Periodic Law and the Periodic Table 60
  - Modern Periodic Table Organization 62 Ions and the Periodic Table 64
  - Chemistry and Medicine** The Elements of Life 65
- 2.8 Atomic Mass: The Average Mass of an Element's Atoms 65
  - Mass Spectrometry: Measuring the Mass of Atoms and Molecules 66
  - Chemistry in Your Day** Evolving Atomic Masses 68
- 2.9 Molar Mass: Counting Atoms by Weighing Them 69
  - The Mole: A Chemist's "Dozen" 69 Converting between Number of Moles and Number of Atoms 70
  - Converting between Mass and Amount (Number of Moles) 71

## CHAPTER IN REVIEW Self-Assessment Quiz 74

Key Terms 75 Key Concepts 76 Key Equations and Relationships 76 Key Learning Outcomes 77

## EXERCISES Review Questions 77 Problems by Topic 78

Cumulative Problems 81 Challenge Problems 82  
Conceptual Problems 83 Questions for Group Work 83  
Data Interpretation and Analysis 84  
Answers to Conceptual Connections 85

# 3 Molecules, Compounds, and Chemical Equations 86

## 3.1 Hydrogen, Oxygen, and Water 87

## 3.2 Chemical Bonds 89

Ionic Bonds 89 Covalent Bonds 90

## 3.3 Representing Compounds: Chemical Formulas and Molecular Models 90

Types of Chemical Formulas 90 Molecular Models 92

## 3.4 An Atomic-Level View of Elements and Compounds 92

## 3.5 Ionic Compounds: Formulas and Names 96

Writing Formulas for Ionic Compounds 96  
Naming Ionic Compounds 97 Naming Binary Ionic Compounds Containing a Metal That Forms Only One Type of Cation 98 Naming Binary Ionic Compounds Containing a Metal That Forms More Than One Kind of Cation 99 Naming Ionic Compounds Containing Polyatomic Ions 100 Hydrated Ionic Compounds 101

## 3.6 Molecular Compounds: Formulas and Names 101

Naming Molecular Compounds 102 Naming Acids 103 Naming Binary Acids 103 Naming Oxyacids 104

**Chemistry in the Environment** Acid Rain 104

## 3.7 Summary of Inorganic Nomenclature 105

## 3.8 Formula Mass and the Mole Concept for Compounds 107

Molar Mass of a Compound 107 Using Molar Mass to Count Molecules by Weighing 107

## 3.9 Composition of Compounds 109

Mass Percent Composition as a Conversion Factor 110 Conversion Factors from Chemical Formulas 112

**Chemistry and Medicine** Methylmercury in Fish 114

## 3.10 Determining a Chemical Formula from Experimental Data 114

Determining Molecular Formulas for Compounds 116 Combustion Analysis 117

## 3.11 Writing and Balancing Chemical Equations 119

## 3.12 Organic Compounds 123

Hydrocarbons 124 Functionalized Hydrocarbons 125

## CHAPTER IN REVIEW Self-Assessment Quiz 127

Key Terms 127 Key Concepts 128 Key Equations and Relationships 128 Key Learning Outcomes 129

## EXERCISES Review Questions 129 Problems by Topic 130

Conceptual Problems 135 Questions for Group Work 135  
Data Interpretation and Analysis 136  
Answers to Conceptual Connections 137

# 4 Chemical Quantities and Aqueous Reactions 138

## 4.1 Climate Change and the Combustion of Fossil Fuels 139

## 4.2 Reaction Stoichiometry: How Much Carbon Dioxide? 141

Making Pizza: The Relationships among Ingredients 141 Making Molecules: Mole-to-Mole Conversions 141 Making Molecules: Mass-to-Mass Conversions 142

## 4.3 Limiting Reactant, Theoretical Yield, and Percent Yield 145

Calculating Limiting Reactant, Theoretical Yield, and Percent Yield 146 Calculating Limiting Reactant, Theoretical Yield, and Percent Yield from Initial Reactant Masses 147

## 4.4 Solution Concentration and Solution Stoichiometry 151

Solution Concentration 151 Using Molarity in Calculations 153 Solution Dilution 154 Solution Stoichiometry 156

## 4.5 Types of Aqueous Solutions and Solubility 158

Electrolyte and Nonelectrolyte Solutions 158 The Solubility of Ionic Compounds 160

- 4.6 Precipitation Reactions** 162
- 4.7 Representing Aqueous Reactions: Molecular, Ionic, and Complete Ionic Equations** 166
- 4.8 Acid–Base and Gas-Evolution Reactions** 167  
Acid–Base Reactions 168 Gas-Evolution Reactions 173
- 4.9 Oxidation–Reduction Reactions** 175  
Oxidation States 176 Identifying Redox Reactions 178
- Chemistry in Your Day** Bleached Blonde 181  
Combustion Reactions 181

**CHAPTER IN REVIEW** Self-Assessment Quiz 182  
Key Terms 183 Key Concepts 184 Key Equations and Relationships 185 Key Learning Outcomes 185

**EXERCISES** Review Questions 186 Problems by Topic 186  
Cumulative Problems 190 Challenge Problems 192  
Conceptual Problems 192 Questions for Group Work 193  
Data Interpretation and Analysis 194  
Answers to Conceptual Connections 195

## 5 Gases 196

- 5.1 Supersonic Skydiving and the Risk of Decompression** 197
- 5.2 Pressure: The Result of Molecular Collisions** 198  
Pressure Units 199 The Manometer: A Way to Measure Pressure in the Laboratory 200  
**Chemistry and Medicine** Blood Pressure 201
- 5.3 The Simple Gas Laws: Boyle's Law, Charles's Law, and Avogadro's Law** 201  
Boyle's Law: Volume and Pressure 202 Charles's Law: Volume and Temperature 204  
**Chemistry in Your Day** Extra-Long Snorkels 205  
Avogadro's Law: Volume and Amount (in Moles) 207
- 5.4 The Ideal Gas Law** 208
- 5.5 Applications of the Ideal Gas Law: Molar Volume, Density, and Molar Mass of a Gas** 211  
Molar Volume at Standard Temperature and Pressure 211 Density of a Gas 212 Molar Mass of a Gas 213
- 5.6 Mixtures of Gases and Partial Pressures** 214  
Deep-Sea Diving and Partial Pressures 217  
Collecting Gases over Water 219

- 5.7 Gases in Chemical Reactions: Stoichiometry Revisited** 221  
Molar Volume and Stoichiometry 222
- 5.8 Kinetic Molecular Theory: A Model for Gases** 224  
How Kinetic Molecular Theory Explains Pressure and the Simple Gas Laws 225 Kinetic Molecular Theory and the Ideal Gas Law 226 Temperature and Molecular Velocities 227
- 5.9 Mean Free Path, Diffusion, and Effusion of Gases** 230
- 5.10 Real Gases: The Effects of Size and Intermolecular Forces** 232  
The Effect of the Finite Volume of Gas Particles 233  
The Effect of Intermolecular Forces 234 Van der Waals Equation 235 Real Gases 235

**CHAPTER IN REVIEW** Self-Assessment Quiz 236  
Key Terms 237 Key Concepts 237 Key Equations and Relationships 238 Key Learning Outcomes 238

**EXERCISES** Review Questions 239 Problems by Topic 240  
Cumulative Problems 243 Challenge Problems 245  
Conceptual Problems 245 Questions for Group Work 246

# PREFACE

## To the Student

As you begin this course, I invite you to think about your reasons for enrolling in it. Why are you taking general chemistry? More generally, why are you pursuing a college education? If you are like most college students taking general chemistry, part of your answer is probably that this course is required for your major and that you are pursuing a college education so you can get a good job some day. Although these are good reasons, I would like to suggest a better one. I think the primary reason for your education is to prepare you to *live a good life*. You should understand chemistry—not for what it can *get* you—but for what it can *do* to you. Understanding chemistry, I believe, is an important source of happiness and fulfillment. Let me explain.

Understanding chemistry helps you to live life to its fullest for two basic reasons. The first is *intrinsic*: through an understanding of chemistry, you gain a powerful appreciation for just how rich and extraordinary the world really is. The second reason is *extrinsic*: understanding chemistry makes you a more informed citizen—it allows you to engage with many of the issues of our day. In other words, understanding chemistry makes *you* a deeper and richer person and makes your country and the world a better place to live. These reasons have been the foundation of education from the very beginnings of civilization.

How does chemistry help prepare you for a rich life and conscientious citizenship? Let me explain with two examples. My first one comes from the very first page of Chapter 1 of this book. There, I ask the following question: What is the most important idea in all of scientific knowledge? My answer to that question is this: **the behavior of matter is determined by the properties of molecules and atoms**. That simple statement is the reason I love chemistry. We humans have been able to study the substances that compose the world around us and explain their behavior by reference to particles so small that they can hardly be imagined. If you have never realized the remarkable sensitivity of the world we *can* see to the world we *cannot*, you have missed out on a fundamental truth about our universe. To have never encountered this truth is like never having read a play by Shakespeare or seen a sculpture by Michelangelo—or, for that matter, like never having discovered that the world is round. It robs you of an amazing and unforgettable experience of the world and the human ability to understand it.

My second example demonstrates how science literacy helps you to be a better citizen. Although I am largely sympathetic to the environmental movement, a lack of science literacy within some sectors of that movement and the resulting anti-environmental backlash create confusion that impedes

real progress and opens the door to what could be misinformed policies. For example, I have heard conservative pundits say that volcanoes emit more carbon dioxide—the most significant greenhouse gas—than does petroleum combustion. I have also heard a liberal environmentalist say that we have to stop using hairspray because it is causing holes in the ozone layer that will lead to global warming. Well, the claim about volcanoes emitting more carbon dioxide than petroleum combustion can be refuted by the basic tools you will learn to use in Chapter 4 of this book. We can easily show that volcanoes emit only 1/50th as much carbon dioxide as petroleum combustion. As for hairspray depleting the ozone layer and thereby leading to global warming, the chlorofluorocarbons that deplete ozone have been banned from hairspray since 1978, and ozone depletion has nothing to do with global warming anyway. People with special interests or axes to grind can conveniently distort the truth before an ill-informed public, which is why we all need to be knowledgeable.

So this is why I think you should take this course. Not just to satisfy the requirement for your major, and not just to get a good job some day, but to help you to lead a fuller life and to make the world a little better for everyone. I wish you the best as you embark on the journey to understand the world around you at the molecular level. The rewards are well worth the effort.

## To the Professor

First and foremost, thanks to all of you who adopted this book in its previous editions. You helped to make this book one of the most popular general chemistry textbooks in the world. I am grateful beyond words. Second, I have listened carefully to your feedback on the previous edition. The changes you see in this edition are the direct result of your input, as well as my own experience using the book in my general chemistry courses. If you have reviewed content or have contacted me directly, you will likely see your suggestions reflected in the changes I have made. Thank you.

Some of the most exciting changes in this edition are in the media associated with the book. I have added approximately 57 new Key Concept Videos and 61 new Interactive Worked examples to the media package. You can see a more detailed description of these videos in the following section entitled *What's New in This Edition*. This means that you now have a library of over 150 interactive videos to enhance your course. In my courses, I use these videos to implement a *before, during, after* strategy for my students. My goal is simple: *Engage students in active learning before class, during class, and after class*. To that end, I assign a key concept video *before* each class session.

The video introduces students to a key concept for that day and gets them thinking about it before they come to class. *During* class, I expand on the concept and use *Learning Catalytics* to question my students. Instead of passively listening to a lecture, they are interacting with the concepts through questions that I pose. Some of these questions are answered individually; other times I have them pair up with a partner. This approach has changed my classroom. Students engage in the material in new ways. They have to think and process and interact. It is deeply satisfying for me to see my students so engaged. Finally, *after* class, I give them another assignment, often an interactive worked example with a follow-up question. At this point, they have to apply what they have learned to solve a problem.

The results have been fantastic. My students are enjoying the process because they are engaged before, during, and after class rather than only looking at material the night before a problem set is due. I have seen evidence of their improved learning through increases in their scores on the American Chemical Society Standard General Chemistry Exam, which I always administer as the final exam for my course.

Although we have added exciting new media elements and made other changes to the book, the book's goal remains the same: *to present a rigorous and accessible treatment of general chemistry in the context of relevance*. Teaching general chemistry would be much easier if all of our students had exactly the same level of preparation and ability. But alas, that is not the case. Even though I teach at a relatively selective institution, my courses are populated with students with a range of backgrounds and abilities in chemistry. The challenge of successful teaching, in my opinion, is figuring out how to instruct and challenge the best students while not losing those with lesser backgrounds and abilities. My strategy has always been to set the bar relatively high, while at the same time providing the motivation and support necessary to reach the high bar. That is exactly the philosophy of this book. We do not have to compromise away rigor in order to make chemistry accessible to our students. In this book, I have worked hard to combine rigor with accessibility—to create a book that does not dilute the content, yet can be used and understood by any student willing to put in the necessary effort.

*Chemistry: A Molecular Approach* is first and foremost a *student-oriented book*. My main goal is to motivate students and get them to achieve at the highest possible level. As we all know, many students take general chemistry because it is a requirement; they do not see the connection between chemistry and their lives or their intended careers. *Chemistry: A Molecular Approach* strives to make those connections consistently and effectively. Unlike other books, which often teach chemistry as something that happens only in the laboratory or in industry, this book teaches chemistry in the context of relevance. It shows students *why* chemistry is important to them, to their future careers, and to their world.

Second, *Chemistry: A Molecular Approach* is a *pedagogically driven book*. In seeking to develop problem-solving skills, a consistent approach (Sort, Strategize, Solve, and Check) is applied, usually in a two- or three-column format.

In the two-column format, the left column shows the student how to analyze the problem and devise a solution strategy. It also lists the steps of the solution, explaining the rationale for each one, while the right column shows the implementation of each step. In the three-column format, the left column outlines the general procedure for solving an important category of problems that is then applied to two side-by-side examples. This strategy allows students to see both the general pattern and the slightly different ways in which the procedure may be applied in differing contexts. The aim is to help students understand both the *concept of the problem* (through the formulation of an explicit conceptual plan for each problem) and the *solution to the problem*.

Third, *Chemistry: A Molecular Approach* is a *visual book*. Wherever possible, I use images to deepen the student's insight into chemistry. In developing chemical principles, multipart images help show the connection between everyday processes visible to the unaided eye and what atoms and molecules are actually doing. Many of these images have three parts: macroscopic, molecular, and symbolic. This combination helps students to see the relationships between the formulas they write down on paper (symbolic), the world they see around them (macroscopic), and the atoms and molecules that compose that world (molecular). In addition, most figures are designed to teach rather than just to illustrate. They are rich with annotations and labels intended to help the student grasp the most important processes and the principles that underlie them. The resulting images are rich with information but also uncommonly clear and quickly understood.

Fourth, *Chemistry: A Molecular Approach* is a “big picture” book. At the beginning of each chapter, a short paragraph helps students to see the key relationships between the different topics they are learning. Through a focused and concise narrative, I strive to make the basic ideas of every chapter clear to the student. Interim summaries are provided at selected spots in the narrative, making it easier to grasp (and review) the main points of important discussions. And to make sure that students never lose sight of the forest for the trees, each chapter includes several *Conceptual Connections*, which ask them to think about concepts and solve problems without doing any math. I want students to learn the concepts, not just plug numbers into equations to churn out the right answer. This philosophy is also integral to the *Key Concept Videos*, which concisely reinforce student appreciation of the core concepts in each chapter.

*Chemistry: A Molecular Approach* is lastly a book that delivers the depth of coverage faculty want. We do not have to cut corners and water down the material in order to get our students interested. We have to meet them where they are, challenge them to the highest level of achievement, and support them with enough pedagogy to allow them to succeed.

I hope that this book supports you in your vocation of teaching students chemistry. I am increasingly convinced of the importance of our task. Please feel free to email me with any questions or comments about the book.

Nivaldo J. Tro  
tro@westmont.edu

## What's New in This Edition?

The book has been extensively revised and contains more small changes than can be detailed here. The most significant changes to the book and its supplements are listed below:

- **NEW!** Chapter 12: *Solids and Modern Materials*. This chapter contains new topics and consolidates content on materials that was found in other parts of the book in previous editions into one new chapter. All chapters beyond Chapter 12 have been renumbered.
- With the help of my colleagues, Thomas Greenbowe (University of Oregon), Kristin Ziebert (Oregon State University), and Michael Everest (Westmont College), I have added two new categories of end-of-chapter questions designed to help students build what we call “twenty-first-century skills.” The first new category of questions is *Data Interpretation and Analysis*. These questions present real data in real-life situations and ask students to analyze that data. These in-depth exercises give students much needed practice in reading graphs, digesting tables, and making data-driven decisions. The second new category of questions is *Questions for Group Work*. Our group work questions give students the opportunity to work with their peers in small groups. The questions can be used in or out of the classroom, but the idea is to foster collaborative learning and to encourage students to work together as a team to solve problems.
- I have added approximately 57 new Key Concept Videos and 61 new Interactive Worked Examples to the media package that accompanies the book. (Since the previous edition had 40 Interactive worked examples, there is now a total of 158 interactive videos.) These tools are designed to help professors engage their students in active learning. Recent research has conclusively demonstrated that students learn better when they are active in the learning process, as opposed to passively listening and simply taking in content. The Key Concept Videos are brief (two to five minutes), and each introduces a key concept from a chapter. The student does not just passively listen to the video; the video stops in the middle and poses a question to the student. The student must answer the question before the video continues. Each video also includes a follow-up question that is assignable in MasteringChemistry™. The Interactive Worked Examples are similar in concept, but instead of explaining a key concept, they walk the student through one of the in-chapter worked examples from the book. Like the Key Concept Videos, Interactive Worked Examples stop in the middle and force the student to interact by completing a step in the example. The examples also have a follow-up question that is assignable in MasteringChemistry™. The power of interactivity to make connections in problem solving is immense. I did not quite realize this power until we started creating the Interactive Worked Examples and I saw how I could use the animations to make connections that are just not possible on the static page.

- There are approximately 21 new Conceptual Connection questions throughout the book.
- All the data throughout the book have been updated to reflect the most recent measurements available. These updates include *Figure 4.2 Carbon Dioxide in the Atmosphere*; *Figure 4.3 Global Temperatures*; *Figure 4.25 U.S. Energy Consumption*; the unnumbered figure in Section 6.10 of *U.S. Energy Consumption*; *Figure 6.12 Energy Consumption by Source*; *Table 6.6 Changes in National Average Pollutant Levels, 1980–2013*; *Table 14.4 Change in Pollutant Levels*; *Figure 14.19 Ozone Depletion in the Antarctic Spring*; *Figure 16.15 Sources of U.S. Energy*; *Figure 16.16 Acid Rain*; and *Figure 16.18 U.S. Sulfur Dioxide Pollutant Levels*.
- Example 4.13 *Writing Equations for Acid–Base Reactions Involving a Strong Acid* and Example 14.2 *Determining the Order and Rate Constant of a Reaction* have been expanded.
- New worked examples have been added, including Example 4.14 *Writing Equations for Acid–Base Reactions Involving a Weak Acid*; Example 18.2 *Calculating  $\Delta S$  for a Change of State*; Example 12.2 *Calculating the Packing Efficiency of a Unit Cell*; and Example 12.3 *Relating Unit Cell Volume, Edge Length, and Atomic Radius*.
- Several chapter-opening sections and (or) the corresponding art, including Sections 1.1, 2.1, 5.1, 16.1, and 17.1, have been replaced or modified.
- New information about *Thermoluminescent Dosimeters*, including new Figure 20.7, has been added.
- A definition and explanation for the heat (or enthalpy) of sublimation have been added to Section 11.6.
- A new section (Section 18.4) on the *Entropy Changes Associated with State Changes* has been added. This section also includes expanded coverage on reversible and irreversible processes.
- Several sections in Chapter 20: *Radioactivity and Nuclear Chemistry* have been modified, including Sections 20.3 and 20.5 and Tables 20.1 and 20.4.
- Approximately 40 end-of-chapter problems (in addition to over 40 new problems that have been added to new Chapter 12) have been added or modified.

## Acknowledgments

The book you hold in your hands bears my name on the cover, but I am really only one member of a large team that carefully crafted this book. Most importantly, I thank my editor, Terry Haugen. Terry is a great editor and friend. He gives me the right balance of freedom and direction and always supports me in my endeavors. Thanks, Terry, for all you have done for me and for general chemistry courses throughout the world. I am also grateful to Jennifer Hart, who has now worked with me on multiple editions of several books and in several different roles, including her role overseeing development. Jennifer, your guidance, organizational skills, and wisdom are central to the success of my projects, and I am eternally grateful. I also thank my development editor Erin

Mulligan, who has worked with me on many projects over several editions. Erin is an outstanding thinker and word-smith who also has a great eye for detail and helps me tremendously on all aspects of my projects. Thank you, Erin. Thanks also to my media editor, Jackie Jakob. Jackie has been instrumental in helping me craft and develop the Key Concept Videos and Interactive Worked Examples that accompany this text. Her expertise, vision, and attention to detail are second to none. The quality and success of these videos are largely attributable to Jackie. Thanks, Jackie.

New to this edition is Sarah Shefveland. Although we have only worked together a short while, I am already indebted to her helpfulness. I am also grateful to Lindsey Pruett, who helped with organizing reviews, as well as numerous other tasks associated with keeping the team running smoothly. I am also grateful to Jeanne Zalesky, Editor-in-Chief for Physical Sciences. She has supported me and my projects and allowed me to succeed. I am also grateful to my team of marketing managers, Chris Barker and Elizabeth Ellsworth. Chris and I go way back, and I am excited to work with him in this new role. Elizabeth and I have only worked together for a short while, but I am already impressed by her energy and ideas for marketing this book. I continue to owe a special word of thanks to Glenn and Meg Turner of Burrston House, ideal collaborators whose contributions to the first edition of the book were extremely important and much appreciated. Quade and Emiko Paul, who make my ideas come alive with their art, have been with us from the beginning, and I owe a special debt of gratitude to them. I am also grateful to Derek Bacchus and Elise Landson for their creativity and hard work in crafting the design of this text. Finally, I would like to thank Beth Sweeten and the rest of the Pearson production team. They are a first-class operation—this text has benefited immeasurably from their talents and hard work. I also thank Francesca Monaco and her coworkers at CodeMantra. I am a picky author and Francesca is endlessly patient and a true professional. I am also greatly indebted to my copy editor, Betty Pessagno, for her dedication and professionalism, and to Eric Schrader for his exemplary photo research. And of course, I am continually grateful for Paul Corey, with whom I have now worked for over 15 years and 12 projects. Paul is a man of incredible energy and vision, and it is my great privilege to work with him. Paul told me many years ago (when he first signed me on to the Pearson team) to dream big, and then he provided the resources I needed to make those dreams come true. *Thanks, Paul.* I would also like to thank my first editor at Pearson, Kent Porter-Hamann. Kent and I spent many good years together writing books, and I continue to miss her presence in my work.

I acknowledge the help of my colleagues Allan Nishimura, Kristi Lazar, David Marten, Stephen Contakes, Michael Everest, and Carrie Hill who have supported me in my department while I worked on this book. I am also grateful to Gayle Beebe and Mark Sargent, the president and provost (respectively) of Westmont College, who have allowed me the time and space to work on my books. Thank you, Gayle and Mark, for allowing me to pursue my gifts and my vision. I am also grateful to those who have supported me personally. First on that list is my wife,

Ann. Her patience and love for me are beyond description, and without her, this book would never have been written. I am also indebted to my children, Michael, Ali, Kyle, and Kaden, whose smiling faces and love of life always inspire me. I come from a large Cuban family whose closeness and support most people would envy. Thanks to my parents, Nivaldo and Sara; my siblings, Sarita, Mary, and Jorge; my siblings-in-law, Jeff, Nachy, Karen, and John; and my nephews and nieces, Germain, Danny, Lisette, Sara, and Kenny. These are the people with whom I celebrate life.

I am especially grateful to Michael Tro, who put in many hours proofreading my manuscript, working problems and quiz questions, and organizing art codes and appendices. Michael, you are an amazing kid—it is my privilege to have you work with me on this project.

I would like to thank all of the general chemistry students who have been in my classes throughout my 25 years as a professor at Westmont College. You have taught me much about teaching that is now in this book.

Lastly, I am indebted to the many reviewers, listed on the following pages, whose ideas are embedded throughout this book. They have corrected me, inspired me, and sharpened my thinking on how best to teach this subject we call chemistry. I deeply appreciate their commitment to this project. I am particularly grateful to Thomas Greenbowe, Michael Everest, Kristin Ziebart, Michael Burand, Jeff Bryan, and Ali Sezer who played particularly important roles in many of the new features of this edition. I am also grateful to the accuracy reviewers (Michael Burand, Brian Gute, Tracy Knowles, Tom McGrath, Gary Mines, and Allison Soult) who tirelessly checked page proofs for correctness.

# 21st Century Skills

Tro's approach to General Chemistry addresses 21st century skills, including the ability to analyze and interpret data and the capacity to work well in groups. Concepts are covered in a thorough and approachable manner, which ensures that every explanation is relevant and helps students see the real-world importance and applications of Chemistry. Students can learn concepts and build skills through numerous resources for use before, during, and after class.

## Data Interpretation and Analysis

### UV Radiation and Sunscreen

**114.** On average sunlight shines on the surface of Earth with an intensity of  $910 \text{ Watts/m}^2$ . Some of this energy is in the form of ultraviolet (UV) radiation. The compounds in chemical sunscreens absorb ultraviolet rays and release the energy as lower-energy infrared (IR) rays, thereby preventing the skin-damaging UV rays from reaching the skin. You may have noticed

Sunscreen Compound	Chemical Formula	$M$ (g/mol)
tetrathylthiobenzenesulfonic acid (TDSA)	$\text{C}_{24}\text{H}_{34}\text{O}_2\text{S}_2$	562.70
2-ethylhexyl p-methoxycinnamate (2-EHMC)	$\text{C}_{24}\text{H}_{38}\text{O}_2$	290.29

**FIGURE a** Chemical Formula and Molar Mass ( $M$ ) of Chemicals Commonly Found in Sunscreens

Organic molecules have groups of atoms bonded together that can vibrate and rotate, making more energy states available. As a result, instead of absorbing exact wavelengths of radiation as elements do, organic molecules absorb over a broad range of wavelengths. Figure b plots absorbance versus wavelength for 2-EHMC and TDSA. Greater absorbance indicates that the compound absorbs more light.

**FIGURE b** Sunscreen Absorption  
<http://mcpss.com/critical-wavelength-broad-spectrum-uv-protection/>

references to UV-A (320–400 nm) and UV-B (280–320 nm) protection in sunscreen packaging and advertisements. Figure a lists the chemical formula and molar mass of two compounds, 2-ethylhexyl p-methoxycinnamate (2-EHMC), a UV-B sunscreen, and tetrathylthiobenzenesulfonic acid (TDSA), a UV-A sunscreen.

Use the information provided in the figures to answer the following questions:

- Calculate the energy absorbed by TDSA at its maximum absorption for one photon of UV radiation.
- Calculate the energy absorbed by 2-EHMC at its maximum absorption for one photon of UV radiation.
- Which absorbs more energy, 2-EHMC or TDSA, at their respective maximum wavelengths?
- Why are these two compounds commonly included in sunscreen products?
- A person does not apply sunscreen and has  $0.42 \text{ m}^2$  of skin exposed to the sun for 1.00 hour. Calculate the total energy (in joules) absorbed by the skin. Assume there are  $3.06 \times 10^{23}$  photons/ $\text{m}^2/\text{sec}$ . Assume an average wavelength of 330 nm in order to calculate the energy of a UV photon. Assume half of the photons that strike the skin are reflected.
- In order for a sunscreen product with equal amounts of TDSA and 2-EHMC to provide adequate protection from UV-A and UV-B rays for 1.00 hour, how many molecules of TDSA and 2-EHMC must be present on the skin? Assume one molecule of TDSA and one molecule 2-EHMC can each absorb 10,000 photons per hour. Assume the photon rate is the same as in part e.
- Calculate the mass of TDSA and 2-EHMC in grams that must be present on the exposed skin referenced in parts e and f in order to protect the skin.

**NEW! Data Interpretation and Analysis** questions present real data in real life situations and ask students to analyze that data. These in-depth exercises give students practice reading graphs, digesting tables, and making data-driven decisions.

## Data Interpretation and Analysis

### Heavy Metals in Recycled Paper Packages

**142.** Demand for recycled paper has increased as consumers have become more aware of the environmental issues surrounding waste disposal. Paper is a natural raw material made from renewable wood and plants. Recycled paper is made from waste paper and paperboard. Both new paper and recycled paper contain traces of heavy metals. However, some types of recycled paper contain more heavy metals than new paper due, in part, to the inks used for printing or adding color to the original paper. Metals can migrate from the paper packaging and containers used for food to the food itself. This metal migration is controlled and monitored to reduce the exposure of humans to heavy metals.

Food agencies in each country determine the limit of cadmium, zinc, nickel, and copper in packaging materials. Most countries impose a limit of heavy metals in recycled paper not to exceed 100.0 ppm or 100.0 mg/kg. The limit for lead in egg, fruit, or vegetable packaging is lower—not to exceed—20.0 mg/kg. The table in Figure a lists the results of the analysis of samples of recycled paper produced by a manufacturer during a three-month period.

	Zn	Pb	Cd	Ni	Cu
March	2.7	3.5	0.129	1.7	32.3
April	3.2	2.8	0.092	1.6	29.2
May	2.7	2.4	0.096	1.5	19.9

**FIGURE a** Heavy Metal Values in Three Samples of Recycled Paper (mg/kg  $\pm$  0.1)

The goal of the manufacturer is to reduce the amount of heavy metals—especially lead—in the recycled paper it produces and sells. From March to May, the manufacturer varied the methods of production each month to determine which method would produce paper with the lowest metal content. Each month, lab technicians cut small samples of recycled paper with an area of  $1.000 \text{ dm}^2$  and a thickness of  $0.0500 \text{ cm}$ . The technicians then prepared the samples for analysis. The average density of the samples is  $800.0 \pm 0.0245 \text{ kg/m}^3$ .

Use the information provided in the figure to answer the following questions:

- Did the company reduce the amount of lead in its product between March and May?
- Which metal was not reduced?
- Each month's sample represents a different manufacturing process. Which process would you recommend the manufacturer choose to continue to use over the next year while additional processes are tested? Why?
- What is the total amount of the five metals for the April sample (in mg/kg)?
- What is the total mass (in mg) of the five metals for the April sample found in the  $1.000 \text{ dm}^2 \times 0.0500 \text{ cm}$  sample?
- Lead has four stable isotopes:  $^{204}\text{Pb}$ ,  $^{206}\text{Pb}$ ,  $^{207}\text{Pb}$ ,  $^{208}\text{Pb}$  with % abundances of 1.40, 24.10, 22.10, and 52.40, respectively. Determine the mass (in mg) of  $^{206}\text{Pb}$  in the April sample.
- Sketch the mass spectrum for lead.

# 21st Century Skills

## Active Classroom Learning

### Questions for Group Work

Discuss these questions with the group and record your consensus answer.

148. Assign one of the three simple gas laws to each member of your group. For the assigned gas law, have each member write two equations, draw a graph, and describe it in a complete sentence. Have each group member present his or her law to the group.
149. Review the ideal gas law. Without referring back to the text, use algebra to write the ideal gas law and solve for each of the individual variables it contains. Have each group member solve for a different variable and present answers to the group.
150. Hydrogen peroxide ( $\text{H}_2\text{O}_2$ ) decomposes in the presence of a catalyst to form water and oxygen. The catalyst is added to 5.00 mL of a hydrogen peroxide solution at 25.0 °C, and 49.5 mL of gas is collected over water at a total pressure of 763.8 mmHg.
  - a. Write and balance the chemical reaction (note: catalysts do not appear in balanced chemical equations).
  - b. Look up the vapor pressure of water under these conditions.
  - c. What is the partial pressure of oxygen collected over the water?
  - d. How many moles of oxygen are collected?
  - e. How many grams of hydrogen peroxide were in the original sample?
  - f. What is the concentration (in mol/L) of the hydrogen peroxide solution?
  - g. Which part of this process is conceptually most difficult for your group?
151. A box contains equal amounts of helium, argon, and krypton (all gases) at 25 °C. Using complete sentences, describe the temperatures, masses, average velocities, and average kinetic energy of the three kinds of gas in the mixture. What do they have in common? What are the differences? How are these properties related?
152. Calculate the pressure exerted by 1 mol of an ideal gas in a box that is 0.500 L and 298 K. Have each group member calculate the pressure of 1 mol of the following gases in the same box at the same temperature: He, Ne,  $\text{H}_2$ ,  $\text{CH}_4$ , and  $\text{CO}_2$ . Compare group members' answers as well as all answers with the pressure of an ideal gas. Assuming that the van der Waals equation predictions are accurate, account for why the pressure of each gas is higher or lower than that predicted for an ideal gas.

## Active Classroom Learning

### Questions for Group Work

Discuss these questions with the group and record your consensus answer.

130. Have each member of your group represent an atom of a metal or an atom of a nonmetal. Each group member holds a coin to represent an electron. Which group members are most reluctant to give up their electrons? Which group members are most willing to give up their electrons? Determine which kind of bond could form between each pair of group members. Tabulate your results.
131. Spend a few minutes reviewing the Lewis dot symbols for the atoms H through Ne. Form a circle and have each group member ask the group member on his or her right to draw the Lewis symbol for a specific atom. Keep going around until each group member can write all the Lewis dot symbols for the atoms H through Ne. Determine the formal charge for each symbol. In a complete sentence or two, describe why they are all the same.
132. Draw the Lewis dot symbols for the atoms Al and O. Use the Lewis model to determine the formula for the compound formed from these two atoms.
133. Draft a list of step-by-step instructions for writing the correct Lewis dot structure for any molecule or polyatomic ion.
134. Pass a piece of paper around the group and ask each group member in turn to perform the next step in the process of determining a correct Lewis structure (including formal charges on all atoms and resonance structures, if appropriate) for the following molecules and ions:  $\text{N}_2\text{H}_4$ ,  $\text{CCl}_4$ ,  $\text{CO}_3^{2-}$ , and  $\text{NH}_4^+$ .

**NEW! Questions for Group Work** give students the opportunity to work with their peers in small groups. The questions can be used in or out of the classroom, and the goal is to foster collaborative learning and encourage students to work together as a team to solve problems.

# Interactive Problem-Solving Strategy

A unique and consistent step-by-step format encourages logical thinking throughout the problem-solving process, driving students to think through problems critically, rather than to simply memorize formulas.

## Example 17.6 Strong Acid–Strong Base Titration pH Curve

A 50.0-mL sample of 0.200 M sodium hydroxide is titrated with 0.200 M nitric acid. Calculate pH:

- (a) after adding 30.00 mL of  $\text{HNO}_3$       (b) at the equivalence point

### SOLUTION

(a) Begin by calculating the initial amount of NaOH (in moles) from the volume and molarity of the NaOH solution. Because NaOH is a strong base, it dissociates completely, so the amount of  $\text{OH}^-$  is equal to the amount of NaOH.

$$\begin{aligned}\text{moles NaOH} &= 0.0500 \text{ L} \times \frac{0.200 \text{ mol}}{1 \text{ L}} \\ &= 0.0100 \text{ mol} \\ \text{moles OH}^- &= 0.0100 \text{ mol}\end{aligned}$$

Calculate the amount of  $\text{HNO}_3$  (in moles) added at 30.0 mL from the molarity of the  $\text{HNO}_3$  solution.

$$\begin{aligned}\text{mol HNO}_3 \text{ added} &= 0.0300 \text{ L} \times \frac{0.200 \text{ mol}}{1 \text{ L}} \\ &= 0.00600 \text{ mol HNO}_3\end{aligned}$$

As  $\text{HNO}_3$  is added to the solution, it neutralizes some of the  $\text{OH}^-$ . Calculate the number of moles of  $\text{OH}^-$  remaining by setting up a table based on the neutralization reaction that shows the amount of  $\text{OH}^-$  before the addition, the amount of  $\text{H}_3\text{O}^+$  added, and the amounts left after the addition.

	$\text{OH}^-(\text{aq})$	+	$\text{H}_3\text{O}^+(\text{aq})$	$\longrightarrow$	$2 \text{H}_2\text{O}(\text{l})$
Before addition	0.0100 mol		$\approx 0.00$ mol		
Addition	—		0.00600 mol		
After addition	0.0040 mol		0.00 mol		

Calculate the  $\text{OH}^-$  concentration by dividing the amount of  $\text{OH}^-$  remaining by the total volume (initial volume plus added volume).

$$\begin{aligned}[\text{OH}^-] &= \frac{0.0040 \text{ mol}}{0.0500 \text{ L} + 0.0300 \text{ L}} \\ &= 0.0500 \text{ M}\end{aligned}$$

Calculate the pOH from  $[\text{OH}^-]$ .

$$\begin{aligned}\text{pOH} &= -\log(0.0500) \\ &= 1.30\end{aligned}$$

Calculate the pH from the pOH using the equation  $\text{pH} + \text{pOH} = 14$ .

$$\begin{aligned}\text{pH} &= 14 - \text{pOH} \\ &= 14 - 1.30 \\ &= 12.70\end{aligned}$$

(b) At the equivalence point, the strong base has completely neutralized the strong acid. The  $[\text{H}_3\text{O}^+]$  at 25 °C from the ionization of water is  $1.00 \times 10^{-7} \text{ M}$  and the pH is therefore 7.00.

$$\text{pH} = 7.00$$

**FOR PRACTICE 17.6** Calculate the pH in the titration in Example 17.6 after the addition of 60.0 mL of 0.200 M  $\text{HNO}_3$ .

Icons appear next to examples indicating an **Interactive Worked Example** digital version is available in the eText and on mobile devices via a QR code located here, and on the back cover of your textbook.

## NEW! 61 Interactive Worked Examples

make Tro's unique problem-solving strategies interactive, bringing his award-winning teaching directly to all students using his text. In these digital, mobile versions, students are shown how to break down problems using Tro's proven "Sort, Strategize, Solve, and Check" technique, helping to learn how to consistently solve chemical problems. These examples can be utilized as an after class activity.

### Strong Acid–Strong Base Titration pH Curve

A 50.0-mL sample of 0.200 M sodium hydroxide is titrated with 0.200 M nitric acid.

Calculate: (a) the pH after adding 30.00 mL of  $\text{HNO}_3$

$$\begin{aligned}\text{moles NaOH} &= 0.0500 \text{ L} \times \frac{0.200 \text{ mol}}{1 \text{ L}} \\ &= 0.0100 \text{ mol} \\ \text{moles OH}^- &= 0.0100 \text{ mol}\end{aligned}$$

$$\begin{aligned}\text{moles HNO}_3 \text{ added} &= 0.0300 \text{ L} \times \frac{0.200 \text{ mol}}{1 \text{ L}} \\ &= 0.00600 \text{ mol HNO}_3\end{aligned}$$

$$[\text{OH}^-] = \frac{0.0040 \text{ mol}}{0.0500 \text{ L} + 0.0300 \text{ L}} = 0.0500 \text{ M}$$

	$\text{OH}^-(\text{aq})$	+	$\text{H}_3\text{O}^+(\text{aq})$	$\longrightarrow$	$2 \text{H}_2\text{O}(\text{l})$
Before addition	0.0100 mol		$\approx 0.00$ mol		
Addition	—		0.00600 mol		
After addition	0.0040 mol		$\approx 0.00$ mol		

What is the pH of the solution at this point?

- a) 0.0500  
b) 1.30  
c) 12.70

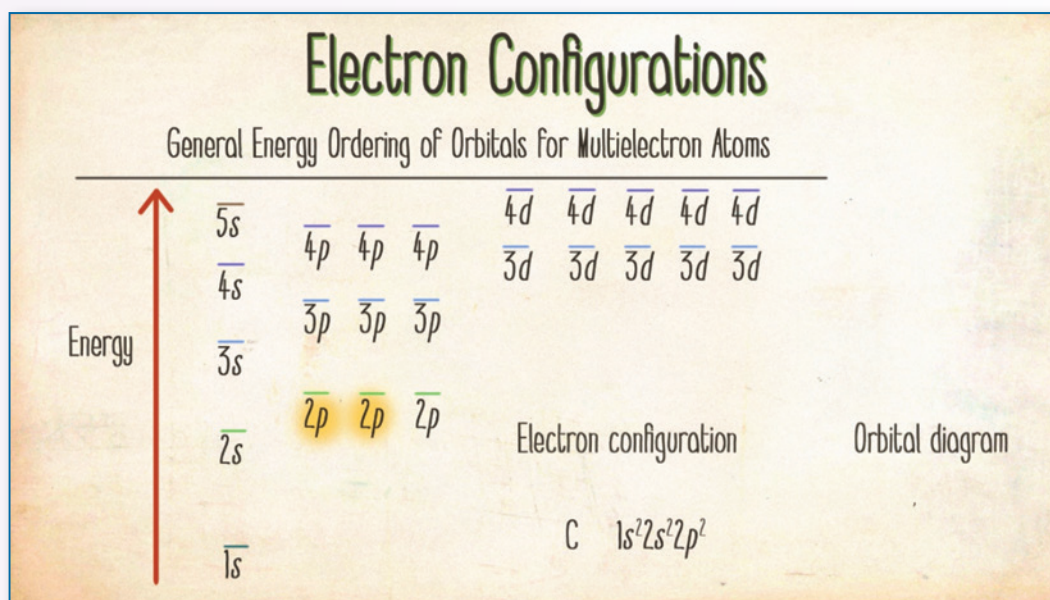

# A Focus on Conceptual Understanding

**NEW! 57 Key Concept Videos** combine artwork from the textbook with both 2D and 3D animations to create a dynamic on-screen viewing and learning experience. These short videos include narration and brief live-action clips of author Niva Tro explaining the key concepts of each chapter. These videos can be utilized as a before class activity.

**Electron Configurations**

**NEW!**

## Chapter 12—Solids and Modern Materials

This chapter contains new topics and consolidates content on materials that was found in other parts of the book in previous editions into one new chapter. New and consolidated topics include unit cells, carbon and silicates, ceramics, cement, glass, polymorphs, polyethylene, and the band gap in Group 4A elements.

CHAPTER

# 12

## Solids and Modern Materials

Should we not suppose that in the formation of a crystal, the particles are not only established in rows and columns set in regular figures, but also by means of some polar property have turned identical sides in identical directions?

—ISAAC NEWTON (1642–1727)

12.1 Friday Night Experiments: The Discovery of Graphene 000

12.2 X-Ray Crystallography 000

12.3 Unit Cells and Basic Structures 000

12.4 The Fundamental Types of Crystalline Solids 000

12.5 The Structures of Ionic Solids 000

12.6 Network Covalent Atomic Solids: Carbon and Silicates 000

12.7 Ceramics, Cement, and Glass 000

12.8 Semiconductors and Band Theory 000

12.9 Polymers and Plastics 000

KEY LEARNING OUTCOMES 000

In this chapter, we focus on the solid state of matter. We first examine the structures of solids, keeping in mind that these structures determine the properties of solids. For example, the repeating hexagonal pattern of water molecules in crystalline ice determines the hexagonal shape of a snowflake, and the repeating cubic pattern of sodium and chloride ions in sodium chloride determines the cubic shape of salt grains. We then turn our attention to the study and development of solids with unique and useful properties, a field known as *materials science*. The ceramics that compose your coffee cups, the semiconductors in your electronic devices, and the plastics that are most likely all around you even at this moment are materials developed to have specific properties that serve specific purposes. In this chapter, we take a brief look at each of these kinds of materials.

### 12.1 Friday Night Experiments: The Discovery of graphene

In 2010, Andre Geim (1958–) and Konstantin Novoselov (1974–) were awarded the Nobel Prize in Physics for the discovery of a new material—graphene. Graphene is the thinnest known material (only one atom thick); it is also the strongest. It conducts heat and electricity, it is transparent, and it is completely impermeable to all substances, including helium. Although its many possible applications are yet to be realized, graphene may one day be used to make faster computers, foldable touchscreens, ultrathin light panels,

# Active and Adaptive

MasteringChemistry is the leading online homework, tutorial, and assessment system, designed to improve results by engaging students before, during, and after class with powerful content. Instructors can ensure students arrive ready to learn by assigning educationally effective content before class, and encourage critical thinking and retention with in-class resources. Students can further master concepts after class through traditional and adaptive homework assignments that provide hints and answer-specific feedback.

**NEW! Ready-to-Go Teaching Modules** in the Instructor Resources section help instructors efficiently make use of the available teaching tools for each chapter. Pre-built before class assignments, in-class activities, and after-class assignments are provided for ease of use. Instructors can incorporate active learning into their course with the suggested activity ideas, Learning Catalytics questions, and clicker questions.

## BEFORE CLASS

**Dynamic Study Modules** help students study effectively on their own by continuously assessing their activity and performance in real time. In this edition, 66 topics include key math skills, general chemistry skills such as nuclear chemistry, phases of matter, redox reactions, acids and bases, and organic and biochemistry skills.

PEARSON  
Acids (Binary and Oxyacids)  
QUESTION 4  
Set 2 | Question 4 of 8  
What is the formula for acetic acid?  
ANSWER  
If you are sure, click one answer twice.  
If you are unsure, click two answers.  
☐ HCOOH  
☐ CH<sub>3</sub>OH  
☒ CH<sub>3</sub>COOH  
☐ COOH

Mathematical Order of Operations  
Learning Goal:  
The goal of this exercise is to understand the importance of, and correctly apply, order of operations for mathematical expressions. This order should be applied to calculations for chemistry problems.  
The following is a list of mathematical procedures, known as operations. These operations should be performed in the given order.  
1. Expressions in parentheses are calculated first, starting with the innermost parentheses. Within a set of parentheses, follow the order given in steps 2 to 4.  
2. Exponents are calculated before multiplication/division and addition/subtraction steps.  
3. Multiplication and division steps are performed next, from left to right.  
4. Addition and subtraction steps are performed last, from left to right.  
To remember this order many students use the acronym PEMDAS (Parentheses, Exponents, Multiplication & Division, Addition & Subtraction).

Order of Operations  
$$4 \times 2 + 3^2 - 6 \div 2$$
$$8 + 9 - 3$$
$$8 + 6$$
$$= 14$$
  
Order of Operations: PEMDAS  
Parentheses  
Exponents  
Multiplication & Division  
Addition & Subtraction

**NEW! The Chemistry Primer** is a series of tutorials focused on remediating students in preparation for their first college chemistry course. The primer is offered as a pre-built assignment automatically generated as a default assignment with every newly created General Chemistry Course.

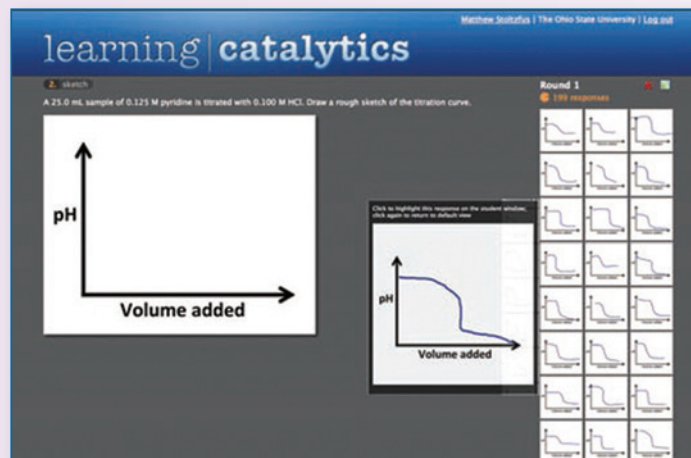

## DURING CLASS

**Learning Catalytics™** generates class discussion, guides lecture, and promotes peer-to-peer learning with real-time analytics. MasteringChemistry with eText now provides Learning Catalytics—an interactive student response tool that uses students' smartphones, tablets, or laptops to engage them in more sophisticated tasks and thinking. Instructors can:

- Pose a variety of open-ended questions that help students develop critical thinking skills
- Monitor responses to find out where students are struggling
- Use real-time data to adjust instructional strategy and try other ways of engaging students during class
- Manage student interactions by automatically grouping students for discussion, teamwork, and peer-to-peer learning

### Questions for Group Work

Tools for active learning have been enhanced throughout the book, allowing students to dive into material in an engaging and effective way.

### Questions for Group Work

Discuss these questions with the group and record your consensus answer.

**140.** Have each group member write a problem involving the transfer of heat from one material in Table 6.4 to another material in the table. Working as a group, solve each problem. The group member who wrote each problem may act as the group facilitator when the group is working on his or her problem. What do all of your problems have in common? How do they differ?

**141.** Classify each process as endothermic or exothermic. What is the sign of  $\Delta H$  for each process? Explain your answers.

- gasoline burning in an engine
- steam condensing on a mirror
- water boiling in a pot

Provide at least two additional examples of exothermic processes and two additional examples of endothermic processes. Have each member of your group provide an example.

**142.** A propane tank on a home barbecue contains  $10.4 \times 10^3$  g of propane.

- Write the balanced chemical reaction for the combustion of gaseous propane ( $C_3H_8$ ) to form watervapor and gaseous carbon dioxide.
- Use the value for  $\Delta H_{\text{rxn}}$  provided in the text to calculate the total amount of heat produced when the entire contents of the tank of propane is burned.

#### Active Classroom Learning

**c.** What mass of water could be warmed from  $25^\circ\text{C}$  to  $100^\circ\text{C}$  with this much heat?

Solid carbon,  $C(s, \text{graphite})$ , gaseous hydrogen,  $H_2(g)$ , and the sugar glucose,  $C_6H_{12}O_6(s)$  are all burned with oxygen in a calorimeter, and the amount of heat given off is determined for each process. How can these data be used to determine the heat of formation of glucose? Your answer should include both chemical reactions and complete sentences.

**143.** Consider the decomposition of liquid hydrogen peroxide ( $H_2O_2$ ) to form water and oxygen.

- What is the heat of formation for hydrogen peroxide?
- What is the heat of formation for liquid water?
- What is the heat of formation for gaseous oxygen? Why?
- Write the balanced chemical equations that correspond to the  $\Delta H$  values you looked up for parts a, b, and c.
- Write the balanced chemical equation for the decomposition of hydrogen peroxide to form water and oxygen. (Write the equation such that the coefficient on oxygen is 1.)
- What is the heat of reaction for the process in part e?
- Draw a scale diagram of this reaction (1 cm = 100 kJ) that shows the relative energies of reactants (on the left), products (on the right), and the elements in their most stable states (in the middle). Label all the energies you know.

# AFTER CLASS

Exercise 4.34 with feedback

For each of the reactions, calculate the mass (in grams) of the product formed when 15.03 g of the underlined reactant completely reacts. Assume that there is more than enough of the other reactant.

You may want to reference (pages 160–165) Section 4.2 while completing this problem.

**Part A**

$$2 \text{K(s)} + \text{Cl}_2\text{(g)} \rightarrow 2 \text{KCl(s)}$$

Express your answer using four significant figures.

m =

**Incorrect; Try Again**

Check the coefficients of the balanced reaction. There are 2 moles of KCl formed for every mole of  $\text{Cl}_2$  that reacts.

**Part B**

$$2 \text{K(s)} + \text{Br}_2\text{(l)} \rightarrow 2 \text{KBr(s)}$$

Express your answer using four significant figures.

m =

**NEW!** In this edition, 200 more end of chapter problems now contain wrong answer specific feedback with links to the eText.

**Self-Assessment Quizzes** now contain wrong-answer feedback links to the eText, and an additional 10–15 multiple-choice questions authored in the ACS-exams and MCAT style in each chapter. These improvements help students optimize the use of quizzing to improve their understanding and class performance.

## Self-Assessment Quiz

- Q1.** Which wavelength of light has the highest frequency?
- a) 10 nm b) 10 mm c) 1 m d) 1 km
- Q2.** Which kind of electromagnetic radiation contains the greatest energy per photon?
- a) microwaves b) gamma rays  
c) X-rays d) visible light
- Q3.** How much energy (in J) is contained in 1.00 mole of 552-nm photons?
- a)  $3.60 \times 10^{-19}$  J b)  $2.17 \times 10^3$  J  
c)  $3.60 \times 10^{-19}$  J d)  $5.98 \times 10^{-43}$  J
- Q4.** Light from three different lasers (A, B, and C), each with a different wavelength, was shined onto the same metal surface. Laser A produced no photoelectrons. Laser B and C both produced photoelectrons, but the photoelectrons produced by laser B had a greater velocity than those produced by laser C. Arrange the lasers in order of increasing wavelength.
- a) A < B < C b) B < C < A  
c) C < B < A d) A < C < B
- Q5.** Calculate the wavelength of an electron traveling at  $1.85 \times 10^7$  m/s.
- a)  $2.54 \times 10^{-10}$  m  
b)  $3.93 \times 10^{-10}$  m  
c)  $2.54 \times 10^{-9}$  m  
d)  $3.93 \times 10^{-10}$  m

- Q6.** Which set of three quantum numbers does not specify an orbital in the hydrogen atom?
- a)  $n = 2, l = 1, m_l = -1$  b)  $n = 3, l = 3, m_l = -2$   
c)  $n = 2, l = 0, m_l = 0$  d)  $n = 3, l = 2, m_l = 2$
- Q7.** Calculate the wavelength of light emitted when an electron in the hydrogen atom makes a transition from an orbital with  $n = 5$  to an orbital with  $n = 3$ .
- a)  $1.28 \times 10^{-6}$  m b)  $6.04 \times 10^{-7}$  m  
c)  $2.28 \times 10^{-6}$  m d)  $1.55 \times 10^{-6}$  m
- Q8.** Which electron transition produces light of the highest frequency in the hydrogen atom?
- a)  $5p \rightarrow 1s$  b)  $4p \rightarrow 1s$   
c)  $3p \rightarrow 1s$  d)  $2p \rightarrow 1s$
- Q9.** How much time (in seconds) does it take light in a vacuum to travel 1.00 billion km?
- a)  $3.00 \times 10^{17}$  s b) 3.33 s  
c)  $3.33 \times 10^3$  s d)  $3.00 \times 10^{20}$  s
- Q10.** Which orbital is a d orbital?
- a)
- b)
- c)
- d) None of the above

**Interactive Simulation—Density Determination of a Metal**

The density of a substance is an intrinsic property and is independent of the amount of substance present. It is often used to identify a substance. Click a tag or select the range to view the simulation, which demonstrates density calculations for metals using water displacement to calculate volume and a ruler to calculate mass. You may need to click and hold some of the buttons to complete the specified step.

**Calculation of density of a metal using water displacement**

Water displacement can be used to find the volume of a solid by placing the object in a known volume of water. When the object is added to water, the measured final volume increases. The final volume is equal to the volume of the initial water plus the volume of the object. Using a scale to measure the mass of the object, you can now calculate the density of the object as its mass divided by its volume.

For example, if you add 15.7 g of silver to 20.0 mL of water, the final volume observed in the measuring cylinder is 21.3 mL. The change in volume is  $21.3 \text{ mL} - 20.0 \text{ mL} = 1.3 \text{ mL}$ . The density of silver is thus:

$$\frac{15.7 \text{ g}}{1.3 \text{ mL}} = 12.1 \text{ g/mL}$$

**Part A**

Follow the steps provided in the simulation to add water to the graduated cylinder, add a metal sample, and calculate the density of the metal.

1. Add water by clicking and holding **Prepare a known volume of water**.
2. To set the mass, click and hold **Prepare a known mass of metal**.
3. Transfer the metal to water and then click **Calculate density**.

Use the following activity to collect the data needed to determine the density of different metals.

- Click and hold the **Prepare a known volume of water** button. Note the initial volume.
- Select a metal.
- Prepare a known quantity of metal by clicking and holding the **Weigh out metal** button. Release button to stop the addition of metal to the balance pan.
- Note the mass of the metal sample.
- Transfer the metal sample to the graduated cylinder.
- Note the change in total volume.
- Select **Calculate density** to use the data to determine the density of the metal.
- Repeat with metals samples of different masses and compositions or with different initial volumes of water.

**Part B**

You add 5.7 g iron to 20.0 mL of water and observe that the volume of iron added is 0.4 mL. Express your answer to two significant figures with the appropriate units.

Value  Units

**Multimedia-rich Tutorials** feature specific wrong-answer feedback, hints, and a wide variety of educationally effective content to guide your students through the toughest topics in chemistry. The hallmark Hints and Feedback offer instruction similar to what students would experience in an office hours visit, allowing them to learn from their mistakes without being given the answer.

<b>Test Bank</b> 0134126327 / 9780134126326		✓	Instructor	The Test Bank, prepared by Christine Hermann, contains more than 3,000 multiple choice, matching, and short-answer questions.
<b>Solutions Manual</b> 0134066251 / 9780134066257	✓		Instructor	Prepared by Kathy Shaginaw, this manual contains step-by-step solutions to all end-of-chapter exercises. With instructor permission, this manual may be made available to students.
<b>Instructor's Manual for Laboratory Manual</b> 0134143485 / 9780134143484		✓	Instructor	This manual provides solutions to the questions asked before each experiment in the accompanying Laboratory Manual, and provides background and suggestions for the instructor directing the lab.

# Matter, Measurement, and Problem Solving

The most incomprehensible thing about  
the universe is that it is comprehensible.

—ALBERT EINSTEIN (1879–1955)

- 1.1** Atoms and Molecules 1
- 1.2** The Scientific Approach to Knowledge 3
- 1.3** The Classification of Matter 5
- 1.4** Physical and Chemical Changes and Physical and Chemical Properties 9

- 1.5** Energy: A Fundamental Part of Physical and Chemical Change 12
- 1.6** The Units of Measurement 13
- 1.7** The Reliability of a Measurement 20
- 1.8** Solving Chemical Problems 26

**KEY LEARNING OUTCOMES 36**

**W**hat do you think is the most important idea in all of human knowledge? There are, of course, many possible answers to this question—some practical, some philosophical, and some scientific. If we limit ourselves only to scientific answers, mine would be this: **the properties of matter are determined by the properties of atoms and molecules.** Atoms and molecules determine how matter behaves—if they were different, matter would be different. The properties of water molecules determine how water behaves, the properties of sugar molecules determine how sugar behaves, and the properties of the molecules that compose our bodies determine how our bodies behave. The understanding of matter at the molecular level gives us unprecedented control over that matter. For example, our understanding of the details of the molecules that compose living organisms has revolutionized biology over the last 50 years.

▲ This image portrays the Disneyland ride, *Adventure Thru Inner Space*. The premise of the ride is that you enter a microscope and get shrunk down to the size of an atom. The red and white spheres shown here depict oxygen and hydrogen atoms bound together to form water molecules.

## 1.1 Atoms and Molecules

As I sat in the “omnimover” and listened to the narrator’s voice telling me that I was shrinking down to the size of an atom, I grew apprehensive but curious. Just minutes before, while waiting in line, I witnessed what appeared to be full-sized humans entering a microscope and emerging from the other end many times smaller. I was seven years old, and I was about to ride *Adventure Thru Inner Space*, a Disneyland ride

Atoms and Molecules

(in Tomorrowland) that simulated the process of shrinking down to the size of an atom. The ride began with darkness and shaking, but then the shaking stopped and giant snowflakes appeared. The narrator explained that you were in the process of shrinking to an ever-smaller size (which explains why the snowflakes grew larger and larger). Soon, you entered the wall of the snowflake itself and began to see water molecules all around you. These also grew larger as you continued your journey into inner space and eventually ended up within the atom itself. Although this Disneyland ride bordered on being corny, and although it has since been shut down, it was my favorite ride as a young child.

That ride sparked my interest in the world of atoms and molecules, an interest that has continued and grown to this day. I am a chemist because I am obsessed with the connection between the “stuff” around us and the atoms and molecules that compose that stuff. More specifically, I love the idea that we humans have been able to figure out the connection between the *properties of the stuff* around us and the *properties of atoms and molecules*. **Atoms** are sub-microscopic particles that are the fundamental building blocks of ordinary matter. Free atoms are rare in nature; instead they bind together in specific geometrical arrangements to form **molecules**. A good example of a molecule is the water molecule, which I remember so well from the Disneyland ride.

A water molecule is composed of one oxygen atom bound to two hydrogen atoms in the shape shown at left. The exact properties of the water molecule—the atoms that compose it, the distances between those atoms, and the geometry of how the atoms are bound together—determine the properties of water. If the molecule were different, water would be different. For example, if water contained two oxygen atoms instead of just one, it would be a molecule like this:

This molecule is hydrogen peroxide, which you may have encountered if you have ever bleached your hair. A hydrogen peroxide molecule is composed of *two* oxygen atoms and two hydrogen atoms. This seemingly small molecular difference results in a huge difference in the properties of water and hydrogen peroxide. Water is the familiar and stable liquid we all drink and bathe in. Hydrogen peroxide, in contrast, is an unstable liquid that, in its pure form, burns the skin on contact and is used in rocket fuel. When you pour water onto your hair, your hair simply becomes wet. However, if you put diluted hydrogen peroxide on your hair, a chemical reaction occurs that strips your hair of its color.

The details of how specific atoms bond to form a molecule—in a straight line, at a particular angle, in a ring, or in some other pattern—as well as the type of atoms in the molecule, determine everything about the substance that the molecule composes. If we want to understand the substances around us, we must understand the atoms and molecules that compose them—this is the central goal of chemistry. A good simple definition of **chemistry** is

**Chemistry—the science that seeks to understand the behavior of matter by studying the behavior of atoms and molecules.**

Throughout this book, we explore the connection between atoms and molecules and the matter they compose. We seek to understand how differences on the atomic or molecular level affect the properties on the macroscopic level. Before we move on, let's examine one more example that demonstrates this principle. Consider the structures of graphite and diamond shown on the next page.

The hydrogen peroxide we use as an antiseptic or bleaching agent is considerably diluted.

The term *atoms* in this definition can be interpreted loosely to include atoms that have lost or gained electrons.

Graphite is the slippery black substance (often called pencil lead) that you have probably used in a mechanical pencil. Diamond is the brilliant gemstone found in jewelry. Graphite and diamond are both composed of exactly the same atoms—carbon atoms. The striking differences between the substances are a result of how those atoms are arranged. In graphite, the atoms are arranged in sheets. The atoms within each sheet are tightly bound to each other, but the sheets are *not* tightly bound to other sheets. Therefore the sheets can slide past each other, which is why the graphite in a pencil leaves a trail as you write. In diamond, by contrast, the carbon atoms are all bound together in a three-dimensional structure where layers are strongly bound to other layers, resulting in the strong, nearly unbreakable substance. This example illustrates how even the same atoms can compose vastly different substances when they are bound together in different patterns. Such is the atomic and molecular world—small differences in atoms and molecules can result in large differences in the substances that they compose.

## 1.2 The Scientific Approach to Knowledge

Throughout history, humans have approached knowledge about the physical world in different ways. For example, the Greek philosopher Plato (427–347 B.C.E.) thought that the best way to learn about reality was not through the senses but through reason. He believed that the physical world was an imperfect representation of a perfect and transcendent world (a world beyond space and time). For him, true knowledge came not through observing the real physical world, but through reasoning and thinking about the ideal one.

The *scientific* approach to knowledge, however, is exactly the opposite of Plato's. Scientific knowledge is empirical—it is based on *observation* and *experiment*. Scientists observe and perform experiments on the physical world to learn about it. Some observations and experiments are qualitative (noting or describing how a process happens), but many are quantitative (measuring or quantifying something about the process). For example, Antoine Lavoisier (1743–1794), a French chemist who studied combustion (burning), made careful measurements of the mass of objects before and after burning them in closed containers. He noticed that there was no change in the total mass of material within the container during combustion. In doing so, Lavoisier made an important *observation* about the physical world.

Observations often lead scientists to formulate a **hypothesis**, a tentative interpretation or explanation of the observations. For example, Lavoisier explained his observations on combustion by hypothesizing that when a substance burns, it combines with a component of air. A good hypothesis is *falsifiable*, which means that it makes predictions that can be confirmed or refuted by further observations. Scientists test hypotheses by **experiments**, highly controlled procedures designed to generate observations that confirm or refute a hypothesis. The results of an experiment may support a hypothesis or prove it wrong—in which case the scientist must modify or discard the hypothesis.

In some cases, a series of similar observations leads to the development of a **scientific law**, a brief statement that summarizes past observations and predicts future ones. Lavoisier summarized his observations on combustion with the **law of conservation of mass**, which states, “In a chemical reaction, matter is neither created nor destroyed.” This statement summarized his observations on chemical reactions and predicted the

Although some Greek philosophers, such as Aristotle, did use observation to attain knowledge, they did not emphasize experiment and measurement to the extent that modern science does.

▲ French chemist Antoine Lavoisier with his wife, Marie, who helped him in his work by illustrating his experiments and translating scientific articles from English. Lavoisier, who also made significant contributions to agriculture, industry, education, and government administration, was executed during the French Revolution. (The Metropolitan Museum of Art)

outcome of future observations on reactions. Laws, like hypotheses, are also subject to experiments, which can support them or prove them wrong.

Scientific laws are not *laws* in the same sense as civil or governmental laws. Nature does not follow laws in the way that we obey the laws against speeding or running a stop sign. Rather, scientific laws *describe* how nature behaves—they are generalizations about what nature does. For that reason, some people find it more appropriate to refer to them as *principles* rather than *laws*.

One or more well-established hypotheses may form the basis for a scientific **theory**. A scientific theory is a model for the way nature is and tries to explain not merely what nature does but why. As such, well-established theories are the pinnacle of scientific knowledge, often predicting behavior far beyond the observations or laws from which they were developed. A good example of a theory is the **atomic theory** proposed by English chemist John Dalton (1766–1844). Dalton explained the law of conservation of mass, as well as other laws and observations of the time, by proposing that matter is composed of small, indestructible particles called atoms. Since these particles are merely rearranged in chemical changes (and not created or destroyed), the total amount of mass remains the same. Dalton's theory is a model for the physical world—it gives us insight into how nature works and, therefore, *explains* our laws and observations.

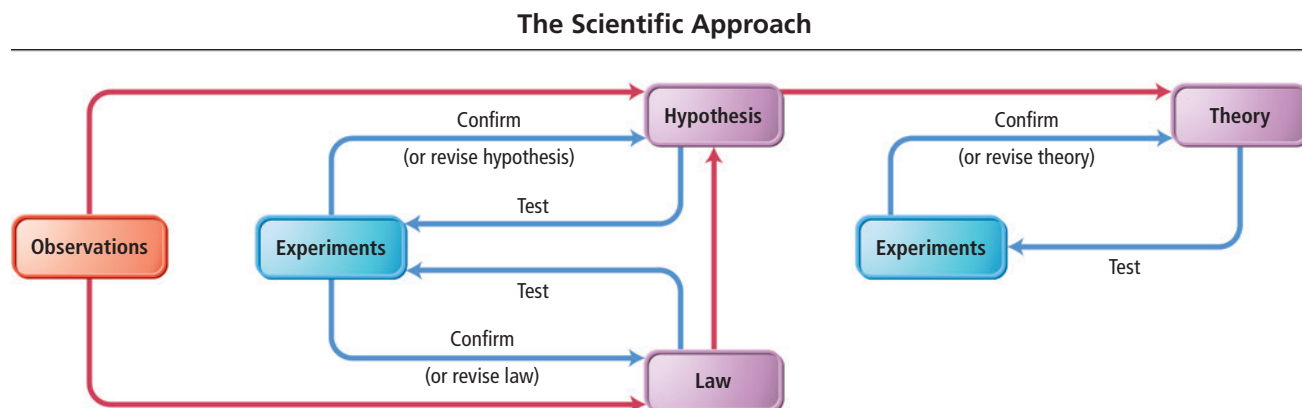

Finally, the scientific approach returns to observation to test theories. For example, scientists can test the atomic theory by trying to isolate single atoms or by trying to image them (both of which, by the way, have already been accomplished). Theories are validated by experiments; however, theories can never be conclusively proven because some new observation or experiment always has the potential to reveal a flaw. Notice that the scientific approach to knowledge begins with observation and ends with observation. An experiment is in essence a highly controlled procedure for generating critical observations designed to test a theory or hypothesis. Each new set of observations has the potential to refine the original model. Figure 1.1 summarizes one way to map the scientific approach to knowledge. Scientific laws, hypotheses, and theories are all subject to continued experimentation. If a law, hypothesis, or theory is proved wrong by an experiment, it must be revised and tested with new experiments. Over time, the scientific community eliminates or corrects poor theories and laws, and valid theories and laws—those consistent with experimental results—remain.

Established theories with strong experimental support are the most powerful pieces of scientific knowledge. You may have heard the phrase “That is just a theory,” as if theories are easily dismissible. Such a statement reveals a deep misunderstanding of the nature of a scientific theory. Well-established theories are as close to truth as we get in science. The idea that all matter is made of atoms is “just a theory,” but it has over 200 years of experimental evidence to support it. It is a powerful piece of scientific knowledge on which many other scientific ideas are based.

One last word about the scientific approach to knowledge: some people wrongly imagine science to be a strict set of rules and procedures that automatically leads to inarguable, objective facts. This is not the case. Even our diagram of the scientific approach to knowledge is only an idealization of real science, useful to help us see the

In Dalton's time, people thought atoms were indestructible. Today, because of nuclear reactions, we know that atoms can be broken apart into their smaller components.

▼ **FIGURE 1.1** The Scientific Approach to Knowledge

key distinctions of science. Real science requires hard work, care, creativity, and even a bit of luck. Scientific theories do not just arise out of data—men and women of genius and creativity craft theories. A great theory is not unlike a master painting, and many see a similar kind of beauty in both. (For more on this aspect of science, see the box below entitled *Thomas S. Kuhn and Scientific Revolutions*.)

## CONCEPTUAL CONNECTION 1.1

**Laws and Theories** Which statement best explains the difference between a law and a theory?

- (a) A law is truth; a theory is mere speculation.
- (b) A law summarizes a series of related observations; a theory gives the underlying reasons for them.
- (c) A theory describes *what* nature does; a law describes *why* nature does it.

## The Nature OF Science

### Thomas S. Kuhn and Scientific Revolutions

**W**hen scientists talk about science, they often talk in ways that imply that theories are “true.” Further, they talk as if they arrive at theories in logical and unbiased ways. For example, a theory central to chemistry that we have discussed in this chapter is John Dalton’s atomic theory—the idea that all matter is composed of atoms. Is this theory “true”? Was it reached in logical, unbiased ways? Will this theory still be around in 200 years?

The answers to these questions depend on how we view science and its development. One way to view science—let’s call it the *traditional view*—is as the continual accumulation of knowledge and the building of increasingly precise theories. In this view, a scientific theory is a model of the world that reflects what is *actually in* nature. New observations and experiments result in gradual adjustments to theories. Over time, theories get better, giving us a more accurate picture of the physical world.

In the twentieth century, a different view of scientific knowledge began to develop. A book by Thomas Kuhn (1922–1996), published in 1962 and entitled *The Structure of Scientific Revolutions*, challenged the traditional view. Kuhn’s ideas came from his study of the history of science, which, he argued, does not support the idea that science progresses in a smooth cumulative way. According to Kuhn, science goes through fairly quiet periods that he called *normal science*. In these periods, scientists make their data fit the reigning theory, or paradigm. Small inconsistencies are swept aside during periods of normal science. However, when too many inconsistencies and anomalies develop, a crisis

emerges. The crisis brings about a *revolution* and a new reigning theory. According to Kuhn, the new theory is usually quite different from the old one; it not only helps us to make sense of new or anomalous information, but it also enables us to see accumulated data from the past in a dramatically new way.

Kuhn further contended that theories are held for reasons that are not always logical or unbiased, and that theories are not *true* models—in the sense of a one-to-one mapping—of the physical world. Because new theories are often so different from the ones they replace, he argued, and because old theories always make good sense to those holding them, they must not be “True” with a capital T; otherwise “truth” would be constantly changing.

Kuhn’s ideas created a controversy among scientists and science historians that continues to this day. Some, especially postmodern philosophers of science, have taken Kuhn’s ideas one step further. They argue that scientific knowledge is *completely* biased and lacks any objectivity. Most scientists, including Kuhn, would disagree. Although Kuhn pointed out that scientific knowledge has *arbitrary elements*, he also said, “*Observation . . . can and must drastically restrict the range of admissible scientific belief, else there would be no science.*” In other words, saying that science contains arbitrary elements is quite different from saying that science itself is arbitrary.

### QUESTION

*In his book, Kuhn stated, “A new theory . . . is seldom or never just an increment to what is already known.” From your knowledge of the history of science, can you think of any examples that support Kuhn’s statement? Do you know of any instances in which a new theory or model was drastically different from the one it replaced?*

## 1.3 The Classification of Matter

Classifying Matter

**Matter** is anything that occupies space and has mass. Your desk, your chair, and even your body are all composed of matter. Less obviously, the air around you is also matter—it too occupies space and has mass. We call a specific instance of matter—such as air, water, or sand—a **substance**. We classify matter according to its **state** (its physical form) and its **composition** (the basic components that make it up).

The state of matter changes from solid to liquid to gas with increasing temperature.

Glass and other amorphous solids can be thought of, from one point of view, as intermediate between solids and liquids. Their atoms are fixed in position at room temperature, but they have no long-range structure and do not have distinct melting points.

**Crystalline Solid:**  
Regular  
three-dimensional pattern

**Diamond**  
C (s, diamond)

**▲ FIGURE 1.2 Crystalline Solid** Diamond (first discussed in Section 1.1) is a crystalline solid composed of carbon atoms arranged in a regular, repeating pattern.

## The States of Matter: Solid, Liquid, and Gas

Matter exists in three different states: **solid**, **liquid**, and **gas**. In *solid matter*, atoms or molecules pack closely to each other in fixed locations. Although the atoms and molecules in a solid vibrate, they do not move around or past each other. Consequently, a solid has a fixed volume and rigid shape. Ice, aluminum, and diamond are examples of solids. Solid matter may be **crystalline**, in which case its atoms or molecules are in patterns with long-range, repeating order (Figure 1.2▲), or it may be **amorphous**, in which case its atoms or molecules do not have any long-range order. Table salt and diamond are examples of *crystalline* solids; the well-ordered geometric shapes of salt and diamond crystals reflect the well-ordered geometric arrangement of their atoms (although this is not the case for *all* crystalline solids). Examples of *amorphous* solids include glass and plastic. In *liquid matter*, atoms or molecules pack about as closely as they do in solid matter, but they are free to move relative to each other, giving liquids a fixed volume but not a fixed shape. Liquids assume the shape of their containers. Water, alcohol, and gasoline are all substances that are liquids at room temperature.

▲ In a solid, the atoms or molecules are fixed in place and can only vibrate. In a liquid, although the atoms or molecules are closely packed, they can move past one another, allowing the liquid to flow and assume the shape of its container. In a gas, the atoms or molecules are widely spaced, making gases compressible as well as fluid (able to flow).

In *gaseous matter*, atoms or molecules have a lot of space between them and are free to move relative to one another, making gases *compressible* (Figure 1.3▶). When you squeeze a balloon or sit down on an air mattress, you force the atoms and molecules into a smaller space so that they are closer together. Gases always assume the shape *and* volume of their containers. Substances that are gases at room temperature include helium, nitrogen (the main component of air), and carbon dioxide.

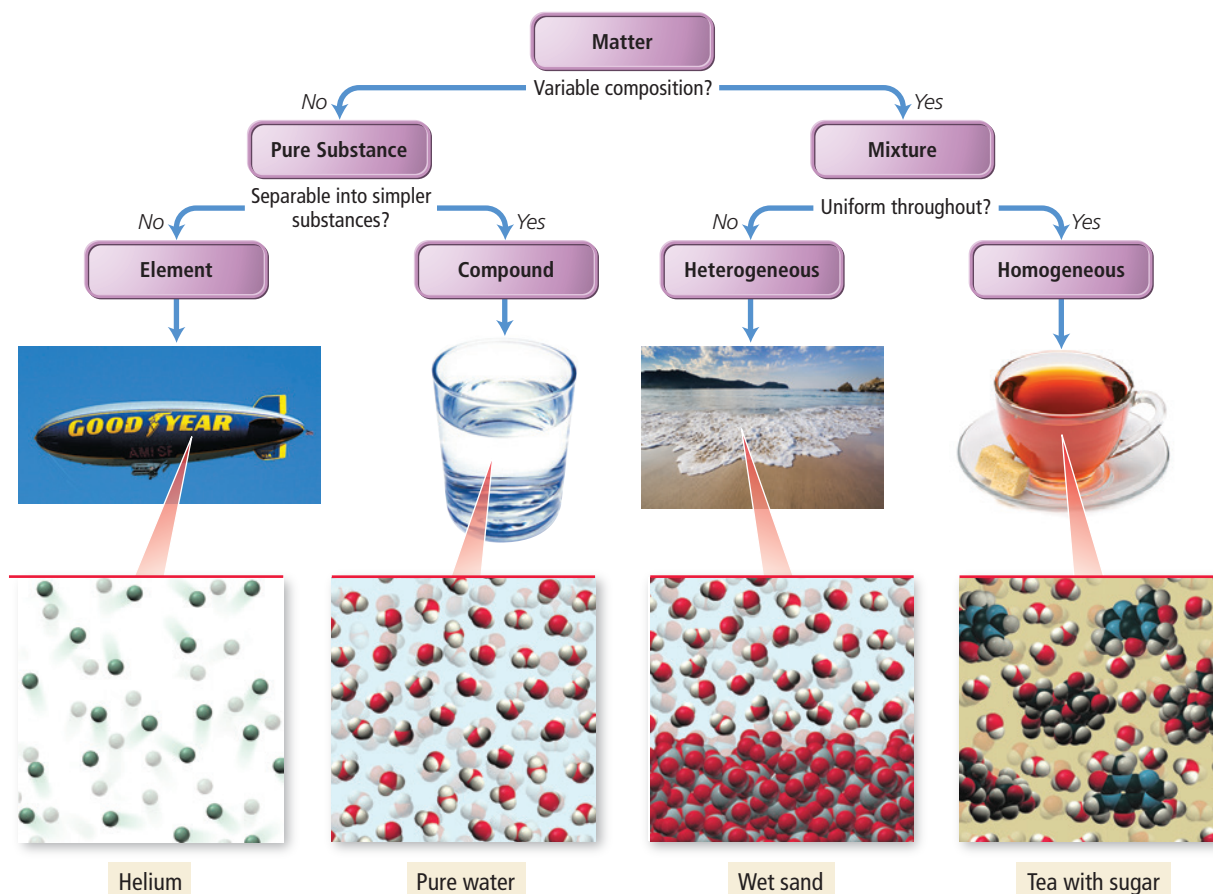

**FIGURE 1.3 The Compressibility of Gases** Gases can be compressed—squeezed into a smaller volume—because there is so much empty space between atoms or molecules in the gaseous state.

## Classifying Matter according to Its Composition: Elements, Compounds, and Mixtures

In addition to classifying matter according to its state, we classify it according to its composition, as shown in the following chart:

The first division in the classification of matter is between a *pure substance* and a *mixture*. A **pure substance** is made up of only one component, and its composition is invariant (it does not vary from one sample to another). The *components* of a pure substance can be individual atoms or groups of atoms joined together. For example, helium, water, and table salt (sodium chloride) are all pure substances. Each of these substances is made up of only one component: helium is made up of helium atoms, water is made up of water molecules, and sodium chloride is made up of sodium chloride units. The composition of a pure sample of any one of these substances is always exactly the same (because you can't vary the composition of a substance made up of only one component).

A **mixture**, by contrast, is composed of two or more components in proportions that can vary from one sample to another. For example, sweetened tea, composed primarily of water molecules and sugar molecules (with a few other substances mixed in), is a mixture. We can make tea slightly sweet (a small proportion of sugar to water) or very sweet (a large proportion of sugar to water) or any level of sweetness in between.

We categorize pure substances themselves into two types—*elements* and *compounds*—depending on whether or not they can be broken down (or decomposed) into simpler substances. Helium, which we just noted is a pure substance, is also a good example of an **element**, a substance that cannot be chemically broken down into simpler substances. Water, also a pure substance, is a good example of a **compound**, a substance composed of two or more elements (in this case hydrogen and oxygen) in a fixed, definite proportion. On Earth, compounds are more common than pure elements because most elements combine with other elements to form compounds.

We also categorize mixtures into two types—heterogeneous and homogeneous—depending on how *uniformly* the substances within them mix. Wet sand is a **heterogeneous mixture**, one in which the composition varies from one region of the mixture to another. Sweetened tea is a **homogeneous mixture**, one with the same composition throughout. Homogeneous mixtures have uniform compositions because the atoms or molecules that compose them mix uniformly. Heterogeneous mixtures are made up of distinct regions because the atoms or molecules that compose them separate. Here again we see that the properties of matter are determined by the atoms or molecules that compose it.

Classifying a substance according to its composition is not always obvious and requires that we either know the true composition of the substance or are able to test it in a laboratory. For now, we focus on relatively common substances that you are likely to have encountered. Throughout this course, you will gain the knowledge to understand the composition of a larger variety of substances.

All known elements are listed in the periodic table in the inside front cover of this book.

## CONCEPTUAL CONNECTION 1.2

**Pure Substances and Mixtures** Let a small circle represent an atom of one type of element and a small square represent an atom of a second type of element. Make a drawing of (a) a pure substance (a compound) composed of the two elements (in a one-to-one ratio), (b) a homogeneous mixture composed of the two elements, and (c) a heterogeneous mixture composed of the two elements.

## Separating Mixtures

Chemists often want to separate a mixture into its components. Such separations can be easy or difficult, depending on the components in the mixture. In general, mixtures are separable because the different components have different physical or chemical properties. We can use various techniques that exploit these differences to achieve separation. For example, we can separate a mixture of sand and water by **decanting**—carefully pouring off—the water into another container. A homogeneous mixture of liquids can usually be separated by **distillation**, a process in which the mixture is heated to boil off the more **volatile** (easily vaporizable) liquid. The volatile liquid is then recondensed in a condenser and collected in a separate flask (Figure 1.4▶). If a mixture is composed of an insoluble solid and a liquid, we can separate the two by **filtration**, in which the mixture is poured through filter paper in a funnel (Figure 1.5▶).

## Distillation

▲ **FIGURE 1.4 Separating Substances by Distillation** When a liquid mixture is heated, the component with the lowest boiling point vaporizes first, leaving behind less volatile liquids or dissolved solids. The vapor is then cooled, condensing it back to a liquid, and collected.

## Filtration

▲ **FIGURE 1.5 Separating Substances by Filtration** A solid and liquid mixture can be separated by pouring the mixture through a funnel containing filter paper designed to allow only the liquid to pass.

## 1.4 Physical and Chemical Changes and Physical and Chemical Properties

Every day we witness changes in matter: ice melts, iron rusts, gasoline burns, fruit ripens, and water evaporates. What happens to the molecules or atoms that compose these substances during such changes? The answer depends on the type of change. Changes that alter only state or appearance, but not composition, are **physical changes**. The atoms or molecules that compose a substance *do not change* their identity during a physical change. For example, when water boils, it changes its state from a liquid to a gas, but the gas remains composed of water molecules, so this is a physical change (Figure 1.6▶).

▶ **FIGURE 1.6 Boiling, a Physical Change** When water boils, it turns into a gas but does not alter its chemical identity—the water molecules are the same in both the liquid and gaseous states. Boiling is a physical change, and the boiling point of water is a physical property.

A physical change results in a different form of the same substance, while a chemical change results in a completely different substance.

In Chapter 19 we will discuss *nuclear changes*, which can involve atoms of one element changing into atoms of a different element.

**▲ FIGURE 1.7 Rusting, a Chemical Change** When iron rusts, the iron atoms combine with oxygen atoms to form a different chemical substance, the compound iron oxide. Rusting is a chemical change, and the tendency of iron to rust is a chemical property.

In contrast, changes that alter the composition of matter are **chemical changes**. During a chemical change, atoms rearrange, transforming the original substances into different substances. For example, the rusting of iron is a chemical change. The atoms that compose iron (iron atoms) combine with oxygen molecules from air to form iron oxide, the orange substance we call rust (Figure 1.7◀). Figure 1.8▶ illustrates other examples of physical and chemical changes.

Physical and chemical changes are manifestations of physical and chemical properties. A **physical property** is a property that a substance displays without changing its composition, whereas a **chemical property** is a property that a substance displays only by changing its composition via a chemical change. The smell of gasoline is a physical property—gasoline does not change its composition when it exhibits its odor. The flammability of gasoline, in contrast, is a chemical property—gasoline does change its composition when it burns, turning into completely new substances (primarily carbon dioxide and water). Physical properties include odor, taste, color, appearance, melting point, boiling point, and density. Chemical properties include corrosiveness, flammability, acidity, toxicity, and other such characteristics.

The differences between physical and chemical changes are not always apparent. Only chemical examination can confirm whether a particular change is physical or chemical. In many cases, however, we can identify chemical and physical changes based on what we know about the changes. Changes in the state of matter, such as melting or boiling, or changes in the physical condition of matter, such as those that result from cutting or crushing, are typically physical changes. Changes involving chemical reactions—often evidenced by temperature or color changes—are chemical changes.

### Example 1.1 Physical and Chemical Changes and Properties

Determine whether each change is physical or chemical. What kind of property (chemical or physical) is demonstrated in each case?

- (a) the evaporation of rubbing alcohol
- (b) the burning of lamp oil
- (c) the bleaching of hair with hydrogen peroxide
- (d) the formation of frost on a cold night

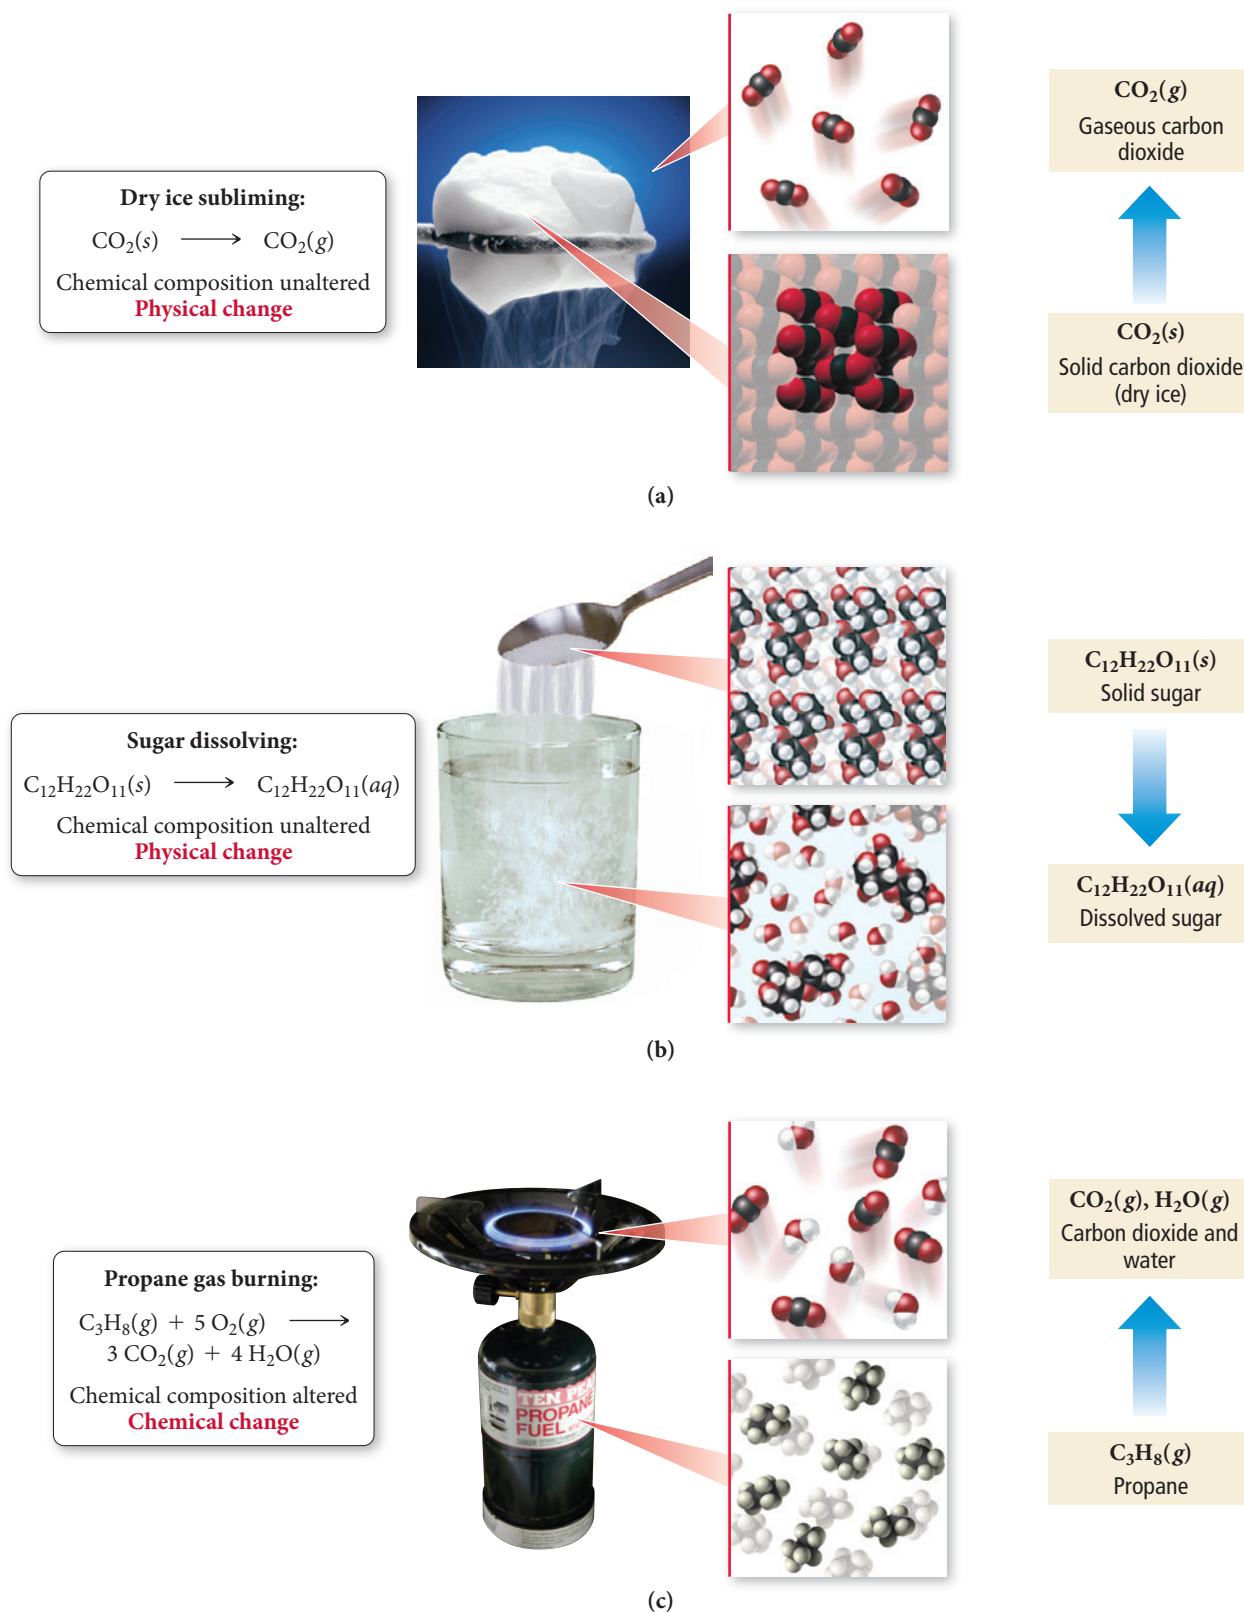

#### SOLUTION

- (a) When rubbing alcohol evaporates, it changes from liquid to gas, but it remains alcohol—this is a physical change. The volatility (the ability to evaporate easily) of alcohol is therefore a physical property.
- (b) Lamp oil burns because it reacts with oxygen in air to form carbon dioxide and water—this is a chemical change. The flammability of lamp oil is therefore a chemical property.
- (c) Applying hydrogen peroxide to hair changes pigment molecules in hair that give it color—this is a chemical change. The susceptibility of hair to bleaching is therefore a chemical property.
- (d) Frost forms on a cold night because water vapor in air changes its state to form solid ice—this is a physical change. The temperature at which water freezes is therefore a physical property.

**FOR PRACTICE 1.1** Determine whether each change is physical or chemical. What kind of property (chemical or physical) is demonstrated in each case?

- (a) A copper wire is hammered flat.
- (b) A nickel dissolves in acid to form a blue-green solution.
- (c) Dry ice sublimates without melting.
- (d) A match ignites when struck on a flint.

## Physical Change versus Chemical Change

**▲ FIGURE 1.8 Physical and Chemical Changes** (a) The sublimation (the state change from a solid to a gas) of dry ice (solid  $\text{CO}_2$ ) is a physical change. (b) The dissolution of sugar is a physical change. (c) The burning of propane is a chemical change.

## CONCEPTUAL CONNECTION 1.3

**Chemical and Physical Changes** The diagram on the left represents liquid water molecules in a pan. Which of the three diagrams (a, b, or c) best represents the water molecules after they have been vaporized by the boiling of liquid water?

(a)

(b)

(c)

## 1.5 Energy: A Fundamental Part of Physical and Chemical Change

The physical and chemical changes discussed in Section 1.4 are usually accompanied by energy changes. For example, when water evaporates from your skin (a physical change), the water molecules absorb energy from your body, making you feel cooler. When you burn natural gas on the stove (a chemical change), energy is released, heating the food you are cooking. Understanding the physical and chemical changes of matter—that is, understanding chemistry—requires that you understand energy changes and energy flow.

The scientific definition of **energy** is *the capacity to do work*. **Work** is defined as the action of a force through a distance. For instance, when you push a box across the floor or pedal your bicycle across the street, you have done work.

Force acts through distance; work is done.

### ▲ FIGURE 1.9 Energy

**Conversions** Gravitational potential energy is converted into kinetic energy when the weight is dropped. The kinetic energy is converted mostly to thermal energy when the weight strikes the ground.

The **total energy** of an object is a sum of its **kinetic energy** (the energy associated with its motion) and its **potential energy** (the energy associated with its position or composition). For example, a weight held several meters above the ground has potential energy due to its position within Earth's gravitational field (Figure 1.9◀). If you drop the weight, it accelerates, and its potential energy is converted to kinetic energy. When the weight hits the ground, its kinetic energy is converted primarily to **thermal energy**, the energy associated with the temperature of an object. Thermal energy is actually a type of kinetic energy because it is associated with the motion of the individual atoms or molecules that make up an object. When the weight hits the ground, its kinetic energy is essentially transferred to the atoms and molecules that compose the ground, raising the temperature of the ground ever so slightly.

The first principle to note about how energy changes as the weight falls to the ground is that *energy is neither created nor destroyed*. The potential energy of the weight becomes kinetic energy as the weight accelerates toward the ground. The kinetic energy then becomes thermal energy when the weight hits the ground. The total amount of thermal energy that is released through the process is exactly equal to the initial potential energy of the weight. The idea that energy is neither created nor destroyed is known as the **law of conservation of energy**. Although energy can change from one type into another, and although it can flow from one object to another, the **total quantity** of energy does not change—it remains constant.

In Chapter 20 we will discuss how energy conservation is actually part of a more general law that allows for the interconvertibility of mass and energy.

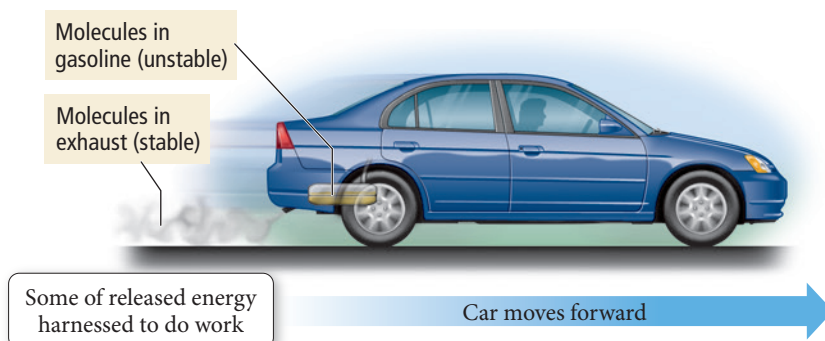

The second principle to note about the raised weight and its fall is *the tendency of systems with high potential energy to change in a way that lowers their potential energy*. For this reason, objects or systems with high potential energy tend to be *unstable*. The weight lifted several meters from the ground is unstable because it contains a significant amount of potential energy. Unless restrained, the weight will naturally fall, lowering its potential energy (due to its position in Earth's gravitational field). We can harness some of the raised weight's potential energy to do work. For example, we can attach the weight to a rope that turns a paddle wheel or spins a drill as the weight falls. After the weight falls to the ground, it contains less potential energy—it has become more *stable*.

Some chemical substances are like the raised weight just described. For example, the molecules that compose gasoline have a relatively high potential energy—energy is concentrated in them just as energy is concentrated in the raised weight. The molecules in the gasoline tend to undergo chemical changes (specifically combustion) that lower the molecules' potential energy. As the energy of the molecules is released, some of it can be harnessed to do work, such as moving a car forward (Figure 1.10▲). The molecules that result from the chemical change have less potential energy than the original molecules in gasoline and are more stable.

Chemical potential energy, such as the energy contained in the molecules that compose gasoline, arises primarily from electrostatic forces between the electrically charged particles (protons and electrons) that compose atoms and molecules. We will learn more about those particles, as well as the properties of electrical charge, in Chapter 2, but for now, know that molecules contain specific, usually complex, arrangements of these charged particles. Some of these arrangements—such as the one within the molecules that compose gasoline—have a much higher potential energy than others. When gasoline undergoes combustion, the arrangement of these particles changes, creating molecules with much lower potential energy and transferring a great deal of energy (mostly in the form of heat) to the surroundings.

#### Summarizing Energy:

- ▶ Energy is always conserved in a physical or chemical change; it is neither created nor destroyed.
- ▶ Systems with high potential energy tend to change in ways that lower their potential energy, releasing energy into the surroundings.

▲ **FIGURE 1.10 Using Chemical Energy to Do Work** The compounds produced when gasoline burns have less chemical potential energy than the gasoline molecules.

## 1.6 The Units of Measurement

In 1999, NASA lost the \$125 million *Mars Climate Orbiter*. The chairman of the commission that investigated the disaster concluded, “The root cause of the loss of the spacecraft was a failed translation of English units into metric units.” As a result, the orbiter—which was supposed to monitor weather on Mars—descended too far into the Martian atmosphere and burned up. In chemistry as in space exploration, **units**—standard quantities used to specify measurements—are critical. If we get them wrong, the consequences can be disastrous.

The two most common unit systems are the **metric system**, used in most of the world, and the **English system**, used in the United States. Scientists use the **International System of Units (SI)**, which is based on the metric system.

### Standard Units

Table 1.1, on the next page, shows the standard SI base units. In this chapter, we focus on the first four of these units: the *meter*, the standard unit of length; the *kilogram*, the

▲ The \$125 million *Mars Climate Orbiter* was lost in the Martian atmosphere in 1999 because two groups of engineers failed to communicate to each other the units that they used in their calculations.

The abbreviation *SI* comes from the French, *Système International d'Unités*.

▲ The Empire State Building is 443 m tall. A basketball player stands about 2 m tall.

The velocity of light in a vacuum is  $3.00 \times 10^8$  m/s.

Scientists commonly deal with a wide range of lengths and distances. The separation between the sun and the closest star (Proxima Centauri) is about  $3.8 \times 10^{16}$  m, while many chemical bonds measure about  $1.5 \times 10^{-10}$  m.

▲ A nickel (5 cents) weighs about 5 g.

TABLE 1.1 SI Base Units		
Quantity	Unit	Symbol
Length	Meter	m
Mass	Kilogram	kg
Time	Second	s
Temperature	Kelvin	K
Amount of substance	Mole	mol
Electric current	Ampere	A
Luminous intensity	Candela	cd

standard unit of mass; the *second*, the standard unit of time; and the *kelvin*, the standard unit of temperature.

### The Meter: A Measure of Length

The **meter (m)** is slightly longer than a yard (1 yard is 36 inches, while 1 meter is 39.37 inches).

Thus, a 100-yard (yd) football field measures only 91.4 m. The meter was originally defined as 1/10,000,000 of the distance from the equator to the North Pole (through Paris). The International Bureau of Weights and Measures now defines it more precisely as the distance light travels through a vacuum in a certain period of time, 1/299,792,458 second. A tall human is about 2 m tall, and the Empire State Building stands 443 m tall (including its mast).

### The Kilogram: A Measure of Mass

The **kilogram (kg)**, defined as the mass of a metal cylinder kept at the International Bureau of Weights and Measures at Sèvres, France, is a measure of *mass*, a quantity different from *weight*. The **mass** of an object is a measure of the quantity of matter within it, while the weight of an object is a measure of the *gravitational pull* on its matter. If you could weigh yourself on the moon, for example, its weaker gravity would pull on you with less force than does Earth's gravity, resulting in a lower weight. A 130-pound (lb) person on Earth would weigh only 21.5 lb on the moon. However, a person's mass—the quantity of matter in his or her body—remains the same on every planet. One kilogram of mass is the equivalent of 2.205 lb of weight on Earth, so expressed in kilograms, a 130-lb person has a mass of approximately 59 kg and this book has a mass of about 2.5 kg. A second common unit of mass is the gram (g). One gram is 1/1000 kg. A nickel (5¢) has a mass of about 5 g.

CONCEPTUAL  
CONNECTION 1.4

**The Mass of a Gas** We put a drop of water into a container and seal the container. The drop of water then vaporizes. Does the mass of the sealed container and its contents change upon vaporization?

### The Second: A Measure of Time

If you live in the United States, the **second (s)** is perhaps the SI unit most familiar to you. The International Bureau of Weights and Measures originally defined the second in terms of the day and the year, but a second is now defined more precisely as the

duration of 9,192,631,770 periods of the radiation emitted from a certain transition in a cesium-133 atom. (We discuss transitions and the emission of radiation by atoms in Chapter 7.) Scientists measure time on a large range of scales. The human heart beats about once every second, the age of the universe is estimated to be about  $4.32 \times 10^{17}$  s (13.7 billion years), and some molecular bonds break or form in time periods as short as  $1 \times 10^{-15}$  s.

## The Kelvin: A Measure of Temperature

The **kelvin (K)** is the SI unit of **temperature**. The temperature of a sample of matter is a measure of the average kinetic energy—the energy due to motion—of the atoms or molecules that compose the matter. The molecules in a *hot* glass of water are, on average, moving faster than the molecules in a *cold* glass of water. Temperature is a measure of this molecular motion.

Temperature also determines the direction of thermal energy transfer, what we commonly call *heat*. Thermal energy transfers from hot objects to cold ones. For example, when you touch another person's warm hand (and yours is cold), thermal energy flows *from his or her hand to yours*, making your hand feel warmer. However, if you touch an ice cube, thermal energy flows *out of your hand* to the ice, cooling your hand (and possibly melting some of the ice cube).

Figure 1.11 shows the three common temperature scales. The most common in the United States is the **Fahrenheit (°F) scale**, shown on the left in Figure 1.11. On the Fahrenheit scale, water freezes at 32 °F and boils at 212 °F at sea level. Room temperature is approximately 72 °F. The Fahrenheit scale was originally determined by assigning 0 °F to the freezing point of a concentrated saltwater solution and 96 °F to normal body temperature.

Scientists and citizens of most countries other than the United States typically use the **Celsius (°C) scale**, shown in the middle in Figure 1.11. On this scale, pure water freezes at 0 °C and boils at 100 °C (at sea level). Room temperature is approximately 22 °C. The Fahrenheit scale and the Celsius scale differ both in the size of their respective degrees and the temperature each designates as “zero.” Both the Fahrenheit and Celsius scales allow for negative temperatures.

Normal body temperature was later measured more accurately to be 98.6 °F.

**FIGURE 1.11 Comparison of the Fahrenheit, Celsius, and Kelvin Temperature Scales** The Fahrenheit degree is five-ninths the size of the Celsius degree and the kelvin. The zero point of the Kelvin scale is absolute zero (the lowest possible temperature), whereas the zero point of the Celsius scale is the freezing point of water.

The Celsius Temperature Scale

0 °C – Water freezes

10 °C – Brisk fall day

22 °C – Room temperature

45 °C – Summer day in Death Valley

Molecular motion does not *completely* stop at absolute zero because of the uncertainty principle in quantum mechanics, which we discuss in Chapter 7.

Note that we give Kelvin temperatures in kelvins (*not* “degrees Kelvin”) or K (*not* °K).

The SI unit for temperature is the kelvin, shown in Figure 1.11. The **Kelvin scale** (sometimes also called the *absolute scale*) avoids negative temperatures by assigning 0 K to the coldest temperature possible, absolute zero. Absolute zero (−273 °C or −459 °F) is the temperature at which molecular motion virtually stops. Lower temperatures do not exist. The size of the kelvin is identical to that of the Celsius degree; the only difference is the temperature that each scale designates as zero. We can convert between the temperature scales with these formulas:

$$\begin{aligned} ^\circ\text{C} &= \frac{(^{\circ}\text{F} - 32)}{1.8} \\ \text{K} &= ^\circ\text{C} + 273.15 \end{aligned}$$

Throughout this book we provide examples worked out in formats that are designed to help you develop problem-solving skills. The most common format uses two columns to guide you through the worked example. The left column describes the thought processes and steps used in solving the problem, while the right column shows the implementation. Example 1.2 follows this two-column format.

Example 1.2 Converting between Temperature Scales

A sick child has a temperature of 40.00 °C. What is the child’s temperature in **(a)** K and **(b)** °F?

SOLUTION

<b>(a)</b> Begin by finding the equation that relates the quantity that is given (°C) and the quantity you are trying to find (K).	$\text{K} = ^\circ\text{C} + 273.15$
Since this equation gives the temperature in K directly, substitute in the correct value for the temperature in °C and calculate the answer.	$\begin{aligned} \text{K} &= ^\circ\text{C} + 273.15 \\ \text{K} &= 40.00 + 273.15 = 313.15 \text{ K} \end{aligned}$
<b>(b)</b> To convert from °C to °F, first find the equation that relates these two quantities.	$^\circ\text{C} = \frac{(^{\circ}\text{F} - 32)}{1.8}$
Since this equation expresses °C in terms of °F, solve the equation for °F.	$\begin{aligned} ^\circ\text{C} &= \frac{(^{\circ}\text{F} - 32)}{1.8} \\ 1.8(^{\circ}\text{C}) &= (^{\circ}\text{F} - 32) \\ ^{\circ}\text{F} &= 1.8(^{\circ}\text{C}) + 32 \end{aligned}$
Now substitute °C into the equation and calculate the answer. <i>Note: The number of digits reported in this answer follows significant figure conventions, covered in Section 1.7.</i>	$\begin{aligned} ^{\circ}\text{F} &= 1.8(^{\circ}\text{C}) + 32 \\ ^{\circ}\text{F} &= 1.8(40.00 ^\circ\text{C}) + 32 = 104.00 ^\circ\text{F} \end{aligned}$

**FOR PRACTICE 1.2** Gallium is a solid metal at room temperature but it will melt to a liquid in your hand. The melting point of gallium is 85.6 °F. What is this temperature on **(a)** the Celsius scale and **(b)** the Kelvin scale?

Prefix Multipliers

Scientific notation (see Appendix 1A) allows us to express very large or very small quantities in a compact manner by using exponents. For example, the diameter of a hydrogen atom is  $1.06 \times 10^{-10}$  m. The International System of Units uses the **prefix multipliers** listed in Table 1.2 with the standard units. These multipliers change the value of the unit by powers of 10 (just like an exponent does in scientific notation). For example, the kilometer has the prefix *kilo* meaning 1000 or  $10^3$ . Therefore,

1 kilometer = 1000 meters =  $10^3$  meters

Similarly, the millimeter has the prefix *milli* meaning 0.001 or  $10^{-3}$ .

1 millimeter = 0.001 meters =  $10^{-3}$  meters

TABLE 1.2 SI Prefix Multipliers			
Prefix	Symbol	Multiplier	
exa	E	1,000,000,000,000,000,000	( $10^{18}$ )
peta	P	1,000,000,000,000,000	( $10^{15}$ )
tera	T	1,000,000,000,000	( $10^{12}$ )
giga	G	1,000,000,000	( $10^9$ )
mega	M	1,000,000	( $10^6$ )
kilo	k	1000	( $10^3$ )
deci	d	0.1	( $10^{-1}$ )
centi	c	0.01	( $10^{-2}$ )
milli	m	0.001	( $10^{-3}$ )
micro	$\mu$	0.000001	( $10^{-6}$ )
nano	n	0.000000001	( $10^{-9}$ )
pico	p	0.000000000001	( $10^{-12}$ )
femto	f	0.000000000000001	( $10^{-15}$ )
atto	a	0.000000000000000001	( $10^{-18}$ )

When reporting a measurement, choose a prefix multiplier close to the size of the quantity you are measuring. For example, to state the diameter of a hydrogen atom, which is  $1.06 \times 10^{-10}$  m, use picometers (106 pm) or nanometers (0.106 nm) rather than micrometers or millimeters. Choose the prefix multiplier that is most convenient for a particular number.

**Prefix Multipliers** What prefix multiplier is appropriate for reporting a measurement of  $5.57 \times 10^{-5}$  m?

CONCEPTUAL  
CONNECTION 1.5

Derived Units: Volume and Density

A **derived unit** is a combination of other units. For example, the SI unit for speed is meters per second (m/s), a derived unit. Notice that this unit is formed from two other SI units—meters and seconds—put together. You are probably more familiar with speed measured in miles/hour or kilometers/hour—these are also examples of derived units. Two other common derived units are those for volume (SI base unit is  $m^3$ ) and density (SI base unit is  $kg/m^3$ ).

Relationship between Length and Volume

▲ FIGURE 1.12 The Relationship between Length and Volume

Volume

**Volume** is a measure of space. Any unit of length, when cubed (raised to the third power), becomes a unit of volume. The cubic meter (m<sup>3</sup>), cubic centimeter (cm<sup>3</sup>), and cubic millimeter (mm<sup>3</sup>) are all units of volume. The cubic nature of volume is not always intuitive, and studies have shown that our brains are not naturally wired to process abstract concepts such as volume. For example, consider this question: how many small cubes measuring 1 cm on each side are required to construct a large cube measuring 10 cm (or 1 dm) on a side?

The answer to this question, as you can see by carefully examining the unit cube in Figure 1.12, is 1000 small cubes. When we go from a linear, one-dimensional distance to three-dimensional volume, we must raise both the linear dimension *and* its unit to the third power (not multiply by 3). Thus the volume of a cube is equal to the length of its edge cubed.

volume of cube = (edge length)<sup>3</sup>

A cube with a 10-cm edge has a volume of (10 cm)<sup>3</sup> or 1000 cm<sup>3</sup>, and a cube with a 100-cm edge has a volume of (100 cm)<sup>3</sup> = 1,000,000 cm<sup>3</sup>.

Other common units of volume in chemistry are the **liter (L)** and the **milliliter (mL)**. One milliliter (10<sup>-3</sup> L) is equal to 1 cm<sup>3</sup>. A gallon of gasoline contains 3.785 L. Table 1.3 lists some common units—for volume and other quantities—and their equivalents.

TABLE 1.3 Some Common Units and Their Equivalents		
Length	Mass	Volume
1 kilometer (km) = 0.6214 mile (mi)	1 kilogram (kg) = 2.205 pounds (lb)	1 liter (L) = 1000 mL = 1000 cm <sup>3</sup>
1 meter (m) = 39.37 inches (in) = 1.094 yards (yd)	1 pound (lb) = 453.59 grams (g)	1 liter (L) = 1.057 quarts (qt)
1 foot (ft) = 30.48 centimeters (cm)	1 ounce (oz) = 28.35 grams (g)	1 U.S. gallon (gal) = 3.785 liters (L)
1 inch (in) = 2.54 centimeter (cm) (exact)		

Density

An old riddle asks, “Which weighs more, a ton of bricks or a ton of feathers?” The answer is neither—they both weigh the same (1 ton). If you answered bricks, you confused weight with density. The **density** (*d*) of a substance is the ratio of its mass (*m*) to its volume (*V*).

Density =  $\frac{\text{mass}}{\text{volume}}$  or  $d = \frac{m}{V}$

Density is a characteristic physical property of substances (see Table 1.4 on the next page) that depends on temperature. Density is an example of an **intensive property**, one that is *independent* of the amount of the substance. The density of aluminum, for example, is the same whether you have a gram or a kilogram. Intensive properties are often used to identify substances because these properties depend only on the type of substance, not on the amount of it. For example, from Table 1.4 you can see that pure gold has a density of 19.3 g/cm<sup>3</sup>. One way to determine whether a substance is pure gold is to determine its density and compare it to 19.3 g/cm<sup>3</sup>. Mass, in contrast, is an **extensive property**, one that depends on the amount of the substance. If you know only the mass of a sample of gold, that information alone will not allow you to identify it as gold.

The units of density are those of mass divided by volume. Although the SI-derived unit for density is kg/m<sup>3</sup>, the density of liquids and solids is most often expressed in g/cm<sup>3</sup> or g/mL. (Remember that cm<sup>3</sup> and mL are equivalent units: 1 cm<sup>3</sup> = 1 mL.) Aluminum is among the least dense metals with a density of 2.7 g/cm<sup>3</sup>, while platinum is one of the densest metals with a density of 21.4 g/cm<sup>3</sup>.

The *m* in the equation for density is in italic type, meaning that it stands for mass rather than for meters. In general, the symbols for units such as meters (m), seconds (s), or kelvins (K) appear in regular type while those for variables such as mass (*m*), volume (*V*), and time (*t*) appear in italics.

Calculating Density

We can calculate the density of a substance by dividing the mass of a given amount of the substance by its volume. For example, suppose a small nugget we suspect to be gold has a mass of 22.5 g and a volume of 2.38 cm<sup>3</sup>. To find its density, we divide the mass by the volume:

d = m / V = 22.5 g / 2.38 cm^3 = 9.45 g/cm^3

In this case, the density reveals that the nugget is not pure gold because the density of gold is 19.3 g/cm<sup>3</sup>.

Example 1.3 Calculating Density

A man receives a platinum ring from his fiancée. Before the wedding, he notices that the ring feels a little light for its size, and so he decides to determine its density. He places the ring on a balance and finds that it has a mass of 3.15 g. He then finds that the ring displaces 0.233 cm<sup>3</sup> of water. Is the ring made of platinum? (Note: The volume of irregularly shaped objects is often measured by the displacement of water. To use this method, the object is placed in water and the change in volume of the water is measured. This increase in the total volume represents the volume of water displaced by the object and is equal to the volume of the object.)

Set up the problem by writing the important information that is given as well as the information that you are asked to find. In this case, we need to find the density of the ring and compare it to that of platinum.  
Note: In Section 1.8, we discuss this standardized way of setting up problems.

GIVEN: m = 3.15 g  
V = 0.233 cm^3  
FIND: Density in g/cm^3

Next, write down the equation that defines density.

EQUATION d = m / V

Solve the problem by substituting the correct values of mass and volume into the expression for density.

SOLUTION  
d = m / V = 3.15 g / 0.233 cm^3 = 13.5 g/cm^3

The density of the ring is much too low to be platinum (platinum density is 21.4 g/cm<sup>3</sup>), and the ring is therefore a fake.

- FOR PRACTICE 1.3 The woman in Example 1.3 is shocked that the ring is fake and returns it. She buys a new ring that has a mass of 4.53 g and a volume of 0.212 cm<sup>3</sup>. Is the new ring genuine?
- FOR MORE PRACTICE 1.3 A metal cube has an edge that is 11.4 mm long and a mass of 6.67 g. Calculate the density of the metal and use Table 1.4 to determine the likely identity of the metal.

TABLE 1.4 The Density of Some Common Substances at 20 °C

Substance	Density (g/cm^3)
Charcoal (from oak)	0.57
Ethanol	0.789
Ice	0.917 (at 0 °C)
Water	1.00 (at 4 °C)
Sugar (sucrose)	1.58
Table salt (sodium chloride)	2.16
Glass	2.6
Aluminum	2.70
Titanium	4.51
Iron	7.86
Copper	8.96
Lead	11.4
Mercury	13.55
Gold	19.3
Platinum	21.4

Density The density of copper decreases as temperature increases (as does the density of most substances). Which change occurs in a sample of copper when it is warmed from room temperature to 95 °C?

- (a) The sample becomes lighter.
- (b) The sample becomes heavier.
- (c) The sample expands.
- (d) The sample contracts.

## Chemistry AND Medicine

### Bone Density

**O**steoporosis—which means *porous bone*—is a condition in which bone density becomes low. The healthy bones of a young adult have a density of about  $1.0 \text{ g/cm}^3$ . Patients suffering from osteoporosis, however, can have bone densities as low as  $0.22 \text{ g/cm}^3$ . These low densities indicate that the bones have deteriorated and weakened, resulting in increased susceptibility to fractures, especially hip fractures. Patients suffering from osteoporosis can also experience height loss and disfigurement such as dowager's hump, a condition in which the patient becomes hunched over due to compression of the vertebrae. Osteoporosis is most common in postmenopausal women, but it can also occur in people (including men) who have certain diseases, such as insulin-dependent diabetes, or who take certain medications, such as prednisone. Osteoporosis is usually diagnosed and monitored with hip X-rays. Low-density bones absorb less of the X-rays than do high-density bones, producing characteristic differences in the X-ray image. Treatments for osteoporosis include calcium and vitamin D supplements, drugs that prevent bone weakening, exercise and strength training, and, in extreme cases, hip-replacement surgery.

#### QUESTION

Suppose you find a large animal bone in the woods, too large to fit in a beaker or flask. How might you approximate its density?

▲ Top: Severe osteoporosis can necessitate surgery to implant an artificial hip joint, seen in this X-ray image. Bottom: Views of the bone matrix in a normal bone (left) and one weakened by osteoporosis (right).

## 1.7 The Reliability of a Measurement

Carbon monoxide is a colorless gas emitted by motor vehicles and found in polluted air. The table shown here lists carbon monoxide concentrations in Los Angeles County as reported by the U.S. Environmental Protection Agency (EPA) over the period 1993–2013:

Year	Carbon Monoxide Concentration (ppm) *
1993	6.9
1998	6.1
2003	4.1
2008	2.5
2013	1.9

\*Second maximum, 8 hour average; ppm = *parts per million*, defined as mL pollutant per million mL of air. (Long Beach Site 060374002)

The first thing you should notice about these values is that they decrease over time. For this decrease, we can thank the Clean Air Act and its amendments, which have resulted in more efficient engines and specially blended fuels and consequently in cleaner air in all major U.S. cities over the last 30 years. The second thing you might notice is the number of digits to which the measurements are reported. The number of digits in a reported measurement indicates the certainty associated with that measurement. A less certain measurement of carbon monoxide levels might be reported as follows:

Year	Carbon Monoxide Concentration (ppm)
1993	7
1998	6
2003	4
2008	3
2013	2

Notice that the first set of data is reported to the nearest 0.1 ppm while the second set is reported to the nearest 1 ppm. Scientists report measured quantities in an agreed-upon standard way. The number of reported digits reflects the certainty in the measurement: more digits, more certainty; fewer digits, less certainty. Numbers are usually written so that the uncertainty is in the last reported digit. (We assume that uncertainty to be  $\pm 1$  in the last digit unless otherwise indicated.) By reporting the 2013 carbon monoxide concentration as 1.9 ppm, the scientists mean  $1.9 \pm 0.1$  ppm. The carbon monoxide concentration is between 1.8 and 2.0 ppm—it might be 2.0 ppm, for example, but it could not be 3.0 ppm. In contrast, if the reported value was 2 ppm (as in the second set of measurements), this would mean  $2 \pm 1$  ppm, or between 1 and 3 ppm. In general,

**Scientific measurements are reported so that every digit is certain except the last, which is estimated.**

For example, consider the following reported number:

5.213  
↑ ↑  
 certain      estimated

The first three digits are certain; the last digit is estimated.

The number of digits reported in a measurement depends on the measuring device. Consider weighing a pistachio nut on two different balances (Figure 1.13 ►). The balance on the top has marks every 1 g, while the balance on the bottom has marks every 0.1 g. For the balance on the top, we mentally divide the space between the 1- and 2-g marks into ten equal spaces and estimate that the pointer is at about 1.2 g. We then write the measurement as 1.2 g, indicating that we are sure of the “1” but we have estimated the “2.” The balance on the bottom, with marks every *tenth* of a gram, requires that we write the result with more digits. The pointer is between the 1.2-g mark and the 1.3-g mark. We again divide the space between the two marks into ten equal spaces and estimate the third digit. For the figure shown, we report 1.27 g.

### Example 1.4 Reporting the Correct Number of Digits

The graduated cylinder shown in the right margin has markings every 0.1 mL. Report the volume (which is read at the bottom of the meniscus) to the correct number of digits. (Note: The meniscus is the crescent-shaped surface at the top of a column of liquid.)

#### SOLUTION

Since the bottom of the meniscus is between the 4.5 and 4.6 mL markings, mentally divide the space between the markings into ten equal spaces and estimate the next digit. In this case, you should report the result as 4.57 mL.

What if you estimated a little differently and wrote 4.56 mL? In general, a one-unit difference in the last digit is acceptable because the last digit is estimated and different people might estimate it slightly differently. However, if you wrote 4.63 mL, you would have misreported the measurement.

**FOR PRACTICE 1.4** Record the temperature on the thermometer shown in the right margin to the correct number of digits.

## Estimation in Weighing

(a)

Markings every 1 g  
Estimated reading 1.2 g

(b)

Markings every 0.1 g  
Estimated reading 1.27 g

**▲ FIGURE 1.13 Estimation in Weighing** (a) This scale has markings every 1 g, so we mentally divide the space into ten equal spaces to estimate the last digit. This reading is 1.2 g. (b) Because this balance has markings every 0.1 g, we estimate to the hundredths place. This reading is 1.27 g.

## Counting Significant Figures

The precision of a measurement—which depends on the instrument used to make the measurement—must be preserved, not only when recording the measurement, but also when performing calculations that use the measurement. We can accomplish the preservation of this precision by using *significant figures*. In any reported measurement, the non-place-holding digits—those that are not simply marking the decimal place—are called **significant figures** (or **significant digits**). *The greater the number of significant figures, the greater the certainty of the measurement.* For example, the number 23.5 has three significant figures while the number 23.56 has four. To determine the number of significant figures in a number containing zeroes, we distinguish between zeroes that are significant and those that simply mark the decimal place. For example, in the number 0.0008, the leading zeroes (zeroes to the left of the first nonzero digit) mark the decimal place but *do not* add to the certainty of the measurement and are therefore not significant; this number has only one significant figure. In contrast, the trailing zeroes (zeroes at the end of a number) in the number 0.000800 *do add* to the certainty of the measurement and are therefore counted as significant; this number has three significant figures.

**To determine the number of significant figures in a number, follow these rules:**

### Significant Figure Rules

1. All nonzero digits are significant.
2. Interior zeroes (zeroes between two nonzero digits) are significant.
3. Leading zeroes (zeroes to the left of the first nonzero digit) are not significant. They only serve to locate the decimal point.
4. Trailing zeroes (zeroes at the end of a number) are categorized as follows:
  - Trailing zeroes after a decimal point are always significant.
  - Trailing zeroes before a decimal point (and after a nonzero number) are always significant.
  - Trailing zeroes before an *implied* decimal point are ambiguous and should be avoided by using scientific notation.
  - Some textbooks put a decimal point after one or more trailing zeroes if the zeroes are to be considered significant. We avoid that practice in this book, but you should be aware of it.

### Examples

28.03                      0.0540

408                        7.0301

0.0032                      0.00006

↙                      ↘  
not significant

45.000                      3.5600

140.00                      2500.55

1200	ambiguous
$1.2 \times 10^3$	2 significant figures
$1.20 \times 10^3$	3 significant figures
$1.200 \times 10^3$	4 significant figures
1200.	4 significant figures (common in some textbooks)

## Exact Numbers

**Exact numbers** have no uncertainty and thus do not limit the number of significant figures in any calculation. We can regard an exact number as having an unlimited number of significant figures. Exact numbers originate from three sources:

- From the accurate counting of discrete objects. For example, 3 atoms means 3.00000... atoms.
- From defined quantities, such as the number of centimeters in 1 m. Because 100 cm is defined as 1 m,

$$100 \text{ cm} = 1 \text{ m means } 100.00000 \dots \text{ cm} = 1.0000000 \dots \text{ m}$$

- From integral numbers that are part of an equation. For example, in the equation  $\text{radius} = \frac{\text{diameter}}{2}$ , the number 2 is exact and therefore has an unlimited number of significant figures.

**Example 1.5** Determining the Number of Significant Figures in a Number

How many significant figures are in each number?

(a) 0.04450 m    (b) 5.0003 km    (c) 10 dm = 1 m    (d)  $1.000 \times 10^5$  s    (e) 0.00002 mm    (f) 10,000 m

**SOLUTION**

(a) 0.04450 m	Four significant figures. The two 4s and the 5 are significant (Rule 1). The trailing zero is after a decimal point and is therefore significant (Rule 4). The leading zeroes only mark the decimal place and are therefore not significant (Rule 3).
(b) 5.0003 km	Five significant figures. The 5 and 3 are significant (Rule 1), as are the three interior zeroes (Rule 2).
(c) 10 dm = 1 m	Unlimited significant figures. Defined quantities have an unlimited number of significant figures.
(d) $1.000 \times 10^5$ s	Four significant figures. The 1 is significant (Rule 1). The trailing zeroes are after a decimal point and therefore significant (Rule 4).
(e) 0.00002 mm	One significant figure. The 2 is significant (Rule 1). The leading zeroes only mark the decimal place and are therefore not significant (Rule 3).
(f) 10,000 m	Ambiguous. The 1 is significant (Rule 1), but the trailing zeroes occur before an implied decimal point and are therefore ambiguous (Rule 4). Without more information, you would assume one significant figure. It is better to write this as $1 \times 10^5$ to indicate one significant figure or as $1.0000 \times 10^5$ to indicate five (Rule 4).

**FOR PRACTICE 1.5** How many significant figures are in each number?

(a) 554 km    (b) 7 pennies    (c)  $1.01 \times 10^5$  m    (d) 0.00099 s    (e) 1.4500 km    (f) 21,000 m

**Significant Figures in Calculations**

When we use measured quantities in calculations, the results of the calculation must reflect the precision of the measured quantities. We should not lose or gain precision during mathematical operations. Follow these rules when carrying significant figures through calculations.

**Rules for Calculations****Examples**

1. In multiplication or division, the result carries the same number of significant figures as the factor with the fewest significant figures.

$$\begin{array}{ccccccc} 1.052 & \times & 12.504 & \times & 0.53 & = & 6.7208 = 6.7 \\ \text{4 (sig. figures)} & & \text{(5 sig. figures)} & & \text{(2 sig. figures)} & & \text{(2 sig. figures)} \\ \\ 2.0035 & \div & 3.20 & = & 0.626094 & = & 0.626 \\ \text{(5 sig. figures)} & & \text{(3 sig. figures)} & & & & \text{(3 sig. figures)} \end{array}$$

2. In addition or subtraction, the result carries the same number of decimal places as the quantity with the fewest decimal places.

$$\begin{array}{r} 2.345 \\ 0.07 \\ \hline 2.9975 \\ \text{5.4125} = 5.41 \end{array} \qquad \begin{array}{r} 5.9 \\ -0.221 \\ \hline 5.679 = 5.7 \end{array}$$

In addition and subtraction, it is helpful to draw a line next to the number with the fewest decimal places. This line determines the number of decimal places in the answer.

3. When rounding to the correct number of significant figures, round down if the last (or leftmost) digit dropped is four or less; round up if the last (or leftmost) digit dropped is five or more.

Rounding to two significant figures:

5.37 rounds to 5.4  
5.34 rounds to 5.3  
5.35 rounds to 5.4  
5.349 rounds to 5.3

Notice in the last example (5.349) that only the *leftmost digit being dropped* (in this example, the 4) determines how you round the number. You ignore all the digits to the right of the leftmost digit you are dropping (in this example, you ignore the 9).

A few books recommend a slightly different rounding procedure for cases in which the last digit is 5. However, the procedure presented here is consistent with electronic calculators and will be used throughout this book.

Rules for Calculations

4. To avoid rounding errors in multi-step calculations, round only the final answer—do not round intermediate steps. If you write down intermediate answers, keep track of significant figures by underlining the least significant digit.

Examples

$$6.78 \times 5.903 \times (5.489 - 5.01)$$
$$= 6.78 \times 5.903 \times 0.479$$
$$= 19.1707$$
$$= 19$$

underline least significant digit

Notice that for multiplication or division, the quantity with the fewest *significant figures* determines the number of *significant figures* in the answer, but for addition and subtraction, the quantity with the fewest *decimal places* determines the number of *decimal places* in the answer. In multiplication and division, we focus on significant figures, but in addition and subtraction we focus on decimal places. When a problem involves addition or subtraction, the answer may have a different number of significant figures than the initial quantities. Keep this in mind in problems that involve both addition or subtraction and multiplication or division. For example,

$$\frac{1.002 - 0.999}{3.754} = \frac{0.003}{3.754}$$
$$= 7.99 \times 10^{-4}$$
$$= 8 \times 10^{-4}$$

The answer has only one significant figure, even though the initial numbers had three or four.

Example 1.6 Significant Figures in Calculations

Perform each calculation to the correct number of significant figures.

- (a)  $1.10 \times 0.5120 \times 4.0015 \div 3.4555$
- (b)  $0.355$   
 $+105.1$   
 $-100.5820$
- (c)  $4.562 \times 3.99870 \div (452.6755 - 452.33)$
- (d)  $(14.84 \times 0.55) - 8.02$

SOLUTION

(a) Round the intermediate result (in blue) to three significant figures to reflect the three significant figures in the quantity with the fewest significant figures (1.10).	$1.10 \times 0.5120 \times 4.0015 \div 3.4555$ $= 0.65219$ $= 0.652$
(b) Round the intermediate answer (in blue) to one decimal place to reflect the quantity with the fewest decimal places (105.1). Notice that 105.1 is <i>not</i> the quantity with the fewest significant figures, but it has the fewest decimal places and therefore determines the number of decimal places in the answer.	$\begin{array}{r} 0.355 \\ +105.1 \\ -100.5820 \\ \hline 4.8730 \end{array} = 4.9$
(c) Mark the intermediate result to two decimal places to reflect the number of decimal places in the quantity within the parentheses having the fewest number of decimal places (452.33). Round the final answer to two significant figures to reflect the two significant figures in the least precisely known quantity (0.3455).	$4.562 \times 3.99870 \div (452.6755 - 452.33)$ $= 4.562 \times 3.99870 \div 0.3455$ $= 52.79904$ $= 53$

- (d) Mark the intermediate result to two significant figures to reflect the number of significant figures in the quantity within the parentheses having the fewest number of significant figures (0.55). Round the final answer to one decimal place to reflect the one decimal place in the least precisely known quantity (8.162).

$$\begin{aligned}(14.84 \times 0.55) - 8.02 &= 8.162 - 8.02 \\ &= 0.142 \\ &= 0.1\end{aligned}$$

**FOR PRACTICE 1.6** Perform each calculation to the correct number of significant figures.

(a)  $3.10007 \times 9.441 \times 0.0301 \div 2.31$

(b)  $0.881$

$$+132.1$$

$$-12.02$$

(c)  $2.5110 \times 21.20 \div (44.11 + 1.223)$

(d)  $(12.01 \times 0.3) + 4.811$

## Precision and Accuracy

Scientists often repeat measurements several times to increase confidence in the result. We distinguish between two different kinds of certainty—accuracy and precision—associated with such measurements. **Accuracy** refers to how close the measured value is to the actual value. **Precision** refers to how close a series of measurements are to one another or how reproducible they are. A series of measurements can be precise (close to one another in value and reproducible) but not accurate (not close to the true value). Consider the results of three students who repeatedly weighed a lead block known to have a true mass of 10.00 g (indicated by the solid horizontal blue line on the graphs in the accompanying figure).

	Student A	Student B	Student C
Trial 1	10.49 g	9.78 g	10.03 g
Trial 2	9.79 g	9.82 g	9.99 g
Trial 3	9.92 g	9.75 g	10.03 g
Trial 4	10.31 g	9.80 g	9.98 g
Average	10.13 g	9.79 g	10.01 g

▲ Measurements are said to be precise if they are consistent with one another, but they are accurate only if they are close to the actual value.

- The results of student A are both inaccurate (not close to the true value) and imprecise (not consistent with one another). The inconsistency is the result of **random error**, error that has equal probability of being too high or too low. Almost all measurements have some degree of random error. Random error can, with enough trials, average itself out.
- The results of student B are precise (close to one another in value) but inaccurate. The inaccuracy is the result of **systematic error**, error that tends to be either too high or too low. In contrast to random error, systematic error does not average out with repeated trials. For instance, if a balance is not properly calibrated, it will systematically read too high or too low.
- The results of student C display little systematic error or random error—they are both accurate and precise.

## Chemistry IN YOUR DAY Integrity in Data Gathering

Most scientists spend many hours collecting data in the laboratory. Often, the data do not turn out exactly as the scientist had expected (or hoped). A scientist may then be tempted to “fudge” the results. For example, suppose you are expecting a particular set of measurements to follow a certain pattern. After working hard over several days or weeks to make the measurements, you notice that a few of them do not quite fit the pattern that you anticipated. You might find yourself wishing that you could simply change or omit the “faulty” measurements. Altering data in this way is considered highly unethical in the scientific community and, when discovered, is punished severely.

In 2004, Dr. Hwang Woo Suk, a stem cell researcher at the Seoul National University in Korea, published a research paper in *Science* (a highly respected research journal) claiming that he and his colleagues had cloned human embryonic stem cells. As part of his evidence, he showed photographs of the cells. The paper was hailed as an incredible breakthrough, and Dr. Hwang traveled the world lecturing on his work. *Time* magazine even included him on its “people that

matter” list for 2004. Several months later, however, one of his coworkers revealed that the photographs were fraudulent. According to the coworker, the photographs came from a computer data bank of stem cell photographs, not from a cloning experiment. A university panel investigated the results and confirmed that the photographs and other data had indeed been faked. Dr. Hwang was forced to resign his prestigious post at the university.

Although not common, incidents like this do occur from time to time. They are damaging to a community that is largely built on trust. A scientist’s peers (other researchers in similar fields) review all published research papers, but usually they are judging whether the data support the conclusion—they assume that the experimental measurements are authentic. The pressure to succeed sometimes leads researchers to betray that trust. However, over time, the tendency of scientists to reproduce and build upon one another’s work results in the discovery of the fraudulent data. When that happens, the researchers at fault are usually banished from the community and their careers are ruined.

### Solving Chemical Problems

## 1.8 Solving Chemical Problems

Learning to solve problems is one of the most important skills you will acquire in this course. No one succeeds in chemistry—or in life, really—without the ability to solve problems. Although no simple formula applies to every chemistry problem, you can learn problem-solving strategies and begin to develop some chemical intuition. Many of the problems you will solve in this course are *unit conversion problems*, where you are given one or more quantities and asked to convert them into different units. Other problems require that you use *specific equations* to get to the information you are trying to find. In the sections that follow, you will find strategies to help you solve both of these types of problems. Of course, many problems contain both conversions and equations, requiring the combination of these strategies, and some problems may require an altogether different approach.

### Converting from One Unit to Another

In Section 1.6, we discussed the SI unit system, the prefix multipliers, and a few other units. Knowing how to work with and manipulate these units in calculations is central to solving chemical problems. In calculations, units help to determine correctness. Using

units as a guide to solving problems is called **dimensional analysis**. Units should always be included in calculations; they are multiplied, divided, and canceled like any other algebraic quantity.

Consider converting 12.5 inches (in) to centimeters (cm). We know from Table 1.3 that 1 in = 2.54 cm (exact), so we can use this quantity in the calculation.

$$12.5 \text{ in} \times \frac{2.54 \text{ cm}}{1 \text{ in}} = 31.8 \text{ cm}$$

The unit, in, cancels, and we are left with cm as our final unit. The quantity  $\frac{2.54 \text{ cm}}{1 \text{ in}}$  is a **conversion factor**—a fractional quantity with the units we are *converting from* on the bottom and the units we are *converting to* on the top. Conversion factors are constructed from any two equivalent quantities. In this example, 2.54 cm = 1 in, so we construct the conversion factor by dividing both sides of the equality by 1 in and canceling the units.

$$\begin{aligned} 2.54 \text{ cm} &= 1 \text{ in} \\ \frac{2.54 \text{ cm}}{1 \text{ in}} &= \frac{1 \text{ in}}{1 \text{ in}} \\ \frac{2.54 \text{ cm}}{1 \text{ in}} &= 1 \end{aligned}$$

Because the quantity  $\frac{2.54 \text{ cm}}{1 \text{ in}}$  is equivalent to 1, multiplying by the conversion factor affects only the units, not the actual quantity. To convert the other way, from centimeters to inches, we must—using units as a guide—use a different form of the conversion factor. If we accidentally use the same form, we will get the wrong result, indicated by erroneous units. For example, suppose that we want to convert 31.8 cm to inches.

$$31.8 \text{ cm} \times \frac{2.54 \text{ cm}}{1 \text{ in}} = \frac{80.8 \text{ cm}^2}{\text{in}}$$

The units in the answer (cm<sup>2</sup>/in), as well as the value of the answer, are obviously wrong. When we solve a problem, we always look at the final units. Are they the desired units? We must always look at the magnitude of the numerical answer as well. Does it make sense? In this case, our mistake was the form of the conversion factor. It should have been inverted so that the units cancel as follows:

$$31.8 \text{ cm} \times \frac{1 \text{ in}}{2.54 \text{ cm}} = 12.5 \text{ in}$$

We can invert conversion factors because they are equal to 1 and the inverse of 1 is 1. Therefore,

$$\frac{2.54 \text{ cm}}{1 \text{ in}} = 1 = \frac{1 \text{ in}}{2.54 \text{ cm}}$$

Most unit conversion problems take the following form:

Information given  $\times$  conversion factor(s) = information sought

$$\text{Given unit} \times \frac{\text{desired unit}}{\text{given unit}} = \text{desired unit}$$

In this book, we diagram problem solutions using a *conceptual plan*. A conceptual plan is a visual outline that helps us to see the general flow of the problem solution. For unit conversions, the conceptual plan focuses on units and the conversion from one unit to another. The conceptual plan for converting in to cm is:

The conceptual plan for converting the other way, from cm to in, is just the reverse, with the reciprocal conversion factor:

Each arrow in a conceptual plan for a unit conversion has an associated conversion factor, with the units of the previous step in the denominator and the units of the following step in the numerator. In the following section, we incorporate the idea of a conceptual plan into an overall approach to solving numerical chemical problems.

## General Problem-Solving Strategy

In this book, we introduce a standard problem-solving procedure that you can adapt to many of the problems encountered in general chemistry and beyond. One of the difficulties beginning students encounter when trying to solve problems in general chemistry is not knowing where to begin. To solve any problem, you must assess the information given in the problem and devise a way to determine the requested information. In other words, you must do the following:

- Identify the starting point (the **given** information).
- Identify the end point (what you must **find**).
- Devise a way to get from the starting point to the end point using what is given as well as what you already know or can look up. (As we just discussed, this is the **conceptual plan**.)

In graphic form, we can represent this progression as:

**Given → Conceptual Plan → Find**

Although no problem-solving procedure is applicable to all problems, the following four-step procedure can be helpful in working through many of the numerical problems you will encounter in this book.

1. **Sort.** Begin by sorting the information in the problem. *Given* information is the basic data provided by the problem—often one or more numbers with their associated units. *Find* indicates what information you will need for your answer.
2. **Strategize.** This is usually the most challenging part of solving a problem. In this process, you must develop a *conceptual plan*—a series of steps that take you from the given information to the information you are trying to find. You have already seen conceptual plans for simple unit conversion problems. Each arrow in a conceptual plan represents a computational step. On the left side of the arrow is the quantity you had before the step, on the right side of the arrow is the quantity you have after the step, and below the arrow is the information you need to get from one to the other—the relationship between the quantities.

Often such relationships take the form of conversion factors or equations. These may be given in the problem, in which case you will have written them down under “Given” in step 1. Usually, however, you will need other information—which may include physical constants, formulas, or conversion factors—to help get you from what you are given to what you must find. This information comes from what you have learned or can look up in the chapter or in tables within the book.

In some cases, you may get stuck at the strategize step. If you cannot figure out how to get from the given information to the information you are asked to find, you might try working backward. For example, you can look at the units of the quantity you are trying to find and attempt to find conversion factors to get to the units of the given quantity. You may even try a combination of strategies; work forward, backward, or some of both. If you persist, you will develop a strategy to solve the problem.

3. **Solve.** This is the easiest part of solving a problem. Once you set up the problem properly and devise a conceptual plan, you simply follow the plan to solve the problem. Carry out any mathematical operations (paying attention to the rules for significant figures in calculations) and cancel units as needed.
4. **Check.** This is the step beginning students most often overlook. Experienced problem solvers always ask, “Does this answer make sense? Are the units correct? Is the number of significant figures correct?” When solving multistep problems,

Most problems can be solved in more than one way. The solutions in this book tend to be the most straightforward but certainly are not the only way to solve the problem.

errors can easily creep into the solution. You can catch most of these errors by simply checking the answer. For example, suppose you are calculating the number of atoms in a gold coin and end up with an answer of  $1.1 \times 10^{-6}$  atoms. Could the gold coin really be composed of one-millionth of one atom?

In Examples 1.7 and 1.8, this problem-solving procedure is applied to unit conversion problems. The procedure is summarized in the left column, and two examples of applying the procedure are provided in the middle and right columns. This three-column format is used in selected examples throughout this text. It allows you to see how to apply a particular procedure to two different problems. Work through one problem first (from top to bottom) and then see how you can apply the same procedure to the other problem. Recognizing the commonalities and differences between problems is a key part of developing problem-solving skills.

### Procedure for...

<b>Solving Unit Conversion Problems</b>	<b>Example 1.7</b> <b>Unit Conversion</b> Convert 1.76 yards to centimeters.	<b>Example 1.8</b> <b>Unit Conversion</b> Convert 1.8 quarts to cubic centimeters.
<b>SORT</b> Begin by sorting the information in the problem into <i>given</i> and <i>find</i> .	<b>GIVEN:</b> 1.76 yd <b>FIND:</b> cm	<b>GIVEN:</b> 1.8 qt <b>FIND:</b> cm <sup>3</sup>
<b>STRATEGIZE</b> Devise a <i>conceptual plan</i> for the problem. Begin with the <i>given</i> quantity and symbolize each conversion step with an arrow. Below each arrow, write the appropriate conversion factor for that step. Focus on the units. The conceptual plan should end at the <i>find</i> quantity and its units. In these examples, the other information you need consists of relationships between the various units.	<b>CONCEPTUAL PLAN</b>  <b>RELATIONSHIPS USED</b> $1.094 \text{ yd} = 1 \text{ m}$ $1 \text{ cm} = 10^{-2} \text{ m}$ (These conversion factors are from Tables 1.2 and 1.3.)	<b>CONCEPTUAL PLAN</b>  <b>RELATIONSHIPS USED</b> $1.057 \text{ qt} = 1 \text{ L}$ $1 \text{ mL} = 10^{-3} \text{ L}$ $1 \text{ mL} = 1 \text{ cm}^3$ (These conversion factors are from Tables 1.2 and 1.3.)
<b>SOLVE</b> Follow the conceptual plan. Begin with the <i>given</i> quantity and its units. Multiply by the appropriate conversion factor(s), canceling units, to arrive at the <i>find</i> quantity.  Round the answer to the correct number of significant figures following the rules in Section 1.7. Remember that exact conversion factors do not limit significant figures.	<b>SOLUTION</b> $1.76 \text{ yd} \times \frac{1 \text{ m}}{1.094 \text{ yd}} \times \frac{1 \text{ cm}}{10^{-2} \text{ m}}$ $= 160.8775 \text{ cm}$ $160.8775 \text{ cm} = 161 \text{ cm}$	<b>SOLUTION</b> $1.8 \text{ qt} \times \frac{1 \text{ L}}{1.057 \text{ qt}} \times \frac{1 \text{ mL}}{10^{-3} \text{ L}} \times \frac{1 \text{ cm}^3}{1 \text{ mL}}$ $= 1.70293 \times 10^3 \text{ cm}^3$ $1.70293 \times 10^3 \text{ cm}^3 = 1.7 \times 10^3 \text{ cm}^3$
<b>CHECK</b> Check your answer. Are the units correct? Does the answer make sense?	The units (cm) are correct. The magnitude of the answer (161) makes sense because a centimeter is a much smaller unit than a yard.	The units (cm <sup>3</sup> ) are correct. The magnitude of the answer (1700) makes sense because a cubic centimeter is a much smaller unit than a quart.
	<b>FOR PRACTICE 1.7</b> Convert 288 cm to yards.	<b>FOR PRACTICE 1.8</b> Convert 9255 cm <sup>3</sup> to gallons.

## Units Raised to a Power

When building conversion factors for units raised to a power, remember to raise both the number and the unit to the power. For example, to convert from  $\text{in}^2$  to  $\text{cm}^2$ , we construct the conversion factor as follows:

$$\begin{aligned} 2.54 \text{ cm} &= 1 \text{ in} \\ (2.54 \text{ cm})^2 &= (1 \text{ in})^2 \\ (2.54)^2 \text{ cm}^2 &= 1^2 \text{ in}^2 \\ 6.45 \text{ cm}^2 &= 1 \text{ in}^2 \\ \frac{6.45 \text{ cm}^2}{1 \text{ in}^2} &= 1 \end{aligned}$$

Example 1.9 demonstrates how to use conversion factors involving units raised to a power.

### Example 1.9 Unit Conversions Involving Units Raised to a Power

Calculate the displacement (the total volume of the cylinders through which the pistons move) of a 5.70-L automobile engine in cubic inches.

**SORT** Sort the information in the problem into *given* and *find*.

**GIVEN:** 5.70 L

**FIND:**  $\text{in}^3$

**STRATEGIZE** Write a conceptual plan. Begin with the given information and devise a path to the information that you are asked to find. For cubic units, you must cube the conversion factors.

#### CONCEPTUAL PLAN

#### RELATIONSHIPS USED

$$1 \text{ mL} = 10^{-3} \text{ L}$$

$$1 \text{ mL} = 1 \text{ cm}^3$$

$$2.54 \text{ cm} = 1 \text{ in}$$

(These conversion factors are from Tables 1.2 and 1.3.)

**SOLVE** Follow the conceptual plan to solve the problem. Round the answer to three significant figures to reflect the three significant figures in the least precisely known quantity (5.70 L). These conversion factors are all exact and therefore do not limit the number of significant figures.

#### SOLUTION

$$\begin{aligned} 5.70 \text{ L} &\times \frac{1 \text{ mL}}{10^{-3} \text{ L}} \times \frac{1 \text{ cm}^3}{1 \text{ mL}} \times \frac{(1 \text{ in})^3}{(2.54 \text{ cm})^3} \\ &= 347.835 \text{ in}^3 = 348 \text{ in}^3 \end{aligned}$$

**CHECK** The units of the answer are correct, and the magnitude makes sense. The unit cubic inches is smaller than liters, so the volume in cubic inches should be larger than the volume in liters.

**FOR PRACTICE 1.9** How many cubic centimeters are there in  $2.11 \text{ yd}^3$ ?

**FOR MORE PRACTICE 1.9** A vineyard has 145 acres of Chardonnay grapes. A particular soil supplement requires 5.50 g for every square meter of vineyard. How many kilograms of the soil supplement are required for the entire vineyard? ( $1 \text{ km}^2 = 247 \text{ acres}$ )

### Example 1.10 Density as a Conversion Factor

The mass of fuel in a jet must be calculated before each flight to ensure that the jet is not too heavy to fly. A 747 is fueled with 173,231 L of jet fuel. If the density of the fuel is  $0.768 \text{ g/cm}^3$ , what is the mass of the fuel in kilograms?

**SORT** Begin by sorting the information in the problem into *given* and *find*.

**GIVEN:** fuel volume = 173,231 L

density of fuel =  $0.768 \text{ g/cm}^3$

**FIND:** mass in kg

**STRATEGIZE** Draw the conceptual plan by beginning with the given quantity—in this case the volume in liters (L). The overall goal of this problem is to find the mass. You can convert between volume and mass using density ( $\text{g}/\text{cm}^3$ ). However, you must first convert the volume to  $\text{cm}^3$ . After you convert the volume to  $\text{cm}^3$ , use the density to convert to g. Finally, convert g to kg.

#### CONCEPTUAL PLAN

#### RELATIONSHIPS USED

$$1 \text{ mL} = 10^{-3} \text{ L}$$

$$1 \text{ mL} = 1 \text{ cm}^3$$

$$d = 0.768 \text{ g}/\text{cm}^3$$

$$1000 \text{ g} = 1 \text{ kg}$$

(These conversion factors are from Tables 1.2 and 1.3.)

**SOLVE** Follow the conceptual plan to solve the problem. Round the answer to three significant figures to reflect the three significant figures in the density.

#### SOLUTION

$$\begin{aligned}
 173,231 \text{ L} \times \frac{1 \text{ mL}}{10^{-3} \text{ L}} \times \frac{1 \text{ cm}^3}{1 \text{ mL}} \times \frac{0.768 \text{ g}}{1 \text{ cm}^3} \times \frac{1 \text{ kg}}{1000 \text{ g}} \\
 = 1.33 \times 10^5 \text{ kg}
 \end{aligned}$$

**CHECK** The units of the answer (kg) are correct. The magnitude makes sense because the mass ( $1.33 \times 10^5 \text{ kg}$ ) is similar in magnitude to the given volume ( $173,231 \text{ L}$  or  $1.73231 \times 10^5 \text{ L}$ ), as expected for a density close to  $1(0.768 \text{ g}/\text{cm}^3)$ .

**FOR PRACTICE 1.10** Backpackers often use canisters of white gas to fuel a cooking stove's burner. If one canister contains 1.45 L of white gas and the density of the gas is  $0.710 \text{ g}/\text{cm}^3$ , what is the mass of the fuel in kilograms?

**FOR MORE PRACTICE 1.10** A drop of gasoline has a mass of 22 mg and a density of  $0.754 \text{ g}/\text{cm}^3$ . What is its volume in cubic centimeters?

## Order-of-Magnitude Estimations

Calculation is an integral part of chemical problem solving. But precise numerical calculation is not always necessary, or even possible. Sometimes data are only approximate; other times we may not need a high degree of precision—a rough estimate or a simplified “back of the envelope” calculation is enough. We can also use approximate calculations to get an initial feel for a problem or to make a quick check to see whether our solution is “in the right ballpark.”

One way to make such estimates is to simplify the numbers so that they can be manipulated easily. The technique known as *order-of-magnitude estimation* is based on focusing only on the exponential part of numbers written in scientific notation, according to these guidelines:

- If the decimal part of the number is less than 5, just drop it. Thus,  $4.36 \times 10^5$  becomes  $10^5$  and  $2.7 \times 10^{-3}$  becomes  $10^{-3}$ .
- If the decimal part is 5 or more, round it up to 10 and rewrite the number as a power of 10. Thus,  $5.982 \times 10^7$  becomes  $10 \times 10^7 = 10^8$ , and  $6.1101 \times 10^{-3}$  becomes  $10 \times 10^{-3} = 10^{-2}$ .

When we make these approximations, we are left with powers of 10, which are easier to multiply and divide. Of course, our answer is only as reliable as the numbers used to get it, so we should not assume that the results of an order-of-magnitude calculation are accurate to more than an order of magnitude.

Suppose, for example, that we want to estimate the number of atoms that an immortal being could have counted in the 14 billion ( $1.4 \times 10^{10}$ ) years that the universe has been in existence, assuming a counting rate of ten atoms per second. Since a year has  $3.2 \times 10^7$  seconds, we can approximate the number of atoms counted as follows:

$$\begin{array}{ccccccc}
 10^{10} \text{ years} & \times & 10^7 \frac{\text{seconds}}{\text{years}} & \times & 10^1 \frac{\text{atoms}}{\text{second}} & \approx & 10^{18} \text{ atoms} \\
 \text{(number of years)} & & \text{(number of seconds per year)} & & \text{(number of atoms counted per second)} & & 
 \end{array}$$

A million trillion atoms ( $10^{18}$ ) may seem like a lot, but as we discuss in Chapter 2, a speck of matter made up of a million trillion atoms is nearly impossible to see without a microscope.

In our general problem-solving procedure, the last step is to check whether the results seem reasonable. Order-of-magnitude estimations often help us catch the kinds of mistakes that can happen in a detailed calculation, such as entering an incorrect exponent or sign into a calculator, or multiplying when we should have divided.

## Problems Involving an Equation

We can solve problems involving equations in much the same way as problems involving conversions. Usually, in problems involving equations, we must find one of the variables in the equation, given the others. The *conceptual plan* concept outlined earlier can be used for problems involving equations. For example, suppose we are given the mass ( $m$ ) and volume ( $V$ ) of a sample and asked to calculate its density. The conceptual plan shows how the *equation* takes us from the *given* quantities to the *find* quantity:

Here, instead of a conversion factor under the arrow, this conceptual plan has an equation. The equation shows the *relationship* between the quantities on the left of the arrow and the quantities on the right. Note that at this point the equation need not be solved for the quantity on the right (although in this particular case it is). The procedure that follows, as well as the two examples, offer guidance for developing a strategy to solve problems involving equations. We again use the three-column format. Work through one problem from top to bottom and then see how you can apply the same general procedure to the second problem.

### Procedure for...

<b>Solving Problems Involving Equations</b>	<b>Example 1.11</b> <b>Problems with Equations</b> Find the radius ( $r$ ) in centimeters of a spherical water droplet with a volume ( $V$ ) of $0.058 \text{ cm}^3$ . For a sphere, $V = (4/3) \pi r^3$ .	<b>Example 1.12</b> <b>Problems with Equations</b> Find the density (in $\text{g/cm}^3$ ) of a metal cylinder with a mass ( $m$ ) of $8.3 \text{ g}$ , a length ( $l$ ) of $1.94 \text{ cm}$ , and a radius ( $r$ ) of $0.55 \text{ cm}$ . For a cylinder, $V = \pi r^2 l$ .
<b>SORT</b> Begin by sorting the information in the problem into <i>given</i> and <i>find</i> .	<b>GIVEN:</b> $V = 0.058 \text{ cm}^3$ <b>FIND:</b> $r$ in cm	<b>GIVEN:</b> $m = 8.3 \text{ g}$ $l = 1.94 \text{ cm}$ $r = 0.55 \text{ cm}$ <b>FIND:</b> $d$ in $\text{g/cm}^3$
<b>STRATEGIZE</b> Write a conceptual plan for the problem. Focus on the equation(s). The conceptual plan shows how the equation takes you from the <i>given</i> quantity (or quantities) to the <i>find</i> quantity. The conceptual plan may have several parts, involving other equations or required conversions. In these examples, you use the geometrical relationships given in the problem statements as well as the definition of density, $d = m/V$ , which you learned in this chapter.	<b>CONCEPTUAL PLAN</b>  $V = \frac{4}{3} \pi r^3$ <b>RELATIONSHIPS USED</b> $V = \frac{4}{3} \pi r^3$	<b>CONCEPTUAL PLAN</b>  $V = \pi r^2 l$ $d = \frac{m}{V}$ <b>RELATIONSHIPS USED</b> $V = \pi r^2 l$ $d = \frac{m}{V}$

<p><b>SOLVE</b> Follow the conceptual plan. Solve the equation(s) for the <i>find</i> quantity (if it is not already). Gather each of the quantities that must go into the equation in the correct units. (Convert to the correct units if necessary.) Substitute the numerical values and their units into the equation(s) and calculate the answer.</p> <p>Round the answer to the correct number of significant figures.</p>	<p><b>SOLUTION</b></p> $V = \frac{4}{3} \pi r^3$ $r^3 = \frac{3}{4\pi} V$ $r = \left( \frac{3}{4\pi} V \right)^{1/3}$ $= \left( \frac{3}{4\pi} 0.058 \text{ cm}^3 \right)^{1/3}$ $= 0.24013 \text{ cm}$ $0.24013 \text{ cm} = 0.24 \text{ cm}$	<p><b>SOLUTION</b></p> $V = \pi r^2 l$ $= \pi (0.55 \text{ cm})^2 (1.94 \text{ cm})$ $= 1.8436 \text{ cm}^3$ $d = \frac{m}{V}$ $= \frac{8.3 \text{ g}}{1.8436 \text{ cm}^3} = 4.50195 \text{ g/cm}^3$ $4.50195 \text{ g/cm}^3 = 4.5 \text{ g/cm}^3$
<p><b>CHECK</b> Check your answer. Are the units correct? Does the answer make sense?</p>	<p>The units (cm) are correct and the magnitude makes sense.</p>	<p>The units (g/cm<sup>3</sup>) are correct. The magnitude of the answer seems correct for one of the lighter metals (see Table 1.4).</p>
	<p><b>FOR PRACTICE 1.11</b> Find the radius (<i>r</i>) of an aluminum cylinder that is 2.00 cm long and has a mass of 12.4 g. For a cylinder, <math>V = \pi r^2 l</math>.</p>	<p><b>FOR PRACTICE 1.12</b> Find the density, in g/cm<sup>3</sup>, of a metal cube with a mass of 50.3 g and an edge length (<i>l</i>) of 2.65 cm. For a cube, <math>V = l^3</math>.</p>

## Self-Assessment Quiz

- Q1.** A chemist mixes sodium with water and witnesses a violent reaction between the metal and water. This is best classified as
- a) an observation.                      b) a law.  
c) a hypothesis.                         d) a theory.
- Q2.** This image represents a particulate view of a sample of matter. Classify the sample according to its composition.

- a) The sample is a pure element.  
b) The sample is a homogeneous mixture.  
c) The sample is a compound.  
d) The sample is a heterogeneous mixture.
- Q3.** Which change is a physical change?
- a) wood burning  
b) iron rusting  
c) dynamite exploding  
d) gasoline evaporating

- Q4.** Which property of rubbing alcohol is a chemical property?
- a) density (0.786 g/cm<sup>3</sup>)  
b) flammability  
c) boiling point (82.5 °C)  
d) melting point (−89 °C)
- Q5.** Convert 85.0 °F to K.
- a) 181.1 K    b) 358 K    c) 29.4 K    d) 302.6 K
- Q6.** Express the quantity  $33.2 \times 10^{-4}$  m in mm.
- a) 33.2 mm                                b) 3.32 mm  
c) 0.332 mm                               d)  $3.32 \times 10^{-6}$  mm
- Q7.** What is the mass of a 1.75 L sample of a liquid that has a density of 0.921 g/mL?
- a)  $1.61 \times 10^3$  g                            b)  $1.61 \times 10^{-3}$  g  
c)  $1.90 \times 10^3$  g                            d)  $1.90 \times 10^{-3}$  g
- Q8.** Perform the calculation to the correct number of significant figures.
- $(43.998 \times 0.00552) / 2.002$
- a) 0.121    b) 0.12    c) 0.12131    d) 0.1213
- Q9.** Perform the calculation to the correct number of significant figures.
- $(8.01 - 7.50) / 3.002$
- a) 0.1698867    b) 0.17    c) 0.170    d) 0.1700
- Q10.** Convert 1285 cm<sup>2</sup> to m<sup>2</sup>.
- a)  $1.285 \times 10^7$  m<sup>2</sup>                        b) 12.85 m<sup>2</sup>  
c) 0.1285 m<sup>2</sup>                              d)  $1.285 \times 10^5$  m<sup>2</sup>

Continued—

- Q11.** The first diagram depicts a compound in its liquid state. Which of the other diagrams best depicts the compound after it has evaporated into a gas?

(a)

(b)

(c)

(d)

Answers: 1. (a) 2. (c) 3. (d) 4. (b) 5. (d) 6. (b) 7. (a) 8. (a) 9. (b) 10. (c) 11. (a) 12. (c) 13. (d) 14. (c) 15. (a)

- Q12.** Three samples, each of a different substance, are weighed and their volume is measured. The results are tabulated. List the substances in order of decreasing density.

	Mass	Volume
Substance I	10.0 g	10.0 mL
Substance II	10.0 kg	12.0 L
Substance III	12.0 mg	10.0 $\mu\text{L}$

- a) III > II > I  
 b) I > II > III  
 c) III > I > II  
 d) II > I > III
- Q13.** A solid metal sphere has a radius of 3.53 cm and a mass of 1.796 kg. What is the density of the metal in  $\text{g}/\text{cm}^3$ ? (The volume of a sphere is  $V = \frac{4}{3}\pi r^3$ .)
- a)  $34.4 \text{ g}/\text{cm}^3$   
 b)  $0.103 \text{ g}/\text{cm}^3$   
 c)  $121 \text{ g}/\text{cm}^3$   
 d)  $9.75 \text{ g}/\text{cm}^3$
- Q14.** The gas mileage of a certain German automobile is 22 km/L. Convert this quantity to miles per gallon.
- a) 9.4 mi/gal  
 b)  $1.3 \times 10^2 \text{ mi/gal}$   
 c) 52 mi/gal  
 d) 3.6 mi/gal
- Q15.** A wooden block has a volume of  $18.5 \text{ in}^3$ . Express the volume of the cube in  $\text{cm}^3$ .
- a)  $303 \text{ cm}^3$   
 b)  $47.0 \text{ cm}^3$   
 c)  $1.13 \text{ cm}^3$   
 d)  $7.28 \text{ cm}^3$

## Chapter 1 IN REVIEW

### Key Terms

#### Section 1.1

atoms (2)  
 molecules (2)  
 chemistry (2)

#### Section 1.2

hypothesis (3)  
 experiment (3)  
 scientific law (3)  
 law of conservation  
 of mass (3)  
 theory (4)  
 atomic theory (4)

#### Section 1.3

matter (5)  
 substance (5)  
 state (5)  
 composition (5)  
 solid (6)  
 liquid (6)  
 gas (6)  
 crystalline (6)  
 amorphous (6)  
 pure substance (8)  
 mixture (8)  
 element (8)

compound (8)  
 heterogeneous mixture (8)  
 homogeneous mixture (8)  
 decanting (8)  
 distillation (8)  
 volatile (8)  
 filtration (8)

#### Section 1.4

physical change (9)  
 chemical change (10)  
 physical property (10)  
 chemical property (10)

**Section 1.5**

energy (12)  
work (12)  
kinetic energy (12)  
potential energy (12)  
thermal energy (12)  
law of conservation of energy (12)

**Section 1.6**

units (13)  
metric system (13)  
English system (13)  
International System of Units (SI) (13)  
meter (m) (14)

kilogram (kg) (14)  
mass (14)  
second (s) (14)  
kelvin (K) (15)  
temperature (15)  
Fahrenheit (°F) scale (15)  
Celsius (°C) scale (15)  
Kelvin scale (16)  
prefix multipliers (17)  
derived unit (17)  
volume (V) (18)  
liter (L) (18)  
milliliter (mL) (18)  
density (d) (18)

intensive property (18)  
extensive property (18)

**Section 1.7**

significant figures (significant digits) (22)  
exact numbers (22)  
accuracy (25)  
precision (25)  
random error (26)  
systematic error (26)

**Section 1.8**

dimensional analysis (27)  
conversion factor (27)

## Key Concepts

**Atoms and Molecules (1.1)**

- ▶ All matter is composed of atoms and molecules.
- ▶ Chemistry is the science that investigates the properties of matter by examining the atoms and molecules that compose it.

**The Scientific Approach to Knowledge (1.2)**

- ▶ Science begins with the observation of the physical world. A number of related observations can be summarized in a statement or generalization called a scientific law.
- ▶ A hypothesis is a tentative interpretation or explanation of observations. One or more well-established hypotheses may prompt the development of a scientific theory, a model for nature that explains the underlying reasons for observations and laws.
- ▶ Laws, hypotheses, and theories all give rise to predictions that can be tested by experiments, carefully controlled procedures designed to produce critical new observations. If scientists cannot confirm the predictions, they must modify or replace the law, hypothesis, or theory.

**The Classification of Matter (1.3)**

- ▶ We classify matter according to its state (solid, liquid, or gas) or according to its composition (pure substance or mixture).
- ▶ A pure substance can either be an element, which cannot be chemically broken down into simpler substances, or a compound, which is composed of two or more elements in fixed proportions.
- ▶ A mixture can be either homogeneous, with the same composition throughout, or heterogeneous, with different compositions in different regions.

**The Properties of Matter (1.4)**

- ▶ We classify the properties of matter into two types: physical and chemical. Matter displays its physical properties without changing its composition.
- ▶ Changes in matter in which composition does not change are physical changes. Changes in matter in which composition does change are chemical changes.

**Energy (1.5)**

- ▶ In chemical and physical changes, matter often exchanges energy with its surroundings. In these exchanges, the total energy is always conserved; energy is neither created nor destroyed.
- ▶ Systems with high potential energy tend to change in the direction of lower potential energy, releasing energy into the surroundings.

**The Units of Measurement and Significant Figures (1.6, 1.7)**

- ▶ Scientists use SI units, which are based on the metric system. The SI base units include the meter (m) for length, the kilogram (kg) for mass, the second (s) for time, and the kelvin (K) for temperature.
- ▶ Derived units are formed from a combination of other units. Common derived units include those for volume (cm<sup>3</sup> or m<sup>3</sup>) and density (g/cm<sup>3</sup>).
- ▶ The number of digits in a reported measurement reflects the uncertainty in the measurement. Significant figures are the non-place-holding digits in a reported number.

## Key Equations and Relationships

Relationship between Kelvin (K) and Celsius (°C) Temperature Scales (1.6)

$$K = ^\circ C + 273.15$$

Relationship between Celsius (°C) and Fahrenheit (°F) Temperature Scales (1.6)

$$^\circ C = \frac{(^{\circ}F - 32)}{1.8}$$

Relationship between Density (d), Mass (m), and Volume (V) (1.6)

$$d = \frac{m}{V}$$

## Key Learning Outcomes

CHAPTER OBJECTIVES	ASSESSMENT
Determining Physical and Chemical Changes and Properties (1.4)	Example 1.1 For Practice 1.1 Exercises 43–50
Converting between the Temperature Scales: Fahrenheit, Celsius, and Kelvin (1.6)	Example 1.2 For Practice 1.2 Exercises 51–54
Calculating the Density of a Substance (1.6)	Example 1.3 For Practice 1.3 For More Practice 1.3 Exercises 65–68
Reporting Scientific Measurements to the Correct Digit of Uncertainty (1.7)	Example 1.4 For Practice 1.4 Exercises 73, 74
Working with Significant Figures (1.7)	Examples 1.5, 1.6 For Practice 1.5, 1.6 Exercises 77, 78, 80, 83–88
Using Conversion Factors (1.8)	Examples 1.7, 1.8, 1.9, 1.10 For Practice 1.7, 1.8, 1.9, 1.10 For More Practice 1.9, 1.10 Exercises 93, 94, 98–101, 103, 104
Solving Problems Involving Equations (1.8)	Examples 1.11, 1.12 For Practice 1.11, 1.12 Exercises 119, 120

## EXERCISES

### Review Questions

1. Explain this statement in your own words and give an example.  
*The properties of the substances around us depend on the atoms and molecules that compose them.*
2. Explain the main goal of chemistry.
3. Describe the scientific approach to knowledge. How does it differ from other approaches?
4. Explain the differences between a hypothesis, a law, and a theory.
5. What observations did Antoine Lavoisier make? What law did he formulate?
6. What theory did John Dalton formulate?
7. What is wrong with the expression “That is just a theory,” if by *theory* the speaker is referring to a scientific theory?
8. What are two different ways to classify matter?
9. How do solids, liquids, and gases differ?
10. What is the difference between a crystalline solid and an amorphous solid?
11. Explain the difference between a pure substance and a mixture.
12. Explain the difference between an element and a compound.
13. Explain the difference between a homogeneous and a heterogeneous mixture.
14. What kind of mixtures can be separated by filtration?
15. Explain how distillation is used to separate mixtures.
16. What is the difference between a physical property and a chemical property?
17. What is the difference between a physical change and a chemical change? List some examples of each.
18. Explain the significance of the law of conservation of energy.
19. What kind of energy is chemical energy? In what way is an elevated weight similar to a tank of gasoline?
20. What are the standard SI base units of length, mass, time, and temperature?
21. What are the three common temperature scales? Does the size of a degree differ among them?
22. What are prefix multipliers? List some examples.
23. What is a derived unit? List an example.
24. Explain the difference between density and mass.
25. Explain the difference between *intensive* and *extensive* properties.
26. What is the meaning of the number of digits reported in a measured quantity?
27. When multiplying or dividing measured quantities, what determines the number of significant figures in the result?
28. When adding or subtracting measured quantities, what determines the number of significant figures in the result?
29. What are the rules for rounding off the results of calculations?
30. Explain the difference between precision and accuracy.
31. Explain the difference between random error and systematic error.
32. What is dimensional analysis?

### Problems by Topic

Note: Answers to all odd-numbered Problems, numbered in blue, can be found in Appendix III. Exercises in the Problems by Topic section are paired, with each odd-numbered problem followed by a similar even-numbered problem. Exercises in the Cumulative Problems section are also paired, but more loosely. Challenge Problems and Conceptual Problems, because of their nature, are unpaired.

#### The Scientific Approach to Knowledge

33. Classify each statement as an observation, a law, or a theory.
  - a. All matter is made of tiny, indestructible particles called atoms.
  - b. When iron rusts in a closed container, the mass of the container and its contents does not change.

- c. In chemical reactions, matter is neither created nor destroyed.
- d. When a match burns, heat is released.
34. Classify each statement as an observation, a law, or a theory.
- Chlorine is a highly reactive gas.
  - If elements are listed in order of increasing mass of their atoms, their chemical reactivities follow a repeating pattern.
  - Neon is an inert (or nonreactive) gas.
  - The reactivity of elements depends on the arrangement of their electrons.
35. A chemist decomposes several samples of carbon monoxide into carbon and oxygen and weighs the resultant elements. The results are shown in the table.

Sample	Mass of Carbon (g)	Mass of Oxygen (g)
1	6	8
2	12	16
3	18	24

- a. Do you notice a pattern in these results?

Next, the chemist decomposes several samples of hydrogen peroxide into hydrogen and oxygen. The results are shown in the table.

Sample	Mass of Hydrogen (g)	Mass of Oxygen (g)
1	0.5	8
2	1	16
3	1.5	24

- b. Do you notice a similarity between these results and those for carbon monoxide in part a?
- c. Can you formulate a law from your observations in a and b?
- d. Can you formulate a hypothesis that might explain your law in c?
36. When astronomers observe distant galaxies, they can tell that most of them are moving away from one another. In addition, the more distant the galaxies, the more rapidly they are likely to be moving away from each other. Can you devise a hypothesis to explain these observations?

### The Classification and Properties of Matter

37. Classify each substance as a pure substance or a mixture. If it is a pure substance, classify it as an element or a compound. If it is a mixture, classify it as homogeneous or heterogeneous.
- sweat
  - carbon dioxide
  - aluminum
  - vegetable soup
38. Classify each substance as a pure substance or a mixture. If it is a pure substance, classify it as an element or a compound. If it is a mixture, classify it as homogeneous or heterogeneous.
- wine
  - beef stew
  - iron
  - carbon monoxide
39. Complete the table.

Substance	Pure or mixture	Type
aluminum	pure	element
apple juice	_____	_____
hydrogen peroxide	_____	_____
chicken soup	_____	_____

40. Complete the table.

Substance	Pure or mixture	Type
water	pure	compound
coffee	_____	_____
ice	_____	_____
carbon	_____	_____

41. Determine whether each molecular diagram represents a pure substance or a mixture. If it represents a pure substance, classify the substance as an element or a compound. If it represents a mixture, classify the mixture as homogeneous or heterogeneous.

42. Determine whether each molecular diagram represents a pure substance or a mixture. If it represents a pure substance, classify the substance as an element or a compound. If it represents a mixture, classify the mixture as homogeneous or heterogeneous.

43. Classify each of the listed properties of isopropyl alcohol (also known as rubbing alcohol) as physical or chemical.
- colorless
  - flammable
  - liquid at room temperature
  - density = 0.79 g/mL
  - mixes with water

44. Classify each of the listed properties of ozone (a pollutant in the lower atmosphere but part of a protective shield against UV light in the upper atmosphere) as physical or chemical.
- bluish color
  - pungent odor
  - very reactive
  - decomposes on exposure to ultraviolet light
  - gas at room temperature
45. Classify each property as physical or chemical.
- the tendency of ethyl alcohol to burn
  - the shine on silver
  - the odor of paint thinner
  - the flammability of propane gas
46. Classify each property as physical or chemical.
- the boiling point of ethyl alcohol
  - the temperature at which dry ice evaporates
  - the tendency of iron to rust
  - the color of gold
47. Classify each change as physical or chemical.
- Natural gas burns in a stove.
  - The liquid propane in a gas grill evaporates because the valve was left open.
  - The liquid propane in a gas grill burns in a flame.
  - A bicycle frame rusts on repeated exposure to air and water.
48. Classify each change as physical or chemical.
- Sugar burns when heated in a skillet.
  - Sugar dissolves in water.
  - A platinum ring becomes dull because of continued abrasion.
  - A silver surface becomes tarnished after exposure to air for a long period of time.
49. Based on the molecular diagram, classify each change as physical or chemical.

50. Based on the molecular diagram, classify each change as physical or chemical.

(a)

(b)

(c)

## Units in Measurement

51. Convert each temperature.
- $32^{\circ}\text{F}$  to  $^{\circ}\text{C}$  (temperature at which water freezes)
  - $77\text{ K}$  to  $^{\circ}\text{F}$  (temperature of liquid nitrogen)
  - $-109^{\circ}\text{F}$  to  $^{\circ}\text{C}$  (temperature of dry ice)
  - $98.6^{\circ}\text{F}$  to  $\text{K}$  (body temperature)
52. Convert each temperature.
- $212^{\circ}\text{F}$  to  $^{\circ}\text{C}$  (temperature of boiling water at sea level)
  - $22^{\circ}\text{C}$  to  $\text{K}$  (approximate room temperature)
  - $0.00\text{ K}$  to  $^{\circ}\text{F}$  (coldest temperature possible, also known as absolute zero)
  - $2.735\text{ K}$  to  $^{\circ}\text{C}$  (average temperature of the universe as measured from background black body radiation)
53. The coldest temperature ever measured in the United States is  $-80^{\circ}\text{F}$ , recorded on January 23, 1971, in Prospect Creek, Alaska. Convert that temperature to  $^{\circ}\text{C}$  and  $\text{K}$ . (Assume that  $-80^{\circ}\text{F}$  is precise to two significant figures.)
54. The warmest temperature ever measured in the United States is  $134^{\circ}\text{F}$ , recorded on July 10, 1913, in Death Valley, California. Convert that temperature to  $^{\circ}\text{C}$  and  $\text{K}$ .
55. Use the prefix multipliers to express each measurement without exponents.
- $1.2 \times 10^{-9}\text{ m}$
  - $22 \times 10^{-15}\text{ s}$
  - $1.5 \times 10^9\text{ g}$
  - $3.5 \times 10^6\text{ L}$
56. Use prefix multipliers to express each measurement without exponents.
- $38.8 \times 10^5\text{ g}$
  - $55.2 \times 10^{-10}\text{ s}$
  - $23.4 \times 10^{11}\text{ m}$
  - $87.9 \times 10^{-7}\text{ L}$
57. Use scientific notation to express each quantity with only base units (no prefix multipliers).
- $4.5\text{ ns}$
  - $18\text{ fs}$
  - $128\text{ pm}$
  - $35\text{ }\mu\text{m}$
58. Use scientific notation to express each quantity with only base units (no prefix multipliers).
- $35\text{ }\mu\text{L}$
  - $225\text{ Mm}$
  - $133\text{ Tg}$
  - $1.5\text{ cg}$

59. Complete the table.

a. 1245 kg	$1.245 \times 10^6$ g	$1.245 \times 10^9$ mg
b. 515 km	_____ dm	_____ cm
c. 122.355 s	_____ ms	_____ ks
d. 3.345 kJ	_____ J	_____ mJ

60. Complete the table.

a. 355 km/s	_____ cm/s	_____ m/ms
b. 1228 g/L	_____ g/mL	_____ kg/mL
c. 554 mK/s	_____ K/s	_____ $\mu$ K/ms
d. 2.554 mg/mL	_____ g/L	_____ $\mu$ g/mL

61. Express the quantity 254,998 m in each unit.

- a. km      b. Mm      c. mm      d. cm

62. Express the quantity  $556.2 \times 10^{-12}$  s in each unit.

- a. ms      b. ns      c. ps      d. fs

63. How many 1-cm squares would it take to construct a square that is 1 m on each side?

64. How many 1-cm cubes would it take to construct a cube that is 4 cm on edge?

### Density

65. A new penny has a mass of 2.49 g and a volume of  $0.349 \text{ cm}^3$ . Is the penny made of pure copper? Explain your answer.

66. A titanium bicycle frame displaces 0.314 L of water and has a mass of 1.41 kg. What is the density of the titanium in  $\text{g/cm}^3$ ?

67. Glycerol is a syrupy liquid often used in cosmetics and soaps. A 3.25 L sample of pure glycerol has a mass of  $4.10 \times 10^3$  g. What is the density of glycerol in  $\text{g/cm}^3$ ?

68. A supposedly gold nugget displaces 19.3 mL of water and has a mass of 371 g. Could the nugget be made of gold?

69. Ethylene glycol (antifreeze) has a density of  $1.11 \text{ g/cm}^3$ .

- a. What is the mass in g of 417 mL of ethylene glycol?  
b. What is the volume in L of 4.1 kg of ethylene glycol?

70. Acetone (nail polish remover) has a density of  $0.7857 \text{ g/cm}^3$ .

- a. What is the mass in g of 28.56 mL of acetone?  
b. What is the volume in mL of 6.54 g of acetone?

71. A small airplane takes on 245 L of fuel. If the density of the fuel is  $0.821 \text{ g/mL}$ , what mass of fuel has the airplane taken on?

72. Human fat has a density of  $0.918 \text{ g/cm}^3$ . How much volume (in  $\text{cm}^3$ ) is gained by a person who gains 10.0 lb of pure fat?

### The Reliability of a Measurement and Significant Figures

73. Read each measurement to the correct number of significant figures. Laboratory glassware should always be read from the bottom of the meniscus.

74. Read each measurement to the correct number of significant figures. Laboratory glassware should always be read from the bottom of the meniscus. Digital balances normally display mass

to the correct number of significant figures for that particular balance.

75. For each number, underline the zeroes that are significant and draw an x through the zeroes that are not.

- a. 1,050,501 km      b. 0.0020 m  
c. 0.000000000000002 s      d. 0.001090 cm

76. For each number, underline the zeroes that are significant and draw an x through the zeroes that are not.

- a. 180,701 mi      b. 0.001040 m  
c. 0.005710 km      d. 90,201 m

77. How many significant figures are in each number?

- a. 0.000312 m      b. 312,000 s      c.  $3.12 \times 10^5$  km  
d. 13,127 s      e. 2000

78. How many significant figures are in each number?

- a. 0.1111 s      b. 0.007 m      c. 108,700 km  
d.  $1.563300 \times 10^{11}$  m      e. 30,800

79. Which numbers are exact (and therefore have an unlimited number of significant figures)?

- a.  $\pi = 3.14$   
b. 12 in = 1 ft  
c. EPA gas mileage rating of 26 miles per gallon  
d. 1 gross = 144

80. Indicate the number of significant figures in each number. If the number is an exact number, indicate an unlimited number of significant figures.

- a. 318,857,056 (2014 U.S. population)      b. 2.54 cm = 1 in  
c.  $11.4 \text{ g/cm}^3$  (density of lead)      d. 12 = 1 dozen

81. Round each number to four significant figures.

- a. 156.852      b. 156.842      c. 156.849      d. 156.899

82. Round each number to three significant figures.

- a. 79,845.82      b.  $1.548937 \times 10^7$   
c. 2.3499999995      d. 0.000045389

### Significant Figures in Calculations

83. Calculate to the correct number of significant figures.

- a.  $9.15 \div 4.970$       b.  $1.54 \times 0.03060 \times 0.69$   
c.  $27.5 \times 1.82 \div 100.04$       d.  $(2.290 \times 10^6) \div (6.7 \times 10^4)$

84. Calculate to the correct number of significant figures.

- a.  $89.3 \times 77.0 \times 0.08$       b.  $(5.01 \times 10^5) \div (7.8 \times 10^2)$   
c.  $4.005 \times 74 \times 0.007$       d.  $453 \div 2.031$

85. Calculate to the correct number of significant figures.

- a.  $43.7 - 2.341$       b.  $17.6 + 2.838 + 2.3 + 110.77$   
c.  $19.6 + 58.33 - 4.974$       d.  $5.99 - 5.572$

86. Calculate to the correct number of significant figures.

- a.  $0.004 + 0.09879$       b.  $1239.3 + 9.73 + 3.42$   
c.  $2.4 - 1.777$       d.  $532 + 7.3 - 48.523$

87. Calculate to the correct number of significant figures.

- a.  $(24.6681 \times 2.38) + 332.58$   
b.  $(85.3 - 21.489) \div 0.0059$   
c.  $(512 \div 986.7) + 5.44$   
d.  $[(28.7 \times 10^5) \div 48.533] + 144.99$

88. Calculate to the correct number of significant figures.

- $[(1.7 \times 10^6) \div (2.63 \times 10^5)] + 7.33$
- $(568.99 - 232.1) \div 5.3$
- $(9443 + 45 - 9.9) \times 8.1 \times 10^6$
- $(3.14 \times 2.4367) - 2.34$

89. A flask containing 11.7 mL of a liquid weighs 132.8 g with the liquid in the flask and 124.1 g when empty. Calculate the density of the liquid in g/mL to the correct number of significant digits.

90. A flask containing 9.55 mL of a liquid weighs 157.2 g with the liquid in the flask and 148.4 g when empty. Calculate the density of the liquid in g/mL to the correct number of significant digits.

## Unit Conversions

91. Perform each unit conversion.

- 27.8 L to  $\text{cm}^3$
- 1898 mg to kg
- 198 km to cm

92. Perform each unit conversion.

- 28.9 nm to  $\mu\text{m}$
- 1432  $\text{cm}^3$  to L
- 1211 Tm to Gm

93. Perform each unit conversion.

- 154 cm to in
- 3.14 kg to g
- 3.5 L to qt
- 109 mm to in

94. Perform each unit conversion.

- 1.4 in to mm
- 116 ft to cm
- 1845 kg to lb
- 815 yd to km

95. A runner wants to run 10.0 km. Her running pace is 7.5 mi per hour. How many minutes must she run?

96. A cyclist rides at an average speed of 18 mi per hour. If she wants to bike 212 km, how long (in hours) must she ride?

97. A certain European automobile has a gas mileage of 17 km/L. What is the gas mileage in miles per gallon?

98. A gas can holds 5.0 gal of gasoline. Express this quantity in  $\text{cm}^3$ .

99. A house has an area of 195  $\text{m}^2$ . What is its area in each unit?

- $\text{km}^2$
- $\text{dm}^2$
- $\text{cm}^2$

100. A bedroom has a volume of 115  $\text{m}^3$ . What is its volume in each unit?

- $\text{km}^3$
- $\text{dm}^3$
- $\text{cm}^3$

101. The average U.S. farm occupies 435 acres. How many square miles is this? (1 acre = 43,560  $\text{ft}^2$ , 1 mile = 5280 ft)

102. Total U.S. farmland occupies 954 million acres. How many square miles is this? (1 acre = 43,560  $\text{ft}^2$ , 1 mi = 5280 ft). Total U.S. land area is 3.537 million square miles. What percentage of U.S. land is farmland?

103. An acetaminophen suspension for infants contains 80 mg/0.80 mL suspension. The recommended dose is 15 mg/kg body weight. How many mL of this suspension should be given to an infant weighing 14 lb? (Assume two significant figures.)

104. An ibuprofen suspension for infants contains 100 mg/5.0 mL suspension. The recommended dose is 10 mg/kg body weight. How many mL of this suspension should be given to an infant weighing 18 lb? (Assume two significant figures.)

## Cumulative Problems

105. There are exactly 60 seconds in a minute, exactly 60 minutes in an hour, exactly 24 hours in a mean solar day, and 365.24 solar days in a solar year. How many seconds are in a solar year? Give your answer with the correct number of significant figures.

106. Determine the number of picoseconds in 2.0 hours.

107. Classify each property as intensive or extensive.

- volume
- boiling point
- temperature
- electrical conductivity
- energy

108. At what temperatures are the readings on the Fahrenheit and Celsius thermometers the same?

109. Suppose you design a new thermometer called the X thermometer. On the X scale the boiling point of water is 130 °X, and the freezing point of water is 10 °X. At what temperature are the readings on the Fahrenheit and X thermometers the same?

110. On a new Jekyll temperature scale, water freezes at 17 °J and boils at 97 °J. On another new temperature scale, the Hyde scale, water freezes at 0 °H and boils at 120 °H. If methyl alcohol boils at 84 °H, what is its boiling point on the Jekyll scale?

111. Force is defined as mass times acceleration. Starting with SI base units, derive a unit for force. Using SI prefixes, suggest a convenient unit for the force resulting from a collision with a 10-ton trailer truck moving at 55 mi per hour and for the force resulting from the collision of a molecule of mass around  $10^{-20}$  kg moving almost at the speed of light ( $3 \times 10^8$  m/s) with the wall of its container. (Assume a 1-second deceleration time for both collisions.)

112. A temperature measurement of 25 °C has three significant figures, while a temperature measurement of -196 °C has only two significant figures. Explain.

113. Do each calculation without your calculator and give the answers to the correct number of significant figures.

- $1.76 \times 10^{-3} / 8.0 \times 10^2$
- $1.87 \times 10^{-2} + 2 \times 10^{-4} - 3.0 \times 10^{-3}$
- $[(1.36 \times 10^5)(0.000322) / 0.082](129.2)$

114. The value of the euro was recently \$1.15 U.S., and the price of 1 liter of gasoline in France is 1.42 euro. What is the price of 1 gallon of gasoline in U.S. dollars in France?

115. A thief uses a can of sand to replace a solid gold cylinder that sits on a weight-sensitive, alarmed pedestal. The can of sand and the gold cylinder have exactly the same dimensions (length = 22 and radius = 3.8 cm).

- Calculate the mass of each cylinder (ignore the mass of the can itself). (density of gold = 19.3  $\text{g}/\text{cm}^3$ , density of sand = 3.00  $\text{g}/\text{cm}^3$ )

b. Does the thief set off the alarm? Explain.

116. The proton has a radius of approximately  $1.0 \times 10^{-13}$  cm and a mass of  $1.7 \times 10^{-24}$  g. Determine the density of a proton for a sphere  $V = (4/3)\pi r^3$ .

117. The density of titanium is 4.51  $\text{g}/\text{cm}^3$ . What is the volume (in cubic inches) of 3.5 lb of titanium?

118. The density of iron is 7.86  $\text{g}/\text{cm}^3$ . What is its density in pounds per cubic inch ( $\text{lb}/\text{in}^3$ )?

119. A steel cylinder has a length of 2.16 in, a radius of 0.22 in, and a mass of 41 g. What is the density of the steel in  $\text{g}/\text{cm}^3$ ?

120. A solid aluminum sphere has a mass of 85 g. Use the density of aluminum to find the radius of the sphere in inches.

121. A backyard swimming pool holds 185 cubic yards ( $\text{yd}^3$ ) of water. What is the mass of the water in pounds?

122. An iceberg has a volume of 7655  $\text{ft}^3$ . What is the mass of the ice (in kg) composing the iceberg (at 0 °C)?

- 123.** The Toyota Prius, a hybrid electric vehicle, has an EPA gas mileage rating of 52 mi/gal in the city. How many kilometers can the Prius travel on 15 L of gasoline?
- 124.** The Honda Insight, a hybrid electric vehicle, has an EPA gas mileage rating of 41 mi/gal in the city. How many kilometers can the Insight travel on the amount of gasoline that would fit in a soda can? The volume of a soda can is 355 mL.
- 125.** The single proton that forms the nucleus of the hydrogen atom has a radius of approximately  $1.0 \times 10^{-13}$  cm. The hydrogen atom itself has a radius of approximately 52.9 pm. What fraction of the space within the atom is occupied by the nucleus?
- 126.** A sample of gaseous neon atoms at atmospheric pressure and  $0^\circ\text{C}$  contains  $2.69 \times 10^{22}$  atoms per liter. The atomic radius of neon is 69 pm. What fraction of the space do the atoms themselves occupy? What does this reveal about the separation between atoms in the gaseous phase?
- 127.** The diameter of a hydrogen atom is 212 pm. Find the length in kilometers of a row of  $6.02 \times 10^{23}$  hydrogen atoms. The diameter of a ping pong ball is 4.0 cm. Find the length in kilometers of a row of  $6.02 \times 10^{23}$  ping pong balls.
- 128.** The world's record in the 100-m dash is 9.69 s, and in the 100-yd dash it is 9.21 s. Find the speed in mi/hr of the runners who set these records. (Assume three significant figures for 100 m and 100 yd.)
- 129.** Table salt contains 39.33 g of sodium per 100 g of salt. The U.S. Food and Drug Administration (FDA) recommends that adults consume less than 2.40 g of sodium per day. A particular snack mix contains 1.25 g of salt per 100 g of the mix. What mass of the snack mix can an adult consume and still be within the FDA limit? (Assume three significant figures for 100 g.)
- 130.** Lead metal can be extracted from a mineral called galena, which contains 86.6% lead by mass. A particular ore contains 68.5% galena by mass. If the lead can be extracted with 92.5% efficiency, what mass of ore is required to make a lead sphere with a 5.00-cm radius?
- 131.** A length of #8 copper wire (radius = 1.63 mm) has a mass of 24.0 kg and a resistance of 2.061 ohm per km ( $\Omega/\text{km}$ ). What is the overall resistance of the wire?
- 132.** Rolls of aluminum foil are 304 mm wide and 0.016 mm thick. What maximum length of aluminum foil can be made from 1.10 kg of aluminum?
- 133.** Liquid nitrogen has a density of 0.808 g/mL and boils at 77 K. Researchers often purchase liquid nitrogen in insulated 175 L tanks. The liquid vaporizes quickly to gaseous nitrogen (which has a density of 1.15 g/L at room temperature and atmospheric pressure) when the liquid is removed from the tank. Suppose that all 175 L of liquid nitrogen in a tank accidentally vaporized in a lab that measured  $10.00\text{ m} \times 10.00\text{ m} \times 2.50\text{ m}$ . What maximum fraction of the air in the room could be displaced by the gaseous nitrogen?
- 134.** Mercury is often used in thermometers. The mercury sits in a bulb on the bottom of the thermometer and rises up a thin capillary as the temperature rises. Suppose a mercury thermometer contains 3.380 g of mercury and has a capillary that is 0.200 mm in diameter. How far does the mercury rise in the capillary when the temperature changes from  $0.0^\circ\text{C}$  to  $25.0^\circ\text{C}$ ? The density of mercury at these temperatures is  $13.596\text{ g/cm}^3$  and  $13.534\text{ g/cm}^3$ , respectively.

## Challenge Problems

- 135.** A force of  $2.31 \times 10^4\text{ N}$  is applied to a diver's face mask that has an area of  $125\text{ cm}^2$ . Find the pressure in atm on the face mask.
- 136.** The SI unit of force is the newton, derived from the base units by using the definition of force,  $F = ma$ . The dyne is a non-SI unit of force in which mass is measured in grams and time is measured in seconds. The relationship between the two units is  $1\text{ dyne} = 10^{-5}\text{ N}$ . Find the unit of length used to define the dyne.
- 137.** Kinetic energy can be defined as  $\frac{1}{2}mv^2$  or as  $\frac{3}{2}PV$ . Show that the derived SI units of each of these terms are those of energy. (Pressure is force/area and force is mass  $\times$  acceleration.)
- 138.** In 1999, scientists discovered a new class of black holes with masses 100 to 10,000 times the mass of our sun that occupy less space than our moon. Suppose that one of these black holes has a mass of  $1 \times 10^3$  suns and a radius equal to one-half the radius of our moon. What is the density of the black hole in  $\text{g/cm}^3$ ? The radius of our sun is  $7.0 \times 10^5\text{ km}$  and it has an average density of  $1.4 \times 10^3\text{ kg/m}^3$ . The diameter of the moon is  $2.16 \times 10^3\text{ mi}$ .
- 139.** Suppose that polluted air has carbon monoxide (CO) levels of 15.0 ppm. An average human inhales about 0.50 L of air per breath and takes about 20 breaths per minute. How many milligrams of carbon monoxide does the average person inhale in an 8-hour period at this level of carbon monoxide pollution?

Assume that the carbon monoxide has a density of 1.2 g/L. (Hint: 15.0 ppm CO means 15.0 L CO per  $10^6\text{ L}$  air.)

- 140.** Nanotechnology, the field of building ultrasmall structures one atom at a time, has progressed in recent years. One potential application of nanotechnology is the construction of artificial cells. The simplest cells would probably mimic red blood cells, the body's oxygen transporters. Nanocontainers, perhaps constructed of carbon, could be pumped full of oxygen and injected into a person's bloodstream. If the person needed additional oxygen—due to a heart attack perhaps, or for the purpose of space travel—these containers could slowly release oxygen into the blood, allowing tissues that would otherwise die to remain alive. Suppose that the nanocontainers were cubic and had an edge length of 25 nm.
- What is the volume of one nanocontainer? (Ignore the thickness of the nanocontainer's wall.)
  - Suppose that each nanocontainer could contain pure oxygen pressurized to a density of 85 g/L. How many grams of oxygen could each nanocontainer contain?
  - Air typically contains about 0.28 g of oxygen per liter. An average human inhales about 0.50 L of air per breath and takes about 20 breaths per minute. How many grams of oxygen does a human inhale per hour? (Assume two significant figures.)
  - What is the minimum number of nanocontainers that a person would need in his or her bloodstream to provide 1 hour's worth of oxygen?
  - What is the minimum volume occupied by the number of nanocontainers calculated in part d? Is such a volume feasible, given that total blood volume in an adult is about 5 L?

- 141.** Approximate the percent increase in waist size that occurs when a 155-lb person gains 40.0 lb of fat. Assume that the volume of the person can be modeled by a cylinder that is 4.0 ft tall. The average density of a human is about  $1.0 \text{ g/cm}^3$ , and the density of fat is  $0.918 \text{ g/cm}^3$ .

## Conceptual Problems

- 143.** A volatile liquid (one that easily evaporates) is put into a jar, and the jar is then sealed. Does the mass of the sealed jar and its contents change upon the vaporization of the liquid?
- 144.** The diagram shown first represents solid carbon dioxide, also known as dry ice. Which of the other diagrams best represents the dry ice after it has sublimated into a gas?

- 145.** A cube has an edge length of 7 cm. If it is divided into 1-cm cubes, how many 1-cm cubes are there?
- 146.** Substance A has density of  $1.7 \text{ g/cm}^3$ . Substance B has a density of  $1.7 \text{ kg/m}^3$ . Without doing any calculations, determine which substance is more dense.
- 147.** For each box, examine the blocks attached to the balances. Based on their positions and sizes, determine which block is more dense (the dark block or the lighter-colored block), or if

- 142.** A box contains a mixture of small copper spheres and small lead spheres. The total volume of both metals is measured by the displacement of water to be  $427 \text{ cm}^3$ , and the total mass is 4.36 kg. What percentage of the spheres are copper?

the relative densities cannot be determined. (Think carefully about the information being shown.)

- 148.** Let a triangle represent atoms of element A and a circle represent atoms of element B.
- Draw an atomic level view of a homogeneous mixture of elements A and B.
  - Draw an atomic view of the compound AB in a liquid state (molecules close together).
  - Draw an atomic view of the compound AB after it has undergone a physical change (such as evaporation).
  - Draw an atomic view of the compound after it has undergone a chemical change (such as decomposition of AB into A and B).
- 149.** Identify each statement as being most like an observation, a law, or a theory.
- All coastal areas experience two high tides and two low tides each day.
  - The tides in Earth's oceans are caused mainly by the gravitational attraction of the moon.
  - Yesterday, high tide in San Francisco Bay occurred at 2:43 A.M. and 3:07 P.M.
  - Tides are higher at the full moon and new moon than at other times of the month.

## Active Classroom Learning

## Questions for Group Work

Discuss these questions with the group and record your consensus answer.

- 150.** Using white and black circles to represent different kinds of atoms, make a drawing that accurately represents each sample of matter: a solid element, a liquid compound, and a heterogeneous mixture. Make a drawing (clearly showing *before* and *after*) depicting your liquid compound undergoing a physical change. Make a drawing depicting your solid element undergoing a chemical change.
- 151.** Look up the measurement of the approximate thickness of a human hair.
- Convert the measurement to an SI unit (if it isn't already).
  - Write it in scientific notation.
  - Write it without scientific notation.
  - Write it with an appropriate prefix on a base unit.
- Now repeat these steps using the distance from Earth to the sun.

- 152.** The following statements are all true.
- Jessica's house is 5 km from the grocery store.
  - Jessica's house is 4.73 km from the grocery store.
  - Jessica's house is 4.73297 km from the grocery store.

How can all the statements be true? What does the number of digits in each statement communicate? What sort of device would Jessica need to make the measurement in each statement?

- 153.** One inch is equal to 2.54 cm. Draw a line that is 1 in long, and mark the centimeters on the line. Draw a cube that is 1 in on each side. Draw lines on each face of the cube that are 1 cm apart. How many cubic centimeters are there in  $1 \text{ in}^3$ ?
- 154.** Convert the height of each member in your group from feet and inches to meters. Once you have your heights in meters, calculate the sum of all the heights. Use appropriate rules for significant figures at each step.

## Data Interpretation and Analysis

### Density of Water

- 155.** The graph in Figure a plots the density of water as a function of temperature at a pressure of 1.00 atm. The graph in Figure b plots the density of water as a function of temperature over a narrower range, between 0 °C and 10 °C.

**▲ FIGURE a** Density of Water as a Function of Temperature at 1.00 atm.

**▲ FIGURE b** Density of Water as a Function of Temperature Between 0 °C and 10 °C.

Use the information provided in the figures to answer the following questions:

- Compare the density of solid ice at 0 °C to the density of liquid water at 4 °C. Use this information to explain why ice floats on water and why ice forms on the top of ponds and lakes in winter in places such as Wisconsin and Minnesota, allowing fish to survive in the water below the ice.
- Observations by the Hubble Space Telescope estimate Pluto's mean density is between 1.8 g/cm<sup>3</sup> and 2.1 g/cm<sup>3</sup>. In 2006 the International Astronomical Union reclassified Pluto from a planet to a dwarf planet in part due to Pluto's low density. By comparison, the mean density of Earth's moon is 3,346.4 kg/m<sup>3</sup>. The crust of Earth's moon is composed primarily of rock containing oxygen, silicon, magnesium, iron, calcium, and aluminum. Given this information, answer the following questions:
  - Does the mean density of Pluto support a claim that Pluto is mostly ice or does it indicate that Pluto is mostly rock?
  - The temperature of Pluto ranges from −233 °C to −223 °C. A cold winter day in Antarctica is −65.1 °C. How does the density of H<sub>2</sub>O on Pluto compare to the density of H<sub>2</sub>O in Antarctica? (Extrapolate data as needed.)
- Antarctica contains 26.5 million cubic kilometers of ice. Assume that the average temperature of this ice during the summer months is −20 °C. If all of this ice melted, how many km<sup>3</sup> of liquid water would form at 4 °C?
- Pluto has a mass of  $1.27 \times 10^{22}$  kg and contains about 30% ice. Assume that the density of this ice is the same as it is at −175 °C. If humans traveled to Pluto on a spacecraft and were able to remove all of the ice from Pluto, and melt the ice, how many km<sup>3</sup> of liquid water would form at 4 °C? Is there more water on Antarctica or on Pluto?

## Answers to Conceptual Connections

### Laws and Theories

- 1.1 (b)** A law only summarizes a series of related observations; a theory gives the underlying reasons for them.

### Pure Substances and Mixtures

**1.2**

### Chemical and Physical Changes

- 1.3** View (a) best represents the water after vaporization. Vaporization is a physical change, so the molecules must remain the same before and after the change.

### The Mass of a Gas

- 1.4** No, the mass does not change. The water vaporizes and becomes a gas, but the water molecules are still present within the flask and have the same mass.

### Prefix Multipliers

- 1.5** The prefix micro ( $10^{-6}$ ) is appropriate. The measurement would be reported as 55.7  $\mu\text{m}$ .

### Density

- 1.6 (c)** The copper sample expands. However, because its mass remains constant while its volume increases, its density decreases.

# Atoms and Elements

These observations have tacitly led to the conclusion which seems universally adopted, that all bodies of sensible magnitude . . . are constituted of a vast number of extremely small particles, or atoms of matter . . . .

KEY LEARNING OUTCOMES 77

If you cut a piece of graphite from the tip of a pencil into smaller and smaller pieces, how far could you go? Could you divide it forever? Would you eventually run into some basic particles that were no longer divisible, not because of their sheer smallness, but because of the nature of matter? This fundamental question about the nature of matter has been asked by thinkers for over two millennia. Their answers have varied over time. On the scale of everyday objects, matter appears continuous, or infinitely divisible. And until about 200 years ago, many scientists thought that matter was indeed continuous—but they were proven wrong. If you were to divide the graphite from your pencil tip into smaller and smaller pieces (far smaller than the eye could see), you would eventually end up with individual carbon atoms. The word *atom* comes from the Greek *atomos*, meaning “indivisible.” You cannot divide a carbon atom into smaller pieces and still have carbon. Atoms compose all ordinary matter—if you want to understand matter, you must begin by understanding atoms.

▲ Scottish botanist Robert Brown observed random motion in tiny particles suspended in water. This motion later confirmed the particulate nature of matter.

## 2.1 Brownian Motion: Atoms Confirmed

In 1827, Scottish botanist Robert Brown (1773–1858) looked through his microscope at water-suspended particles that had come from pollen grains. He noticed that the pollen particles were in continuous motion. Any one particle traveled a random, jittery path

through the liquid water. Brown initially thought that the particles might be alive and were perhaps the male sexual cells of plants (similar to sperm). However, similar particles from plants long dead exhibited the same jittery motion, and so did the dust from pulverized stones. Brown concluded that the source of the motion must not come from the particles themselves. What was causing this motion?

The definitive answer to this question did not come until 1905, when Albert Einstein (1879–1955) developed a theory that quantitatively explained what was by then called *Brownian motion*. Einstein's model explained the motion Brown had observed as a result of the molecular bombardments of the particles due to the thermal energy of the surrounding water. In other words, the water molecules in liquid water—constantly in motion due to thermal energy—were continuously battering the pollen and dust particles, causing them to oscillate and move. In Einstein's model, the jittering pollen particles are like a beach ball that is thrown into a crowd at a graduation ceremony. As the eager graduates strike the ball over and over again, the ball moves through the crowd in a jittery random path. The difference is that, in the case of Brownian motion, the “crowd” is composed of molecules much too small to see.

In 1908, French physicist Jean Perrin (1870–1942) conducted experimental measurements to test Einstein's model. His measurements confirmed that Einstein's model was valid. In 1926, Perrin was awarded the Nobel Prize in Physics. During the award speech, the presenter said, “the object of the researches of Professor Jean Perrin which have gained for him the Nobel Prize in Physics for 1926 was to put a definite end to the long struggle regarding the real existence of molecules.” In other words, the work of Einstein, and then Perrin, removed any lingering doubt about the particulate nature of matter.

In Einstein's day, the existence of atoms was inferred from the jittery motion first witnessed by Brown. Today, with a type of microscope called a scanning tunneling microscope (STM), we can form images of atoms themselves. In fact, STM can be used to *pick up and move* individual atoms, allowing structures and patterns to be made one atom at a time. Figure 2.1◀, for example, shows the Kanji characters for the word “atom” written with individual iron atoms on top of a copper surface. If all of the words in the books in the Library of Congress—35 million books occupying 840 miles of shelves—were written in letters the size of these Kanji characters, they would fit into an area of about five square millimeters. Scientists at IBM have also succeeded in making a short video entitled *A Boy and His Atom*, in which the main character (a boy) is animated using a few dozen atoms. In the video, which has been viewed millions of times on YouTube, the boy plays with an atom like a real boy would play with a ball.

As we discussed in Chapter 1, it was only 200 years ago that John Dalton proposed his atomic theory, and about 100 years ago that the theory was confirmed through the work of Einstein and Perrin. Yet today we can image atoms, move them, and even build tiny machines out of just a few dozen atoms (an area of research called nanotechnology). These atomic machines, and the atoms that compose them, are almost unimaginably small. To get an idea of the size of an atom, imagine picking up a grain of sand at a beach. That grain contains more atoms than you could count in a lifetime. In fact, the number of atoms in one sand grain far exceeds the number of grains on an entire beach.

In spite of their small size, atoms are the key to connecting the macroscopic and microscopic worlds. An *atom* is the smallest identifiable unit of an *element*. There are about 91 different naturally occurring elements. In addition, scientists have succeeded in making over 20 synthetic elements (elements not found in nature). In this chapter, we learn about atoms: what they are made of, how they differ from one another, and how they are structured. We also learn about the elements that are composed of these different kinds of atoms and about some of their characteristic properties. We will also discuss how the elements can be organized in a way that reveals patterns in their properties and helps us to understand what underlies those properties.

**▲ FIGURE 2.1 Imaging Atoms** The Japanese Kanji characters for “atom” written with iron atoms (red) on a copper surface (blue). The copper atoms are not as distinct as the iron atoms, but they appear as blue ripples in the background.

The exact number of naturally occurring elements is controversial because some elements that were first discovered when they were synthesized are believed to also be present in trace amounts in nature.

## 2.2 Early Ideas about the Building Blocks of Matter

The first people to propose that matter was composed of small, indestructible particles were Leucippus (fifth century B.C., exact dates unknown) and his student Democritus (460–370 B.C.). These Greek philosophers theorized that matter is ultimately composed of small, indivisible particles they named *atomos*. Democritus wrote, “Nothing exists except atoms and empty space; everything else is opinion.” Leucippus and Democritus proposed that many different kinds of atoms exist, each different in shape and size, and that they move randomly through empty space. Other influential Greek thinkers of the time, such as Plato and Aristotle, did not embrace the atomic ideas of Leucippus and Democritus. Instead, Plato and Aristotle held that matter had no smallest parts and that different substances were composed of various proportions of fire, air, earth, and water. Since there was no experimental way to test the relative merits of the competing ideas, Aristotle’s view prevailed, largely because he was so influential. The idea that matter is composed of atoms took a back seat in intellectual thought for nearly 2000 years.

In the sixteenth century, modern science began to emerge. A greater emphasis on observation led Nicolaus Copernicus (1473–1543) to publish *On the Revolution of the Heavenly Orbs* in 1543. The publication of that book—which proposed that the sun, not Earth, is at the center of the universe—marks the beginning of what we now call the *scientific revolution*. The next 200 years—and the work of scientists such as Francis Bacon (1561–1626), Johannes Kepler (1571–1630), Galileo Galilei (1564–1642), Robert Boyle (1627–1691), and Isaac Newton (1642–1727)—brought rapid advancement as the scientific approach became the established way to learn about the physical world. By the early 1800s, certain observations led the English chemist John Dalton (1766–1844) to offer convincing evidence that supported the early atomic ideas of Leucippus and Democritus. However, debate continued about whether atoms actually exist until the description of Brownian motion by Einstein in 1905 and subsequent experimental verification of the description in 1908 by Perrin (see Section 2.1).

## 2.3 Modern Atomic Theory and the Laws That Led to It

Atomic Theory

Recall the discussion of the scientific approach to knowledge from Chapter 1. The *atomic theory* (the idea that all matter is composed of atoms) grew out of observations and laws. The three most important laws that led to the development and acceptance of the atomic theory are the law of conservation of mass, the law of definite proportions, and the law of multiple proportions.

### The Law of Conservation of Mass

In 1789, as we saw in Chapter 1, Antoine Lavoisier formulated the **law of conservation of mass**, which states:

**In a chemical reaction, matter is neither created nor destroyed.**

In other words, when a chemical reaction occurs, the total mass of the substances involved in the reaction does not change. For example, consider the reaction between sodium and chlorine to form sodium chloride. The combined mass of the sodium and chlorine that react (the *reactants*) exactly equals the mass of the sodium chloride that forms (the *product*). This law is consistent with the idea that matter is composed of small, indestructible particles. The particles rearrange during a chemical reaction, but the amount of matter is conserved because the particles themselves are indestructible (at least by chemical means).

We will see in Chapter 20 that the **law of conservation of mass** is a slight oversimplification. However, the changes in mass in ordinary chemical processes are so minute that they can be ignored for all practical purposes.

## CONCEPTUAL CONNECTION 2.1

**The Law of Conservation of Mass** When a log completely burns in a campfire, the mass of the ash is much less than the mass of the log. What happens to the matter that composed the log?

## The Law of Definite Proportions

In 1797, the French chemist Joseph Proust (1754–1826) made observations on the composition of compounds. He found that the elements composing a given compound always occur in fixed (or definite) proportions in all samples of the compound. In contrast, the components of a mixture can be present in any proportions whatsoever. Proust summarized his observations in the **law of definite proportions**:

**All samples of a given compound, regardless of their source or how they were prepared, have the same proportions of their constituent elements.**

For example, the decomposition of 18.0 g of water results in 16.0 g of oxygen and 2.0 g of hydrogen, or an oxygen-to-hydrogen mass ratio of:

$$\text{Mass ratio} = \frac{16.0 \text{ g O}}{2.0 \text{ g H}} = 8.0 \text{ or } 8:1$$

This ratio holds for any sample of pure water, regardless of its origin. The law of definite proportions applies to every compound. Consider ammonia, a compound composed of nitrogen and hydrogen. Ammonia contains 14.0 g of nitrogen for every 3.0 g of hydrogen, resulting in a nitrogen-to-hydrogen mass ratio of 4.7.

$$\text{Mass ratio} = \frac{14.0 \text{ g N}}{3.0 \text{ g H}} = 4.7 \text{ or } 4.7:1$$

The law of definite proportions is sometimes called the law of constant composition.

Again, this ratio is the same for every sample of ammonia. The law of definite proportions also hints at the idea that matter is composed of atoms. Compounds have definite proportions of their constituent elements because the atoms that compose them, each with its own specific mass, occur in a definite ratio. Since the ratio of atoms is the same for all samples of a particular compound, the ratio of masses is also the same.

### Example 2.1 Law of Definite Proportions

Two samples of carbon dioxide are decomposed into their constituent elements. One sample produces 25.6 g of oxygen and 9.60 g of carbon, and the other produces 21.6 g of oxygen and 8.10 g of carbon. Show that these results are consistent with the law of definite proportions.

#### SOLUTION

To show this, for both samples calculate the mass ratio of one element to the other by dividing the mass of one element by the mass of the other. For convenience, divide the larger mass by the smaller one.

For the first sample:

$$\frac{\text{Mass oxygen}}{\text{Mass carbon}} = \frac{25.6}{9.60} = 2.67 \text{ or } 2.67:1$$

For the second sample:

$$\frac{\text{Mass oxygen}}{\text{Mass carbon}} = \frac{21.6}{8.10} = 2.67 \text{ or } 2.67:1$$

The ratios are the same for the two samples, so these results are consistent with the law of definite proportions.

**FOR PRACTICE 2.1** Two samples of carbon monoxide are decomposed into their constituent elements. One sample produces 17.2 g of oxygen and 12.9 g of carbon, and the other sample produces 10.5 g of oxygen and 7.88 g of carbon. Show that these results are consistent with the law of definite proportions.

Answers to For Practice and For More Practice Problems can be found in Appendix IV.

## The Law of Multiple Proportions

In 1804, John Dalton published his **law of multiple proportions**:

**When two elements (call them A and B) form two different compounds, the masses of element B that combine with 1 g of element A can be expressed as a ratio of small whole numbers.**

Dalton suspected that matter was composed of atoms, so that when two elements A and B combine to form more than one compound, an atom of A combines with either one, two, three, or more atoms of B ( $AB_1$ ,  $AB_2$ ,  $AB_3$ , etc.). Therefore, the masses of B that react with a fixed mass of A are always related to one another as small whole-number ratios. Consider the compounds carbon monoxide and carbon dioxide. Carbon monoxide and carbon dioxide are two compounds composed of the same two elements: carbon and oxygen. We saw in Example 2.1 that the mass ratio of oxygen to carbon in carbon dioxide is 2.67:1; therefore, 2.67 g of oxygen reacts with 1 g of carbon. In carbon monoxide, however, the mass ratio of oxygen to carbon is 1.33:1, or 1.33 g of oxygen to every 1 g of carbon.

The ratio of these two masses is itself a small whole number.

$$\frac{\text{Mass oxygen to 1 g carbon in carbon dioxide}}{\text{Mass oxygen to 1 g carbon in carbon monoxide}} = \frac{2.67}{1.33} = 2$$

With the help of the molecular models in the margin, we can see why the ratio is 2:1—carbon dioxide contains two oxygen atoms to every carbon atom, while carbon monoxide contains only one. Of course, neither John Dalton nor Joseph Proust had access to any kind of modern instrumentation that could detect individual atoms—Dalton supported his atomic ideas primarily by using the *masses* of samples.

**Example 2.2** Law of Multiple Proportions

Nitrogen forms several compounds with oxygen, including nitrogen dioxide and dinitrogen monoxide. Nitrogen dioxide contains 2.28 g oxygen to every 1.00 g nitrogen, while dinitrogen monoxide contains 0.570 g oxygen to every 1.00 g nitrogen. Show that these results are consistent with the law of multiple proportions.

**SOLUTION**

Calculate the ratio of the mass of oxygen from one compound to the mass of oxygen in the other. Always divide the larger of the two masses by the smaller one.

$$\frac{\text{Mass oxygen to 1 g nitrogen in nitrogen dioxide}}{\text{Mass oxygen to 1 g nitrogen in dinitrogen monoxide}} = \frac{2.28}{0.570} = 4.00$$

The ratio is a small whole number (4); these results are consistent with the law of multiple proportions.

**FOR PRACTICE 2.2** Hydrogen and oxygen form both water and hydrogen peroxide. The decomposition of a sample of water forms 0.125 g hydrogen to every 1.00 g oxygen. The decomposition of a sample of hydrogen peroxide forms 0.0625 g hydrogen to every 1.00 g oxygen. Show that these results are consistent with the law of multiple proportions.

**John Dalton and the Atomic Theory**

In 1808, John Dalton explained the laws we just discussed with his **atomic theory**:

1. Each element is composed of tiny, indestructible particles called atoms.
2. All atoms of a given element have the same mass and other properties that distinguish them from the atoms of other elements.
3. Atoms combine in simple, whole-number ratios to form compounds.
4. Atoms of one element cannot change into atoms of another element. In a chemical reaction, atoms only change the way they are *bound together* with other atoms.

Today, the evidence for the atomic theory is overwhelming. Matter is indeed composed of atoms.

In Section 2.6, we will see that, contrary to Dalton's theory, all atoms of a given element do not have exactly the same mass.

**Chemistry** IN YOUR DAY **Atoms and Humans**

**Y**ou and I are composed of atoms. We get those atoms from the food we eat. Yesterday's cheeseburger contributes to today's skin, muscle, and hair. Not only are we made of atoms, but we are made of *recycled* atoms. The carbon atoms that compose our bodies were used by other living organisms before we got them. And they will be used by still others when we are done with them. In fact, it is likely that at this moment, your body contains some (over one trillion\*) carbon atoms that were at one time part of your chemistry professor.

The idea that humans are composed of atoms acting in accord with the laws of chemistry and physics has significant implications and raises important questions. If atoms compose our brains, for example, do those atoms determine our thoughts and emotions? Are our feelings caused by atoms acting according to the laws of chemistry and physics?

\*This calculation assumes that all of the carbon atoms metabolized by your professor over the last 40 years have been uniformly distributed into atmospheric carbon dioxide, and subsequently incorporated into the plants you have eaten.

Richard Feynman (1918–1988), a Nobel Prize-winning physicist, said that “The most important hypothesis in all of biology is that everything that animals do, atoms do. In other words, there is nothing that living things do that cannot be understood from the point of view that they are made of atoms acting according to the laws of physics.” Indeed, biology has undergone a revolution in the last 50 years, mostly through investigation of the atomic and molecular basis for life. Some people have seen the atomic view of life as a devaluation of human life. We have always wanted to distinguish ourselves from everything else, and the idea that we are made of the same basic particles as all other matter takes something away from that distinction . . . or does it?

**QUESTIONS**

*Do you find the idea that you are made of recycled atoms disturbing? Why or why not? Reductionism is the idea that complex systems can be understood by understanding their parts. Is reductionism a good way to understand humans? Is it the only way?*

**The Laws of Definite and Multiple Proportions** Explain the difference between the law of definite proportions and the law of multiple proportions.

## CONCEPTUAL CONNECTION 2.2

## 2.4 The Discovery of the Electron

By the end of the nineteenth century, scientists were convinced that matter is made up of atoms, the permanent, supposedly indestructible building blocks that compose everything. However, further experiments revealed that the atom itself is composed of even smaller, more fundamental particles.

### Cathode Rays

In the late 1800s, an English physicist named J. J. Thomson (1856–1940), working at Cambridge University, performed experiments to probe the properties of **cathode rays**. Thomson constructed a partially evacuated glass tube called a **cathode ray tube**, shown in Figure 2.2▼. Thomson then applied a high electrical voltage between two electrodes at either end of the tube. He found that a beam of particles, called cathode rays, traveled from the negatively charged electrode (which is called the cathode) to the positively charged one (which is called the anode).

Thomson found that the particles that compose the cathode ray have the following properties: they travel in straight lines; they are independent of the composition of the material from which they originate (the cathode); and they carry a negative **electrical charge**. Electrical charge is a fundamental property of some of the particles that compose atoms and results in attractive and repulsive forces—called *electrostatic forces*—between those particles. The area around a charged particle where these forces exist is called an *electric field*. The characteristics of electrical charge are summarized in the figure in the margin. You have probably experienced excess electrical charge when brushing your hair on a dry day. The brushing action causes the accumulation of charged particles in your hair, which repel each other, making your hair stand on end.

◀ **FIGURE 2.2** Cathode Ray Tube

J. J. Thomson measured the charge-to-mass ratio of the cathode ray particles by deflecting them using electric and magnetic fields, as shown in Figure 2.3▶, on the next page. The value he measured,  $-1.76 \times 10^8$  coulombs (C) per gram, implied that the cathode ray particle was about 2000 times lighter (less massive) than hydrogen, the lightest known atom. These results were revolutionary—the indestructible atom could apparently be chipped!

J. J. Thomson had discovered the **electron**, a negatively charged, low-mass particle present within all atoms. He wrote, “We have in the cathode rays matter in a new state, a state in which the subdivision of matter is carried very much further . . . a state in which all matter . . . is of one and the same kind; this matter being the substance from which all the chemical elements are built up.”

### Properties of Electrical Charge

Positive and negative charges of exactly the same magnitude sum to zero when combined.

For a full explanation of electrical voltage, see Chapter 19.

The coulomb (C) is the SI unit for charge.

► **FIGURE 2.3 Thomson's Measurement of the Charge-to-Mass Ratio of the Electron**

J. J. Thomson used electric and magnetic fields to deflect the electron beam in a cathode ray tube. By measuring the strengths at which the effects of the two fields (electric and magnetic) cancel exactly, leaving the beam undeflected, he was able to calculate the charge-to-mass ratio of the electron.

**Millikan's Oil Drop Experiment:  
The Charge of the Electron**

In 1909, American physicist Robert Millikan (1868–1953), working at the University of Chicago, performed his now famous oil drop experiment in which he deduced the charge of a single electron. The apparatus for the oil drop experiment is shown in Figure 2.4 ▼.

In his experiment, Millikan sprayed oil into fine droplets using an atomizer. The droplets were allowed to fall under the influence of gravity through a small hole into the lower portion of the apparatus where Millikan viewed them with the aid of a light source and a viewing microscope. During their fall, the drops acquired electrons Millikan had produced by bombarding the air in the chamber with ionizing radiation (a kind of energy described in Chapter 7). The electrons imparted a negative charge to the drops. In the lower portion of the apparatus, Millikan could create an electric field between two metal plates. Since the lower plate was negatively charged, and since Millikan could vary the strength of the electric field, he could slow or even reverse the free fall of the negatively charged drops. (Remember that like charges repel each other.)

By measuring the strength of the electric field required to halt the free fall of the drops, and by figuring out the masses of the drops themselves (determined from their radii and density), Millikan calculated the charge of each drop. He then reasoned that, since each drop must contain an integral (or whole) number of electrons, the charge of each drop must be a whole-number multiple of the electron's charge. Indeed, Millikan was correct; the measured charge on any drop is always a whole-number multiple of  $-1.60 \times 10^{-19} \text{ C}$ , the fundamental charge of a single electron.

► **FIGURE 2.4 Millikan's Measurement of the Electron's Charge** Millikan calculated the charge on oil droplets falling in an electric field. He found that it was always a whole-number multiple of  $-1.60 \times 10^{-19} \text{ C}$ , the charge of a single electron.

With this number in hand, and knowing Thomson's mass-to-charge ratio for electrons, we can deduce the mass of an electron:

$$\text{Charge} \times \frac{\text{mass}}{\text{charge}} = \text{mass}$$

$$-1.60 \times 10^{-19} \text{ C} \times \frac{\text{g}}{-1.76 \times 10^8 \text{ C}} = 9.10 \times 10^{-28} \text{ g}$$

As Thomson had correctly determined, this mass is about 2000 times lighter than hydrogen, the lightest atom.

Why did scientists work so hard to measure the charge of the electron? Since the electron is a fundamental building block of matter, scientists want to know its properties, including its charge. The magnitude of the charge of the electron is of tremendous importance because it determines how strongly an atom holds its electrons. Imagine how matter would be different if electrons had a much smaller charge, so that atoms held them more loosely. Many atoms might not even be stable. On the other hand, imagine how matter would be different if electrons had a much greater charge, so that atoms held them more tightly. Since atoms form compounds by exchanging and sharing electrons (more on this in Chapter 3), there could be fewer compounds or maybe even none. Without the abundant diversity of compounds, life would not be possible. So, the magnitude of the charge of the electron—even though it may seem like an insignificantly small number—has great importance.

**The Millikan Oil Drop Experiment** Suppose that one of Millikan's oil drops has a charge of  $-4.8 \times 10^{-19} \text{ C}$ . How many excess electrons does the drop contain?

## CONCEPTUAL CONNECTION 2.3

## 2.5 The Structure of the Atom

The discovery of negatively charged particles within atoms raised a new question. Since atoms are charge-neutral, they must contain a positive charge that neutralizes the negative charge of the electrons—but how do the positive and negative charges fit together? Are atoms just a jumble of even more fundamental particles? Are they solid spheres? Do they have some internal structure? J. J. Thomson proposed that the negatively charged electrons were small particles held within a positively charged sphere.

This model, the most popular of the time, became known as the plum-pudding model (shown at right). The model suggested by Thomson, to those of us not familiar with plum pudding (an English dessert), was like a blueberry muffin; the blueberries are the electrons, and the muffin is the positively charged sphere.

The discovery of **radioactivity**—the emission of small energetic particles from the core of certain unstable atoms—by scientists Henri Becquerel (1852–1908) and Marie Curie (1867–1934) at the end of the nineteenth century allowed researchers to experimentally probe the structure of the atom. At the time, scientists had identified three different types of radioactivity: alpha ( $\alpha$ ) particles, beta ( $\beta$ ) particles, and gamma ( $\gamma$ ) rays. We will discuss these and other types of radioactivity in more detail in Chapter 20. For now, just know that  $\alpha$  particles are positively charged and that they are by far the most massive of the three.

In 1909, Ernest Rutherford (1871–1937), who had worked under Thomson and subscribed to his plum-pudding model, performed an experiment in an attempt to confirm Thomson's model. Rutherford's experiment, which employed  $\alpha$  particles, proved Thomson wrong instead. In the experiment, Rutherford directed the positively charged  $\alpha$  particles at an ultrathin sheet of gold foil, as shown in Figure 2.5►, on the next page.

These particles were to act as probes of the gold atoms' structure. If the gold atoms were indeed like blueberry muffins or plum pudding—with their mass and charge spread throughout the entire volume of the atom—Rutherford reasoned that these speeding probes would pass right through the gold foil with minimum deflection.

Alpha particles are about 7000 times more massive than electrons.

► **FIGURE 2.5 Rutherford's Gold Foil Experiment** Alpha particles are directed at a thin sheet of gold foil. Most of the particles pass through the foil, but a small fraction are deflected, and a few even bounce backward.

Rutherford and his coworkers performed the experiment, but the results were not what they expected. The majority of the particles did pass directly through the foil, but some particles were deflected, and some (approximately 1 in 20,000) even bounced back. The results puzzled Rutherford, who wrote that they were “about as credible as if you had fired a 15-inch shell at a piece of tissue paper and it came back and hit you.” What sort of atomic structure could explain this odd behavior? Rutherford created a new model—a modern version of which is shown in Figure 2.6 alongside the plum-pudding model—to explain his results.

Rutherford realized that to account for the deflections he observed, the mass and positive charge of an atom must be concentrated in a space much smaller than the size of the atom itself. He concluded that, in contrast to the plum-pudding model, matter must not be as uniform as it appears. It must contain large regions of empty space dotted with small regions of very dense matter. Building on this idea, he proposed the **nuclear theory** of the atom, with three basic parts:

1. Most of the atom's mass and all of its positive charge are contained in a small core called the **nucleus**.
2. Most of the volume of the atom is empty space, throughout which tiny, negatively charged electrons are dispersed.
3. There are as many negatively charged electrons outside the nucleus as there are positively charged particles (named **protons**) within the nucleus, so the atom is electrically neutral.

► **FIGURE 2.6 The Nuclear Atom** Rutherford's results could not be explained by the plum-pudding model. Instead, they suggest that the atom has a small, dense nucleus.

Although Rutherford's model was highly successful, scientists realized that it was incomplete. For example, hydrogen atoms contain one proton, and helium atoms contain two, yet a hydrogen atom has only one-fourth the mass of a helium atom. Why? The helium atom must contain some additional mass. Later work by Rutherford and one of his students, British scientist James Chadwick (1891–1974), demonstrated that the previously unaccounted for mass was due to **neutrons**, neutral particles within the nucleus. The mass of a neutron is similar to that of a proton, but a neutron has no electrical charge. The helium atom is four times as massive as the hydrogen atom because its nucleus contains two protons *and two neutrons* (while hydrogen contains only one proton and no neutrons).

The dense nucleus contains over 99.9% of the mass of the atom but occupies very little of its volume. For now, we can think of the electrons that surround the nucleus in analogy to the water droplets that make up a cloud—although their mass is almost negligibly small, they are dispersed over a very large volume. Consequently, an atom, like a cloud, is mostly empty space.

Rutherford's nuclear theory was a success and is still valid today. The revolutionary part of this theory is the idea that matter—at its core—is much less uniform than it appears. If the nucleus of the atom were the size of the period at the end of this sentence, the average electron would be about 10 meters away. Yet the period would contain nearly all of the atom's mass. Imagine what matter would be like if atomic structure were different. What if matter were composed of atomic nuclei piled on top of each other like marbles in a box? Such matter would be incredibly dense; a single grain of sand composed of solid atomic nuclei would have a mass of 5 million kilograms (or a weight of about 11 million pounds). Astronomers believe there are some objects in the universe composed of such matter—neutron stars.

If matter really is mostly empty space, as Rutherford suggested, then why does it appear so solid? Why can we tap our knuckles on a table and feel a solid thump? Matter appears solid because the variation in its density is on such a small scale that our eyes cannot see it. Imagine a scaffolding 100 stories high and the size of a football field as shown in the margin. The volume of the scaffolding is mostly empty space. Yet if you viewed it from an airplane, it would appear as a solid mass. Matter is similar. When you tap your knuckle on the table, it is much like one giant scaffolding (your finger) crashing into another (the table). Even though they are both primarily empty space, one does not fall into the other.

## 2.6 Subatomic Particles: Protons, Neutrons, and Electrons in Atoms

All atoms are composed of the same subatomic particles: protons, neutrons, and electrons. Protons and neutrons, as we discussed earlier, have nearly identical masses. In SI units, the mass of the proton is  $1.67262 \times 10^{-27}$  kg, and the mass of the neutron is  $1.67493 \times 10^{-27}$  kg. A more common unit to express these masses is the **atomic mass unit (amu)**, defined as 1/12 the mass of a carbon atom that contains six protons and six neutrons. The mass of a proton or neutron is approximately 1 amu. Electrons, by contrast, have an almost negligible mass of  $0.00091 \times 10^{-27}$  kg or 0.00055 amu.

The proton and the electron both have electrical *charge*. We know from Millikan's oil drop experiment that the electron has a charge of  $-1.60 \times 10^{-19}$  C. In atomic (or relative) units, the electron is assigned a charge of  $-1$  and the proton is assigned a charge of  $+1$ . *The charge of the proton and the charge of the electron are equal in magnitude but opposite in sign*, so that when the two particles are paired, the charges sum to zero. The neutron has no charge.

Matter is usually charge-neutral (it has no overall charge) because protons and electrons are normally present in equal numbers. When matter does acquire charge imbalances, these imbalances usually equalize quickly, often in dramatic ways. For example, the shock you receive when touching a doorknob during dry weather is the equalization

KCV Subatomic Particles and Isotope Symbols

If a proton had the mass of a baseball, an electron would have the mass of a rice grain.

▲ When the normal charge balance of matter is disturbed, as happens during an electrical storm, it quickly equalizes, often in dramatic ways.

of a charge imbalance that developed as you walked across the carpet. Lightning is an equalization of charge imbalances that develop during electrical storms.

A sample of matter—even a tiny sample, such as a sand grain—composed of only protons or only electrons, would have extraordinary repulsive forces inherent within it and would be unstable. Luckily, matter is not that way. Table 2.1 summarizes the properties of protons, neutrons, and electrons.

TABLE 2.1 Subatomic Particles				
	Mass (kg)	Mass (amu)	Charge (relative)	Charge (C)
Proton	$1.67262 \times 10^{-27}$	1.00727	+1	$+1.60218 \times 10^{-19}$
Neutron	$1.67493 \times 10^{-27}$	1.00866	0	0
Electron	$0.00091 \times 10^{-27}$	0.00055	−1	$-1.60218 \times 10^{-19}$

### Elements: Defined by Their Numbers of Protons

If all atoms are composed of the same subatomic particles, what makes the atoms of one element different from those of another? The answer is the *number* of these particles. The most important number to the *identity* of an atom is the number of protons in its nucleus. *The number of protons defines the element.* For example, an atom with two protons in its nucleus is a helium atom, an atom with six protons in its nucleus is a carbon atom (Figure 2.7▼), and an atom with 92 protons in its nucleus is a uranium atom. The number of protons in an atom’s nucleus is its **atomic number** and is given the symbol *Z*. The atomic numbers of known elements range from 1 to 116 (although evidence for the synthesis of additional elements is currently being considered), as shown in the periodic table of the elements (Figure 2.8►). In the periodic table, described in more detail in Section 2.7, the elements are arranged so that those with similar properties are in the same column.

Each element, identified by its unique atomic number, is represented with a unique **chemical symbol**, a one- or two-letter abbreviation listed directly below its atomic number on the periodic table. The chemical symbol for helium is He; for carbon, the symbol is C; and for uranium, it is U. The chemical symbol and the atomic number always go together. If the atomic number is 2, the chemical symbol *must be* He. If the atomic number is 6, the chemical symbol *must be* C. This is another way of saying that the number of protons defines the element.

#### The Number of Protons Defines the Element

► **FIGURE 2.7 How Elements Differ** Each element is defined by a unique atomic number (*Z*), the number of protons in the nucleus of every atom of that element.

▲ **FIGURE 2.8 The Periodic Table** Each element is represented by its symbol and atomic number. Elements in the same column have similar properties.

Most chemical symbols are based on the English name of the element. For example, the symbol for sulfur is S; for oxygen, O; and for chlorine, Cl. Several of the oldest known elements, however, have symbols based on their original Latin names. For example, the symbol for sodium is Na from the Latin *natrium*, and the symbol for tin is Sn from the Latin *stannum*. Early scientists often gave newly discovered elements names that reflect their properties. For example, argon originates from the Greek word *argos* meaning inactive, referring to argon's chemical inertness (it does not react with other elements). Chlorine originates from the Greek word *chloros* meaning pale green, referring to chlorine's pale green color. Other elements, including helium, selenium, and mercury, are named after figures from Greek or Roman mythology or astronomical bodies. Still others (such as europium, polonium, and berkelium) are named for the places where they were discovered or where their discoverers were born. More recently, elements have been named after scientists; for example, curium for Marie Curie, einsteinium for Albert Einstein, and rutherfordium for Ernest Rutherford.

## Isotopes: When the Number of Neutrons Varies

All atoms of a given element have the same number of protons; however, they do not necessarily have the same number of neutrons. Since neutrons have nearly the same mass as protons (1 amu), this means that—contrary to what John Dalton originally proposed in his atomic theory—all atoms of a given element *do not* have the same mass. For example, all neon atoms contain 10 protons, but they may contain 10, 11, or 12 neutrons. All three types of neon atoms exist, and each has a slightly different mass. Atoms with the same number of protons but different numbers of neutrons are

▲ Element 96 is named curium, after Marie Curie, co-discoverer of radioactivity.

**isotopes.** Some elements, such as beryllium (Be) and aluminum (Al), have only one naturally occurring isotope, while other elements, such as neon (Ne) and chlorine (Cl), have two or more.

The relative amount of each different isotope in a naturally occurring sample of a given element is roughly constant. For example, in any natural sample of neon atoms, 90.48% of them are the isotope with 10 neutrons, 0.27% are the isotope with 11 neutrons, and 9.25% are the isotope with 12 neutrons. These percentages are the **natural abundance** of the isotopes. Each element has its own characteristic natural abundance of isotopes. However, advances in mass spectrometry (see Section 2.8) have allowed accurate measurements that reveal small but significant variations in the natural abundance of isotopes for many elements.

The sum of the number of neutrons and protons in an atom is its **mass number**. We represent mass number with the symbol  $A$ .

$$A = \text{number of protons (p)} + \text{number of neutrons (n)}$$

For neon, with 10 protons, the mass numbers of the three different naturally occurring isotopes are 20, 21, and 22, corresponding to 10, 11, and 12 neutrons, respectively.

We symbolize isotopes using the notation:

where  $X$  is the chemical symbol,  $A$  is the mass number, and  $Z$  is the atomic number. Therefore, the symbols for the neon isotopes are:

Notice that the chemical symbol, Ne, and the atomic number, 10, are redundant: if the atomic number is 10, the symbol must be Ne. The mass numbers, however, are different for the different isotopes, reflecting the different number of neutrons in each one.

A second common notation for isotopes is the chemical symbol (or chemical name) followed by a dash and the mass number of the isotope.

In this notation, the neon isotopes are:

We summarize the neon isotopes in the following table:

Symbol	Number of Protons	Number of Neutrons	$A$ (Mass Number)	Natural Abundance (%)
Ne-20 or ${}^{20}_{10}\text{Ne}$	10	10	20	90.48
Ne-21 or ${}^{21}_{10}\text{Ne}$	10	11	21	0.27
Ne-22 or ${}^{22}_{10}\text{Ne}$	10	12	22	9.25

Notice that all isotopes of a given element have the same number of protons (otherwise they would be different elements). Notice also that the mass number is the *sum* of the number of protons and the number of neutrons. The number of neutrons in an isotope is therefore the difference between the mass number and the atomic number ( $A - Z$ ). The different isotopes of an element generally exhibit the same chemical behavior—the three isotopes of neon, for example, all exhibit chemical inertness.

**Example 2.3** Atomic Numbers, Mass Numbers, and Isotope Symbols

- (a) What are the atomic number ( $Z$ ), mass number ( $A$ ), and symbol of the chlorine isotope with 18 neutrons?  
 (b) How many protons, electrons, and neutrons are present in an atom of  $^{52}_{24}\text{Cr}$ ?

**SOLUTION**

<p>(a) Look up the atomic number (<math>Z</math>) for chlorine on the periodic table. The atomic number specifies the number of protons.</p> <p>The mass number (<math>A</math>) for an isotope is the sum of the number of protons and the number of neutrons.</p> <p>The symbol for an isotope is its chemical symbol with the atomic number (<math>Z</math>) in the lower left corner and the mass number (<math>A</math>) in the upper left corner.</p>	<p><math>Z = 17</math>, so chlorine has 17 protons.</p> <p><math>A = \text{number of protons} + \text{number of neutrons}</math>  <math>= 17 + 18 = 35</math></p> <p><math>^{35}_{17}\text{Cl}</math></p>
<p>(b) For any isotope (in this case <math>^{52}_{24}\text{Cr}</math>) the atomic number located at the lower left indicates the number of protons. Since this is a neutral atom, the number of electrons equals the number of protons.</p> <p>The number of neutrons is equal to the mass number (upper left) minus the atomic number (lower left).</p>	<p>Number of protons = <math>Z = 24</math>          Number of electrons = 24 (neutral atom)</p> <p>Number of neutrons = <math>52 - 24 = 28</math></p>

**FOR PRACTICE 2.3**

- (a) What are the atomic number, mass number, and symbol for the carbon isotope with seven neutrons?  
 (b) How many protons and neutrons are present in an atom of  $^{39}_{19}\text{K}$ ?

**Isotopes** Carbon has two naturally occurring isotopes: C-12 (natural abundance is 98.93%) and C-13 (natural abundance is 1.07%). Using circles to represent protons and squares to represent neutrons, draw the nucleus of each isotope. How many C-13 atoms are present, on average, in a 10,000-atom sample of carbon?

**CONCEPTUAL CONNECTION 2.4****Ions: Losing and Gaining Electrons**

The number of electrons in a neutral atom is equal to the number of protons in its nucleus (designated by its atomic number  $Z$ ). During chemical changes, however, atoms can lose or gain electrons and become charged particles called **ions**. For example, neutral lithium (Li) atoms contain three protons and three electrons; however, in many chemical reactions lithium atoms lose one electron ( $e^-$ ) to form  $\text{Li}^+$  ions.

The charge of an ion is indicated in the upper right corner of the chemical symbol. Since the  $\text{Li}^+$  ion contains three protons and only two electrons, its charge is 1+ (ion charges are written as the magnitude first followed by the sign of the charge; for a charge of 1+, the 1 is usually dropped and the charge is written as simply +).

Ions can also be negatively charged. For example, neutral fluorine (F) atoms contain nine protons and nine electrons; however, in many chemical reactions fluorine atoms gain one electron to form  $\text{F}^-$  ions.

The  $\text{F}^-$  ion contains nine protons and 10 electrons, resulting in a charge of 1– (written simply as –). For many elements, such as lithium and fluorine, the ion is much more common than the neutral atom. In fact, lithium and fluorine occur in nature mostly as ions.

Positively charged ions, such as  $\text{Li}^+$ , are **cations**, and negatively charged ions, such as  $\text{F}^-$ , are **anions**. Ions behave quite differently than their corresponding atoms. Neutral sodium atoms, for example, are extremely unstable, reacting violently with

most things they contact. Sodium cations ( $\text{Na}^+$ ), by contrast, are relatively inert—we eat them all the time in sodium chloride (table salt). In ordinary matter, cations and anions always occur together so that matter is charge neutral overall.

## Chemistry IN YOUR DAY

### Where Did Elements Come From?

**W**e find ourselves on a planet containing many different kinds of elements. If it were otherwise, we would not exist and would not be here to reflect on why. Where did these elements come from? The story of element formation is as old as the universe itself, and we have to go back to the very beginning to tell the story.

The birth of the universe is described by the Big Bang theory, which asserts that the universe began as a hot, dense collection of matter and energy that expanded rapidly. As it expanded, it cooled, and within the first several hours, subatomic particles formed the first atomic nuclei: hydrogen and helium. These two elements were (and continue to be) the most abundant in the universe. As the universe continued expanding, some of the hydrogen and helium clumped together under the influence of gravity to form *nebulae* (clouds of gas) that eventually gave birth to stars and galaxies. These stars and galaxies became the nurseries where all other elements formed.

Stars are fueled by nuclear fusion, which we will discuss in more detail in Chapter 20. Under the conditions within the core of a star, hydrogen nuclei can combine (or fuse) to form helium. Fusion gives off enormous quantities of energy, which is why stars emit so much heat and light. The fusion of hydrogen to helium can fuel a star for billions of years.

After it burns through large quantities of hydrogen, if a star is large enough, the helium that builds up in its core can in turn fuse to form carbon. The carbon then builds up in the core and (again, if the star is large enough) can fuse to form even heavier elements. The fusion process ends with iron, which has a highly stable nucleus. By the time iron is formed, however, the star is near the end of its existence and may enter a phase of expansion, transforming into a *supernova*. Within a supernova, which is in essence a large exploding star, a shower of neutrons allows the lighter elements (which formed during the lifetime of the star through the fusion processes just described) to capture extra neutrons. These neutrons can transform into protons (through processes that we discuss in Chapter 20), contributing ultimately to the formation of elements heavier than iron, all the way up to uranium. As the supernova continues to expand, the elements present within it are blown out into space, where they can incorporate into other nebulae and perhaps even eventually form planets that orbit stars like our own sun.

▲ Stars are born in nebulae such as the Eagle Nebula (also known as M16). This image was taken by the Hubble Space Telescope and shows a gaseous pillar in a star-forming region of the Eagle Nebula.

## CONCEPTUAL CONNECTION 2.5

### The Nuclear Atom, Isotopes, and Ions Which statement is true?

- (a) For a given element, the size of an isotope with more neutrons is larger than one with fewer neutrons.
- (b) For a given element, the size of an atom is the same for all of the element's isotopes.

## 2.7 Finding Patterns: The Periodic Law and the Periodic Table

The modern periodic table grew out of the work of Dmitri Mendeleev (1834–1907), a nineteenth-century Russian chemistry professor. In his time, scientists had discovered about 65 different elements, and chemists had identified many of the

properties of these elements—such as their relative masses, their chemical activity, and some of their physical properties. However, no one had developed any systematic way of organizing them.

In 1869, Mendeleev noticed that certain groups of elements had similar properties. He also found that when he listed elements in order of increasing mass, these similar properties recurred in a periodic pattern (Figure 2.9▼). Mendeleev summarized these observations in the **periodic law**:

**When the elements are arranged in order of increasing mass, certain sets of properties recur periodically.**

▲ Many of the elements that we know today were discovered during Mendeleev's lifetime.

To be periodic means to exhibit a repeating pattern.

### The Periodic Law

1 H	2 He	3 Li	4 Be	5 B	6 C	7 N	8 O	9 F	10 Ne	11 Na	12 Mg	13 Al	14 Si	15 P	16 S	17 Cl	18 Ar	19 K	20 Ca
--------	---------	---------	---------	--------	--------	--------	--------	--------	----------	----------	----------	----------	----------	---------	---------	----------	----------	---------	----------

Elements with similar properties recur in a regular pattern.

▲ **FIGURE 2.9 Recurring Properties** These elements are listed in order of increasing atomic number. Elements with similar properties are represented with the same color. Notice that the colors form a repeating pattern, much like musical notes form a repeating pattern on a piano keyboard.

Mendeleev organized the known elements in a table consisting of a series of rows in which mass increases from left to right. He arranged the rows so that elements with similar properties fall in the same vertical columns (Figure 2.10►).

Since many elements had not yet been discovered, Mendeleev's table contained some gaps, which allowed him to predict the existence (and even the properties) of yet undiscovered elements. For example, Mendeleev predicted the existence of an element he called eka-silicon, which fell below silicon on the table and between gallium and arsenic (*eka* means the one beyond). In 1886, eka-silicon was discovered by German chemist Clemens Winkler (1838–1904), who named it germanium, after his home country.

### A Simple Periodic Table

1 H											2 He
3 Li	4 Be	5 B	6 C	7 N	8 O	9 F	10 Ne				
11 Na	12 Mg	13 Al	14 Si	15 P	16 S	17 Cl	18 Ar				
19 K	20 Ca										

Elements with similar properties fall into columns.

▲ **FIGURE 2.10 Making a Periodic Table** We can arrange the elements in Figure 2.9 in a table in which atomic number increases from left to right and elements with similar properties (as represented by the different colors) are aligned in columns.

▲ Dmitri Mendeleev, a Russian chemistry professor who proposed the periodic law and arranged early versions of the periodic table, was honored on a Soviet postage stamp.

## Modern Periodic Table Organization

Mendeleev's original listing evolved into the modern periodic table shown in Figure 2.11▼. In the modern table, elements are listed in order of increasing atomic number rather than increasing relative mass. The modern periodic table also contains more elements than Mendeleev's original table because more have been discovered since his time. Mendeleev's periodic law was based on observation. Like all scientific laws, the periodic law summarizes many observations but does not give the underlying reason for the observations—only theories do that. For now, we accept the periodic law as it is, but in Chapters 7 and 8 we will examine a powerful theory—called quantum mechanics—that explains the law and gives the underlying reasons for it.

We can broadly classify the elements in the periodic table as metals, nonmetals, or metalloids, as shown in Figure 2.11. **Metals** lie on the lower left side and middle of the periodic table and share some common properties: they are good conductors of heat and electricity, they can be pounded into flat sheets (malleability), they can be drawn into wires (ductility), they are often shiny, and they tend to lose electrons when they undergo chemical changes. Chromium, copper, strontium, and lead are typical metals.

**Nonmetals** lie on the upper right side of the periodic table. The dividing line between metals and nonmetals is the zigzag diagonal line running from boron to astatine. Nonmetals have varied properties—some are solids at room temperature, others are liquids or gases—but typically they tend to be poor conductors of heat and electricity, and they all tend to gain electrons when they undergo chemical changes. Oxygen, carbon, sulfur, bromine, and iodine are nonmetals.

**▲ FIGURE 2.12 The Periodic Table: Main-Group and Transition Elements** The elements in the periodic table fall into columns. The two columns at the left and the six columns at the right comprise the main-group elements. Each of these eight columns is a group or family. The properties of main-group elements can generally be predicted from their position in the periodic table. The properties of the elements in the middle of the table, known as transition elements, are less predictable.

Many of the elements that lie along the zigzag diagonal line that divides metals and nonmetals are **metalloids** and exhibit mixed properties. Several metalloids are also classified as **semiconductors** because of their intermediate (and highly temperature-dependent) electrical conductivity. Our ability to change and control the conductivity of semiconductors makes them useful to us in the manufacture of the electronic chips and circuits central to computers, cellular telephones, and many other modern devices. Good examples of metalloids are silicon, arsenic, and antimony.

Metalloids are sometimes called semimetals.

We can also divide the periodic table, as shown in Figure 2.12▲, into **main-group elements**, whose properties tend to be largely predictable based on their position in the periodic table, and **transition elements** or **transition metals**, whose properties tend to be less predictable based simply on their position in the periodic table. Main-group elements are in columns labeled with a number and the letter A. Transition elements are in columns labeled with a number and the letter B. An alternative numbering system does not use letters, but only the numbers 1–18. Both numbering systems are shown in most of the periodic tables in this book. Each column within the main-group regions of the periodic table is a **family** or **group** of elements.

The elements within a group usually have similar properties. For example, the group 8A elements, called the **noble gases**, are mostly unreactive. The most familiar noble gas is probably helium, used to fill buoyant balloons. Helium is chemically stable—it does not combine with other elements to form compounds—and is therefore safe to put into balloons. Other noble gases are neon (often used in electronic signs), argon (a small component of our atmosphere), krypton, and xenon.

The group 1A elements, the **alkali metals**, are all reactive metals. A marble-sized piece of sodium explodes violently when dropped into water. Lithium, potassium, and rubidium are also alkali metals.

The group 2A elements, the **alkaline earth metals**, are also fairly reactive, although not quite as reactive as the alkali metals. Calcium, for example, reacts fairly vigorously when dropped into water but does not explode as dramatically as sodium. Other alkaline earth metals include magnesium (a common low-density structural metal), strontium, and barium.

## Halogens

F
Cl
Br
I
At

The group 7A elements, the **halogens**, are very reactive nonmetals. One of the most familiar halogens is chlorine, a greenish-yellow gas with a pungent odor. Because of its reactivity, chlorine is used as a sterilizing and disinfecting agent. Other halogens include bromine, a red-brown liquid that easily evaporates into a gas; iodine, a purple solid; and fluorine, a pale-yellow gas.

## Ions and the Periodic Table

In chemical reactions, metals tend to lose electrons (forming cations) and nonmetals tend to gain them (forming anions). The number of electrons lost or gained, and therefore the charge of the resulting ion, is often predictable for a given element, especially main-group elements. Main-group elements tend to form ions that have the same number of electrons as the nearest noble gas (i.e., the noble gas that has the number of electrons closest to that of the element).

- **A main-group metal tends to lose electrons, forming a cation with the same number of electrons as the nearest noble gas.**
- **A main-group nonmetal tends to gain electrons, forming an anion with the same number of electrons as the nearest noble gas.**

For example, lithium, a metal with three electrons, tends to lose one electron, forming a  $1+$  cation that has the same number of electrons (two) as helium. Chlorine, a nonmetal with 17 electrons, tends to gain one electron, forming a  $1-$  anion that has the same number of electrons (18) as argon.

In general, the alkali metals (group 1A) tend to lose one electron and form  $1+$  ions. The alkaline earth metals (group 2A) tend to lose two electrons and form  $2+$  ions. The halogens (group 7A) tend to gain one electron and form  $1-$  ions. The oxygen family nonmetals (group 6A) tend to gain two electrons and form  $2-$  ions. More generally, for the main-group elements that form cations with predictable charge, the charge is equal to the group number. For main-group elements that form anions with predictable charge, the charge is equal to the group number minus eight. Transition elements may form various different ions with different charges. Figure 2.13 shows the ions formed by the main-group elements that form ions with predictable charges. In Chapters 7 and 8, we will introduce quantum-mechanical theory, which more fully explains *why* these groups form ions as they do.

### Example 2.4 Predicting the Charge of Ions

Predict the charges of the monoatomic (single atom) ions formed by these main-group elements.

- (a) Al                      (b) S

#### SOLUTION

- (a) Aluminum is a main-group metal and tends to lose electrons to form a cation with the same number of electrons as the nearest noble gas. Aluminum atoms have 13 electrons and the nearest noble gas is neon, which has 10 electrons. Aluminum therefore loses three electrons to form a cation with a  $3+$  charge ( $\text{Al}^{3+}$ ).
- (b) Sulfur is a nonmetal and tends to gain electrons to form an anion with the same number of electrons as the nearest noble gas. Sulfur atoms have 16 electrons and the nearest noble gas is argon, which has 18 electrons. Sulfur therefore gains two electrons to form an anion with a  $2-$  charge ( $\text{S}^{2-}$ ).

**FOR PRACTICE 2.4** Predict the charges of the monoatomic ions formed by these main-group elements.

- (a) N                      (b) Rb

## Chemistry AND Medicine The Elements of Life

What kind of atoms compose us? In terms of mass, our bodies are 65% oxygen (because of the large amount of water), 18% carbon, and 10% hydrogen, with a few other elements present in smaller quantities, as shown in Figure 2.14 and Table 2.2. Because the atoms of different elements have different masses (more on this in Sections 2.8 and 2.9), if we consider number of atoms (instead of mass), hydrogen comes in first (because hydrogen atoms are so light), with oxygen second and carbon third.

TABLE 2.2 Approximate Percent Elemental Composition of Humans

Element	% by Mass	% by Number of Atoms
Oxygen	65	26.4
Carbon	18	9.2
Hydrogen	10	62.3
Nitrogen	3	1.4
Calcium	1.5	0.2
Phosphorus	1	0.3
Other	1.5	0.2

■ Oxygen: 65%	■ Calcium: 1.5%
■ Carbon: 18%	■ Phosphorus: 1%
■ Hydrogen: 10%	■ Other: 1.5%
■ Nitrogen: 3%	

▲ FIGURE 2.14 Elemental Composition of Humans (by Mass)

Much of the *chemistry* of life revolves not around oxygen or hydrogen but around carbon, an element that forms a disproportionately large number of compounds with a few other elements such as hydrogen, oxygen, and nitrogen. We will explore the chemistry of carbon—called organic chemistry—briefly in Chapter 3 and in more detail in Chapter 21.

## 2.8 Atomic Mass: The Average Mass of an Element's Atoms

An important part of Dalton's atomic theory is that all atoms of a given element have the same mass. In Section 2.6, we learned that because of isotopes, the atoms of a given element often have different masses, so Dalton was not completely correct. We can, however, calculate an average mass—called the **atomic mass**—for each element.

The atomic mass of each element is listed directly beneath the element's symbol in the periodic table and represents the average mass of the isotopes that compose that element, *weighted according to the natural abundance of each isotope*. For example, the

Atomic mass is sometimes called *atomic weight* or *standard atomic weight*.

In this book, we use the atomic masses recommended by IUPAC for users needing an atomic mass value for an unspecified sample. Detailed studies of the atomic masses of many samples, however, have shown that atomic masses are not constants of nature because the exact isotopic abundances in any given sample depend on the history of the sample (see the Chemistry in Your Day box later in this section).

When we use percentages in calculations, we convert them to their decimal value by dividing by 100.

periodic table lists the atomic mass of chlorine as 35.45 amu. Naturally occurring chlorine consists of 75.77% chlorine-35 atoms (mass 34.97 amu) and 24.23% chlorine-37 atoms (mass 36.97 amu). We can calculate its atomic mass accordingly:

$$\text{Atomic mass} = 0.7577(34.97 \text{ amu}) + 0.2423(36.97 \text{ amu}) = 35.45 \text{ amu}$$

Notice that the atomic mass of chlorine is closer to 35 than 37. Naturally occurring chlorine contains more chlorine-35 atoms than chlorine-37 atoms, so the weighted average mass of chlorine is closer to 35 amu than to 37 amu.

In general, we calculate the atomic mass with the equation:

$$\begin{aligned} \text{Atomic mass} &= \sum_n (\text{fraction of isotope } n) \times (\text{mass of isotope } n) \\ &= (\text{fraction of isotope 1} \times \text{mass of isotope 1}) \\ &\quad + (\text{fraction of isotope 2} \times \text{mass of isotope 2}) \\ &\quad + (\text{fraction of isotope 3} \times \text{mass of isotope 3}) + \dots \end{aligned}$$

where the fractions of each isotope are the percent natural abundances converted to their decimal values. The concept of atomic mass is useful because it allows us to assign a characteristic mass to each element, and, as we will see shortly, it allows us to quantify the number of atoms in a sample of that element.

### Example 2.5 Atomic Mass

Copper has two naturally occurring isotopes: Cu-63 with a mass of 62.9291 amu and a natural abundance of 69.17%, and Cu-65 with a mass of 64.9278 amu and a natural abundance of 30.83%. Calculate the atomic mass of copper.

#### SOLUTION

Convert the percent natural abundances into decimal form by dividing by 100.

$$\text{Fraction Cu-63} = \frac{69.17}{100} = 0.6917$$

$$\text{Fraction Cu-65} = \frac{30.83}{100} = 0.3083$$

Calculate the atomic mass using the equation given in the text.

$$\begin{aligned} \text{Atomic mass} &= 0.6917(62.9296 \text{ amu}) + 0.3083(64.9278 \text{ amu}) \\ &= 43.5284 \text{ amu} + 20.0172 \text{ amu} = \underline{63.5456} = 63.55 \text{ amu} \end{aligned}$$

**FOR PRACTICE 2.5** Magnesium has three naturally occurring isotopes with masses of 23.99 amu, 24.99 amu, and 25.98 amu and natural abundances of 78.99%, 10.00%, and 11.01%, respectively. Calculate the atomic mass of magnesium.

**FOR MORE PRACTICE 2.5** Gallium has two naturally occurring isotopes: Ga-69 with a mass of 68.9256 amu and a natural abundance of 60.11%, and Ga-71. Use the atomic mass of gallium from the periodic table to find the mass of Ga-71.

### CONCEPTUAL CONNECTION 2.6

**Atomic Mass** Recall from Conceptual Connection 2.4 that carbon has two naturally occurring isotopes: C-12 (natural abundance is 98.93%; mass is 12.0000 amu) and C-13 (natural abundance is 1.07%; mass is 13.0034 amu). Without doing any calculations, determine which mass is closest to the atomic mass of carbon.

- (a) 12.00 amu      (b) 12.50 amu      (c) 13.00 amu

## Mass Spectrometry: Measuring the Mass of Atoms and Molecules

The masses of atoms and the percent abundances of isotopes of elements are measured using **mass spectrometry**, a technique that separates particles according to their mass. In a mass spectrometer, such as the one in Figure 2.15►, the sample (containing

## Mass Spectrometer

the atoms whose mass is to be measured) is injected into the instrument and vaporized. The vaporized atoms are ionized by an electron beam—the electrons in the beam collide with the atoms, removing electrons and creating positively charged ions. The ions are then accelerated into a magnetic field. When ions drift through a magnetic field, they experience a force that bends their trajectory. The amount of bending depends on the mass of the ions—the trajectories of lighter ions are bent more than those of heavier ones.

In the right side of the spectrometer in Figure 2.15, you can see three different paths, each corresponding to ions of different mass. Finally, the ions strike a detector and produce an electrical signal that is recorded. The result is the separation of the ions according to their mass, producing a mass spectrum such as the one in Figure 2.16. The *position* of each peak on the x-axis indicates the *mass of the isotope* that was ionized, and the *intensity* (indicated by the height of the peak) indicates the *relative abundance of that isotope*.

The mass spectrum of an elemental sample can be used to determine the atomic mass of that sample of the element. For example, consider the mass spectrum of a naturally occurring sample of silver:

The two peaks correspond to the two isotopes of silver. We can determine the percent abundance of each isotope from the intensity of each line. However, the *total* intensity must be *normalized*—it must be made to equal 100%. We can accomplish this by dividing the intensity of each peak by the total intensity:

$$\text{Abundance of Ag-107} = \frac{100.0\%}{100.0\% + 92.90\%} \times 100\% = 51.84\%$$

$$\text{Abundance of Ag-109} = \frac{92.90\%}{100.0\% + 92.90\%} \times 100\% = 48.16\%$$

Then we can calculate the atomic mass of silver:

$$\begin{aligned} \text{Ag atomic mass} &= 0.5184 (106.905 \text{ amu}) + 0.4816 (108.904 \text{ amu}) \\ &= 55.4195 \text{ amu} + 52.4482 \text{ amu} = 107.8677 = 107.87 \text{ amu} \end{aligned}$$

Mass spectrometry can also be used on molecules. Because molecules often fragment (break apart) during ionization, the mass spectrum of a molecule usually

**▲ FIGURE 2.15 The Mass Spectrometer** Atoms are converted to positively charged ions, accelerated, and passed through a magnetic field that deflects their path. The heaviest ions undergo the least deflection.

**▲ FIGURE 2.16 The Mass Spectrum of Chlorine** The position of each peak on the x-axis indicates the mass of the isotope. The intensity (or height) of the peak indicates the relative abundance of the isotope. The intensity of the highest peak is usually set to 100% and the intensity of all other peaks is reported relative to the most intense one.

## Evolving Atomic Masses

At the beginning of 2011, IUPAC (International Union of Pure and Applied Chemistry) published a new periodic table with atomic masses that looked different from previous IUPAC periodic tables. For the first time, instead of listing a single atomic mass for each element, IUPAC listed upper and lower bounds for the atomic masses of several elements (see the periodic table in this box). For example, previous IUPAC periodic tables reported the atomic mass of O (rounded to four significant figures) as 16.00. However, the new periodic table reports the atomic mass as [15.99, 16.00] denoting the upper and lower bounds for the possible atomic masses of terrestrial oxygen.

Why did this happen? The changes were necessary because developments in mass spectrometry have increasingly demonstrated that the atomic masses of several elements are not constant from one sample to another because the isotopic composition is not constant from one sample to another. In other words, the isotopic composition of a sample of a given element can vary depending on the source of the sample.

For example, the lower bound for the atomic mass of oxygen (15.99 amu) comes from measurements of oxygen from Antarctic precipitation, and the upper bound (16.00 amu) comes from measurements of oxygen in marine  $\text{N}_2\text{O}$  (dinitrogen monoxide). Although we have long treated atomic masses as *constants of nature*, they are not, and the new periodic table reflects this.

So what do we do if we need an atomic mass for an element of unknown or unspecified origin? IUPAC has recommended values that apply to most samples found on Earth. The values are rounded so that atomic mass variations in samples found on Earth are plus or minus one in the last digit (just like accepted significant figure conventions). These values are adopted throughout all of the periodic tables in this book except the one shown below, which displays the upper and lower bound for those elements in which variation occurs. For further reading see IUPAC. *Pure Appl. Chem.* 2011, 83(2), 359–396.

IUPAC Periodic Table of the Elements

1 H hydrogen [1.007, 1.009]																	2 He helium 4.003
3 Li lithium [6.938, 6.997]	4 Be beryllium 9.012											5 B boron [10.80, 10.83]	6 C carbon [12.00, 12.02]	7 N nitrogen [14.00, 14.01]	8 O oxygen [15.99, 16.00]	9 F fluorine 19.00	10 Ne neon 20.18

Mass spectroscopy can be used to identify an unknown molecule and to determine how much of it is present in a particular sample. For example, mass spectrometry has been used to detect organic (carbon-containing) compounds present in meteorites, a puzzling observation that some scientists speculate may be evidence of life outside of our planet. Most scientists think that the carbon compounds in meteorites probably formed in the same way as the first organic molecules on Earth, indicating that the formation of organic molecules may be common in the universe.

Since the early 1990s, researchers have also successfully applied mass spectrometry to biological molecules, including proteins (the workhorse molecules in cells) and nucleic acids (the molecules that carry genetic information). For a long time, these molecules could not be analyzed by mass spectrometry because they were difficult to vaporize and ionize without being destroyed, but modern techniques have overcome this problem. A tumor, for example, can now be instantly analyzed by mass spectrometry to determine whether it contains specific proteins associated with cancer.

## 2.9 Molar Mass: Counting Atoms by Weighing Them

The Mole Concept

Shrimp are normally sold by *count*, which indicates the number of shrimp per pound. For example, 41–50 count shrimp means that there are between 41 and 50 shrimp per pound. The smaller the count, the larger the shrimp. Big tiger prawns have counts as low as 10–15, which means that each shrimp can weigh up to 1/10 of a pound. One advantage of categorizing shrimp in this way is that we can count the shrimp by weighing them. For example, two pounds of 41–50 count shrimp contains between 82 and 100 shrimp.

A similar (but more precise) concept exists for atoms. Counting atoms is much more difficult than counting shrimp, yet as chemists we often need to know the number of atoms in a sample of a given mass. Why? *Because chemical processes happen between particles.* For elements, those particles are atoms. For example, when hydrogen and oxygen combine to form water, two hydrogen atoms combine with one oxygen atom to form one water molecule. If we want to know how much hydrogen to react with a given mass of oxygen to form water, we need to know the number of atoms in the given mass of oxygen. We also need to know the mass of hydrogen that contains exactly twice that number of atoms.

As another example, consider intravenous fluids—fluids that are delivered to patients by directly dripping them into veins. These fluids are saline (sodium chloride) solutions that must have a specific number of sodium and chloride ions per liter of fluid. The number of particles in the fluid directly influences the properties of the fluid. Administering an intravenous fluid with the wrong number of sodium and chloride ions could be fatal.

Atoms are far too small to count by any ordinary means. As we noted earlier, even if you could somehow count atoms, and counted them 24 hours a day for as long as you lived, you would barely begin to count the number of atoms in something as small as a sand grain. Therefore, if we want to know the number of atoms in anything of ordinary size, we count them by weighing.

### The Mole: A Chemist's “Dozen”

When we count large numbers of objects, we often use units such as a dozen (12 objects) or a gross (144 objects) to organize our counting and to keep our numbers more manageable. With atoms, quadrillions of which may be in a speck of dust, we need a much larger number for this purpose. The chemist's “dozen” is the **mole** (abbreviated mol). A mole is the *amount* of material containing  $6.02214 \times 10^{23}$  particles.

$$1 \text{ mol} = 6.02214 \times 10^{23} \text{ particles}$$

This number is **Avogadro's number**, named after Italian physicist Amedeo Avogadro (1776–1856), and is a convenient number to use when working with atoms, molecules, and ions. In this book, we usually round Avogadro's number to four significant figures or

Twenty-two copper pennies contain approximately 1 mol of copper atoms.

Before 1982, when they became almost all zinc with only a copper coating, pennies were mostly copper.

One tablespoon of water contains approximately 1 mol of water molecules.

One tablespoon is approximately 15 mL; one mol of water occupies 18 mL.

$6.022 \times 10^{23}$ . Notice that the definition of the mole is an *amount* of a substance. We often refer to the number of moles of substance as the *amount* of the substance.

The first thing to understand about the mole is that it can specify Avogadro's number of anything. For example, one mole of marbles corresponds to  $6.022 \times 10^{23}$  marbles, and one mole of sand grains corresponds to  $6.022 \times 10^{23}$  sand grains. *One mole of anything is  $6.022 \times 10^{23}$  units of that thing.* One mole of atoms, ions, or molecules, however, makes up objects of everyday sizes. Twenty-two copper pennies, for example, contain approximately 1 mol of copper atoms, and 1 tablespoon of water contains approximately 1 mol of water molecules.

The second, and more fundamental, thing to understand about the mole is how it gets its specific value.

**The value of the mole is equal to the number of atoms in exactly 12 g of pure carbon-12 ( $12 \text{ g C} = 1 \text{ mol C atoms} = 6.022 \times 10^{23} \text{ C atoms}$ ).**

The definition of the mole gives us a relationship between mass (grams of carbon) and number of atoms (Avogadro's number). This relationship, as we will see shortly, allows us to count atoms by weighing them.

## Converting between Number of Moles and Number of Atoms

Converting between number of moles and number of atoms is similar to converting between dozens of eggs and number of eggs. For eggs, you use the conversion factor 1 dozen eggs = 12 eggs. For atoms, you use the conversion factor 1 mol atoms =  $6.022 \times 10^{23}$  atoms. The conversion factors take the following forms:

$$\frac{1 \text{ mol atoms}}{6.022 \times 10^{23} \text{ atoms}} \quad \text{or} \quad \frac{6.022 \times 10^{23} \text{ atoms}}{1 \text{ mol atoms}}$$

Example 2.6 demonstrates how to use these conversion factors in calculations.

### Example 2.6 Converting between Number of Moles and Number of Atoms

Calculate the number of copper atoms in 2.45 mol of copper.

**SORT** You are given the amount of copper in moles and asked to find the number of copper atoms.

**GIVEN:** 2.45 mol Cu

**FIND:** Cu atoms

**STRATEGIZE** Convert between number of moles and number of atoms by using Avogadro's number as a conversion factor.

**CONCEPTUAL PLAN**

**RELATIONSHIPS USED**

$6.022 \times 10^{23} = 1 \text{ mol}$  (Avogadro's number)

**SOLVE** Follow the conceptual plan to solve the problem. Begin with 2.45 mol Cu and multiply by Avogadro's number to get to the number of Cu atoms.

**SOLUTION**

$$2.45 \text{ mol Cu} \times \frac{6.022 \times 10^{23} \text{ Cu atoms}}{1 \text{ mol Cu}} = 1.48 \times 10^{24} \text{ Cu atoms}$$

**CHECK** Since atoms are small, it makes sense that the answer is large. The given number of moles of copper is almost 2.5, so the number of atoms is almost 2.5 times Avogadro's number.

**FOR PRACTICE 2.6** A pure silver ring contains  $2.80 \times 10^{22}$  silver atoms. How many moles of silver atoms does it contain?

## Converting between Mass and Amount (Number of Moles)

To count atoms by weighing them, we need one other conversion factor—the mass of 1 mol of atoms. For the isotope carbon-12, we know that the mass of 1 mol of atoms is exactly 12 g, which is numerically equivalent to carbon-12's atomic mass in atomic mass units. Since the masses of all other elements are defined relative to carbon-12, the same relationship holds for all elements.

The mass of one mole of atoms of an element is its **molar mass**.

**An element's molar mass in grams per mole is numerically equal to the element's atomic mass in atomic mass units.**

For example, copper has an atomic mass of 63.55 amu and a molar mass of 63.55 g/mol. One mole of copper atoms therefore has a mass of 63.55 g. Just as the count for shrimp depends on the size of the shrimp, so the mass of 1 mol of atoms depends on the element: 1 mol of aluminum atoms (which are lighter than copper atoms) has a mass of 26.98 g, 1 mol of carbon atoms (which are even lighter than aluminum atoms) has a mass of 12.01 g, and 1 mol of helium atoms (lighter yet) has a mass of 4.003 g.

$$26.98 \text{ g aluminum} = 1 \text{ mol aluminum} = 6.022 \times 10^{23} \text{ Al atoms}$$

$$12.01 \text{ g carbon} = 1 \text{ mol carbon} = 6.022 \times 10^{23} \text{ C atoms}$$

$$4.003 \text{ g helium} = 1 \text{ mol helium} = 6.022 \times 10^{23} \text{ He atoms}$$

The lighter the atom, the less mass in 1 mol of atoms.

▲ The two dishes contain the same number of objects (12), but the masses are different because peas are less massive than marbles. Similarly, a mole of light atoms will have less mass than a mole of heavier atoms.

The molar mass of any element is the conversion factor between the mass (in grams) of that element and the amount (in moles) of that element. For carbon:

$$12.01 \text{ g C} = 1 \text{ mol C} \quad \text{or} \quad \frac{12.01 \text{ g C}}{\text{mol C}} \quad \text{or} \quad \frac{1 \text{ mol C}}{12.01 \text{ g C}}$$

Example 2.7, on the next page, demonstrates how to use these conversion factors.

**Example 2.7** Converting between Mass and Amount (Number of Moles)

Calculate the amount of carbon (in moles) contained in a 0.0265 g pencil “lead.” (Assume that the pencil lead is made of pure graphite, a form of carbon.)

**SORT** You are given the mass of carbon and asked to find the amount of carbon in moles.

**GIVEN:** 0.0265 g C

**FIND:** mol C

**STRATEGIZE** Convert between mass and amount (in moles) of an element by using the molar mass of the element.

**CONCEPTUAL PLAN**

**RELATIONSHIPS USED**

12.01 g C = 1 mol C (carbon molar mass)

**SOLVE** Follow the conceptual plan to solve the problem.

**SOLUTION**

$$0.0265 \text{ g C} \times \frac{1 \text{ mol C}}{12.01 \text{ g C}} = 2.21 \times 10^{-3} \text{ mol C}$$

**CHECK** The given mass of carbon is much less than the molar mass of carbon, so it makes sense that the answer (the amount in moles) is much less than 1 mol of carbon.

**FOR PRACTICE 2.7** Calculate the amount of copper (in moles) in a 35.8 g pure copper sheet.

**FOR MORE PRACTICE 2.7** Calculate the mass (in grams) of 0.473 mol of titanium.

We now have all the tools to count the number of atoms in a sample of an element by weighing it. First, we obtain the mass of the sample. Then we convert it to an amount in moles using the element’s molar mass. Finally, we convert it to number of atoms using Avogadro’s number. The conceptual plan for these kinds of calculations takes the following form:

Examples 2.8 and 2.9 demonstrate these conversions.

**Example 2.8** The Mole Concept—Converting between Mass and Number of Atoms

How many copper atoms are in a copper penny with a mass of 3.10 g? (Assume that the penny is composed of pure copper.)

**SORT** You are given the mass of copper and asked to find the number of copper atoms.

**GIVEN:** 3.10 g Cu

**FIND:** Cu atoms

**STRATEGIZE** Convert between the mass of an element in grams and the number of atoms of the element by first converting to moles (using the molar mass of the element) and then to number of atoms (using Avogadro’s number).

**CONCEPTUAL PLAN**

**RELATIONSHIPS USED**

63.55 g Cu = 1 mol Cu (molar mass of copper)

$6.022 \times 10^{23} = 1 \text{ mol}$  (Avogadro’s number)

**SOLVE** Follow the conceptual plan to solve the problem. Begin with 3.10 g Cu and multiply by the appropriate conversion factors to arrive at the number of Cu atoms.

**SOLUTION**

$$3.10 \text{ g Cu} \times \frac{1 \text{ mol Cu}}{63.55 \text{ g Cu}} \times \frac{6.022 \times 10^{23} \text{ Cu atoms}}{1 \text{ mol Cu}} = 2.94 \times 10^{22} \text{ Cu atoms}$$

**CHECK** The answer (the number of copper atoms) is less than  $6.022 \times 10^{23}$  (1 mol). This is consistent with the given mass of copper atoms, which is less than the molar mass of copper.

**FOR PRACTICE 2.8** How many carbon atoms are there in a 1.3-carat diamond? Diamonds are a form of pure carbon. (1 carat = 0.20 g)

**FOR MORE PRACTICE 2.8** Calculate the mass of  $2.25 \times 10^{22}$  tungsten atoms.

Notice that numbers with large exponents, such as  $6.022 \times 10^{23}$ , are almost unbelievably large. Twenty-two copper pennies contain  $6.022 \times 10^{23}$  or 1 mol of copper atoms, but  $6.022 \times 10^{23}$  pennies would cover Earth's entire surface to a depth of 300 m. Even objects small by everyday standards occupy a huge space when we have a mole of them. For example, a grain of sand has a mass of less than 1 mg and a diameter of less than 0.1 mm, yet 1 mol of sand grains would cover the state of Texas to a depth of several feet. For every increase of 1 in the exponent of a number, the number increases by a factor of 10, so  $10^{23}$  is incredibly large. Of course 1 mol has to be a large number if it is to have practical value because atoms are so small.

### Example 2.9 The Mole Concept

An aluminum sphere contains  $8.55 \times 10^{22}$  aluminum atoms. What is the sphere's radius in centimeters? The density of aluminum is  $2.70 \text{ g/cm}^3$ .

**SORT** You are given the number of aluminum atoms in a sphere and the density of aluminum. You are asked to find the radius of the sphere.

**GIVEN:**  $8.55 \times 10^{22}$  Al atoms

$$d = 2.70 \text{ g/cm}^3$$

**FIND:** radius ( $r$ ) of sphere

**STRATEGIZE** The heart of this problem is density, which relates mass to volume; though you aren't given the mass directly, you are given the number of atoms, which you can use to find mass.

1. Convert from number of atoms to number of moles using Avogadro's number as a conversion factor.
2. Convert from number of moles to mass using molar mass as a conversion factor.
3. Convert from mass to volume (in  $\text{cm}^3$ ) using density as a conversion factor.
4. Once you calculate the volume, find the radius from the volume using the formula for the volume of a sphere.

**CONCEPTUAL PLAN**

**RELATIONSHIPS AND EQUATIONS USED**

$$6.022 \times 10^{23} = 1 \text{ mol (Avogadro's number)}$$

$$26.98 \text{ g Al} = 1 \text{ mol Al (molar mass of aluminum)}$$

$$2.70 \text{ g/cm}^3 \text{ (density of aluminum)}$$

$$V = \frac{4}{3} \pi r^3 \text{ (volume of a sphere)}$$

—Continued on the next page

—Continued

**SOLVE**

Finally, follow the conceptual plan to solve the problem. Begin with  $8.55 \times 10^{22}$  Al atoms and multiply by the appropriate conversion factors to arrive at volume in  $\text{cm}^3$ .

Then solve the equation for the volume of a sphere for  $r$  and substitute the volume to calculate  $r$ .

**SOLUTION**

$$8.55 \times 10^{22} \text{ Al atoms} \times \frac{1 \text{ mol Al}}{6.022 \times 10^{23} \text{ Al atoms}} \times \frac{26.98 \text{ g Al}}{1 \text{ mol Al}} \times \frac{1 \text{ cm}^3}{2.70 \text{ g Al}} = 1.4187 \text{ cm}^3$$

$$V = \frac{4}{3}\pi r^3$$

$$r = \sqrt[3]{\frac{3V}{4\pi}} = \sqrt[3]{\frac{3(1.4187 \text{ cm}^3)}{4\pi}} = 0.697 \text{ cm}$$

**CHECK** The units of the answer (cm) are correct. The magnitude cannot be estimated accurately, but a radius of about one-half of a centimeter is reasonable for just over one-tenth of a mole of aluminum atoms.

**FOR PRACTICE 2.9** A titanium cube contains  $2.86 \times 10^{23}$  atoms. What is the edge length of the cube? The density of titanium is  $4.50 \text{ g/cm}^3$ .

**FOR MORE PRACTICE 2.9** Find the number of atoms in a copper rod with a length of 9.85 cm and a radius of 1.05 cm. The density of copper is  $8.96 \text{ g/cm}^3$ .

### CONCEPTUAL CONNECTION 2.7

**Avogadro's Number** Why is Avogadro's number defined as  $6.022 \times 10^{23}$  and not a simpler round number such as  $1.00 \times 10^{23}$ ?

### CONCEPTUAL CONNECTION 2.8

**The Mole** Without doing any calculations, determine which sample contains the most atoms.

- (a) a 1-g sample of copper
- (b) a 1-g sample of carbon
- (c) a 10-g sample of uranium

## Self-Assessment Quiz

- Q1.** Two samples of a compound containing elements A and B are decomposed. The first sample produces 15 g of A and 35 g of B. The second sample produces 25 g of A and what mass of B?  
a) 11 g    b) 58 g    c) 21 g    d) 45 g
- Q2.** A compound containing only carbon and hydrogen has a carbon-to-hydrogen mass ratio of 11.89. Which carbon-to-hydrogen mass ratio is possible for another compound composed only of carbon and hydrogen?  
a) 2.50    b) 3.97    c) 4.66    d) 7.89
- Q3.** Which idea came out of Rutherford's gold foil experiment?  
a) Atoms contain protons and neutrons.  
b) Matter is composed of atoms.

- c) Elements have isotopes.  
d) Atoms are mostly empty space.

- Q4.** A student re-creates the Millikan oil drop experiment and tabulates the relative charges of the oil drops in terms of a constant,  $\alpha$ .

Drop #1	$\alpha$
Drop #2	$\frac{3}{2}\alpha$
Drop #3	$\frac{5}{2}\alpha$
Drop #4	$3\alpha$

What charge for the electron (in terms of  $\alpha$ ) is consistent with these data?

- a)  $\frac{1}{2}\alpha$     b)  $\alpha$     c)  $\frac{3}{2}\alpha$     d)  $2\alpha$

- Q5.** Determine the number of protons and neutrons in the isotope Fe-58.  
 a) 26 protons and 58 neutrons  
 b) 32 protons and 26 neutrons  
 c) 26 protons and 32 neutrons  
 d) 58 protons and 58 neutrons
- Q6.** An isotope of an element contains 82 protons and 122 neutrons. What is the symbol for the isotope?  
 a)  $^{204}_{82}\text{Pb}$  b)  $^{122}_{82}\text{Pb}$  c)  $^{122}_{40}\text{Zr}$  d)  $^{204}_{40}\text{Zr}$
- Q7.** Determine the number of electrons in the  $\text{Cr}^{3+}$  ion.  
 a) 24 electrons b) 27 electrons  
 c) 3 electrons d) 21 electrons
- Q8.** Which pair of elements do you expect to be most similar in their chemical properties?  
 a) K and Fe b) O and Si  
 c) Ne and N d) Br and I
- Q9.** Which element is *not* a main-group element?  
 a) Se b) Mo c) Sr d) Ba
- Q10.** What is the charge of the ion most commonly formed by S?  
 a) 2+ b) + c) - d) 2-
- Q11.** A naturally occurring sample of an element contains only two isotopes. The first isotope has a mass of 68.9255 amu and a natural abundance of 60.11%. The second isotope has a mass of 70.9247 amu. Find the atomic mass of the element.  
 a) 70.13 amu b) 69.72 amu  
 c) 84.06 amu d) 69.93 amu
- Q12.** Which sample contains the greatest number of atoms?  
 a) 14 g C b) 49 g Cr c) 102 g Ag d) 202 g Pb
- Q13.** Determine the number of atoms in 1.85 mL of mercury. (The density of mercury is 13.5 g/mL.)  
 a)  $3.02 \times 10^{27}$  atoms b)  $4.11 \times 10^{20}$  atoms  
 c)  $7.50 \times 10^{22}$  atoms d)  $1.50 \times 10^{25}$  atoms
- Q14.** A 20.0 g sample of an element contains  $4.95 \times 10^{23}$  atoms. Identify the element.  
 a) Cr b) O c) Mg d) Fe
- Q15.** Copper has two naturally occurring isotopes with masses 62.94 amu and 64.93 amu and has an atomic mass of 63.55 amu. Which mass spectrum is most likely to correspond to a naturally occurring sample of copper?

(a)

(b)

(c)

(d)

Answers: 1. (b) 2. (b) 3. (d) 4. (a) 5. (c) 6. (a) 7. (d) 8. (d) 9. (b) 10. (d) 11. (b) 12. (a) 13. (c) 14. (c) 15. (a)

## Chapter 2 IN REVIEW

### Key Terms

#### Section 2.3

law of conservation of mass (47)  
 law of definite proportions (48)  
 law of multiple proportions (49)  
 atomic theory (50)

#### Section 2.4

cathode rays (51)  
 cathode ray tube (51)  
 electrical charge (51)  
 electron (51)

#### Section 2.5

radioactivity (53)  
 nuclear theory (54)  
 nucleus (54)  
 proton (54)  
 neutron (55)

**Section 2.6**

atomic mass unit (amu) (55)  
 atomic number ( $Z$ ) (56)  
 chemical symbol (56)  
 isotope (58)  
 natural abundance (58)  
 mass number ( $A$ ) (58)  
 ion (59)  
 cation (59)  
 anion (59)

**Section 2.7**

periodic law (61)  
 metal (62)  
 nonmetal (62)  
 metalloid (63)  
 semiconductor (63)  
 main-group elements (63)  
 transition elements  
 (transition metals) (63)  
 family (group) (63)  
 noble gases (63)

alkali metals (63)  
 alkaline earth metals (63)  
 halogens (64)

**Section 2.8**

atomic mass (65)  
 mass spectrometry (66)

**Section 2.9**

mole (mol) (69)  
 Avogadro's number (69)  
 molar mass (71)

## Key Concepts

**Brownian Motion (2.1)**

- ▶ Brownian motion is the erratic, jittery motion of small particles that was first observed by Robert Brown in 1827. The description of Brownian motion by Einstein in 1905 and confirmation by Perrin in 1908 removed any lingering doubt about the particulate nature of matter.

**The Atomic Theory (2.2, 2.3)**

- ▶ Each element is composed of indestructible particles called atoms.
- ▶ All atoms of a given element have the same mass and other properties.
- ▶ Atoms combine in simple, whole-number ratios to form compounds.
- ▶ Atoms of one element cannot change into atoms of another element. In a chemical reaction, atoms change the way that they are bound together with other atoms to form a new substance.

**The Electron (2.4)**

- ▶ J. J. Thomson discovered the electron in the late 1800s through experiments with cathode rays. He deduced that electrons are negatively charged, and he measured their charge-to-mass ratio.
- ▶ Robert Millikan measured the charge of the electron, which—in conjunction with Thomson's results—led to the calculation of the mass of an electron.

**The Nuclear Atom (2.5)**

- ▶ In 1909, Ernest Rutherford probed the inner structure of the atom by working with a form of radioactivity called alpha radiation and developed the nuclear theory of the atom.
- ▶ Nuclear theory states that the atom is mainly empty space, with most of its mass concentrated in a tiny region called the nucleus and most of its volume occupied by relatively light electrons.

**Subatomic Particles (2.6)**

- ▶ Atoms are composed of three fundamental particles: the proton (1 amu, +1 charge), the neutron (1 amu, 0 charge), and the electron (~0 amu, -1 charge).

- ▶ The number of protons in the nucleus of the atom is its atomic number ( $Z$ ) and defines the element.
- ▶ The sum of the number of protons and neutrons is the mass number ( $A$ ).
- ▶ Atoms of an element that have different numbers of neutrons (and therefore different mass numbers) are isotopes.
- ▶ Atoms that lose or gain electrons become charged and are ions. Cations are positively charged and anions are negatively charged.

**The Periodic Table (2.7)**

- ▶ The periodic table tabulates all known elements in order of increasing atomic number.
- ▶ The periodic table is arranged so that similar elements are grouped together in columns.
- ▶ Elements on the left side and in the center of the periodic table are metals and tend to lose electrons in chemical changes.
- ▶ Elements on the upper right side of the periodic table are non-metals and tend to gain electrons in chemical changes.
- ▶ Elements located on the boundary between metals and nonmetals are metalloids.

**Atomic Mass and the Mole (2.8, 2.9)**

- ▶ The atomic mass of an element, listed directly below its symbol in the periodic table, is a weighted average of the masses of the naturally occurring isotopes of the element.
- ▶ One mole of an element is the amount of that element that contains Avogadro's number ( $6.022 \times 10^{23}$ ) of atoms.
- ▶ Any sample of an element with a mass (in grams) that equals its atomic mass contains one mole of the element. For example, the atomic mass of carbon is 12.011 amu; therefore, 12.011 g of carbon contains 1 mol of carbon atoms.

## Key Equations and Relationships

Relationship between Mass Number ( $A$ ), Number of Protons ( $p$ ), and Number of Neutrons ( $n$ ) (2.6)

$$A = \text{number of protons } (p) + \text{number of neutrons } (n)$$

Atomic Mass (2.8)

$$\text{Atomic mass} = \sum_n (\text{fraction of isotope } n) \times (\text{mass of isotope } n)$$

Avogadro's Number (2.9)

$$1 \text{ mol} = 6.0221421 \times 10^{23} \text{ particles}$$

## Key Learning Outcomes

CHAPTER OBJECTIVES	ASSESSMENT
Using the Law of Definite Proportions (2.3)	Example 2.1 For Practice 2.1 Exercises 31, 32
Using the Law of Multiple Proportions (2.3)	Example 2.2 For Practice 2.2 Exercises 35–38
Working with Atomic Numbers, Mass Numbers, and Isotope Symbols (2.6)	Example 2.3 For Practice 2.3 Exercises 51–58
	
Predicting the Charge of Ions (2.7)	Example 2.4 For Practice 2.4 Exercises 59–62
Calculating Atomic Mass (2.8)	Example 2.5 For Practice 2.5 For More Practice 2.5 Exercises 71, 72, 74–77
Converting between Moles and Number of Atoms (2.9)	Example 2.6 For Practice 2.6 Exercises 81, 82
Converting between Mass and Amount (in Moles) (2.9)	Example 2.7 For Practice 2.7 For More Practice 2.7 Exercises 83, 84
	
Using the Mole Concept (2.9)	Examples 2.8, 2.9 For Practice 2.8, 2.9 For More Practice 2.8, 2.9 Exercises 85–94, 112, 113

## EXERCISES

### Review Questions

- What is Brownian motion? How is it related to the development of the idea that matter is particulate?
- Summarize the history of the atomic idea. How was Dalton able to convince others to accept an idea that had been controversial for 2000 years?
- State and explain the law of conservation of mass.
- State and explain the law of definite proportions.
- State and explain the law of multiple proportions. How is the law of multiple proportions different from the law of definite proportions?
- What are the main ideas in Dalton's atomic theory? How do they help explain the laws of conservation of mass, of constant composition, and of definite proportions?
- How and by whom was the electron discovered? What basic properties of the electron were reported with its discovery?
- Explain Millikan's oil drop experiment and how it led to the measurement of the electron's charge. Why is the magnitude of the charge of the electron so important?
- Describe the plum-pudding model of the atom.
- Describe Rutherford's gold foil experiment. How did the experiment prove that the plum-pudding model of the atom was wrong?
- Describe Rutherford's nuclear model of the atom. What was revolutionary about his model?
- If matter is mostly empty space, as suggested by Rutherford, then why does it appear so solid?
- List the three subatomic particles that compose atoms and give the basic properties (mass and charge) of each.
- What defines an element?
- Explain the difference between  $Z$  (the atomic number) and  $A$  (the mass number).
- Where do elements get their names?
- What are isotopes? What is percent natural abundance of isotopes?
- Describe the two different notations used to specify isotopes and give an example of each.
- What is an ion? A cation? An anion?

20. State the periodic law. How did the periodic law lead to the periodic table?
21. Describe the characteristic properties of metals, nonmetals, and metalloids.
22. List the characteristic properties of each group.
  - a. noble gases
  - b. alkali metals
  - c. alkaline earth metals
  - d. halogens
23. How do you predict the charges of ions formed by main-group elements?

24. What is atomic mass? How is it calculated?
25. Explain how a mass spectrometer works.
26. What kind of information can be determined from a mass spectrum?
27. What is a mole? How is the mole concept useful in chemical calculations?
28. Why is the mass corresponding to a mole of one element different from the mass corresponding to a mole of another element?

## Problems by Topic

*Note: Answers to all odd-numbered Problems, numbered in blue, can be found in Appendix III. Exercises in the Problems by Topic section are paired, with each odd-numbered problem followed by a similar even-numbered problem. Exercises in the Cumulative Problems section are also paired, but somewhat more loosely. (Challenge Problems and Conceptual Problems, because of their nature, are unpaired.)*

### The Laws of Conservation of Mass, Definite Proportions, and Multiple Proportions

29. A hydrogen-filled balloon is ignited and 1.50 g of hydrogen is reacted with 12.0 g of oxygen. How many grams of water vapor form? (Assume that water vapor is the only product.)
30. An automobile gasoline tank holds 21 kg of gasoline. When the gasoline burns, 84 kg of oxygen is consumed, and carbon dioxide and water are produced. What is the total combined mass of carbon dioxide and water that is produced?
31. Two samples of carbon tetrachloride are decomposed into their constituent elements. One sample produces 38.9 g of carbon and 448 g of chlorine, and the other sample produces 14.8 g of carbon and 134 g of chlorine. Are these results consistent with the law of definite proportions? Explain your answer.
32. Two samples of sodium chloride are decomposed into their constituent elements. One sample produces 6.98 g of sodium and 10.7 g of chlorine, and the other sample produces 11.2 g of sodium and 17.3 g of chlorine. Are these results consistent with the law of definite proportions? Explain your answer.
33. The mass ratio of sodium to fluorine in sodium fluoride is 1.21:1. A sample of sodium fluoride produces 28.8 g of sodium upon decomposition. How much fluorine (in grams) forms?
34. Upon decomposition, one sample of magnesium fluoride produces 1.65 kg of magnesium and 2.57 kg of fluorine. A second sample produces 1.32 kg of magnesium. How much fluorine (in grams) does the second sample produce?
35. Two different compounds containing osmium and oxygen have the following masses of oxygen per gram of osmium: 0.168 and 0.3369 g. Show that these amounts are consistent with the law of multiple proportions.
36. Palladium forms three different compounds with sulfur. The mass of sulfur per gram of palladium in each compound is listed here. Show that these masses are consistent with the law of multiple proportions.

Compound	Grams S per Gram Pd
A	0.603
B	0.301
C	0.151

37. Sulfur and oxygen form both sulfur dioxide and sulfur trioxide. When samples of these are decomposed, the sulfur dioxide

produces 3.49 g oxygen and 3.50 g sulfur, while the sulfur trioxide produces 6.75 g oxygen and 4.50 g sulfur. Calculate the mass of oxygen per gram of sulfur for each sample and show that these results are consistent with the law of multiple proportions.

38. Sulfur and fluorine form several different compounds including sulfur hexafluoride and sulfur tetrafluoride. Decomposition of a sample of sulfur hexafluoride produces 4.45 g of fluorine and 1.25 g of sulfur, while decomposition of a sample of sulfur tetrafluoride produces 4.43 g of fluorine and 1.87 g of sulfur. Calculate the mass of fluorine per gram of sulfur for each sample and show that these results are consistent with the law of multiple proportions.

### Atomic Theory, Nuclear Theory, and Subatomic Particles

39. Which statements are *consistent* with Dalton's atomic theory as it was originally stated? Why?
  - a. Sulfur and oxygen atoms have the same mass.
  - b. All cobalt atoms are identical.
  - c. Potassium and chlorine atoms combine in a 1:1 ratio to form potassium chloride.
  - d. Lead atoms can be converted into gold.
40. Which statements are *inconsistent* with Dalton's atomic theory as it was originally stated? Why?
  - a. All carbon atoms are identical.
  - b. An oxygen atom combines with 1.5 hydrogen atoms to form a water molecule.
  - c. Two oxygen atoms combine with a carbon atom to form a carbon dioxide molecule.
  - d. The formation of a compound often involves the destruction of one or more atoms.
41. Which statements are *consistent* with Rutherford's nuclear theory as it was originally stated? Why?
  - a. The volume of an atom is mostly empty space.
  - b. The nucleus of an atom is small compared to the size of the atom.
  - c. Neutral lithium atoms contain more neutrons than protons.
  - d. Neutral lithium atoms contain more protons than electrons.
42. Which statements are *inconsistent* with Rutherford's nuclear theory as it was originally stated? Why?
  - a. Since electrons are smaller than protons, and since a hydrogen atom contains only one proton and one electron, it must follow that the volume of a hydrogen atom is mostly due to the proton.
  - b. A nitrogen atom has seven protons in its nucleus and seven electrons outside of its nucleus.
  - c. A phosphorus atom has 15 protons in its nucleus and 150 electrons outside of its nucleus.
  - d. The majority of the mass of a fluorine atom is due to its nine electrons.

43. A chemist in an imaginary universe, where electrons have a different charge than they do in our universe, performs the Millikan oil drop experiment to measure the electron's charge. The charges of several drops are recorded here. What is the charge of the electron in this imaginary universe?

Drop #	Charge
A	$-6.9 \times 10^{-19} \text{ C}$
B	$-9.2 \times 10^{-19} \text{ C}$
C	$-11.5 \times 10^{-19} \text{ C}$
D	$-4.6 \times 10^{-19} \text{ C}$

44. Imagine a unit of charge called the *zorg*. A chemist performs the oil drop experiment and measures the charge of each drop in zorgs. Based on the results shown here, what is the charge of the electron in zorgs (z)? How many electrons are in each drop?

Drop #	Charge
A	$-4.8 \times 10^{-9} \text{ z}$
B	$-9.6 \times 10^{-9} \text{ z}$
C	$-6.4 \times 10^{-9} \text{ z}$
D	$-12.8 \times 10^{-9} \text{ z}$

45. On a dry day, your body can accumulate static charge from walking across a carpet or from brushing your hair. If your body develops a charge of  $-15 \mu\text{C}$  (microcoulombs), how many excess electrons has it acquired? What is their collective mass?
46. How many electrons are necessary to produce a charge of  $-1.0 \text{ C}$ ? What is the mass of this many electrons?
47. Which statements about subatomic particles are true?
- If an atom has an equal number of protons and electrons, it will be charge-neutral.
  - Electrons are attracted to protons.
  - Electrons are much lighter than neutrons.
  - Protons have twice the mass of neutrons.
48. Which statements about subatomic particles are false?
- Protons and electrons have charges of the same magnitude but opposite signs.
  - Protons have about the same mass as neutrons.
  - Some atoms don't have any protons.
  - Protons and neutrons have charges of the same magnitude but opposite signs.
49. How many electrons does it take to equal the mass of a proton?
50. A helium nucleus has two protons and two neutrons. How many electrons does it take to equal the mass of a helium nucleus?

### Isotopes and Ions

51. Write isotopic symbols in the form  $X-A$  (e.g., C-13) for each isotope.
- the silver isotope with 60 neutrons
  - the silver isotope with 62 neutrons
  - the uranium isotope with 146 neutrons
  - the hydrogen isotope with one neutron
52. Write isotopic symbols in the form  ${}^A_ZX$  for each isotope.
- the copper isotope with 34 neutrons
  - the copper isotope with 36 neutrons
  - the potassium isotope with 21 neutrons
  - the argon isotope with 22 neutrons

53. Determine the number of protons and the number of neutrons in each isotope.
- ${}^{14}_7\text{N}$
  - ${}^{23}_{11}\text{Na}$
  - ${}^{222}_{86}\text{Rn}$
  - ${}^{208}_{82}\text{Pb}$
54. Determine the number of protons and the number of neutrons in each isotope.
- ${}^{40}_{19}\text{K}$
  - ${}^{226}_{88}\text{Ra}$
  - ${}^{99}_{43}\text{Tc}$
  - ${}^{33}_{15}\text{P}$
55. The amount of carbon-14 in ancient artifacts and fossils is often used to establish their age. Determine the number of protons and the number of neutrons in carbon-14 and write its symbol in the form  ${}^A_ZX$ .
56. Uranium-235 is used in nuclear fission. Determine the number of protons and the number of neutrons in uranium-235 and write its symbol in the form  ${}^A_ZX$ .
57. Determine the number of protons and the number of electrons in each ion.
- $\text{Ni}^{2+}$
  - $\text{S}^{2-}$
  - $\text{Br}^{-}$
  - $\text{Cr}^{3+}$
58. Determine the number of protons and the number of electrons in each ion.
- $\text{Al}^{3+}$
  - $\text{Se}^{2-}$
  - $\text{Ga}^{3+}$
  - $\text{Sr}^{2+}$
59. Predict the charge of the ion formed by each element.
- O
  - K
  - Al
  - Rb
60. Predict the charge of the ion formed by each element.
- Mg
  - N
  - F
  - Na
61. Fill in the blanks to complete the table.

Symbol	Ion Formed	Number of Electrons in Ion	Number of Protons in Ion
Ca	$\text{Ca}^{2+}$	_____	_____
_____	$\text{Be}^{2+}$	2	_____
Se	_____	_____	34
In	_____	_____	49

62. Fill in the blanks to complete the table.

Symbol	Ion Formed	Number of Electrons in Ion	Number of Protons in Ion
Cl	_____	_____	17
Te	_____	54	_____
Br	$\text{Br}^{-}$	_____	_____
_____	$\text{Sr}^{2+}$	_____	38

### The Periodic Table and Atomic Mass

63. Write the name of each element and classify it as a metal, nonmetal, or metalloid.
- K
  - Ba
  - I
  - O
  - Sb
64. Write the symbol for each element and classify it as a metal, nonmetal, or metalloid.
- gold
  - fluorine
  - sodium
  - tin
  - argon
65. Determine whether or not each element is a main-group element.
- tellurium
  - potassium
  - vanadium
  - manganese

66. Determine whether or not each element is a transition element.
- Cr
  - Br
  - Mo
  - Cs
67. Classify each element as an alkali metal, alkaline earth metal, halogen, or noble gas.
- sodium
  - iodine
  - calcium
  - barium
  - krypton
68. Classify each element as an alkali metal, alkaline earth metal, halogen, or noble gas.
- F
  - Sr
  - K
  - Ne
  - At
69. Which pair of elements do you expect to be most similar? Why?
- N and Ni
  - Mo and Sn
  - Na and Mg
  - Cl and F
  - Si and P
70. Which pair of elements do you expect to be most similar? Why?
- nitrogen and oxygen
  - titanium and gallium
  - lithium and sodium
  - germanium and arsenic
  - argon and bromine
71. Gallium has two naturally occurring isotopes with the following masses and natural abundances:

Isotope	Mass (amu)	Abundance (%)
Ga-69	68.92558	60.108
Ga-71	70.92470	39.892

Sketch the mass spectrum of gallium.

72. Magnesium has three naturally occurring isotopes with the following masses and natural abundances:

Isotope	Mass (amu)	Abundance (%)
Mg-24	23.9850	78.99
Mg-25	24.9858	10.00
Mg-26	25.9826	11.01

Sketch the mass spectrum of magnesium.

73. The atomic mass of fluorine is 18.998 amu, and its mass spectrum shows a large peak at this mass. The atomic mass of chlorine is 35.45 amu, yet the mass spectrum of chlorine does not show a peak at this mass. Explain the difference.
74. The atomic mass of copper is 63.546 amu. Do any copper isotopes have a mass of 63.546 amu? Explain.
75. An element has two naturally occurring isotopes. Isotope 1 has a mass of 120.9038 amu and a relative abundance of 57.4%, and isotope 2 has a mass of 122.9042 amu. Find the atomic mass of this element and identify it.

76. An element has four naturally occurring isotopes with the masses and natural abundances given here. Find the atomic mass of the element and identify it.

Isotope	Mass (amu)	Abundance (%)
1	135.90714	0.19
2	137.90599	0.25
3	139.90543	88.43
4	141.90924	11.13

77. Bromine has two naturally occurring isotopes (Br-79 and Br-81) and has an atomic mass of 79.904 amu. The mass of Br-81 is 80.9163 amu, and its natural abundance is 49.31%. Calculate the mass and natural abundance of Br-79.
78. Silicon has three naturally occurring isotopes (Si-28, Si-29, and Si-30). The mass and natural abundance of Si-28 are 27.9769 amu and 92.2%, respectively. The mass and natural abundance of Si-29 are 28.9765 amu and 4.67%, respectively. Find the mass and natural abundance of Si-30.
79. Use the mass spectrum of europium to determine the atomic mass of europium.

80. Use the mass spectrum of rubidium to determine the atomic mass of rubidium.

## The Mole Concept

81. How many sulfur atoms are there in 5.52 mol of sulfur?
82. How many moles of aluminum do  $3.7 \times 10^{24}$  aluminum atoms represent?
83. What is the amount, in moles, of each elemental sample?
- 11.8 g Ar
  - 3.55 g Zn
  - 26.1 g Ta
  - 0.211 g Li
84. What is the mass, in grams, of each elemental sample?
- $2.3 \times 10^{-3}$  mol Sb
  - 0.0355 mol Ba
  - 43.9 mol Xe
  - 1.3 mol W
85. How many silver atoms are there in 3.78 g of silver?
86. What is the mass of  $4.91 \times 10^{21}$  platinum atoms?

87. Calculate the number of atoms in each sample.  
 a. 5.18 g P      b. 2.26 g Hg  
 c. 1.87 g Bi      d. 0.082 g Sr
88. Calculate the number of atoms in each sample.  
 a. 14.955 g Cr      b. 39.733 g S  
 c. 12.899 g Pt      d. 97.552 g Sn
89. Calculate the mass, in grams, of each sample.  
 a.  $1.1 \times 10^{23}$  gold atoms  
 b.  $2.82 \times 10^{22}$  helium atoms  
 c.  $1.8 \times 10^{23}$  lead atoms  
 d.  $7.9 \times 10^{21}$  uranium atoms
90. Calculate the mass, in kg, of each sample.  
 a.  $7.55 \times 10^{26}$  cadmium atoms  
 b.  $8.15 \times 10^{27}$  nickel atoms  
 c.  $1.22 \times 10^{27}$  manganese atoms  
 d.  $5.48 \times 10^{29}$  lithium atoms
91. How many carbon atoms are there in a diamond (pure carbon) with a mass of 52 mg?

92. How many helium atoms are there in a helium blimp containing 536 kg of helium?
93. Calculate the average mass, in grams, of one platinum atom.
94. Using scanning tunneling microscopy, scientists at IBM wrote the initials of their company with 35 individual xenon atoms (as shown below). Calculate the total mass of these letters in grams.

## Cumulative Problems

95. A 7.83 g sample of HCN contains 0.290 g of H and 4.06 g of N. Find the mass of carbon in a sample of HCN with a mass of 3.37 g.
96. The ratio of sulfur to oxygen by mass in  $\text{SO}_2$  is 1.0:1.0.  
 a. Find the ratio of sulfur to oxygen by mass in  $\text{SO}_3$ .  
 b. Find the ratio of sulfur to oxygen by mass in  $\text{S}_2\text{O}$ .
97. The ratio of oxygen to carbon by mass in carbon monoxide is 1.33:1.00. Find the formula of an oxide of carbon in which the ratio by mass of oxygen to carbon is 2.00:1.00.
98. The ratio of the mass of a nitrogen atom to the mass of an atom of  $^{12}\text{C}$  is 7:6, and the ratio of the mass of nitrogen to oxygen in  $\text{N}_2\text{O}$  is 7:4. Find the mass of 1 mol of oxygen atoms.
99. An  $\alpha$  particle,  $^4\text{He}^{2+}$ , has a mass of 4.00151 amu. Find the value of its charge-to-mass ratio in C/kg.
100. Naturally occurring iodine has an atomic mass of 126.9045 amu. A 12.3849 g sample of iodine is accidentally contaminated with an additional 1.00070 g of  $^{129}\text{I}$ , a synthetic radioisotope of iodine used in the treatment of certain diseases of the thyroid gland. The mass of  $^{129}\text{I}$  is 128.9050 amu. Find the apparent "atomic mass" of the contaminated iodine.
101. Use the mass spectrum of lead to estimate the atomic mass of lead. Estimate the mass and percent intensity values from the graph to three significant figures.

102. Use the mass spectrum of mercury to estimate the atomic mass of mercury. Estimate the masses and percent intensity values from the graph to three significant figures.

103. Nuclei with the same number of *neutrons* but different mass numbers are called *isotones*. Write the symbols of four isotones of  $^{236}\text{Th}$ .
104. Fill in the blanks to complete the table.

Symbol	Z	A	Number of p	Number of e <sup>-</sup>	Number of n	Charge
Si	14	_____	_____	14	14	_____
S <sup>2-</sup>	_____	32	_____	_____	_____	2-
Cu <sup>2+</sup>	_____	_____	_____	_____	34	2+
_____	15	_____	_____	15	16	_____

105. Fill in the blanks to complete the table.

Symbol	Z	A	Number of p	Number of e <sup>-</sup>	Number of n	Charge
_____	8	_____	_____	_____	8	2-
Ca <sup>2+</sup>	20	_____	_____	_____	20	_____
Mg <sup>2+</sup>	_____	25	_____	_____	13	2+
N <sup>3-</sup>	_____	14	_____	10	_____	_____

- 106.** Neutron stars are composed of solid nuclear matter, primarily neutrons. Assume the radius of a neutron is approximately  $1.0 \times 10^{-13}$  cm. Calculate the density of a neutron. [Hint: For a sphere  $V = (4/3)\pi r^3$ .] Assuming that a neutron star has the same density as a neutron, calculate the mass (in kg) of a small piece of a neutron star the size of a spherical pebble with a radius of 0.10 mm.
- 107.** Carbon-12 contains six protons and six neutrons. The radius of the nucleus is approximately 2.7 fm (femtometers) and the radius of the atom is approximately 70 pm (picometers). Calculate the volume of the nucleus and the volume of the atom. What percentage of the carbon atom's volume is occupied by the nucleus? (Assume two significant figures.)
- 108.** A penny has a thickness of approximately 1.0 mm. If you stacked Avogadro's number of pennies one on top of the other on Earth's surface, how far would the stack extend (in km)? [For comparison, the sun is about 150 million km from Earth and the nearest star (Proxima Centauri) is about 40 trillion km from Earth.]
- 109.** Consider the stack of pennies in the previous problem. How much money (in dollars) would this represent? If this money were equally distributed among the world's population of 7.0 billion people, how much would each person receive? Would each person be a millionaire? A billionaire? A trillionaire?
- 110.** The mass of an average blueberry is 0.75 g and the mass of an automobile is  $2.0 \times 10^3$  kg. Find the number of automobiles whose total mass is the same as 1.0 mol of blueberries.
- 111.** Suppose that atomic masses were based on the assignment of a mass of 12.000 g to 1 mol of carbon, rather than 1 mol of  $^{12}\text{C}$ . What would the atomic mass of oxygen be? (The atomic masses of carbon and oxygen based on the assignment of 12.000 g to 1 mol of  $^{12}\text{C}$  are 12.011 amu and 15.9994 amu, respectively.)
- 112.** A pure titanium cube has an edge length of 2.78 in. How many titanium atoms does it contain? Titanium has a density of  $4.50 \text{ g/cm}^3$ .
- 113.** A pure copper sphere has a radius of 0.935 in. How many copper atoms does it contain? [The volume of a sphere is  $(4/3)\pi r^3$  and the density of copper is  $8.96 \text{ g/cm}^3$ .]
- 114.** What is the radius (in cm) of a pure copper sphere that contains  $1.14 \times 10^{24}$  copper atoms? [The volume of a sphere is  $(4/3)\pi r^3$  and the density of copper is  $8.96 \text{ g/cm}^3$ .]
- 115.** What is the edge length (in cm) of a titanium cube that contains  $2.55 \times 10^{24}$  titanium atoms? The density of titanium is  $4.50 \text{ g/cm}^3$ .
- 116.** Boron has only two naturally occurring isotopes. The mass of boron-10 is 10.01294 amu and the mass of boron-11 is 11.00931 amu. Calculate the relative abundances of the two isotopes.
- 117.** Lithium has only two naturally occurring isotopes. The mass of lithium-6 is 6.01512 amu and the mass of lithium-7 is 7.01601 amu. Calculate the relative abundances of the two isotopes.
- 118.** Common brass is a copper and zinc alloy containing 37.0% zinc by mass and having a density of  $8.48 \text{ g/cm}^3$ . A fitting composed of common brass has a total volume of  $112.5 \text{ cm}^3$ . How many atoms (copper and zinc) does the fitting contain?
- 119.** A 67.2 g sample of a gold and palladium alloy contains  $2.49 \times 10^{23}$  atoms. What is the composition (by mass) of the alloy?
- 120.** Naturally occurring chlorine is composed of two isotopes: 75.76% Cl-35 (mass 34.9688 amu) and 24.24% Cl-37 (mass 36.9659 amu). Naturally occurring oxygen is composed of three isotopes: 99.757% O-16 (mass 15.9949 amu), 0.038% O-17 (mass 16.9991 amu), and 0.205% O-18 (mass 17.9991 amu). The compound dichlorine monoxide is composed of two chlorine atoms and one oxygen atom bonded together to form the  $\text{Cl}_2\text{O}$  molecule. How many  $\text{Cl}_2\text{O}$  molecules of different masses naturally exist? Give the masses of the three most abundant  $\text{Cl}_2\text{O}$  molecules.
- 121.** Silver is composed of two naturally occurring isotopes: Ag-107 (51.839%) and Ag-109. The ratio of the masses of the two isotopes is 1.0187. What is the mass of Ag-107?
- 122.** The U.S. Environmental Protection Agency (EPA) sets limits on healthful levels of air pollutants. The maximum level that the EPA considers safe for lead air pollution is  $1.5 \mu\text{g/m}^3$ . If your lungs were filled with air containing this level of lead, how many lead atoms would be in your lungs? (Assume a total lung volume of 5.50 L.)
- 123.** Pure gold is usually too soft for jewelry, so it is often alloyed with other metals. How many gold atoms are in an 0.255-ounce, 18 K gold bracelet? (18 K gold is 75% gold by mass.)

## Challenge Problems

- 124.** In Section 2.9, it was stated that 1 mol of sand grains would cover the state of Texas to several feet. Estimate how many feet by assuming that the sand grains are roughly cube-shaped, each one with an edge length of 0.10 mm. Texas has a land area of 268,601 square miles.
- 125.** Use the concepts in this chapter to obtain an estimate for the number of atoms in the universe. Make the following assumptions: **(a)** All of the atoms in the universe are hydrogen atoms in stars. (This is not a ridiculous assumption because over three-fourths of the atoms in the universe are in fact hydrogen. Gas and dust between the stars represent only about 15% of the visible matter of our galaxy, and planets compose a far tinier fraction.) **(b)** The sun is a typical star composed of pure hydrogen with a density of  $1.4 \text{ g/cm}^3$  and a radius of  $7 \times 10^8 \text{ m}$ .

**(c)** Each of the roughly 100 billion stars in the Milky Way galaxy contains the same number of atoms as our sun. **(d)** Each of the 10 billion galaxies in the visible universe contains the same number of atoms as our Milky Way galaxy.

- 126.** On the previous page is a representation of 50 atoms of a fictitious element called westmontium (Wt). The red spheres represent Wt-296, the blue spheres Wt-297, and the green spheres Wt-298.
- Assuming that the sample is statistically representative of a naturally occurring sample, calculate the percent natural abundance of each Wt isotope.
  - Draw the mass spectrum for a naturally occurring sample of Wt.
  - The mass of each Wt isotope is measured relative to C-12 and tabulated. Use the mass of C-12 to convert each of the masses to amu and calculate the atomic mass of Wt.

Isotope	Mass
Wt-296	$24.6630 \times \text{Mass}(^{12}\text{C})$
Wt-297	$24.7490 \times \text{Mass}(^{12}\text{C})$
Wt-298	$24.8312 \times \text{Mass}(^{12}\text{C})$

- 127.** The ratio of oxygen to nitrogen by mass in  $\text{NO}_2$  is 2.29. The ratio of fluorine to nitrogen by mass in  $\text{NF}_3$  is 4.07. Find the ratio of oxygen to fluorine by mass in  $\text{OF}_2$ .

- 128.** Naturally occurring cobalt consists of only one isotope,  $^{59}\text{Co}$ , whose relative atomic mass is 58.9332. A synthetic radioactive isotope of cobalt,  $^{60}\text{Co}$ , has a relative atomic mass of 59.9338 and is used in radiation therapy for cancer. A 1.5886 g sample of cobalt has an apparent "atomic mass" of 58.9901. Find the mass of  $^{60}\text{Co}$  in this sample.
- 129.** A 7.36 g sample of copper is contaminated with an additional 0.51 g of zinc. Suppose an atomic mass measurement was performed on this sample. What would be the measured atomic mass?
- 130.** The ratio of the mass of O to the mass of N in  $\text{N}_2\text{O}_3$  is 12:7. Another binary compound of nitrogen has a ratio of O to N of 16:7. What is its formula? What is the ratio of O to N in the next member of this series of compounds?
- 131.** Naturally occurring magnesium has an atomic mass of 24.312 and consists of three isotopes. The major isotope is  $^{24}\text{Mg}$ , natural abundance 78.99%, relative atomic mass 23.98504. The next most abundant isotope is  $^{26}\text{Mg}$ , relative atomic mass 25.98259. The third most abundant isotope is  $^{25}\text{Mg}$ , whose natural abundance is in the ratio of 0.9083 to that of  $^{26}\text{Mg}$ . Find the relative atomic mass of  $^{25}\text{Mg}$ .

## Conceptual Problems

- 132.** Which answer is an example of the law of multiple proportions? Explain.
- Two different samples of water are found to have the same ratio of hydrogen to oxygen.
  - When hydrogen and oxygen react, the mass of water formed is exactly equal to the mass of hydrogen and oxygen that reacted.
  - The mass ratio of oxygen to hydrogen in water is 8:1. The mass ratio of oxygen to hydrogen in hydrogen peroxide (a compound that only contains hydrogen and oxygen) is 16:1.
- 133.** Lithium has two naturally occurring isotopes: Li-6 (natural abundance 7.5%) and Li-7 (natural abundance 92.5%). Using circles to represent protons and squares to represent neutrons, draw the nucleus of each isotope. How many Li-6 atoms are present, on average, in a 1000-atom sample of lithium?
- 134.** As we saw in the previous problem, lithium has two naturally occurring isotopes: Li-6 (natural abundance 7.5%; mass 6.0151 amu) and Li-7 (natural abundance 92.5%; mass

7.0160 amu). Without doing any calculations, determine which mass is closest to the atomic mass of Li.

- a. 6.00 amu    b. 6.50 amu    c. 7.00 amu

- 135.** The mole is defined as the amount of a substance containing the same number of particles as exactly 12 g of C-12. The amu is defined as 1/12 of the mass of an atom of C-12. Why is it important that both of these definitions reference the same isotope? What would be the result, for example, of defining the mole with respect to C-12, but the amu with respect to Ne-20?
- 136.** Without doing any calculations, determine which of the samples contains the greatest amount of the element in moles. Which contains the greatest mass of the element?
- a. 55.0 g Cr    b. 45.0 g Ti    c. 60.0 g Zn
- 137.** The atomic radii of the isotopes of an element are identical to one another. However, the atomic radii of the ions of an element are significantly different from the atomic radii of the neutral atom of the element. Explain.

## Active Classroom Learning

### Questions for Group Work

Discuss these questions with the group and record your consensus answer.

- 138.** The table shown here includes data similar to those used by Mendeleev when he created the periodic table. On a small card, write the symbol, atomic mass, and a stable compound formed by each element. Without consulting a periodic table, arrange the cards so that atomic mass increases from left to right and elements with similar properties are above and below each other. Copy the periodic table you have invented onto a piece of paper. There is one element missing. Predict its mass and a stable compound it might form.

Element	Atomic Mass	Stable Compound
Be	9	$\text{BeCl}_2$
S	32	$\text{H}_2\text{S}$
F	19	$\text{F}_2$
Ca	40	$\text{CaCl}_2$
Li	7	$\text{LiCl}$
Si	28	$\text{SiH}_4$
Cl	35.4	$\text{Cl}_2$
B	10.8	$\text{BH}_3$

—Continued on the next page

—Continued

Element	Atomic Mass	Stable Compound
Ge	72.6	GeH <sub>4</sub>
N	14	NF <sub>3</sub>
O	16	H <sub>2</sub> O
Ga	69.7	GaH <sub>3</sub>
As	75	AsF <sub>3</sub>
C	12	CH <sub>4</sub>
K	39	KCl
Mg	24.3	MgCl <sub>2</sub>
Se	79	H <sub>2</sub> Se
Al	27	AlH <sub>3</sub>
Br	80	Br <sub>2</sub>
Na	23	NaCl

139. In a naturally occurring sample, 19.8% of boron atoms have five neutrons and 80.2% have six neutrons. What is the mass number of each boron isotope? Sketch a sample of 10 atoms that is nearly representative of a natural sample. What is the average mass of the atoms in your drawing? What is the atomic mass of boron? (Boron-10 has a mass of 10.01294 amu and boron-11 has a mass of 11.00931 amu.)
140. In complete sentences, describe the similarities and differences between:
- a. different isotopes of an element
  - b. a neutral atom and an ion of the same element
141. Calculate the mass in grams of one mole of each of the following (the mass of a single item is given in parentheses): electrons ( $9.10938 \times 10^{-28}$  g), protons ( $1.67262 \times 10^{-24}$  g), neutrons ( $1.67493 \times 10^{-24}$  g), atoms of carbon-12 ( $1.992646 \times 10^{-23}$  g), and doughnuts (74 g). Compare the mass of one mole of carbon-12 atoms to the sum of the masses of the particles that it contains. If the doughnut mentioned in this question were made entirely of carbon, how many atoms would it contain?

## Data Interpretation and Analysis

### Heavy Metals in Recycled Paper Packages

142. Demand for recycled paper has increased as consumers have become more aware of the environmental issues surrounding waste disposal. Paper is a natural raw material made from renewable wood and plants. Recycled paper is made from waste paper and paperboard. Both new paper and recycled paper contain traces of heavy metals. However, some types of recycled paper contain more heavy metals than new paper due, in part, to the inks used for printing or adding color to the original paper. Metals can migrate from the paper packaging and containers used for food to the food itself. This metal migration is controlled and monitored to reduce the exposure of humans to heavy metals.
- Food agencies in each country determine the limit of cadmium, zinc, nickel, and copper in packaging materials. Most countries impose a limit of heavy metals in recycled paper not to exceed 100.0 ppm or 100.0 mg/kg. The limit for lead in egg-, fruit-, or vegetable-packaging is lower—not to exceed—20.0 mg/kg. The table in Figure a lists the results of the analysis of samples of recycled paper produced by a manufacturer during a three-month period.

The goal of the manufacturer is to reduce the amount of heavy metals—especially lead—in the recycled paper it produces and sells. From March to May, the manufacturer varied the methods of production each month to determine which method would produce paper with the lowest metal content. Each month, lab technicians cut small samples of recycled paper with an area of 1.000 dm<sup>2</sup> and a thickness of 0.0500 cm. The technicians then prepared the samples for analysis. The average density of the samples is  $800.0 \pm 0.0245$  g/m<sup>3</sup>.

Use the information provided in the figure to answer the following questions:

- a. Did the company reduce the amount of lead in its product between March and May?
- b. Which metal was not reduced?
- c. Each month's sample represents a different manufacturing process. Which process would you recommend the manufacturer choose to continue to use over the next year while additional processes are tested? Why?
- d. What is the total amount of the five metals for the April sample (in mg/kg)?
- e. What is the total mass (in mg) of the five metals for the April sample found in the  $1.000 \text{ dm}^2 \times 0.0500 \text{ cm}$  sample?
- f. Lead has four stable isotopes: <sup>204</sup>Pb, <sup>206</sup>Pb, <sup>207</sup>Pb, <sup>208</sup>Pb with % abundances of 1.40, 24.10, 22.10, and 52.40, respectively. Determine the mass (in mg) of <sup>208</sup>Pb in the April sample.
- g. Sketch the mass spectrum for lead.

	Zn	Pb	Cd	Ni	Cu
March	2.7	3.5	0.129	1.7	32.3
April	3.2	2.8	0.092	1.6	29.2
May	3.7	2.4	0.096	1.5	19.9

▲ FIGURE a Heavy Metal Values in Three Samples of Recycled Paper (mg/kg  $\pm$  0.1)

## Answers to Conceptual Connections

### The Law of Conservation of Mass

**2.1** Most of the matter that composed the log undergoes a chemical change by reacting with oxygen molecules in the air. The products of the reaction (mostly carbon dioxide and water) are released as gases into the air.

### The Laws of Definite and Multiple Proportions

**2.2** The law of definite proportions applies to two or more samples of the *same compound* and states that the ratio of one element to the other is always the same. The law of multiple proportions applies to two *different compounds* containing the same two elements (A and B) and states that the masses of B that combine with 1 g of A are always related to each other as a small whole-number ratio.

### The Millikan Oil Drop Experiment

**2.3** The drop contains three excess electrons ( $3 \times (-6 \times 10^{-19} \text{ C}) = -4.8 \times 10^{-19} \text{ C}$ ).

### Isotopes

**2.4**

C-12 nucleus

C-13 nucleus

A 10,000-atom sample of carbon, on average, contains 107 C-13 atoms.

### The Nuclear Atom, Isotopes, and Ions

**2.5 (b)** The number of neutrons in the nucleus of an atom does not affect the atom's size because the nucleus is minuscule compared to the atom itself.

### Atomic Mass

**2.6 (a)** Since 98.93% of the atoms are C-12, we would expect the atomic mass to be very close to the mass of the C-12 isotope.

### Avogadro's Number

**2.7** Avogadro's number is defined with respect to carbon-12—it is the number equal to the number of atoms in exactly 12 g of carbon-12. If Avogadro's number was defined as  $1.00 \times 10^{23}$  (a nice round number), it would correspond to 1.99 g of carbon-12 atoms (an inconvenient number). Avogadro's number is defined with respect to carbon-12 because, as you recall from Section 2.6, the amu (the basic mass unit used for all atoms) is defined relative to carbon-12. Therefore, the mass in grams of 1 mol of *any* element is equal to its atomic mass. As we have seen, these two definitions together make it possible to determine the number of atoms in a known mass of any element.

### The Mole

**2.8 (b)** The carbon sample contains more atoms than the copper sample because carbon has a lower molar mass than copper. Carbon atoms are lighter than copper atoms, so a 1-g sample of carbon contains more atoms than a 1-g sample of copper. The carbon sample also contains more atoms than the uranium sample because even though the uranium sample has 10 times the mass of the carbon sample, a uranium atom is more than 10 times as massive (238 g/mol for uranium versus 12 g/mol for carbon).

# Molecules, Compounds, and Chemical Equations

Almost all aspects of life are engineered at the molecular level, and without understanding molecules we can only have a very sketchy understanding of life itself.

—FRANCIS HARRY COMPTON CRICK (1916–2004)

1	1 H 1.01 hydrogen	2A 2 He
2	3 Li 6.94 lithium	4 Be 9.01 beryllium
3	11 Na 22.99 sodium	12 Mg 24.31 magnesium
4	19 K 39.10 potassium	20 Ca 40.08 calcium
5	37 Rb 85.47 rubidium	38 Sr 87.62 strontium
6	55 Cs 132.91 cesium	56 Ba 137.33 barium

KEY LEARNING OUTCOMES 129

**H**ow many different substances exist? Recall from Chapter 2 that about 91 different elements exist in nature, so there are at least 91 different substances. However, the world would be dull—not to mention lifeless—with only 91 different substances. Fortunately, elements combine with each other to form *compounds*. Just as combinations of only 26 letters in our English alphabet allow for an almost limitless number of words, each with its own specific meaning, combinations of the 91 naturally occurring elements allow for an almost limitless number of compounds, each with its own specific properties. The great diversity of substances that we find in nature is a direct result of the ability of elements to form compounds. Life, for example, could not exist with just 91 different elements. It takes compounds, in all of their diversity, to make life possible.

### 3.1 Hydrogen, Oxygen, and Water

Hydrogen ( $\text{H}_2$ ) is an explosive gas used as a fuel in rocket engines. Oxygen ( $\text{O}_2$ ), also a gas, is a natural component of the air on Earth. Oxygen itself is not flammable but must be present for combustion (burning) to occur. Hydrogen and oxygen both have extremely low boiling points, as you can see from the table on the following page. When hydrogen and oxygen combine to form the compound water ( $\text{H}_2\text{O}$ ), however, a dramatically different substance results.

▲ When a balloon filled with  $\text{H}_2$  and  $\text{O}_2$  is ignited, the two elements react violently to form  $\text{H}_2\text{O}$ .

Selected Properties	Hydrogen 	Oxygen 	Water 
Boiling Point	−253 °C	−183 °C	100 °C
State at Room Temperature	Gas	Gas	Liquid
Flammability	Explosive	Necessary for combustion	Used to extinguish flame

First of all, water is a liquid rather than a gas at room temperature, and its boiling point is hundreds of degrees higher than the boiling points of hydrogen and oxygen. Second, instead of being flammable (like hydrogen gas) or supporting combustion (like oxygen gas), water actually smothers flames. Water is nothing like the hydrogen and oxygen from which it forms. The dramatic difference between the elements hydrogen and oxygen and the compound water is typical of the differences between elements and the compounds that they form. *When two or more elements combine to form a compound, an entirely new substance results.*

Consider as another example common table salt, a highly stable compound composed of sodium and chlorine. Elemental sodium, by contrast, is a highly reactive, silvery metal that can explode on contact with water. Elemental chlorine is a corrosive, greenish-yellow gas that can be fatal if inhaled. Yet the compound formed from the combination of these two elements is sodium chloride (or table salt), a flavor enhancer that tastes great on steak.

Although some of the substances that we encounter in everyday life are elements, most are compounds. As we discussed in Chapter 1, a compound is different from a mixture of elements. In a compound, elements combine in fixed, definite proportions; in a mixture, elements can mix in any proportions whatsoever. Consider the difference between a hydrogen–oxygen mixture and water in Figure 3.1 ▼. A hydrogen–oxygen mixture can have any proportions of hydrogen and oxygen gas. Water, by contrast, is composed of water molecules that always contain two hydrogen atoms to every one oxygen atom. Water has a definite proportion of hydrogen to oxygen.

In this chapter you will learn about compounds: how to represent them, how to name them, how to distinguish between their different types, and how to write chemical equations showing how they form and change. You will also learn how to quantify the elemental composition of a compound. This is important in determining how much of a particular element is contained within a particular compound. For example, patients with high blood pressure (hypertension) often have to reduce their sodium ion intake. The sodium ion is normally consumed in the form of sodium chloride, so a hypertension patient needs to know

### Mixtures and Compounds

#### Hydrogen and Oxygen Mixture

This can have any ratio of hydrogen to oxygen.

#### Water (A Compound)

Water molecules have a fixed ratio of hydrogen (two atoms) to oxygen (one atom).

► **FIGURE 3.1 Mixtures and Compounds** The balloon in this illustration is filled with a mixture of hydrogen gas and oxygen gas. The proportions of hydrogen and oxygen are variable. The glass is filled with water, a compound of hydrogen and oxygen. The ratio of hydrogen to oxygen in water is fixed: water molecules always have two hydrogen atoms for each oxygen atom.

how much sodium is present in a given amount of sodium chloride. Similarly, an iron-mining company needs to know how much iron it can recover from a given amount of iron ore. This chapter provides the tools to understand and answer these kinds of questions.

## 3.2 Chemical Bonds

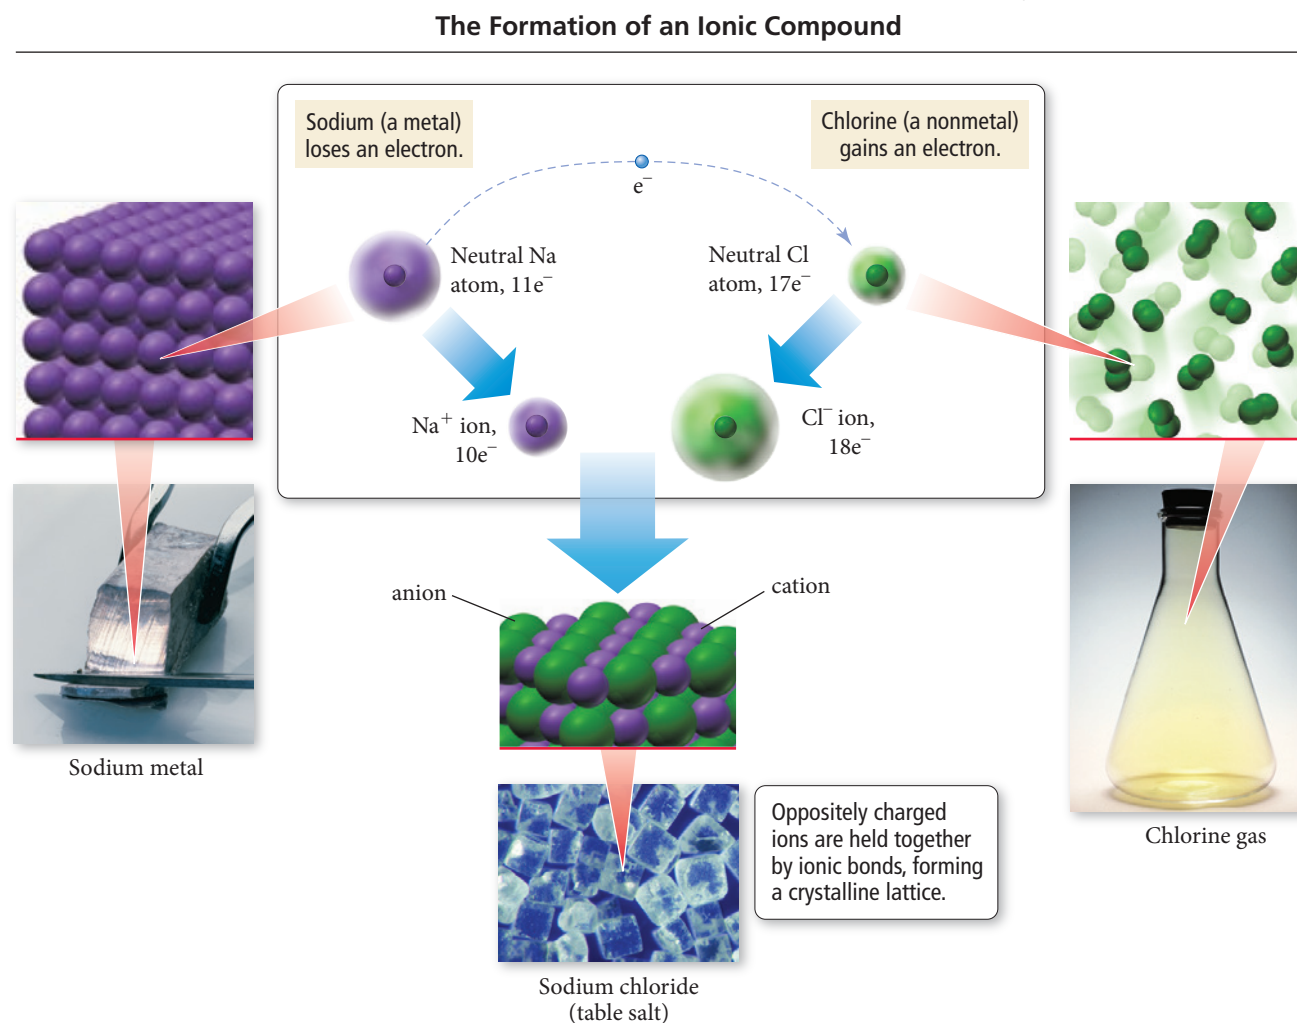

Compounds are composed of atoms held together by *chemical bonds*. Chemical bonds form because of the attractions between the charged particles (the electrons and protons) that compose atoms. We discuss these interactions in more detail in Chapter 9 (see Section 9.2). For now, remember that, as we discussed in Section 2.4, charged particles exert electrostatic forces on one another: like charges repel and opposite charges attract. These forces are responsible for chemical bonding.

We can broadly classify most chemical bonds into two types: ionic and covalent. *Ionic bonds*—which occur between metals and nonmetals—involve the *transfer* of electrons from one atom to another. *Covalent bonds*—which occur between two or more nonmetals—involve the *sharing* of electrons between two atoms.

### Ionic Bonds

Recall from Chapter 2 that metals have a tendency to lose electrons and that nonmetals have a tendency to gain them. Therefore, when a metal interacts with a nonmetal, it can transfer one or more of its electrons to the nonmetal. The metal atom then becomes a *cation* (a positively charged ion), and the nonmetal atom becomes an *anion* (a negatively charged ion) as shown in Figure 3.2. These oppositely charged ions attract one another

▼ **FIGURE 3.2 The Formation of an Ionic Compound** An atom of sodium (a metal) loses an electron to an atom of chlorine (a nonmetal), creating a pair of oppositely charged ions. The sodium cation is attracted to the chloride anion, and the two are held together as part of a crystalline lattice.

by electrostatic forces and form an **ionic bond**. The result is an **ionic compound**, which in the solid phase is composed of a lattice—a regular three-dimensional array—of alternating cations and anions.

## Covalent Bonds

When a nonmetal bonds with another nonmetal, neither atom transfers its electron to the other. Instead the bonding atoms *share* some of their electrons. The shared electrons have lower potential energy than they do in the isolated atoms because they interact with the nuclei of both atoms. The bond is a **covalent bond** and the covalently bound atoms compose a *molecule*. Each molecule is independent of the others—the molecules are themselves not covalently bound to one another. Therefore, we call covalently bonded compounds **molecular compounds**.

We can begin to understand the stability of a covalent bond by considering the most stable (or lowest potential energy) configuration of a negative charge interacting with two positive charges (which are separated by some small distance). Figure 3.3 shows that the lowest potential energy occurs when the negative charge lies *between* the two positive charges because in this arrangement the negative charge can interact with *both* positive charges. Similarly, shared electrons in a covalent chemical bond hold the bonding atoms together by attracting the positively charged nuclei of both bonding atoms.

► **FIGURE 3.3 The Stability of a Covalent Bond** The potential energy of a negative charge interacting with two positive charges is lowest when the negative charge is between the two positive charges.

### CONCEPTUAL CONNECTION 3.1

**Types of Chemical Bonds** What type of bond—ionic or covalent—forms between nitrogen and oxygen?

## 3.3 Representing Compounds: Chemical Formulas and Molecular Models

The quickest and easiest way to represent a compound is with its **chemical formula**, which indicates the elements present in the compound and the relative number of atoms or ions of each element. For example,  $\text{H}_2\text{O}$  is the chemical formula for water—it indicates that water consists of hydrogen and oxygen atoms in a two-to-one ratio. The formula contains the symbol for each element and a subscript indicating the relative number of atoms of the element. A subscript of 1 is typically omitted. Chemical formulas generally list the more metallic (or more positively charged) elements first, followed by the less metallic (or more negatively charged) elements. Other examples of common chemical formulas include  $\text{NaCl}$  for sodium chloride, indicating sodium and chloride ions in a one-to-one ratio;  $\text{CO}_2$  for carbon dioxide, indicating carbon and oxygen atoms in a one-to-two ratio; and  $\text{CCl}_4$  for carbon tetrachloride, indicating carbon and chlorine in a one-to-four ratio.

### Types of Chemical Formulas

We can categorize chemical formulas into three different types: empirical, molecular, and structural. An **empirical formula** gives the *relative* number of atoms of each element in a compound. A **molecular formula** gives the *actual* number of atoms of each element in a molecule of a compound. For example, the empirical formula for hydrogen peroxide is  $\text{HO}$ , but its molecular formula is  $\text{H}_2\text{O}_2$ . The molecular formula is always a

whole-number multiple of the empirical formula. For some compounds, the empirical formula and the molecular formula are identical. For example, the empirical and molecular formula for water is  $\text{H}_2\text{O}$  because water molecules contain two hydrogen atoms and one oxygen atom, and no simpler whole-number ratio can express the relative number of hydrogen atoms to oxygen atoms.

A **structural formula** uses lines to represent covalent bonds and shows how atoms in a molecule connect or bond to each other. The structural formula for  $\text{H}_2\text{O}_2$  is:

We can also write structural formulas to convey a sense of the molecule's geometry. For example, we can write the structural formula for hydrogen peroxide as:

This version of the formula represents the approximate angles between bonds, giving a sense of the molecule's shape.

Structural formulas can also depict the different types of bonds that occur within molecules. For example, consider the structural formula for carbon dioxide:

The two lines between each carbon and oxygen atom represent a double bond, which is generally stronger and shorter than a single bond (represented by a single line). A single bond corresponds to one shared electron pair, while a double bond corresponds to two shared electron pairs. We will learn more about single, double, and even triple bonds in Chapter 9.

The type of formula we use depends on how much we know about the compound and how much we want to communicate. A structural formula communicates the most information, while an empirical formula communicates the least.

### Structural Formulas Write the structural formula for water.

### CONCEPTUAL CONNECTION 3.2

#### Example 3.1 Molecular and Empirical Formulas

Write empirical formulas for the compounds represented by the molecular formulas.

- (a)  $\text{C}_4\text{H}_8$       (b)  $\text{B}_2\text{H}_6$       (c)  $\text{CCl}_4$

#### SOLUTION

To determine the empirical formula from a molecular formula, divide the subscripts by the greatest common factor (the largest number that divides exactly into all of the subscripts).

- (a) For  $\text{C}_4\text{H}_8$ , the greatest common factor is 4. The empirical formula is therefore  $\text{CH}_2$ .  
 (b) For  $\text{B}_2\text{H}_6$ , the greatest common factor is 2. The empirical formula is therefore  $\text{BH}_3$ .  
 (c) For  $\text{CCl}_4$ , the only common factor is 1, so the empirical formula and the molecular formula are identical.

**FOR PRACTICE 3.1** Write the empirical formula for the compounds represented by each molecular formula.

- (a)  $\text{C}_5\text{H}_{12}$       (b)  $\text{Hg}_2\text{Cl}_2$       (c)  $\text{C}_2\text{H}_4\text{O}_2$

Answers to For Practice and For More Practice problems can be found in Appendix IV.

## Molecular Models

A *molecular model* is a more accurate and complete way to specify a compound. A **ball-and-stick molecular model** represents atoms as balls and chemical bonds as sticks; how the two connect reflects a molecule's shape. The balls are typically color-coded to specific elements. For example, carbon is customarily black, hydrogen is white, nitrogen is blue, and oxygen is red. (For a complete list of colors of elements in the molecular models used in this book, see Appendix IIA.)

In a **space-filling molecular model**, atoms fill the space between each other to more closely represent our best estimates for how a molecule might appear if scaled to visible size. Consider the following ways to represent a molecule of methane, the main component of natural gas:

▲ A tetrahedron is a three-dimensional geometrical shape characterized by four equivalent triangular faces.

The molecular formula of methane indicates the number and type of each atom in the molecule: one carbon atom and four hydrogen atoms. The structural formula indicates how the atoms connect: the carbon atom bonds to the four hydrogen atoms. The ball-and-stick model clearly portrays the geometry of the molecule: the carbon atom sits in the center of a *tetrahedron* formed by the four hydrogen atoms. And finally, the space-filling model gives the best sense of the relative sizes of the atoms and how they merge together in bonding.

Throughout this book, you will see molecules represented in all of these ways. As you look at these representations, keep in mind what you learned in Chapter 1: the details about a molecule—the atoms that compose it, the lengths of the bonds between atoms, the angles of the bonds between atoms, and its overall shape—determine the properties of the substance that the molecule composes. Change any of these details and those properties change. Table 3.1 shows various compounds represented in the different ways we have just discussed.

### CONCEPTUAL CONNECTION 3.3

**Representing Molecules** Based on what you learned in Chapter 2 about atoms, what part of the atom do you think the spheres in the molecular space-filling models shown in Table 3.1 represent? If you were to superimpose a nucleus on one of these spheres, how big would you draw it?

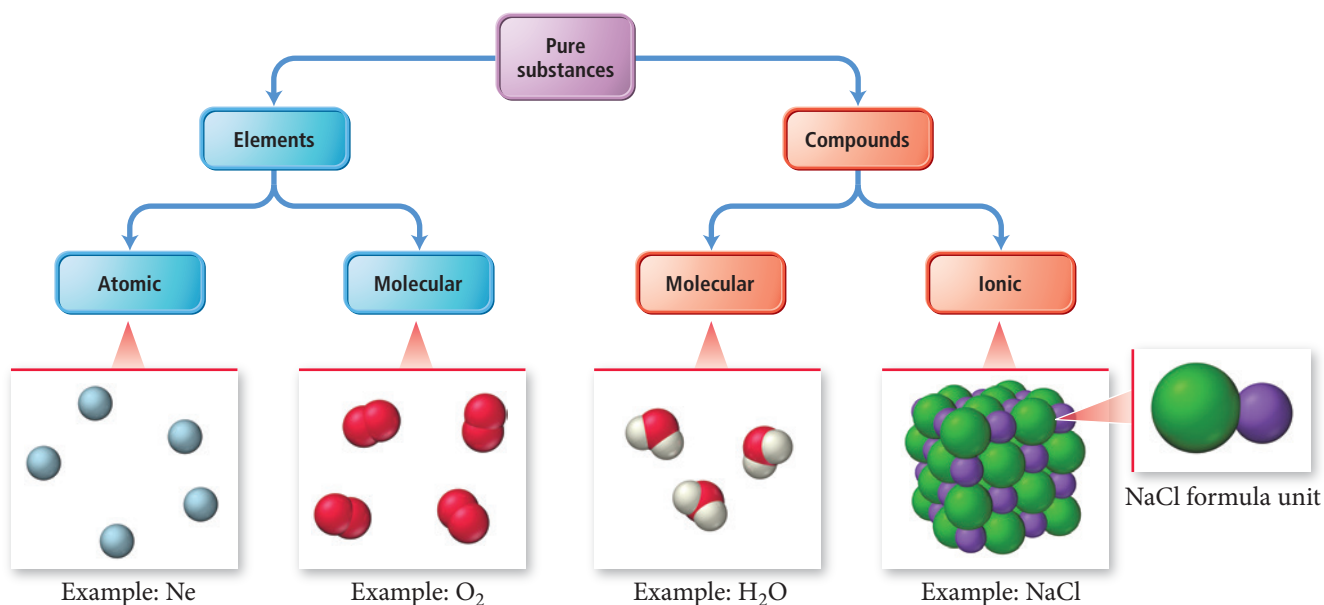

## 3.4 An Atomic-Level View of Elements and Compounds

Recall from Chapter 1 that we categorize pure substances as either elements or compounds. We can subcategorize elements and compounds according to the basic units that compose them, as shown in Figure 3.4►. Elements may be either atomic or molecular. Compounds may be either molecular or ionic.

**Atomic elements** exist in nature with single atoms as their basic units. Most elements fall into this category. For example, helium is composed of helium atoms, aluminum is composed of aluminum atoms, and iron is composed of iron atoms. **Molecular elements** do not normally exist in nature with single atoms as their basic units.

**TABLE 3.1** Benzene, Acetylene, Glucose, and Ammonia

Name of Compound	Empirical Formula	Molecular Formula	Structural Formula	Ball-and-Stick Model	Space-Filling Model
Benzene	CH	C <sub>6</sub> H <sub>6</sub>			
Acetylene	CH	C <sub>2</sub> H <sub>2</sub>	H—C≡C—H		
Glucose	CH <sub>2</sub> O	C <sub>6</sub> H <sub>12</sub> O <sub>6</sub>			
Ammonia	NH <sub>3</sub>	NH <sub>3</sub>			

**Classification of Elements and Compounds****▲ FIGURE 3.4** A Molecular View of Elements and Compounds

## ► FIGURE 3.5 Molecular

**Elements** The highlighted elements exist primarily as diatomic molecules (yellow) or polyatomic molecules (red).

▲ The basic units that compose chlorine gas are diatomic chlorine molecules.

## Molecular Elements

Instead, they exist as molecules—two or more atoms of the element bonded together. Most molecular elements exist as *diatomic* molecules. For example, hydrogen is composed of  $H_2$  molecules, nitrogen is composed of  $N_2$  molecules, and chlorine is composed of  $Cl_2$  molecules. A few molecular elements exist as *polyatomic* molecules. Phosphorus exists as  $P_4$ , and sulfur exists as  $S_8$ . Figure 3.5▲ shows the elements that exist primarily as diatomic or polyatomic molecules.

Molecular compounds are usually composed of two or more covalently bonded nonmetals. The basic units of molecular compounds are molecules composed of the constituent atoms. For example, water is composed of  $H_2O$  molecules, dry ice is composed of  $CO_2$  molecules, and propane (often used as a fuel for grills) is composed of  $C_3H_8$  molecules as illustrated in Figure 3.6(a)▼.

Ionic compounds are usually composed of a metal ionically bonded to one or more nonmetals. The basic unit of an ionic compound is the **formula unit**, the smallest, electrically neutral collection of ions. A formula unit is not a molecule—it does not usually exist as a discrete entity but rather as part of a larger lattice. For example, the ionic

## A Molecular Compound

(a)

## An Ionic Compound

(b)

▲ **FIGURE 3.6 Molecular and Ionic Compounds** (a) Propane is a molecular compound. The basic units that compose propane gas are propane ( $C_3H_8$ ) molecules. (b) Table salt ( $NaCl$ ) is an ionic compound. Its formula unit is the simplest charge-neutral collection of ions: one  $Na^+$  ion and one  $Cl^-$  ion.

Some ionic compounds, such as  $K_2NaPO_4$ , contain more than one type of metal ion.

People occasionally refer to formula units as molecules. This is incorrect because ionic compounds do not contain distinct molecules.

compound table salt, with the formula unit  $\text{NaCl}$ , is composed of  $\text{Na}^+$  and  $\text{Cl}^-$  ions in a one-to-one ratio. In table salt,  $\text{Na}^+$  and  $\text{Cl}^-$  ions exist in a three-dimensional alternating array. Because ionic bonds are not directional, no one  $\text{Na}^+$  ion pairs with a specific  $\text{Cl}^-$  ion. Rather, as illustrated in Figure 3.6(b)◀, any one  $\text{Na}^+$  cation is surrounded by  $\text{Cl}^-$  anions and vice versa.

Many common ionic compounds contain ions that are themselves composed of a group of covalently bonded atoms with an overall charge. For example, the active ingredient in household bleach is sodium hypochlorite, which acts to chemically alter color-causing molecules in clothes (bleaching action) and to kill bacteria (disinfection). Hypochlorite is a **polyatomic ion**—an ion composed of two or more atoms—with the formula  $\text{ClO}^-$ . (Note that the charge on the hypochlorite ion is a property of the whole ion, not just the oxygen atom; this is true for all polyatomic ions.) The hypochlorite ion is often found as a unit in other compounds as well (such as  $\text{KClO}$  and  $\text{Mg}(\text{ClO})_2$ ). Other common compounds that contain polyatomic ions include sodium bicarbonate ( $\text{NaHCO}_3$ ), also known as baking soda; sodium nitrite ( $\text{NaNO}_2$ ), an inhibitor of bacterial growth in packaged meats; and calcium carbonate ( $\text{CaCO}_3$ ), the active ingredient in antacids such as TUMS®.

▲ Polyatomic ions are common in household products such as bleach, which contains sodium hypochlorite ( $\text{NaClO}$ ).

**A Molecular View of Elements and Compounds** Suppose that the two elements A (represented by triangles) and B (represented by squares) form a molecular compound with the molecular formula  $\text{A}_2\text{B}$  and that two other elements, C (represented by circles) and D (represented by diamonds), form an ionic compound with the formula  $\text{CD}$ . Draw a molecular-level view of each compound.

### CONCEPTUAL CONNECTION 3.4

#### Example 3.2 Classifying Substances as Atomic Elements, Molecular Elements, Molecular Compounds, or Ionic Compounds

Classify each of the substances as an atomic element, molecular element, molecular compound, or ionic compound.

- (a) xenon      (b)  $\text{NiCl}_2$       (c) bromine      (d)  $\text{NO}_2$       (e)  $\text{NaNO}_3$

#### SOLUTION

- (a) Xenon is an element. It is not a molecular element (see Figure 3.5); therefore, it is an atomic element.
- (b)  $\text{NiCl}_2$  is a compound composed of a metal (nickel is on the left side of the periodic table) and nonmetal (chlorine is on the right side of the periodic table); therefore, it is an ionic compound.
- (c) Bromine is one of the elements that exists as a diatomic molecule (see Figure 3.5); therefore, it is a molecular element.
- (d)  $\text{NO}_2$  is a compound composed of a nonmetal and a nonmetal; therefore, it is a molecular compound.
- (e)  $\text{NaNO}_3$  is a compound composed of a metal and a polyatomic ion; therefore, it is an ionic compound.

**FOR PRACTICE 3.2** Classify each of the substances as an atomic element, molecular element, molecular compound, or ionic compound.

- (a) fluorine      (b)  $\text{N}_2\text{O}$       (c) silver      (d)  $\text{K}_2\text{O}$       (e)  $\text{Fe}_2\text{O}_3$

## CONCEPTUAL CONNECTION 3.5

**Ionic and Molecular Compounds** Which statement best summarizes the difference between ionic and molecular compounds?

- (a) Molecular compounds contain highly directional covalent bonds, which result in the formation of molecules—discrete particles that do not covalently bond to each other. Ionic compounds contain nondirectional ionic bonds, which result (in the solid phase) in the formation of ionic lattices—extended networks of alternating cations and anions.
- (b) Molecular compounds contain covalent bonds in which one of the atoms shares an electron with the other one, resulting in a new force that holds the atoms together in a covalent molecule. Ionic compounds contain ionic bonds in which one atom donates an electron to the other, resulting in a new force that holds the ions together in pairs (in the solid phase).
- (c) The key difference between ionic and covalent compounds is the types of elements that compose them, not the way that the atoms bond together.
- (d) A molecular compound is composed of covalently bonded molecules. An ionic compound is composed of ionically bonded molecules (in the solid phase).

### Naming Ionic Compounds

▲ Ionic compounds are common in food and consumer products such as reduced-sodium salt (a mixture of NaCl and KCl) and TUMS® (CaCO<sub>3</sub>).

► Calcite (left) is the main component of limestone, marble, and other forms of calcium carbonate (CaCO<sub>3</sub>) commonly found in Earth's crust. Trona (right) is a crystalline form of hydrated sodium carbonate (Na<sub>3</sub>H(CO<sub>3</sub>)<sub>2</sub> · 2 H<sub>2</sub>O).

## 3.5 Ionic Compounds: Formulas and Names

Ionic compounds occur throughout Earth's crust as minerals. Examples include limestone (CaCO<sub>3</sub>), a type of sedimentary rock; gibbsite [Al(OH)<sub>3</sub>], a mineral; and soda ash (Na<sub>2</sub>CO<sub>3</sub>), a natural deposit. We can also find ionic compounds in the foods that we eat. Examples include sodium chloride (NaCl), which is table salt; calcium carbonate (CaCO<sub>3</sub>), a source of calcium necessary for bone health; and potassium chloride (KCl), a source of potassium necessary for fluid balance and muscle function. Ionic compounds are generally very stable because the attractions between cations and anions within ionic compounds are strong and because each ion interacts with several oppositely charged ions in the crystalline lattice.

### Writing Formulas for Ionic Compounds

Since ionic compounds are charge-neutral, and since many elements form only one type of ion with a predictable charge, we can deduce the formulas for many ionic compounds from their constituent elements. For example, the formula for the ionic compound composed of sodium and chlorine must be NaCl because in compounds Na always forms 1+ cations and Cl always forms 1− anions. In order for the compound to be charge-neutral, it must contain one Na<sup>+</sup> cation for every one Cl<sup>−</sup> anion. The formula for the ionic compound composed of *calcium* and chlorine, however, is CaCl<sub>2</sub> because Ca always forms 2+ cations and Cl always forms 1− anions. In order for this compound to be charge-neutral, it must contain one Ca<sup>2+</sup> cation for every two Cl<sup>−</sup> anions.

See Figure 2.13 to review the elements that form ions with a predictable charge.

**Summarizing Ionic Compound Formulas:**

- ▶ Ionic compounds always contain positive and negative ions.
- ▶ In a chemical formula, the sum of the charges of the positive ions (cations) must equal the sum of the charges of the negative ions (anions).
- ▶ The formula of an ionic compound reflects the smallest whole-number ratio of ions.

To write the formula for an ionic compound, follow the procedure in the left column. Two examples of how to apply the procedure are provided in the center and right columns.

**Procedure for...**

Writing Formulas for Ionic Compounds	<b>Example 3.3</b> <b>Writing Formulas for Ionic Compounds</b> Write the formula for the ionic compound that forms between aluminum and oxygen.	<b>Example 3.4</b> <b>Writing Formulas for Ionic Compounds</b> Write the formula for the ionic compound that forms between calcium and oxygen.
1. Write the symbol for the metal cation and its charge followed by the symbol for the nonmetal anion and its charge. Determine charges from the element's group number in the periodic table (refer to Figure 2.13).	$\text{Al}^{3+} \quad \text{O}^{2-}$	$\text{Ca}^{2+} \quad \text{O}^{2-}$
2. Adjust the subscript on each cation and anion to balance the overall charge.	$\begin{array}{ccc} \text{Al}^{3+} & & \text{O}^{2-} \\ & \downarrow & \\ & \text{Al}_2\text{O}_3 & \end{array}$	$\begin{array}{ccc} \text{Ca}^{2+} & & \text{O}^{2-} \\ & \downarrow & \\ & \text{CaO} & \end{array}$
3. Check that the sum of the charges of the cations equals the sum of the charges of the anions.	cations: $2(3+) = 6+$ anions: $3(2-) = 6-$ The charges cancel.	cations: $2+$ anions: $2-$ The charges cancel.
	<b>FOR PRACTICE 3.3</b> Write the formula for the compound formed between potassium and sulfur.	<b>FOR PRACTICE 3.4</b> Write the formula for the compound formed between aluminum and nitrogen.

**Naming Ionic Compounds**

Some ionic compounds—such as NaCl (table salt) and  $\text{NaHCO}_3$  (baking soda)—have **common names**, which are nicknames of sorts learned by familiarity. However, chemists have developed **systematic names** for different types of compounds including ionic ones. Even if you are not familiar with a compound, you can determine its systematic name from its chemical formula. Conversely, you can deduce the formula of a compound from its systematic name.

The first step in naming an ionic compound is to identify it as one. Remember, *ionic compounds are usually composed of metals and nonmetals*; any time you see a metal and one or more nonmetals together in a chemical formula, assume that you have an ionic compound. Ionic compounds can be categorized into two types, depending on the metal in the compound. The first type contains a metal whose charge is invariant from one compound to another. Whenever the metal in this first type of compound forms an ion, the ion always has the same charge.

Since the charge of the metal in this first type of ionic compound is always the same, it need not be specified in the name of the compound. Sodium, for instance, has a  $1+$  charge in all of its

[illegible]

A simplified periodic table diagram. The main groups (yellow) include the elements in groups 1, 2, 13, 14, 15, 16, 17, and 18. The transition metals (blue) fill the d-block between groups 2 and 13. The legend indicates: Main groups (yellow square) and Transition metals (blue square).

Metals that can have different charges in different compounds are usually (but not always) transition metals.

The second type of ionic compound contains a metal with a charge that can differ in different compounds. In other words, the metal in this second type of ionic compound can form more than one kind of cation (depending on the compound), and its charge must therefore be specified for a given compound. Iron, for instance, forms a 2+ cation in some of its compounds and a 3+ cation in others. Metals of this type are often *transition metals* (Figure 3.8◀). However, some transition metals, such as Zn and Ag, form cations with the same charge in all of their compounds, and some main-group metals, such as Pb and Sn, form more than one type of cation.

**Binary compounds** contain only two different elements. The names of binary ionic compounds take the form:

Nonmetal	Symbol for Ion	Base Name	Anion Name
Fluorine	F <sup>−</sup>	fluor	Fluoride
Chlorine	Cl <sup>−</sup>	chlor	Chloride
Bromine	Br <sup>−</sup>	brom	Bromide
Iodine	I <sup>−</sup>	iod	Iodide
Oxygen	O <sup>2−</sup>	ox	Oxide
Sulfur	S <sup>2−</sup>	sulf	Sulfide
Nitrogen	N <sup>3−</sup>	nitr	Nitride
Phosphorus	P <sup>3−</sup>	phosph	Phosphide

base name of  
anion (nonmetal)  
+ *-ide*

KCl      potassium chloride

CaO      calcium oxide

The base names for various nonmetals, and their most common charges in ionic compounds, are shown in Table 3.2.

### Example 3.5 Naming Ionic Compounds Containing a Metal That Forms Only One Type of Cation

Name the compound  $\text{CaBr}_2$ .

#### SOLUTION

The cation is *calcium*. The anion is from bromine, which becomes *bromide*. The correct name is *calcium bromide*.

**FOR PRACTICE 3.5** Name the compound  $\text{Ag}_3\text{N}$ .

**FOR MORE PRACTICE 3.5** Write the formula for rubidium sulfide.

## Naming Binary Ionic Compounds Containing a Metal That Forms More Than One Kind of Cation

For these types of metals, the name of the cation is followed by a Roman numeral (in parentheses) that indicates the charge of the metal in that particular compound. For example, we distinguish between  $\text{Fe}^{2+}$  and  $\text{Fe}^{3+}$  as follows:

The full names for compounds containing metals that form more than one kind of cation have the form:

You can determine the charge of the metal cation by inference from the sum of the charges of the nonmetal anions—remember that the sum of all the charges in the compound must be zero. Table 3.3 shows some of the metals that form more than one cation and their most common charges. For example, in  $\text{CrBr}_3$ , the charge of chromium must be  $3+$  in order for the compound to be charge-neutral with three  $\text{Br}^-$  anions. The cation is named:

The full name of the compound is:

Similarly, in  $\text{CuO}$  the charge of copper must be  $2+$  in order for the compound to be charge-neutral with one  $\text{O}^{2-}$  anion. The cation is therefore named:

The full name of the compound is:

**TABLE 3.3** Some Metals That Form Cations with Different Charges

Metal	Ion	Name	Older Name*
Chromium	$\text{Cr}^{2+}$	Chromium(II)	Chromous
	$\text{Cr}^{3+}$	Chromium(III)	Chromic
Iron	$\text{Fe}^{2+}$	Iron(II)	Ferrous
	$\text{Fe}^{3+}$	Iron(III)	Ferric
Cobalt	$\text{Co}^{2+}$	Cobalt(II)	Cobaltous
	$\text{Co}^{3+}$	Cobalt(III)	Cobaltic
Copper	$\text{Cu}^+$	Copper(I)	Cuprous
	$\text{Cu}^{2+}$	Copper(II)	Cupric
Tin	$\text{Sn}^{2+}$	Tin(II)	Stannous
	$\text{Sn}^{4+}$	Tin(IV)	Stannic
Mercury	$\text{Hg}_2^{2+}$	Mercury(I)	Mercurous
	$\text{Hg}^{2+}$	Mercury(II)	Mercuric
Lead	$\text{Pb}^{2+}$	Lead(II)	Plumbous
	$\text{Pb}^{4+}$	Lead(IV)	Plumbic

\*An older naming system substitutes the names found in this column for the name of the metal and its charge. Under this system, chromium(II) oxide is named chromous oxide. Additionally, the suffix *-ous* indicates the ion with the lesser charge, and *-ic* indicates the ion with the greater charge. We will *not* use the older system in this text.

**Example 3.6** Naming Ionic Compounds Containing a Metal That Forms More Than One Kind of Cation

Name the compound  $\text{PbCl}_4$ .

**SOLUTION**

The charge on Pb must be 4+ for the compound to be charge-neutral with four  $\text{Cl}^-$  anions. The name for  $\text{PbCl}_4$  is the name of the cation, *lead*, followed by the charge of the cation in parentheses (*IV*) and the base name of the anion, *chlor*, with the ending *-ide*. The full name is *lead(IV) chloride*.

$\text{PbCl}_4$  lead(IV) chloride

**FOR PRACTICE 3.6** Name the compound  $\text{FeS}$ .

**FOR MORE PRACTICE 3.6** Write the formula for ruthenium(IV) oxide.

**Naming Ionic Compounds Containing Polyatomic Ions**

We name ionic compounds that contain a polyatomic ion in the same way as other ionic compounds, except that we use the name of the polyatomic ion whenever it occurs. Table 3.4 lists common polyatomic ions and their formulas. For example,  $\text{NaNO}_2$  is named according to its cation,  $\text{Na}^+$  (*sodium*), and its polyatomic anion,  $\text{NO}_2^-$  (*nitrite*). Its full name is *sodium nitrite*.

$\text{NaNO}_2$  sodium nitrite

$\text{FeSO}_4$  is named according to its cation *iron*, its charge (*II*), and its polyatomic ion *sulfate*. Its full name is *iron(II) sulfate*.

$\text{FeSO}_4$  iron(II) sulfate

If the compound contains both a polyatomic cation and a polyatomic anion, use the names of both polyatomic ions. For example,  $\text{NH}_4\text{NO}_3$  is *ammonium nitrate*.

$\text{NH}_4\text{NO}_3$  ammonium nitrate

You should be able to recognize polyatomic ions in a chemical formula, so become familiar with the ions listed in Table 3.4. Most polyatomic ions are **oxyanions**, anions containing oxygen and another element. Notice that when a series of oxyanions contains different numbers of oxygen atoms, they are named systematically according to

**TABLE 3.4** Some Common Polyatomic Ions

Name	Formula	Name	Formula
Acetate	$\text{C}_2\text{H}_3\text{O}_2^-$	Hypochlorite	$\text{ClO}^-$
Carbonate	$\text{CO}_3^{2-}$	Chlorite	$\text{ClO}_2^-$
Hydrogen carbonate (or bicarbonate)	$\text{HCO}_3^-$	Chlorate	$\text{ClO}_3^-$
Hydroxide	$\text{OH}^-$	Perchlorate	$\text{ClO}_4^-$
Nitrite	$\text{NO}_2^-$	Permanganate	$\text{MnO}_4^-$
Nitrate	$\text{NO}_3^-$	Sulfite	$\text{SO}_3^{2-}$
Chromate	$\text{CrO}_4^{2-}$	Hydrogen sulfite (or bisulfite)	$\text{HSO}_3^-$
Dichromate	$\text{Cr}_2\text{O}_7^{2-}$	Sulfate	$\text{SO}_4^{2-}$
Phosphate	$\text{PO}_4^{3-}$	Hydrogen sulfate (or bisulfate)	$\text{HSO}_4^-$
Hydrogen phosphate	$\text{HPO}_4^{2-}$	Cyanide	$\text{CN}^-$
Dihydrogen phosphate	$\text{H}_2\text{PO}_4^-$	Peroxide	$\text{O}_2^{2-}$
Ammonium	$\text{NH}_4^+$		

the number of oxygen atoms in the ion. If there are only two ions in the series, the one with more oxygen atoms has the ending *-ate* and the one with fewer has the ending *-ite*. For example,  $\text{NO}_3^-$  is *nitrate* and  $\text{NO}_2^-$  is *nitrite*.

$\text{NO}_3^-$      *nitrate*

$\text{NO}_2^-$      *nitrite*

If there are more than two ions in the series, then the prefixes *hypo-*, meaning *less than*, and *per-*, meaning *more than*, are used. So  $\text{ClO}^-$  is hypochlorite (less oxygen than chlorite), and  $\text{ClO}_4^-$  is perchlorate (more oxygen than chlorate).

$\text{ClO}^-$      *hypochlorite*

$\text{ClO}_2^-$      *chlorite*

$\text{ClO}_3^-$      *chlorate*

$\text{ClO}_4^-$      *perchlorate*

Other halides (halogen ions) form similar series with similar names. Thus,  $\text{IO}_3^-$  is iodate and  $\text{BrO}_3^-$  is bromate.

### Example 3.7 Naming Ionic Compounds That Contain a Polyatomic Ion

Name the compound  $\text{Li}_2\text{Cr}_2\text{O}_7$ .

#### SOLUTION

The name for  $\text{Li}_2\text{Cr}_2\text{O}_7$  is the name of the cation, *lithium*, followed by the name of the polyatomic ion, *dichromate*. Its full name is *lithium dichromate*.

$\text{Li}_2\text{Cr}_2\text{O}_7$      lithium dichromate

**FOR PRACTICE 3.7** Name the compound  $\text{Sn}(\text{ClO}_3)_2$ .

**FOR MORE PRACTICE 3.7** Write the formula for cobalt(II) phosphate.

## Hydrated Ionic Compounds

The ionic compounds called **hydrates** contain a specific number of water molecules associated with each formula unit. For example, the formula for epsom salts is  $\text{MgSO}_4 \cdot 7 \text{H}_2\text{O}$ , and its systematic name is magnesium sulfate heptahydrate. The seven  $\text{H}_2\text{O}$  molecules associated with the formula unit are *waters of hydration*. Waters of hydration can usually be removed by heating the compound. Figure 3.9 shows a sample of cobalt(II) chloride hexahydrate ( $\text{CoCl}_2 \cdot 6 \text{H}_2\text{O}$ ) before and after heating. The hydrate is pink and the anhydrous salt (the salt without any associated water molecules) is blue. Hydrates are named just as other ionic compounds, but they are given the additional name “*prefixhydrate*,” where the *prefix* indicates the number of water molecules associated with each formula unit.

Common hydrated ionic compounds and their names are as follows:

$\text{CaSO}_4 \cdot \frac{1}{2} \text{H}_2\text{O}$	calcium sulfate <i>hemi</i> hydrate
$\text{BaCl}_2 \cdot 6 \text{H}_2\text{O}$	barium chloride <i>hexa</i> hydrate
$\text{CuSO}_4 \cdot 5 \text{H}_2\text{O}$	copper(II) sulfate <i>penta</i> hydrate

Hydrate

Anhydrous

$\text{CoCl}_2 \cdot 6 \text{H}_2\text{O}$

$\text{CoCl}_2$

### ▲ FIGURE 3.9 Hydrates

Cobalt(II) chloride hexahydrate is pink. Heating the compound removes the waters of hydration, leaving the blue anhydrous cobalt(II) chloride.

Common hydrate prefixes  
 hemi = 1/2  
 mono = 1  
 di = 2  
 tri = 3  
 tetra = 4  
 penta = 5  
 hexa = 6  
 hepta = 7  
 octa = 8

## 3.6 Molecular Compounds: Formulas and Names

In contrast to ionic compounds, the formula for a molecular compound *cannot* readily be determined from its constituent elements because the same combination of elements may form many different molecular compounds, each with a different formula. For example, carbon and oxygen form both  $\text{CO}$  and  $\text{CO}_2$ , and hydrogen and oxygen form both  $\text{H}_2\text{O}$  and  $\text{H}_2\text{O}_2$ . Nitrogen and oxygen form all of the following molecular compounds:  $\text{NO}$ ,  $\text{NO}_2$ ,  $\text{N}_2\text{O}$ ,  $\text{N}_2\text{O}_3$ ,  $\text{N}_2\text{O}_4$ , and  $\text{N}_2\text{O}_5$ . In Chapter 9, we will discuss the stability of these

**Naming Molecular Compounds**

various combinations of the same elements. For now, we focus on naming a molecular compound based on its formula and writing its formula based on its name.

## Naming Molecular Compounds

Like ionic compounds, many molecular compounds have common names. For example,  $\text{H}_2\text{O}$  and  $\text{NH}_3$  have the common names *water* and *ammonia*. However, the sheer number of existing molecular compounds—numbering in the millions—necessitates a systematic approach to naming them.

The first step in naming a molecular compound is identifying it as one. Remember, *molecular compounds are composed of two or more nonmetals*. In this section, we discuss how to name binary (two-element) molecular compounds. Their names have the form:

When writing the name of a molecular compound, as when writing the formula, we first list the more metal-like element (toward the left and bottom of the periodic table). Generally, we write the name of the element with the smallest group number first. If the two elements lie in the same group, then we write the element with the greatest row number first. The prefixes given to each element indicate the number of atoms present:

mono = 1	hexa = 6
di = 2	hepta = 7
tri = 3	octa = 8
tetra = 4	nona = 9
penta = 5	deca = 10

These prefixes are the same as those used in naming hydrates.

If there is only one atom of the *first element* in the formula, the prefix *mono-* is normally omitted. For example, we name  $\text{NO}_2$  according to the first element, *nitrogen*, with no prefix because *mono-* is omitted for the first element, followed by the prefix *di-*, to indicate two oxygen atoms, and the base name of the second element, *ox*, with the ending *-ide*. Its full name is *nitrogen dioxide*.

We name the compound  $\text{N}_2\text{O}$ , sometimes called laughing gas, similarly except that we use the prefix *di-* before nitrogen to indicate two nitrogen atoms and the prefix *mono-* before oxide to indicate one oxygen atom. Its full name is *dinitrogen monoxide*.

When a prefix ends with “o” and the base name begins with “o,” the first “o” is often dropped. For example, mono-oxide becomes *monoxide*.

### Example 3.8 Naming Molecular Compounds

Name each compound.

- (a)  $\text{NI}_3$       (b)  $\text{PCl}_5$       (c)  $\text{P}_4\text{S}_{10}$

#### SOLUTION

- (a) The name of the compound is the name of the first element, *nitrogen*, followed by the base name of the second element, *iod*, prefixed by *tri-* to indicate three and given the suffix *-ide*.

- (b) The name of the compound is the name of the first element, *phosphorus*, followed by the base name of the second element, *chlor*, prefixed by *penta-* to indicate five and given the suffix *-ide*.

- (c) The name of the compound is the name of the first element, *phosphorus*, prefixed by *tetra-* to indicate four, followed by the base name of the second element, *sulf*, prefixed by *deca-* to indicate ten and given the suffix *-ide*.

**FOR PRACTICE 3.8** Name the compound  $\text{N}_2\text{O}_5$ .

**FOR MORE PRACTICE 3.8** Write the formula for phosphorus tribromide.

**Nomenclature** The compound  $\text{NCl}_3$  is nitrogen trichloride, but  $\text{AlCl}_3$  is simply aluminum chloride. Why?

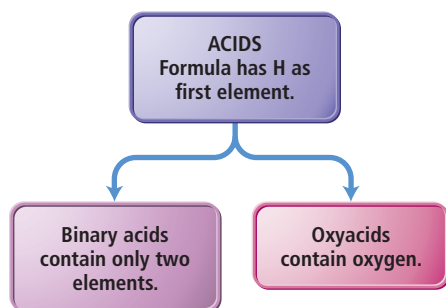

## CONCEPTUAL CONNECTION 3.6

## Naming Acids

We can define acids in a number of ways, as we will discuss in Chapter 16. For now we define **acids** as molecular compounds that release hydrogen ions ( $\text{H}^+$ ) when dissolved in water. Acids are composed of hydrogen, usually written first in their formula, and one or more nonmetals, written second. For example,  $\text{HCl}$  is a molecular compound that, when dissolved in water, forms  $\text{H}^+(\text{aq})$  and  $\text{Cl}^-(\text{aq})$  ions, where *aqueous (aq)* means *dissolved in water*. Therefore,  $\text{HCl}$  is an acid when dissolved in water. To distinguish between gaseous  $\text{HCl}$  (which is named hydrogen monochloride because it is a molecular compound) and  $\text{HCl}$  in solution (which is named hydrochloric acid because it is an acid), we write the former as  $\text{HCl}(\text{g})$  and the latter as  $\text{HCl}(\text{aq})$ .

Acids are characterized by their sour taste and their ability to dissolve many metals. For example, hydrochloric acid is present in stomach fluids, and its sour taste becomes painfully obvious during vomiting. Hydrochloric acid also dissolves some metals. For example, if we put a strip of zinc into a test tube of hydrochloric acid, it slowly dissolves as the  $\text{H}^+(\text{aq})$  ions convert the zinc metal into  $\text{Zn}^{2+}(\text{aq})$  cations (Figure 3.10▼).

Acids are present in foods such as lemons and limes and are used in household products such as toilet bowl cleaner and Lime-A-Way. In this section, we discuss how to name them; in Chapter 16 you will learn more about their properties. We categorize acids into two types: binary acids and oxyacids.

## Naming Binary Acids

**Binary acids** are composed of hydrogen and a nonmetal. Names for binary acids have the form:

▲ Many fruits are acidic and have the characteristically sour taste of acids.

## Acids Dissolve Many Metals

▲ **FIGURE 3.10 Hydrochloric Acid Dissolving Zinc Metal** The zinc atoms are ionized to zinc ions, which dissolve in the water. The  $\text{HCl}$  forms  $\text{H}_2$  gas, which is responsible for the bubbles you can see in the test tube.

For example,  $\text{HCl}(aq)$  is *hydrochloric acid* and  $\text{HBr}(aq)$  is *hydrobromic acid*.

$\text{HCl}(aq)$  hydrochloric acid       $\text{HBr}(aq)$  hydrobromic acid

### Example 3.9 Naming Binary Acids

Name the acid  $\text{HI}(aq)$ .

#### SOLUTION

The base name of I is *iod*, so  $\text{HI}(aq)$  is *hydroiodic acid*.

$\text{HI}(aq)$  hydroiodic acid

**FOR PRACTICE 3.9** Name the acid  $\text{HF}(aq)$ .

## Naming Oxyacids

**Oxyacids** contain hydrogen and an oxyanion (an anion containing a nonmetal and oxygen). The common oxyanions are listed in the table of polyatomic ions (Table 3.4). For example,  $\text{HNO}_3(aq)$  contains the nitrate ( $\text{NO}_3^-$ ) ion,  $\text{H}_2\text{SO}_3(aq)$  contains the sulfite ( $\text{SO}_3^{2-}$ ) ion, and  $\text{H}_2\text{SO}_4(aq)$  contains the sulfate ( $\text{SO}_4^{2-}$ ) ion. Oxyacids are a combination of one or more  $\text{H}^+$  ions with an oxyanion. The number of  $\text{H}^+$  ions depends on the

## Chemistry IN THE Environment Acid Rain

**C**ertain pollutants—such as  $\text{NO}$ ,  $\text{NO}_2$ , and  $\text{SO}_2$ —form acids when mixed with water.  $\text{NO}$  and  $\text{NO}_2$ , primarily emitted in vehicular exhaust, combine with atmospheric oxygen and water to form nitric acid,  $\text{HNO}_3(aq)$ .  $\text{SO}_2$ , emitted primarily from coal-powered electricity generation, combines with atmospheric oxygen and water to form sulfuric acid,  $\text{H}_2\text{SO}_4(aq)$ . Both  $\text{HNO}_3(aq)$  and  $\text{H}_2\text{SO}_4(aq)$  result in acidic rainwater. The problem is greatest in the northeastern United States where pollutants from midwestern electrical power plants combine with rainwater to produce rain that is up to ten times more acidic than normal.

Acid rain can fall or flow into lakes and streams, making these bodies of water more acidic. Some species of aquatic animals—such as trout, bass, snails, salamanders, and clams—cannot tolerate the increased acidity and die. This in turn disturbs the ecosystem of the lake, resulting in imbalances that may lead to the death of other aquatic species. Acid rain also weakens trees by dissolving and washing away nutrients in the soil and by damaging leaves. Appalachian red

spruce trees have been the hardest hit, with many forests showing significant acid rain damage.

In addition, acid rain degrades building materials because acids dissolve iron, the main component of steel, and  $\text{CaCO}_3$  (limestone), a main component of marble and concrete. Consequently, acid rain has damaged many statues, buildings, and bridges in the northeastern United States.

Acid rain has been a problem for many years, but legislation passed toward the end of the last century has begun to address this issue. In 1990, Congress passed several amendments to the Clean Air Act that included provisions requiring electrical utilities to lower  $\text{SO}_2$  emissions. Since then,  $\text{SO}_2$  emissions have decreased and rain in the northeastern United States has become less acidic. With time, and with continued enforcement of the acid rain regulation, lakes, streams, and forests damaged by acid rain should recover.

#### QUESTION

Name each compound:  $\text{NO}$ ,  $\text{NO}_2$ ,  $\text{SO}_2$ ,  $\text{H}_2\text{SO}_4$ ,  $\text{HNO}_3$ ,  $\text{CaCO}_3$ .

◀ A forest damaged by acid rain.

▶ Acid rain damages building materials including the limestone that composes many statues.

charge of the oxyanion; the formula is always charge-neutral. The names of oxyacids depend on the ending of the oxyanion and take the following forms:

oxyanions ending with *-ate*

oxyanions ending with *-ite*

For example,  $\text{HNO}_3(aq)$  is nitric acid (oxyanion is nitrate), and  $\text{H}_2\text{SO}_3(aq)$  is sulfurous acid (oxyanion is sulfite).

### Example 3.10 Naming Oxyacids

Name the acid  $\text{HC}_2\text{H}_3\text{O}_2(aq)$ .

#### SOLUTION

The oxyanion is acetate, which ends in *-ate*; therefore, the name of the acid is *acetic acid*.

**FOR PRACTICE 3.10** Name the acid  $\text{HNO}_2(aq)$ .

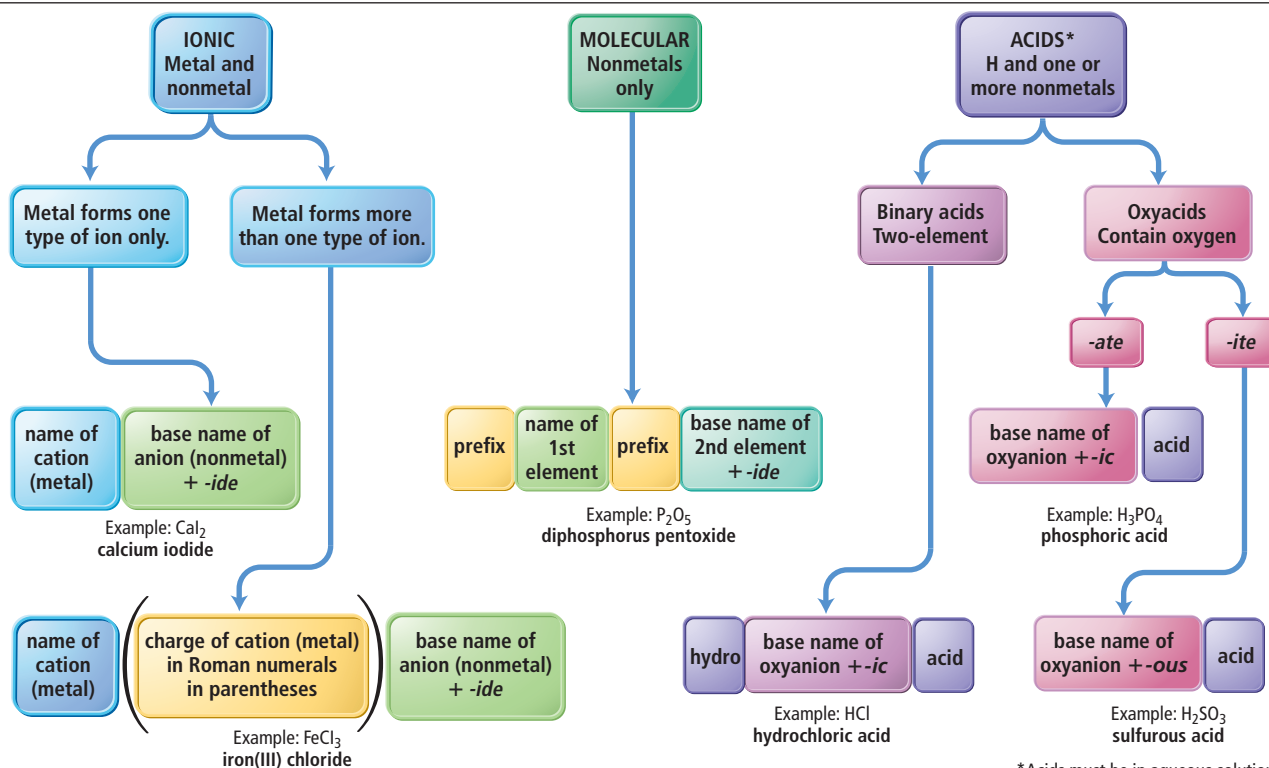

**FOR MORE PRACTICE 3.10** Write the formula for perchloric acid.

## 3.7 Summary of Inorganic Nomenclature

In Section 3.5 and Section 3.6, we discussed naming inorganic compounds, specifically ionic compounds, molecular compounds, and acids. However, we often have to name a compound without initially knowing the category into which it falls. In other words, real-life nomenclature is a bit messier than the categorized nomenclature we just worked through. Figure 3.11 summarizes inorganic nomenclature in a flowchart that will help you to tackle nomenclature from beginning to end.

**FIGURE 3.11 Inorganic Nomenclature Flowchart** The chart summarizes how to name inorganic compounds. Begin by determining if the compound is ionic, molecular, or an acid. Then follow the flowchart for that category from top to bottom until you arrive at a name for the compound.

Inorganic Nomenclature Flow Chart

\*Acids must be in aqueous solution.

▲ **FIGURE 3.12** Flowchart Path for  $\text{MgCl}_2$

To use the flowchart, begin by determining what type of compound you are trying to name. For example, to name the compound  $\text{MgCl}_2$ , you need to decide if the compound is ionic, molecular, or an acid. In this case, since  $\text{MgCl}_2$  is composed of a metal and nonmetal, it is ionic. Therefore, you begin at the box labeled “IONIC” at the far left side of the flowchart.

Next, decide whether the metal in the compound forms only one type of ion or more than one type. You can determine this by looking for the metal (in this case magnesium) in Figure 3.7. Since magnesium is listed in the figure, it forms only one type of ion; therefore, you take the left branch in the flowchart as shown in Figure 3.12◀.

Finally, name the compound according to the blocks at the end of the path in the flowchart. In this case, write the name of the cation (the metal) followed by the base name of the anion (the nonmetal) appended with the ending *-ide*. Its full name is magnesium chloride.

### Example 3.11 Using the Nomenclature Flowchart to Name Compounds

Use the flowchart in Figure 3.11 to name each compound.

(a)  $\text{SO}_2$

(b)  $\text{HClO}_4(aq)$

(c)  $\text{CoF}_2$

#### SOLUTION

(a)  $\text{SO}_2$

Begin by determining whether the compound is ionic, molecular, or an acid.  $\text{SO}_2$  contains only nonmetals; therefore it is molecular.

Name the compound as the name of the first element, *sulfur* (no prefix since the prefix is dropped for mono), followed by the base name of the second element, *ox*, prefixed by *di-* to indicate two, and given the suffix *-ide*.

(b)  $\text{HClO}_4(aq)$

Begin by determining whether the compound is ionic, molecular, or an acid. Since  $\text{HClO}_4(aq)$  contains H and one more nonmetal and is designated as aqueous, it is an acid.

Next determine whether the acid contains oxygen. Since  $\text{HClO}_4$  contains oxygen, it is an oxyacid.

Then determine whether the name of the oxyanion ends in *-ate* or *-ite*. Since the oxyanion is perchlorate, it ends in *-ate*.

Finally, name the acid as the base name of the oxyanion, *perchlor*, with the ending *-ic*, followed by the word *acid*.

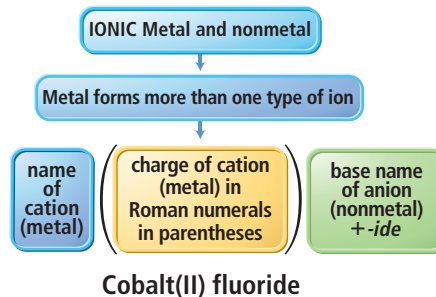

(c)  $\text{CoF}_2$

Begin by determining whether the compound is ionic, molecular, or an acid. Since  $\text{CoF}_2$  contains a metal and a nonmetal, it is ionic.

Next refer to Figure 3.7 to determine whether the metal forms one type of ion or more than one type. Since Co is not listed in Figure 3.7, it must form more than one type of ion.

Name the compound as the name of the cation, *cobalt*, followed by the charge of the cation in parentheses (*II*), and the base name of the anion, *fluor*, with the ending *-ide*.

**FOR PRACTICE 3.11** Use the flowchart in Figure 3.11 to name  $\text{H}_2\text{SO}_3(aq)$ .

### 3.8 Formula Mass and the Mole Concept for Compounds

In Chapter 2, we defined the average mass of an atom of an element as its *atomic mass*. Similarly, we now define the average mass of a molecule (or a formula unit) of a compound as its **formula mass**. (The common terms *molecular mass* and *molecular weight* are synonymous with formula mass.) For any compound, the formula mass is the sum of the atomic masses of all the atoms in its chemical formula.

Remember, ionic compounds do not contain individual molecules. In casual language, the smallest electrically neutral collection of ions is sometimes called a molecule but is more correctly called a formula unit.

$$\text{Formula mass} = \left( \begin{array}{c} \text{Number of atoms} \\ \text{of 1st element in} \\ \text{chemical formula} \end{array} \times \begin{array}{c} \text{Atomic mass} \\ \text{of} \\ \text{1st element} \end{array} \right) + \left( \begin{array}{c} \text{Number of atoms} \\ \text{of 2nd element in} \\ \text{chemical formula} \end{array} \times \begin{array}{c} \text{Atomic mass} \\ \text{of} \\ \text{2nd element} \end{array} \right) + \dots$$

For example, the formula mass of carbon dioxide,  $\text{CO}_2$ , is:

$$\begin{aligned} \text{Formula mass} &= 12.01 \text{ amu} + 2(16.00 \text{ amu}) \\ &= 44.01 \text{ amu} \end{aligned}$$

↙ Multiply by 2 because formula has two oxygen atoms.

and that of sodium oxide,  $\text{Na}_2\text{O}$ , is:

$$\begin{aligned} \text{Formula mass} &= 2(22.99 \text{ amu}) + 16.00 \text{ amu} \\ &= 61.98 \text{ amu} \end{aligned}$$

↙ Multiply by 2 because formula has two sodium atoms.

#### Example 3.12 Calculating Formula Mass

Calculate the formula mass of glucose,  $\text{C}_6\text{H}_{12}\text{O}_6$ .

##### SOLUTION

To find the formula mass, add the atomic masses of each atom in the chemical formula.

$$\begin{aligned} \text{Formula mass} &= 6 \times (\text{atomic mass C}) + 12 \times (\text{atomic mass H}) + 6 \times (\text{atomic mass O}) \\ &= 6(12.01 \text{ amu}) + 12(1.008 \text{ amu}) + 6(16.00 \text{ amu}) \\ &= 180.16 \text{ amu} \end{aligned}$$

**FOR PRACTICE 3.12** Calculate the formula mass of calcium nitrate.

### Molar Mass of a Compound

In Chapter 2 (Section 2.9), we saw that an element's molar mass—the mass in grams of one mole of its atoms—is numerically equivalent to its atomic mass. We then used the molar mass in combination with Avogadro's number to determine the number of atoms in a given mass of the element. We can apply the same concept to compounds. The *molar mass of a compound*—the mass in grams of 1 mol of its molecules or formula units—is numerically equivalent to its formula mass. For example, we just calculated the formula mass of  $\text{CO}_2$  to be 44.01 amu. The molar mass is, therefore:

$$\text{CO}_2 \text{ molar mass} = 44.01 \text{ g/mol}$$

### Using Molar Mass to Count Molecules by Weighing

The molar mass of  $\text{CO}_2$  is a conversion factor between mass (in grams) and amount (in moles) of  $\text{CO}_2$ . Suppose we want to find the number of  $\text{CO}_2$  molecules in a sample of dry ice (solid  $\text{CO}_2$ ) with a mass of 10.8 g. This calculation is analogous to Example 2.8, where we found the number of atoms in a sample of copper of a given mass. We begin with the

mass of 10.8 g and use the molar mass to convert to the amount in moles. Then we use Avogadro's number to convert to number of molecules. The conceptual plan is as follows:

**Conceptual Plan**

To solve the problem, we follow the conceptual plan, beginning with 10.8 g CO<sub>2</sub>, converting to moles, and then to molecules.

**Solution**

$$10.8 \text{ g CO}_2 \times \frac{1 \text{ mol CO}_2}{44.01 \text{ g CO}_2} \times \frac{6.022 \times 10^{23} \text{ CO}_2 \text{ molecules}}{1 \text{ mol CO}_2} = 1.48 \times 10^{23} \text{ CO}_2 \text{ molecules}$$

**Example 3.13** The Mole Concept—Converting between Mass and Number of Molecules

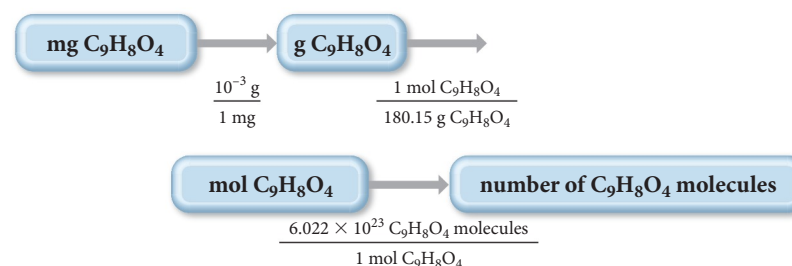

An aspirin tablet contains 325 mg of acetylsalicylic acid (C<sub>9</sub>H<sub>8</sub>O<sub>4</sub>). How many acetylsalicylic acid molecules does it contain?

**SORT** You are given the mass of acetylsalicylic acid and asked to find the number of molecules.

**GIVEN:** 325 mg C<sub>9</sub>H<sub>8</sub>O<sub>4</sub>

**FIND:** number of C<sub>9</sub>H<sub>8</sub>O<sub>4</sub> molecules

**STRATEGIZE** First convert to moles (using the molar mass of the compound) and then to number of molecules (using Avogadro's number). You need both the molar mass of acetylsalicylic acid and Avogadro's number as conversion factors. You also need the conversion factor between g and mg.

**CONCEPTUAL PLAN****RELATIONSHIPS USED**

$$\text{C}_9\text{H}_8\text{O}_4 \text{ molar mass} = 9(12.01) + 8(1.008) + 4(16.00) = 180.15 \text{ g/mol}$$

$$6.022 \times 10^{23} = 1 \text{ mol}$$

$$1 \text{ mg} = 10^{-3} \text{ g}$$

**SOLVE** Follow the conceptual plan to solve the problem.

**SOLUTION**

$$325 \text{ mg C}_9\text{H}_8\text{O}_4 \times \frac{10^{-3} \text{ g}}{1 \text{ mg}} \times \frac{1 \text{ mol C}_9\text{H}_8\text{O}_4}{180.15 \text{ g C}_9\text{H}_8\text{O}_4} \times \frac{6.022 \times 10^{23} \text{ C}_9\text{H}_8\text{O}_4 \text{ molecules}}{1 \text{ mol C}_9\text{H}_8\text{O}_4} = 1.09 \times 10^{21} \text{ C}_9\text{H}_8\text{O}_4 \text{ molecules}$$

**CHECK** The units of the answer, C<sub>9</sub>H<sub>8</sub>O<sub>4</sub> molecules, are correct. The magnitude is smaller than Avogadro's number, as expected, since you have less than 1 molar mass of acetylsalicylic acid.

**FOR PRACTICE 3.13** Find the number of ibuprofen molecules in a tablet containing 200.0 mg of ibuprofen (C<sub>13</sub>H<sub>18</sub>O<sub>2</sub>).

**FOR MORE PRACTICE 3.13** Determine the mass of a sample of water containing  $3.55 \times 10^{22}$  H<sub>2</sub>O molecules.

**Molecular Models and the Size of Molecules** Throughout this book, you will find space-filling molecular models to represent molecules. Which number is the best estimate for the scaling factor used in these models? In other words, by approximately what number would you have to multiply the radius of an actual oxygen atom to get the radius of the sphere used to represent the oxygen atom in the water molecule shown to the right.

- (a) 10      (b)  $10^4$       (c)  $10^8$       (d)  $10^{16}$

### CONCEPTUAL CONNECTION 3.7

## 3.9 Composition of Compounds

A chemical formula, in combination with the molar masses of its constituent elements, indicates the relative quantities of each element in a compound, which is extremely useful information. For example, about 35 years ago, scientists began to suspect that synthetic compounds known as chlorofluorocarbons (or CFCs) were destroying ozone ( $\text{O}_3$ ) in Earth's upper atmosphere. Upper atmospheric ozone is important because it acts as a shield, protecting life on Earth from the sun's harmful ultraviolet light.

CFCs are chemically inert compounds used primarily as refrigerants and industrial solvents. Over time, CFCs accumulated in the atmosphere. In the upper atmosphere, sunlight breaks bonds within CFCs, releasing chlorine atoms. The chlorine atoms react with ozone, converting it into  $\text{O}_2$ . So the harmful part of CFCs is the chlorine atoms that they carry. How can we determine the mass of chlorine in a given mass of a CFC?

One way to express how much of an element is in a given compound is to use the element's mass percent composition for that compound. The **mass percent composition** or **mass percent** of an element is that element's percentage of the compound's total mass. We calculate the mass percent of element X in a compound from the chemical formula as follows:

$$\text{Mass percent of element X} = \frac{\text{mass of element X in 1 mol of compound}}{\text{mass of 1 mol of the compound}} \times 100\%$$

Suppose, for example, that we want to calculate the mass percent composition of Cl in the chlorofluorocarbon  $\text{CCl}_2\text{F}_2$ . The mass percent Cl is given by:

We multiply the molar mass of Cl by 2 because the chemical formula has a subscript of 2 for Cl, indicating that 1 mol of  $\text{CCl}_2\text{F}_2$  contains 2 mol of Cl atoms. We calculate the molar mass of  $\text{CCl}_2\text{F}_2$  as follows:

$$\begin{aligned} \text{Molar mass} &= 12.01 \text{ g/mol} + 2(35.45 \text{ g/mol}) + 2(19.00 \text{ g/mol}) \\ &= 120.91 \text{ g/mol} \end{aligned}$$

So the mass percent of Cl in  $\text{CCl}_2\text{F}_2$  is:

$$\begin{aligned} \text{Mass percent Cl} &= \frac{2 \times \text{molar mass Cl}}{\text{molar mass CCl}_2\text{F}_2} \times 100\% \\ &= \frac{2 \times 35.45 \text{ g/mol}}{120.91 \text{ g/mol}} \times 100\% \\ &= 58.64\% \end{aligned}$$

▲ The chlorine in chlorofluorocarbons caused the ozone hole over Antarctica. The dark blue color indicates depressed ozone levels.

**Example 3.14** Mass Percent Composition

Calculate the mass percent of Cl in Freon-112 ( $\text{C}_2\text{Cl}_4\text{F}_2$ ), a CFC refrigerant.

**SORT** You are given the molecular formula of Freon-112 and asked to find the mass percent of Cl.

**GIVEN:**  $\text{C}_2\text{Cl}_4\text{F}_2$

**FIND:** mass percent Cl

**STRATEGIZE** The molecular formula tells you that there are 4 mol of Cl in each mole of Freon-112. Find the mass percent composition from the chemical formula by using the equation that defines mass percent. The conceptual plan shows you how to use the mass of Cl in 1 mol of  $\text{C}_2\text{Cl}_4\text{F}_2$  and the molar mass of  $\text{C}_2\text{Cl}_4\text{F}_2$  to find the mass percent of Cl.

**CONCEPTUAL PLAN**

$$\text{Mass \% Cl} = \frac{4 \times \text{molar mass Cl}}{\text{molar mass } \text{C}_2\text{Cl}_4\text{F}_2} \times 100\%$$

**RELATIONSHIPS USED**

$$\text{Mass percent of element X} = \frac{\text{mass of element X in 1 mol of compound}}{\text{mass of 1 mol of compound}} \times 100\%$$

**SOLVE** Calculate the necessary parts of the equation and substitute the values into the equation to find mass percent Cl.

**SOLUTION**

$$4 \times \text{molar mass Cl} = 4(35.45 \text{ g/mol}) = 141.8 \text{ g/mol}$$

$$\begin{aligned} \text{Molar mass } \text{C}_2\text{Cl}_4\text{F}_2 &= 2(12.01 \text{ g/mol}) + 4(35.45 \text{ g/mol}) + 2(19.00 \text{ g/mol}) \\ &= 24.02 \text{ g/mol} + 141.8 \text{ g/mol} + 38.00 \text{ g/mol} = 203.8 \text{ g/mol} \end{aligned}$$

$$\begin{aligned} \text{Mass \% Cl} &= \frac{4 \times \text{molar mass Cl}}{\text{molar mass } \text{C}_2\text{Cl}_4\text{F}_2} \times 100\% \\ &= \frac{141.8 \text{ g/mol}}{203.8 \text{ g/mol}} \times 100\% \\ &= 69.58\% \end{aligned}$$

**CHECK** The units of the answer (%) are correct. The magnitude is reasonable because it is between 0 and 100% and chlorine is the heaviest atom in the molecule and there are four atoms of it.

**FOR PRACTICE 3.14** Acetic acid ( $\text{C}_2\text{H}_4\text{O}_2$ ) is the active ingredient in vinegar. Calculate the mass percent composition of oxygen in acetic acid.

**FOR MORE PRACTICE 3.14** Calculate the mass percent composition of sodium in sodium oxide.

**CONCEPTUAL CONNECTION 3.8**

**Chemical Formula and Mass Percent Composition** Without doing any calculations, list the elements in  $\text{C}_6\text{H}_6\text{O}$  in order of decreasing mass percent composition.

**Mass Percent Composition as a Conversion Factor**

The mass percent composition of an element in a compound is a conversion factor between mass of the element and mass of the compound. For example, we saw that the mass percent composition of Cl in  $\text{CCl}_2\text{F}_2$  is 58.64%. Since percent means *per hundred*, there are 58.64 g Cl *per hundred* grams  $\text{CCl}_2\text{F}_2$ , which can be expressed as the ratio:

$$58.64 \text{ g Cl} : 100 \text{ g } \text{CCl}_2\text{F}_2$$

or, in fractional form:

$$\frac{58.64 \text{ g Cl}}{100 \text{ g } \text{CCl}_2\text{F}_2} \quad \text{or} \quad \frac{100 \text{ g } \text{CCl}_2\text{F}_2}{58.64 \text{ g Cl}}$$

These ratios can function as conversion factors between grams of Cl and grams of  $\text{CCl}_2\text{F}_2$ . For example, to calculate the mass of Cl in 1.00 kg  $\text{CCl}_2\text{F}_2$ , we use the following conceptual plan:

### Conceptual Plan

Notice that the mass percent composition acts as a conversion factor between grams of the compound and grams of the constituent element. To calculate grams Cl, we follow the conceptual plan.

### Solution

$$1.00 \text{ kg } \text{CCl}_2\text{F}_2 \times \frac{1000 \text{ g}}{1 \text{ kg}} \times \frac{58.64 \text{ g Cl}}{100 \text{ g } \text{CCl}_2\text{F}_2} = 5.86 \times 10^2 \text{ g Cl}$$

### Example 3.15 Using Mass Percent Composition as a Conversion Factor

The U.S. Food and Drug Administration (FDA) recommends that an adult consume less than 2.4 g of sodium per day. What mass of sodium chloride (in grams) can you consume and still be within the FDA guidelines? Sodium chloride is 39% sodium by mass.

**SORT** You are given a mass of sodium and the mass percent of sodium in sodium chloride. You are asked to find the mass of NaCl that contains the given mass of sodium.

**GIVEN:** 2.4 g Na

**FIND:** g NaCl

**STRATEGIZE** Convert between mass of a constituent element and mass of a compound by using mass percent composition as a conversion factor.

#### CONCEPTUAL PLAN

#### RELATIONSHIPS USED

39 g Na: 100 g NaCl

**SOLVE** Follow the conceptual plan to solve the problem.

#### SOLUTION

$$2.4 \text{ g Na} \times \frac{100 \text{ g NaCl}}{39 \text{ g Na}} = 6.2 \text{ g NaCl}$$

You can consume 6.2 g NaCl and still be within the FDA guidelines.

**CHECK** The units of the answer are correct. The magnitude seems reasonable because it is larger than the amount of sodium, as expected, because sodium is only one of the elements in NaCl.

**FOR PRACTICE 3.15** What mass (in grams) of iron(III) oxide contains 58.7 g of iron? Iron(III) oxide is 69.94% iron by mass.

**FOR MORE PRACTICE 3.15** If someone consumes 22 g of sodium chloride per day, what mass (in grams) of sodium does that person consume? Sodium chloride is 39% sodium by mass.

◀ 12.5 packets of salt contain 6.2 g of NaCl.

## Conversion Factors from Chemical Formulas

Mass percent composition is one way to understand how much chlorine is in a particular chlorofluorocarbon or, more generally, how much of a constituent element is present in a given mass of any compound. However, we can also approach this type of problem in a different way. Chemical formulas contain within them inherent relationships between atoms (or moles of atoms) and molecules (or moles of molecules). For example, the formula for  $\text{CCl}_2\text{F}_2$  tells us that 1 mol of  $\text{CCl}_2\text{F}_2$  contains 2 mol of Cl atoms. We write the ratio as:

With ratios such as these—which come from the chemical formula—we can directly determine the amounts of the constituent elements present in a given amount of a compound without having to calculate mass percent composition. For example, we calculate the number of moles of Cl in 38.5 mol of  $\text{CCl}_2\text{F}_2$  as follows:

### Conceptual Plan

### Solution

$$38.5 \text{ mol CCl}_2\text{F}_2 \times \frac{2 \text{ mol Cl}}{1 \text{ mol CCl}_2\text{F}_2} = 77.0 \text{ mol Cl}$$

As we have seen, however, we often want to know, not the *amount in moles* of an element in a certain number of moles of compound, but the *mass in grams* (or other units) of a constituent element in a given *mass* of the compound. Suppose we want to know the mass (in grams) of Cl in 25.0 g  $\text{CCl}_2\text{F}_2$ . The relationship inherent in the chemical formula (2 mol Cl : 1 mol  $\text{CCl}_2\text{F}_2$ ) applies to the amount in moles, not to mass. Therefore, we first convert the mass of  $\text{CCl}_2\text{F}_2$  to moles  $\text{CCl}_2\text{F}_2$ . Then we use the conversion factor from the chemical formula to convert to moles Cl. Finally, we use the molar mass of Cl to convert to grams Cl.

### Conceptual Plan

### Solution

$$25.0 \text{ g CCl}_2\text{F}_2 \times \frac{1 \text{ mol CCl}_2\text{F}_2}{120.91 \text{ g CCl}_2\text{F}_2} \times \frac{2 \text{ mol Cl}}{1 \text{ mol CCl}_2\text{F}_2} \times \frac{35.45 \text{ g Cl}}{1 \text{ mol Cl}} = 14.7 \text{ g Cl}$$

Notice that we must convert from g  $\text{CCl}_2\text{F}_2$  to mol  $\text{CCl}_2\text{F}_2$  *before* we can use the chemical formula as a conversion factor. *Always remember that the chemical formula indicates the relationship between the amounts (in moles) of substances, not between the masses (in grams) of them.*

The general form for solving problems in which we need to find the mass of an element present in a given mass of a compound is:

We use the atomic or molar mass to convert between mass and moles, and we use relationships inherent in the chemical to convert between moles and moles.

**Example 3.16** Chemical Formulas as Conversion Factors

Hydrogen may be used in the future to replace gasoline as a fuel. Most major automobile companies are developing vehicles that run on hydrogen. These cars have the potential to be less environmentally harmful than our current vehicles because their only emission is water vapor. One way to obtain hydrogen for fuel is to use an emission-free energy source such as wind power to form elemental hydrogen from water. What mass of hydrogen (in grams) is contained in 1.00 gallon of water? (The density of water is 1.00 g/mL.)

**SORT** You are given a volume of water and asked to find the mass of hydrogen it contains. You are also given the density of water.

**GIVEN:** 1.00 gal H<sub>2</sub>O  
 $d_{\text{H}_2\text{O}} = 1.00 \text{ g/mL}$

**FIND:** g H

**STRATEGIZE** The first part of the conceptual plan shows how to convert the units of volume from gallons to liters and then to mL. It also shows how to use the density to convert mL to g.

The second part of the conceptual plan is the basic sequence: mass  $\rightarrow$  moles  $\rightarrow$  moles  $\rightarrow$  mass. Convert between moles and mass using the appropriate molar masses, and convert from mol H<sub>2</sub>O to mol H using the conversion factor derived from the molecular formula.

**CONCEPTUAL PLAN****RELATIONSHIPS USED**

3.785 L = 1 gal (Table 1.3)

1000 mL = 1 L

1.00 g H<sub>2</sub>O = 1 mL H<sub>2</sub>O (density of H<sub>2</sub>O)

Molar mass H<sub>2</sub>O = 2(1.008) + 16.00 = 18.02 g/mol

2 mol H : 1 mol H<sub>2</sub>O

1.008 g H = 1 mol H

**SOLVE** Follow the conceptual plan to solve the problem.

**SOLUTION**

$$\begin{aligned}
 1.00 \text{ gal H}_2\text{O} &\times \frac{3.785 \text{ L}}{1 \text{ gal}} \times \frac{1000 \text{ mL}}{1 \text{ L}} \times \frac{1.00 \text{ g}}{1 \text{ mL}} = 3.785 \times 10^3 \text{ g H}_2\text{O} \\
 3.785 \times 10^3 \text{ g H}_2\text{O} &\times \frac{1 \text{ mol H}_2\text{O}}{18.02 \text{ g H}_2\text{O}} \times \frac{2 \text{ mol H}}{1 \text{ mol H}_2\text{O}} \\
 &\times \frac{1.008 \text{ g H}}{1 \text{ mol H}} = 4.23 \times 10^2 \text{ g H}
 \end{aligned}$$

**CHECK** The units of the answer (g H) are correct. Since a gallon of water is about 3.8 L, its mass is about 3.8 kg. H is a light atom, so its mass should be significantly less than 3.8 kg, which it is in the answer.

**FOR PRACTICE 3.16** Determine the mass of oxygen in a 7.2-g sample of Al<sub>2</sub>(SO<sub>4</sub>)<sub>3</sub>.

**FOR MORE PRACTICE 3.16** Butane (C<sub>4</sub>H<sub>10</sub>) is the liquid fuel in lighters. How many grams of carbon are present within a lighter containing 7.25 mL of butane? (The density of liquid butane is 0.601 g/mL.)

**Chemical Formulas and Elemental Composition** The molecular formula for water is H<sub>2</sub>O. Which ratio can be correctly derived from this formula? Explain.

- (a) 2 g H : 1 g H<sub>2</sub>O    (b) 2 mL H : 1 mL H<sub>2</sub>O    (c) 2 mol H : 1 mol H<sub>2</sub>O

CONCEPTUAL  
**CONNECTION 3.9**

## Chemistry AND Medicine

### Methylmercury in Fish

In the last decade, the U.S. Environmental Protection Agency (EPA) has grown increasingly concerned about mercury levels in fish. Mercury—which is present in fish as methylmercury—affects the central nervous system of humans who eat the fish, especially children and developing fetuses. In a developing fetus, excessive mercury exposure can result in slowed mental development and even retardation. Some lakes now have warnings about eating too much fish caught in the lakes.

Recent regulations force fish vendors to alert customers about the dangers of eating too much of certain kinds of commercial fish, including shark, tuna, and mackerel. These fish tend to contain high levels of methylmercury and therefore should be eaten in moderation, especially by children and pregnant women. The U.S. Food and Drug Administration (FDA) *action level*—the level below which the FDA claims the food has no adverse health effects—for methylmercury in fish is 1.0 ppm or 1.0 g of methylmercury per million grams of fish. However, a number of environmental advocacy groups, including the EPA, have suggested that, while this level may be safe for adults, it is too high for children and pregnant women. Consequently, the FDA suggests that pregnant women limit their intake of fish to 12 ounces per week.

#### QUESTION

The levels of methylmercury in fish are normally tested by laboratory techniques that measure only the mercury (Hg). Suppose a lab analyzes a 14.5 g sample of fish and finds that it contains  $1.03 \times 10^{-5}$  g of mercury. How much methylmercury ( $\text{HgCH}_3\text{Cl}$ ) is in the fish in parts per million (ppm)? Is this above the FDA action level?

▲ Lakes containing mercury—either from natural sources or from pollution—often have posted limits for the number of fish from the lake that can be eaten safely.

### 3.10 Determining a Chemical Formula from Experimental Data

In Section 3.8, we calculated mass percent composition from a chemical formula. Can we also do the reverse? Can we calculate a chemical formula from mass percent composition? This question is important because many laboratory analyses of compounds list the relative masses of each element present in the compound. For example, if we decompose water into hydrogen and oxygen in the laboratory, we can measure the masses of hydrogen and oxygen produced. Can we determine a chemical formula from this data? The answer is a qualified yes. We can determine a chemical formula, but it is an empirical formula (not a molecular formula). To get a molecular formula, we need additional information, such as the molar mass of the compound.

Suppose we decompose a sample of water in the laboratory and find that it produces 0.857 g of hydrogen and 6.86 g of oxygen. How do we determine an empirical formula from these data? We know that an empirical formula represents a ratio of atoms or a ratio of moles of atoms, *not a ratio of masses*. So the first thing we must do is convert our data from mass (in grams) to amount (in moles). How many moles of each element are present in the sample? To convert to moles, we divide each mass by the molar mass of that element:

$$\text{Moles H} = 0.857 \text{ g H} \times \frac{1 \text{ mol H}}{1.01 \text{ g H}} = 0.849 \text{ mol H}$$

$$\text{Moles O} = 6.86 \text{ g O} \times \frac{1 \text{ mol O}}{16.00 \text{ g O}} = 0.429 \text{ mol O}$$

From these data, we know there are 0.849 mol H for every 0.429 mol O. We can now write a *pseudoformula* for water:

To get the smallest whole-number subscripts in our formula, we divide all the subscripts by the smallest one, in this case 0.429:

$$\frac{\text{H}_{0.849}\text{O}_{0.429}}{0.429} = \text{H}_{1.98}\text{O} = \text{H}_2\text{O}$$

Our empirical formula for water, which also happens to be the molecular formula, is  $\text{H}_2\text{O}$ . You can use the procedure shown here to obtain the empirical formula of any compound from experimental data giving the relative masses of the constituent elements. The left column outlines the procedure, and the center and right columns contain two examples of how to apply the procedure.

### Procedure for...

Obtaining an Empirical Formula from Experimental Data		Example 3.17	Example 3.18																		
		<b>Obtaining an Empirical Formula from Experimental Data</b>	<b>Obtaining an Empirical Formula from Experimental Data</b>																		
		A compound containing nitrogen and oxygen is decomposed in the laboratory. It produces 24.5 g nitrogen and 70.0 g oxygen. Calculate the empirical formula of the compound.	A laboratory analysis of aspirin determines the following mass percent composition: C 60.00%; H 4.48%; O 35.52% Find the empirical formula.																		
1. Write down (or calculate) as <i>given</i> the masses of each element present in a sample of the compound. If you are given mass percent composition, assume a 100-g sample and calculate the masses of each element from the given percentages.		<b>GIVEN:</b> 24.5 g N, 70.0 g O <b>FIND:</b> empirical formula	<b>GIVEN:</b> In a 100-g sample: 60.00 g C, 4.48 g H, 35.52 g O <b>FIND:</b> empirical formula																		
2. Convert each of the masses in step 1 to moles by using the appropriate molar mass for each element as a conversion factor.	$24.5 \text{ g N} \times \frac{1 \text{ mol N}}{14.01 \text{ g N}} = 1.75 \text{ mol N}$ $70.0 \text{ g O} \times \frac{1 \text{ mol O}}{16.00 \text{ g O}} = 4.38 \text{ mol O}$	$60.00 \text{ g C} \times \frac{1 \text{ mol C}}{12.01 \text{ g C}} = 4.996 \text{ mol C}$ $4.48 \text{ g H} \times \frac{1 \text{ mol H}}{1.008 \text{ g H}} = 4.44 \text{ mol H}$ $35.52 \text{ g O} \times \frac{1 \text{ mol O}}{16.00 \text{ g O}} = 2.220 \text{ mol O}$																			
3. Write down a pseudoformula for the compound using the number of moles of each element (from step 2) as subscripts.	N <sub>1.75</sub> O <sub>4.38</sub>	C <sub>4.996</sub> H <sub>4.44</sub> O <sub>2.220</sub>																			
4. Divide all the subscripts in the formula by the smallest subscript.	$\text{N}_{\frac{1.75}{1.75}}\text{O}_{\frac{4.38}{1.75}} \longrightarrow \text{N}_1\text{O}_{2.5}$	$\text{C}_{\frac{4.996}{2.220}}\text{H}_{\frac{4.44}{2.220}}\text{O}_{\frac{2.220}{2.220}} \longrightarrow \text{C}_{2.25}\text{H}_2\text{O}_1$																			
5. If the subscripts are not whole numbers, multiply all the subscripts by a small whole number (see table) to get whole-number subscripts.	$\text{N}_1\text{O}_{2.5} \times 2 \longrightarrow \text{N}_2\text{O}_5$ The correct empirical formula is N <sub>2</sub> O <sub>5</sub> .	$\text{C}_{2.25}\text{H}_2\text{O}_1 \times 4 \longrightarrow \text{C}_9\text{H}_8\text{O}_4$ The correct empirical formula is C <sub>9</sub> H <sub>8</sub> O <sub>4</sub> .

0.75	4																				
0.80	5																				

## Determining Molecular Formulas for Compounds

We can find the molecular formula of a compound from the empirical formula if we also know the molar mass of the compound. Recall from Section 3.3 that the molecular formula is always a whole-number multiple of the empirical formula:

$$\text{Molecular formula} = \text{empirical formula} \times n, \text{ where } n = 1, 2, 3, \dots$$

Suppose we want to find the molecular formula for fructose (a sugar found in fruit) from its empirical formula,  $\text{CH}_2\text{O}$ , and its molar mass, 180.2 g/mol. We know that the molecular formula is a whole-number multiple of  $\text{CH}_2\text{O}$ :

$$\begin{aligned}\text{Molecular formula} &= (\text{CH}_2\text{O}) \times n \\ &= \text{C}_n\text{H}_{2n}\text{O}_n\end{aligned}$$

We also know that the molar mass is a whole-number multiple of the **empirical formula molar mass**, the sum of the masses of all the atoms in the empirical formula.

$$\text{Molar mass} = \text{empirical formula molar mass} \times n$$

For a particular compound, the value of  $n$  in both cases is the same. Therefore, we can find  $n$  by calculating the ratio of the molar mass to the empirical formula molar mass:

$$n = \frac{\text{molar mass}}{\text{empirical formula molar mass}}$$

For fructose, the empirical formula molar mass is:

$$\begin{aligned}\text{Empirical formula molar mass} \\ &= 12.01 \text{ g/mol} + 2(1.01 \text{ g/mol}) + 16.00 \text{ g/mol} = 30.03 \text{ g/mol}\end{aligned}$$

Therefore,  $n$  is:

$$n = \frac{180.2 \text{ g/mol}}{30.03 \text{ g/mol}} = 6$$

We can then use this value of  $n$  to find the molecular formula:

$$\text{Molecular formula} = (\text{CH}_2\text{O}) \times 6 = \text{C}_6\text{H}_{12}\text{O}_6$$

### Example 3.19 Determining a Molecular Formula from an Empirical Formula and Molar Mass

Butanedione—the component responsible for the smell and taste of butter and cheese—contains the elements carbon, hydrogen, and oxygen. The empirical formula of butanedione is  $\text{C}_2\text{H}_3\text{O}$ , and its molar mass is 86.09 g/mol. Determine its molecular formula.

**SORT** You are given the empirical formula and molar mass of butanedione and asked to find the molecular formula.

**GIVEN:** Empirical formula =  $\text{C}_2\text{H}_3\text{O}$   
molar mass = 86.09 g/mol

**FIND:** Molecular formula

**STRATEGIZE** A molecular formula is always a whole-number multiple of the empirical formula. Divide the molar mass by the empirical formula molar mass to find the whole number.

$$\begin{aligned}\text{Molecular formula} &= \text{empirical formula} \times n \\ n &= \frac{\text{molar mass}}{\text{empirical formula molar mass}}\end{aligned}$$

**SOLVE** Calculate the empirical formula mass.

$$\begin{aligned}\text{Empirical formula molar mass} \\ &= 2(12.01 \text{ g/mol}) + 3(1.008 \text{ g/mol}) + 16.00 \text{ g/mol} = 43.04 \text{ g/mol}\end{aligned}$$

Divide the molar mass by the empirical formula mass to find  $n$ .

$$n = \frac{\text{molar mass}}{\text{empirical formula molar mass}} = \frac{86.09 \text{ g/mol}}{43.04 \text{ g/mol}} = 2$$

Multiply the empirical formula by  $n$  to obtain the molecular formula.

$$\begin{aligned}\text{Molecular formula} &= \text{C}_2\text{H}_3\text{O} \times 2 \\ &= \text{C}_4\text{H}_6\text{O}_2\end{aligned}$$

**CHECK** Check the answer by calculating the molar mass of the formula as follows:

$$4(12.01 \text{ g/mol}) + 6(1.008 \text{ g/mol}) + 2(16.00 \text{ g/mol}) = 86.09 \text{ g/mol}$$

The calculated molar mass is in agreement with the given molar mass.

**FOR PRACTICE 3.19** A compound has the empirical formula CH and a molar mass of 78.11 g/mol. What is its molecular formula?

**FOR MORE PRACTICE 3.19** Determine the molecular formula for the compound with a molar mass of 60.10 g/mol and the following percent composition:

C, 39.97%

H, 13.41%

N, 46.62%

## Combustion Analysis

In the previous section, we discussed how to determine the empirical formula of a compound from the relative masses of its constituent elements. Another common (and related) way to obtain empirical formulas for unknown compounds, especially those containing carbon and hydrogen, is **combustion analysis**. In combustion analysis, the unknown compound undergoes combustion (or burning) in the presence of pure oxygen, as shown in Figure 3.13 ▼. When the sample burns, all of the carbon converts to  $\text{CO}_2$ , and all of the hydrogen converts to  $\text{H}_2\text{O}$ . The  $\text{CO}_2$  and  $\text{H}_2\text{O}$  are weighed. With these masses, we can use the numerical relationships between moles inherent in the formulas for  $\text{CO}_2$  and  $\text{H}_2\text{O}$  (1 mol  $\text{CO}_2$  : 1 mol C and 1 mol  $\text{H}_2\text{O}$  : 2 mol H) to determine the amounts of C and H in the original sample. We can determine the amounts of any other elemental constituents, such as O, Cl, or N, by subtracting the sum of the masses of C and H from the original mass of the sample. Examples 20 and 21 illustrate how to perform these calculations for a sample containing only C and H and for a sample containing C, H, and O.

Combustion is a type of *chemical reaction*. We discuss chemical reactions and their representation in Section 3.11.

### Combustion Analysis

▲ **FIGURE 3.13 Combustion Analysis Apparatus** The sample is placed in a furnace and burned in oxygen. The water and carbon dioxide produced are absorbed into separate containers and weighed.

## Procedure for...

## Determining an Empirical Formula from Combustion Analysis

1. Write down as *given* the masses of each combustion product and the mass of the sample (if given).
2. Convert the masses of CO<sub>2</sub> and H<sub>2</sub>O from step 1 to moles by using the appropriate molar mass for each compound as a conversion factor.
3. Convert the moles of CO<sub>2</sub> and moles of H<sub>2</sub>O from step 2 to moles of C and moles of H using the conversion factors inherent in the chemical formulas of CO<sub>2</sub> and H<sub>2</sub>O.
4. If the compound contains an element other than C and H, find the mass of the other element by subtracting the sum of the masses of C and H from the mass of the sample. Finally, convert the mass of the other element to moles.
5. Write down a pseudoformula for the compound using the number of moles of each element (from steps 3 and 4) as subscripts.
6. Divide all the subscripts in the formula by the smallest subscript. (Round all subscripts that are within 0.1 of a whole number.)

## Example 3.20

## Determining an Empirical Formula from Combustion Analysis

Upon combustion, a compound containing only carbon and hydrogen produces 1.83 g CO<sub>2</sub> and 0.901 g H<sub>2</sub>O. Find the empirical formula of the compound.

**GIVEN:** 1.83 g CO<sub>2</sub>, 0.901 g H<sub>2</sub>O

**FIND:** empirical formula

$$1.83 \text{ g CO}_2 \times \frac{1 \text{ mol CO}_2}{44.01 \text{ g CO}_2} = 0.0416 \text{ mol CO}_2$$

$$0.901 \text{ g H}_2\text{O} \times \frac{1 \text{ mol H}_2\text{O}}{18.02 \text{ g H}_2\text{O}} = 0.0500 \text{ mol H}_2\text{O}$$

$$0.0416 \text{ mol CO}_2 \times \frac{1 \text{ mol C}}{1 \text{ mol CO}_2} = 0.0416 \text{ mol C}$$

$$0.0500 \text{ mol H}_2\text{O} \times \frac{2 \text{ mol H}}{1 \text{ mol H}_2\text{O}} = 0.100 \text{ mol H}$$

The sample contains no elements other than C and H, so proceed to the next step.

## Example 3.21

## Determining an Empirical Formula from Combustion Analysis

Upon combustion, a 0.8233-g sample of a compound containing only carbon, hydrogen, and oxygen produces 2.445 g CO<sub>2</sub> and 0.6003 g H<sub>2</sub>O. Find the empirical formula of the compound.

**GIVEN:** 0.8233-g sample, 2.445 g CO<sub>2</sub>, 0.6003 g H<sub>2</sub>O

**FIND:** empirical formula

$$2.445 \text{ g CO}_2 \times \frac{1 \text{ mol CO}_2}{44.01 \text{ g CO}_2} = 0.05556 \text{ mol CO}_2$$

$$0.6003 \text{ g H}_2\text{O} \times \frac{1 \text{ mol H}_2\text{O}}{18.02 \text{ g H}_2\text{O}} = 0.03331 \text{ mol H}_2\text{O}$$

$$0.05556 \text{ mol CO}_2 \times \frac{1 \text{ mol C}}{1 \text{ mol CO}_2} = 0.05556 \text{ mol C}$$

$$0.03331 \text{ mol H}_2\text{O} \times \frac{2 \text{ mol H}}{1 \text{ mol H}_2\text{O}} = 0.06662 \text{ mol H}$$

$$\text{Mass C} = 0.05556 \text{ mol C} \times \frac{12.01 \text{ g C}}{1 \text{ mol C}} = 0.6673 \text{ g C}$$

$$\text{Mass H} = 0.06662 \text{ mol H} \times \frac{1.008 \text{ g H}}{1 \text{ mol H}} = 0.06715 \text{ g H}$$

$$\text{Mass O} = 0.8233 \text{ g} - (0.6673 \text{ g} + 0.06715 \text{ g}) = 0.0889 \text{ g}$$

$$\text{Mol O} = 0.0889 \text{ g O} \times \frac{1 \text{ mol O}}{16.00 \text{ g O}} = 0.00556 \text{ mol O}$$

7. If the subscripts are not whole numbers, multiply all the subscripts by a small whole number to get whole-number subscripts.	$\text{C}_1\text{H}_{2.4} \times 5 \longrightarrow \text{C}_5\text{H}_{12}$ The correct empirical formula is $\text{C}_5\text{H}_{12}$ .	The subscripts are whole numbers; no additional multiplication is needed. The correct empirical formula is $\text{C}_{10}\text{H}_{12}\text{O}$ .
	<b>FOR PRACTICE 3.20</b> Upon combustion, a compound containing only carbon and hydrogen produces 1.60 g $\text{CO}_2$ and 0.819 g $\text{H}_2\text{O}$ . Find the empirical formula of the compound.	<b>FOR PRACTICE 3.21</b> Upon combustion, a 0.8009-g sample of a compound containing only carbon, hydrogen, and oxygen produces 1.6004 g $\text{CO}_2$ and 0.6551 g $\text{H}_2\text{O}$ . Find the empirical formula of the compound.

## 3.11 Writing and Balancing Chemical Equations

Writing and Balancing  
Chemical Equations

Combustion analysis (which we just examined in Section 3.10) employs a **chemical reaction**, a process in which one or more substances are converted into one or more different ones. Compounds form and change through chemical reactions. For example, water is formed by the reaction of hydrogen with oxygen. A **combustion reaction** is a particular type of chemical reaction in which a substance combines with oxygen to form one or more oxygen-containing compounds. Combustion reactions also emit heat. The heat produced in a number of combustion reactions is critical to supplying our society's energy needs. For example, the heat from the combustion of gasoline expands the gaseous combustion products in a car engine's cylinders, which push the pistons and propel the car. We use the heat released by the combustion of *natural gas* to cook food and to heat our homes.

We represent a chemical reaction with a **chemical equation**. For example, we represent the combustion of natural gas with the equation:

The substances on the left side of the equation are the **reactants**, and the substances on the right side are the **products**. We often specify the states of each reactant or product in parentheses next to the formula as follows:

The (g) indicates that these substances are gases in the reaction. Table 3.5 summarizes the common states of reactants and products and their symbols used in chemical equations.

The equation just presented for the combustion of natural gas is not complete, however. If we look closely, we can immediately spot a problem.

The left side of the equation has two oxygen atoms, while the right side has three. The reaction as written, therefore, violates the law of conservation of mass because an oxygen atom formed out of nothing. Notice also that the left side has four hydrogen atoms, while the right side has only two.

Two hydrogen atoms have vanished, again violating mass conservation. To correct these problems—that is, to write an equation that more closely represents *what actually happens*—we must **balance** the equation. We need to change the coefficients (the

**TABLE 3.5** States of Reactants and Products in Chemical Equations

Abbreviation	State
(g)	Gas
(l)	Liquid
(s)	Solid
(aq)	Aqueous (water solution)

We cannot change the subscripts when balancing a chemical equation because changing the subscripts changes the substance itself, while changing the coefficients changes the number of molecules of the substance. For example, 2 H<sub>2</sub>O is simply two water molecules, but H<sub>2</sub>O<sub>2</sub> is hydrogen peroxide, a drastically different compound.

numbers *in front of* the chemical formulas), not the subscripts (the numbers within the chemical formulas), to ensure that the number of each type of atom on the left side of the equation is equal to the number on the right side. New atoms do not form during a reaction, nor do atoms vanish—matter must be conserved.

When we add coefficients to the reactants and products to balance an equation, we change the number of molecules in the equation but not the *kind of* molecules. To balance the equation for the combustion of methane, we put the coefficient 2 before O<sub>2</sub> in the reactants, and the coefficient 2 before H<sub>2</sub>O in the products.

The equation is now balanced because the numbers of each type of atom on either side of the equation are equal. The balanced equation tells us that one CH<sub>4</sub> molecule reacts with two O<sub>2</sub> molecules to form one CO<sub>2</sub> molecule and two H<sub>2</sub>O molecules. We verify that the equation is balanced by summing the number of each type of atom on each side of the equation.

Reactants	Products
1 C atom (1 × CH <sub>4</sub> )	1 C atom (1 × CO <sub>2</sub> )
4 H atoms (1 × CH <sub>4</sub> )	4 H atoms (2 × H <sub>2</sub> O)
4 O atoms (2 × O <sub>2</sub> )	4 O atoms (1 × CO <sub>2</sub> + 2 × H <sub>2</sub> O)

The number of each type of atom on both sides of the equation is now equal—the equation is balanced.

We can balance many chemical equations simply by trial and error. However, some guidelines are useful. For example, balancing the atoms in the most complex substances first and the atoms in the simplest substances (such as pure elements) last often makes the process shorter. The following examples of how to balance chemical equations are presented in a two- or three-column format. The general guidelines are shown on the left, with the application of the guidelines on the right. This procedure is meant only as a flexible guide, not a rigid set of steps.

## Procedure for...

### Balancing Chemical Equations

1. Write a skeletal equation by writing chemical formulas for each of the reactants and products. Review Sections 3.5 and 3.6 for nomenclature rules. (If a skeletal equation is provided, go to step 2.)

#### Example 3.22

##### Balancing Chemical Equations

Write a balanced equation for the reaction between solid cobalt(III) oxide and solid carbon to produce solid cobalt and carbon dioxide gas.

#### Example 3.23

##### Balancing Chemical Equations

Write a balanced equation for the combustion of gaseous butane (C<sub>4</sub>H<sub>10</sub>), a fuel used in portable stoves and grills, in which it combines with gaseous oxygen to form gaseous carbon dioxide and gaseous water.

<p>2. Balance atoms that occur in more complex substances first. Always balance atoms in compounds before atoms in pure elements.</p>	<p><b>Begin with O:</b></p> $\text{Co}_2\text{O}_3(\text{s}) + \text{C}(\text{s}) \longrightarrow \text{Co}(\text{s}) + \text{CO}_2(\text{g})$ <p style="text-align: center;">3 O atoms <math>\longrightarrow</math> 2 O atoms</p> <p>To balance O, put a 2 before <math>\text{Co}_2\text{O}_3(\text{s})</math> and a 3 before <math>\text{CO}_2(\text{g})</math>.</p> $2\text{Co}_2\text{O}_3(\text{s}) + \text{C}(\text{s}) \longrightarrow \text{Co}(\text{s}) + 3\text{CO}_2(\text{g})$ <p style="text-align: center;">6 O atoms <math>\longrightarrow</math> 6 O atoms</p>	<p><b>Begin with C:</b></p> $\text{C}_4\text{H}_{10}(\text{g}) + \text{O}_2(\text{g}) \longrightarrow \text{CO}_2(\text{g}) + \text{H}_2\text{O}(\text{g})$ <p style="text-align: center;">4 C atoms <math>\longrightarrow</math> 1 C atom</p> <p>To balance C, put a 4 before <math>\text{CO}_2(\text{g})</math>.</p> $\text{C}_4\text{H}_{10}(\text{g}) + \text{O}_2(\text{g}) \longrightarrow 4\text{CO}_2(\text{g}) + \text{H}_2\text{O}(\text{g})$ <p style="text-align: center;">4 C atoms <math>\longrightarrow</math> 4 C atoms</p> <p><b>Balance H:</b></p> $\text{C}_4\text{H}_{10}(\text{g}) + \text{O}_2(\text{g}) \longrightarrow 4\text{CO}_2(\text{g}) + \text{H}_2\text{O}(\text{g})$ <p style="text-align: center;">10 H atoms <math>\longrightarrow</math> 2 H atoms</p> <p>To balance H, put a 5 before <math>\text{H}_2\text{O}(\text{g})</math>:</p> $\text{C}_4\text{H}_{10}(\text{g}) + \text{O}_2(\text{g}) \longrightarrow 4\text{CO}_2(\text{g}) + 5\text{H}_2\text{O}(\text{g})$ <p style="text-align: center;">10 H atoms <math>\longrightarrow</math> 10 H atoms</p>																
<p>3. Balance atoms that occur as free elements on either side of the equation last. Balance free elements by adjusting their coefficients.</p>	<p><b>Balance Co:</b></p> $2\text{Co}_2\text{O}_3(\text{s}) + \text{C}(\text{s}) \longrightarrow \text{Co}(\text{s}) + 3\text{CO}_2(\text{g})$ <p style="text-align: center;">4 Co atoms <math>\longrightarrow</math> 1 Co atom</p> <p>To balance Co, put a 4 before <math>\text{Co}(\text{s})</math>.</p> $2\text{Co}_2\text{O}_3(\text{s}) + \text{C}(\text{s}) \longrightarrow 4\text{Co}(\text{s}) + 3\text{CO}_2(\text{g})$ <p style="text-align: center;">4 Co atoms <math>\longrightarrow</math> 4 Co atoms</p> <p><b>Balance C:</b></p> $2\text{Co}_2\text{O}_3(\text{s}) + \text{C}(\text{s}) \longrightarrow 4\text{Co}(\text{s}) + 3\text{CO}_2(\text{g})$ <p style="text-align: center;">1 C atom <math>\longrightarrow</math> 3 C atoms</p> <p>To balance C, put a 3 before <math>\text{C}(\text{s})</math>.</p> $2\text{Co}_2\text{O}_3(\text{s}) + 3\text{C}(\text{s}) \longrightarrow 4\text{Co}(\text{s}) + 3\text{CO}_2(\text{g})$	<p><b>Balance O:</b></p> $\text{C}_4\text{H}_{10}(\text{g}) + \text{O}_2(\text{g}) \longrightarrow 4\text{CO}_2(\text{g}) + 5\text{H}_2\text{O}(\text{g})$ <p style="text-align: center;">2 O atoms <math>\longrightarrow</math> 8 O + 5 O = 13 O atom:</p> <p>To balance O, put a 13/2 before <math>\text{O}_2(\text{g})</math>.</p> $\text{C}_4\text{H}_{10}(\text{g}) + 13/2\text{O}_2(\text{g}) \longrightarrow 4\text{CO}_2(\text{g}) + 5\text{H}_2\text{O}(\text{g})$ <p style="text-align: center;">13 O atoms <math>\longrightarrow</math> 13 O atoms</p>																
<p>4. If the balanced equation contains coefficient fractions, clear these by multiplying each of the coefficients in the entire equation by the denominator of the fraction.</p>	<p>This step is not necessary in this example. Proceed to step 5.</p>	$[\text{C}_4\text{H}_{10}(\text{g}) + 13/2\text{O}_2(\text{g}) \longrightarrow 4\text{CO}_2(\text{g}) + 5\text{H}_2\text{O}(\text{g})] \times 2$ $2\text{C}_4\text{H}_{10}(\text{g}) + 13\text{O}_2(\text{g}) \longrightarrow 8\text{CO}_2(\text{g}) + 10\text{H}_2\text{O}(\text{g})$																
<p>5. Check to make certain the equation is balanced by summing the total number of each type of atom on both sides of the equation.</p>	$2\text{Co}_2\text{O}_3(\text{s}) + 3\text{C}(\text{s}) \longrightarrow 4\text{Co}(\text{s}) + 3\text{CO}_2(\text{g})$ <table><thead><tr><th>Left</th><th>Right</th></tr></thead><tbody><tr><td>4 Co atoms</td><td>4 Co atoms</td></tr><tr><td>6 O atoms</td><td>6 O atoms</td></tr><tr><td>3 C atoms</td><td>3 C atoms</td></tr></tbody></table> <p>The equation is balanced.</p>	Left	Right	4 Co atoms	4 Co atoms	6 O atoms	6 O atoms	3 C atoms	3 C atoms	$2\text{C}_4\text{H}_{10}(\text{g}) + 13\text{O}_2(\text{g}) \longrightarrow 8\text{CO}_2(\text{g}) + 10\text{H}_2\text{O}(\text{g})$ <table><thead><tr><th>Left</th><th>Right</th></tr></thead><tbody><tr><td>8 C atoms</td><td>8 C atoms</td></tr><tr><td>20 H atoms</td><td>20 H atoms</td></tr><tr><td>26 O atoms</td><td>26 O atoms</td></tr></tbody></table> <p>The equation is balanced.</p>	Left	Right	8 C atoms	8 C atoms	20 H atoms	20 H atoms	26 O atoms	26 O atoms

	<p><b>FOR PRACTICE 3.22</b></p> <p>Write a balanced equation for the reaction between solid silicon dioxide and solid carbon to produce solid silicon carbide and carbon monoxide gas.</p>	<p><b>FOR PRACTICE 3.23</b></p> <p>Write a balanced equation for the combustion of gaseous ethane (<math>\text{C}_2\text{H}_6</math>), a minority component of natural gas, in which it combines with gaseous oxygen to form gaseous carbon dioxide and gaseous water.</p>																

## CONCEPTUAL CONNECTION 3.10

**Balanced Chemical Equations** Which quantity or quantities must always be the same on both sides of a chemical equation?

- (a) the number of atoms of each kind
- (b) the number of molecules of each kind
- (c) the number of moles of each kind of molecule
- (d) the sum of masses of all substances involved

### Example 3.24 Balancing Chemical Equations Containing Ionic Compounds with Polyatomic Ions

Write a balanced equation for the reaction between aqueous strontium chloride and aqueous lithium phosphate to form solid strontium phosphate and aqueous lithium chloride.

#### SOLUTION

1. Write a skeletal equation by writing chemical formulas for each of the reactants and products. Review Sections 3.5 and 3.6 for naming rules. (If a skeletal equation is provided, go to step 2.)

2. Balance metal ions (cations) first. If a polyatomic cation exists on both sides of the equation, balance it as a unit.

**Begin with  $\text{Sr}^{2+}$ :**

To balance  $\text{Sr}^{2+}$ , put a 3 before  $\text{SrCl}_2(aq)$ .

**Balance  $\text{Li}^+$ :**

To balance  $\text{Li}^+$ , put a 3 before  $\text{LiCl}(aq)$ .

3. Balance nonmetal ions (anions) second. If a polyatomic anion exists on both sides of the equation, balance it as a unit.

**Balance  $\text{PO}_4^{3-}$ :**

To balance  $\text{PO}_4^{3-}$ , put a 2 before  $\text{Li}_3\text{PO}_4(aq)$ .

**Balance  $\text{Cl}^-$ :**

To balance  $\text{Cl}^-$ , replace the 3 before  $\text{LiCl}(aq)$  with a 6. This also corrects the balance for  $\text{Li}^+$ , which was thrown off in the previous step.

Check to make certain the equation is balanced by summing the total number of each type of ion on both sides of the equation.

Left	Right
3 $\text{Sr}^{2+}$ ions	3 $\text{Sr}^{2+}$ ions
6 $\text{Li}^+$ ions	6 $\text{Li}^+$ ions
2 $\text{PO}_4^{3-}$ ions	2 $\text{PO}_4^{3-}$ ions
6 $\text{Cl}^-$ ions	6 $\text{Cl}^-$ ions

The equation is balanced.

**FOR PRACTICE 3.24** Write a balanced equation for the reaction between aqueous lead(II) nitrate and aqueous potassium chloride to form solid lead(II) chloride and aqueous potassium nitrate.

## 3.12 Organic Compounds

Early chemists divided compounds into two types: organic and inorganic. They designated organic compounds as those that originate from living things. Sugar—from sugar-cane or the sugar beet—is a common example of an organic compound. Inorganic compounds, on the other hand, originate from the earth. Salt—mined from the ground or from the ocean—is a common example of an inorganic compound.

Not only did early chemists view organic and inorganic compounds as different in their origin, but also they recognized organic and inorganic compounds to be different in their properties. Organic compounds are easily decomposed. Inorganic compounds, however, are typically more difficult to decompose. Eighteenth-century chemists could synthesize inorganic compounds in the laboratory, but they could not synthesize organic compounds. This was considered to be another great difference between the two different types of compounds. Today, chemists can synthesize both organic and inorganic compounds, and even though organic chemistry is a subfield of chemistry, the differences between organic and inorganic compounds are now viewed as primarily organizational (not fundamental).

Organic compounds are common in everyday substances. Many smells—such as those in perfumes, spices, and foods—are caused by organic compounds. When you sprinkle cinnamon onto your French toast, some cinnamaldehyde—an organic compound present in cinnamon—evaporates into the air. As you inhale cinnamaldehyde molecules, you experience the unique smell of cinnamon. Organic compounds are the major components of living organisms. They are also the main components of most fuels, such as gasoline, oil, and natural gas, and they are the active ingredients in most pharmaceuticals, such as aspirin and ibuprofen.

**Organic compounds** are composed of carbon and hydrogen and a few other elements, including nitrogen, oxygen, and sulfur. The key element in organic chemistry, however, is carbon. In its compounds, carbon always forms four bonds. The simplest organic compound is methane, or  $\text{CH}_4$ .

▲ The organic compound cinnamaldehyde is largely responsible for the taste and smell of cinnamon.

Structural formula

Space-filling model

Methane,  $\text{CH}_4$

The chemistry of carbon is unique and complex because carbon frequently bonds to itself to form chain, branched, and ring structures.

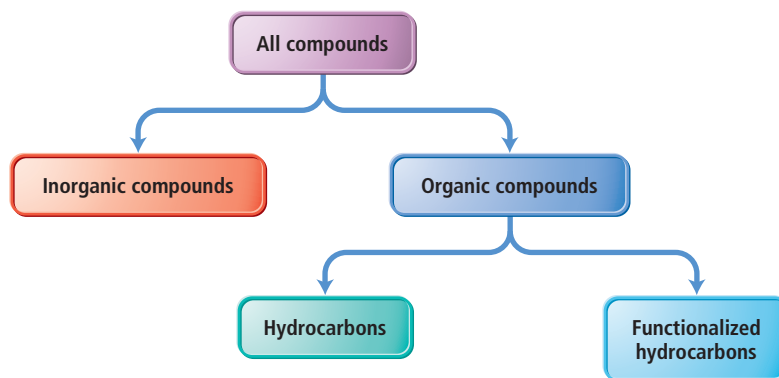

Carbon can also form double bonds and triple bonds with itself and with other elements.

This versatility allows carbon to serve as the backbone of millions of different chemical compounds, which is why a general survey of organic chemistry is a yearlong course.

## Hydrocarbons

We can begin to scratch the surface of organic chemistry by categorizing organic compounds into types: hydrocarbons and functionalized hydrocarbons.

▲ Gasoline is composed mostly of hydrocarbons.

**Hydrocarbons** are organic compounds that contain only carbon and hydrogen. Hydrocarbons compose common fuels such as oil, gasoline, liquid propane gas, and natural gas. Hydrocarbons containing only single bonds are **alkanes**, while those containing double or triple bonds are **alkenes** and **alkynes**, respectively. The names of simple, straight-chain hydrocarbons consist of a base name, which is determined by the number of carbon atoms in the chain, and a suffix, determined by whether the hydrocarbon is an alkane (-ane), alkene (-ene), or alkyne (-yne).

The base names for a number of hydrocarbons are listed here:

meth = 1	hex = 6
eth = 2	hept = 7
prop = 3	oct = 8
but = 4	non = 9
pent = 5	dec = 10

Table 3.6 lists some common hydrocarbons, their names, and their uses.

TABLE 3.6 Common Hydrocarbons				
Name	Molecular Formula	Structural Formula	Space-filling Model	Common Uses
Methane	CH <sub>4</sub>	$  \begin{array}{c}  \text{H} \\    \\  \text{H}-\text{C}-\text{H} \\    \\  \text{H}  \end{array}  $		Primary component of natural gas
Propane	C <sub>3</sub> H <sub>8</sub>	$  \begin{array}{ccccc}  & \text{H} & & \text{H} & & \text{H} \\  &   & &   & &   \\  \text{H} & -\text{C} & - & \text{C} & - & \text{C} & -\text{H} \\  &   & &   & &   \\  & \text{H} & & \text{H} & & \text{H}  \end{array}  $		LP gas for grills and outdoor stoves
<i>n</i> -Butane*	C <sub>4</sub> H <sub>10</sub>	$  \begin{array}{ccccccc}  & \text{H} & & \text{H} & & \text{H} & & \text{H} \\  &   & &   & &   & &   \\  \text{H} & -\text{C} & - & \text{C} & - & \text{C} & - & \text{C} & -\text{H} \\  &   & &   & &   & &   \\  & \text{H} & & \text{H} & & \text{H} & & \text{H}  \end{array}  $		Common fuel for lighters
<i>n</i> -Pentane*	C <sub>5</sub> H <sub>12</sub>	$  \begin{array}{ccccccccc}  & \text{H} & & \text{H} & & \text{H} & & \text{H} & & \text{H} \\  &   & &   & &   & &   & &   \\  \text{H} & -\text{C} & - & \text{C} & - & \text{C} & - & \text{C} & - & \text{C} & -\text{H} \\  &   & &   & &   & &   & &   \\  & \text{H} & & \text{H} & & \text{H} & & \text{H} & & \text{H}  \end{array}  $		Component of gasoline
Ethene	C <sub>2</sub> H <sub>4</sub>	$  \begin{array}{ccc}  & \text{H} & & \text{H} \\  &   & &   \\  & \text{C} = & \text{C} \\  &   & &   \\  & \text{H} & & \text{H}  \end{array}  $		Ripening agent in fruit
Ethyne	C <sub>2</sub> H <sub>2</sub>	H—C≡C—H		Fuel for welding torches

\*The “*n*” in the names of these hydrocarbons stands for “normal,” which means straight chain.

## Functionalized Hydrocarbons

Functionalized hydrocarbons are hydrocarbons in which a **functional group**—a characteristic atom or group of atoms—is incorporated into the hydrocarbon. For example, **alcohols** are organic compounds that have an —OH functional group. We designate the hydrocarbon portion of a molecule as “R,” and we write the general formula for an alcohol

The term *functional group* derives from the functionality or chemical character that a specific atom or group of atoms imparts to an organic compound. Even a carbon–carbon double bond can justifiably be called a “functional group.”

▲ Rubbing alcohol is isopropyl alcohol.

as  $R-OH$ . Some examples of alcohols include methanol (also known as methyl alcohol or wood alcohol) and isopropanol (also known as isopropyl alcohol or rubbing alcohol).

A group of organic compounds with the same functional group forms a **family**. Methanol and isopropyl alcohol are both members of the alcohol family of compounds.

The addition of a functional group to a hydrocarbon usually alters the properties of the compound significantly. Take *methanol*, which can be thought of as methane with an  $-OH$  group substituted for one of the hydrogen atoms. Methanol is a liquid at room temperature, whereas *methane* is a gas. Although each member of a family is unique, the common functional group bestows some chemical similarities on members of the same family. The names of functional groups have suffixes or endings unique to that functional group. Alcohols, for example, always have names that end in *-ol*. Table 3.7 provides examples of some common functional groups, their general formulas, and their characteristic suffixes or endings.

TABLE 3.7 Families of Organic Compounds

Family	Name Ending	General Formula	Example	Name	Occurrence/Use
Alcohols	-ol	$R-OH$	$CH_3CH_2-OH$	Ethanol (ethyl alcohol)	Alcohol in fermented beverages
Ethers	ether	$R-O-R'$	$CH_3CH_2-O-CH_2CH_3$	Diethyl ether	Anesthetic; laboratory solvent
Aldehydes	-al	$R-\overset{\overset{O}{\parallel}}{C}-H$	$H_3C-\overset{\overset{O}{\parallel}}{C}-H$	Ethanal (acetaldehyde)	Perfumes; flavors
Ketones	-one	$R-\overset{\overset{O}{\parallel}}{C}-R'$	$H_3C-\overset{\overset{O}{\parallel}}{C}-CH_3$	Propanone (acetone)	Fingernail polish remover
Carboxylic acids	acid	$R-\overset{\overset{O}{\parallel}}{C}-OH$	$H_3C-\overset{\overset{O}{\parallel}}{C}-OH$	Acetic acid	Vinegar
Esters	-ate	$R-\overset{\overset{O}{\parallel}}{C}-OR'$	$H_3C-\overset{\overset{O}{\parallel}}{C}-OCH_3$	Methyl acetate	Laboratory solvent
Amines	amine	$RNH_2$	$CH_3CH_2-\overset{\overset{H}{\mid}}{N}-H$	Ethyl amine	Smell of rotten fish

## Self-Assessment Quiz

- Q1.** What is the empirical formula of a compound with the molecular formula  $C_{10}H_8$ ?  
a)  $C_5H_3$    b)  $C_2H_4$    c)  $C_5H_4$    d) CH
- Q2.** Which substance is an ionic compound?  
a)  $SrI_2$    b)  $N_2O_4$    c) He   d)  $CCl_4$
- Q3.** What is the correct formula for the compound formed between calcium and sulfur?  
a) CaS   b)  $Ca_2S$    c)  $CaS_2$    d)  $CaS_3$
- Q4.** Name the compound  $SrI_2$ .  
a) strontium iodide   b) strontium diiodide  
c) strontium(II) iodide   d) strontium(II) diiodide
- Q5.** What is the formula for manganese(IV) oxide?  
a)  $Mn_4O$    b)  $MnO_4$    c)  $Mn_2O$    d)  $MnO_2$
- Q6.** Name the compound  $Pb(C_2H_3O_2)_2$ .  
a) lead(II) carbonate   b) lead(II) acetate  
c) lead bicarbonate   d) lead diacetate
- Q7.** Name the compound  $P_2I_4$ .  
a) phosphorus iodide   b) phosphorus diiodide  
c) phosphorus(II) iodide   d) diphosphorus tetraiodide
- Q8.** Name the compound  $HNO_2(aq)$ .  
a) hydrogen nitrogen dioxide  
b) hydrogen nitrate  
c) nitric acid  
d) nitrous acid
- Q9.** Determine the number of  $CH_2Cl_2$  molecules in 25.0 g  $CH_2Cl_2$ .  
a) 0.294 molecules   b)  $1.77 \times 10^{23}$  molecules  
c)  $1.28 \times 10^{27}$  molecules   d)  $1.51 \times 10^{25}$  molecules
- Q10.** List the elements in the compound  $CF_2Cl_2$  in order of decreasing mass percent composition.  
a)  $C > F > Cl$    b)  $F > Cl > C$   
c)  $Cl > C > F$    d)  $Cl > F > C$
- Q11.** Determine the mass of potassium in 35.5 g of KBr.  
a) 17.4 g   b) 0.298 g   c) 11.7 g   d) 32.9 g
- Q12.** A compound is 52.14% C, 13.13% H, and 34.73% O by mass. What is the empirical formula of the compound?  
a)  $C_2H_8O_3$    b)  $C_2H_6O$    c)  $C_4HO_3$    d)  $C_3HO_6$
- Q13.** A compound has the empirical formula  $CH_2O$  and a formula mass of 120.10 amu. What is the molecular formula of the compound?  
a)  $CH_2O$    b)  $C_2H_4O_2$    c)  $C_3H_6O_3$    d)  $C_4H_8O_4$
- Q14.** Combustion of 30.42 g of a compound containing only carbon, hydrogen, and oxygen produces 35.21 g  $CO_2$  and 14.42 g  $H_2O$ . What is the empirical formula of the compound?  
a)  $C_4H_8O_6$    b)  $C_2H_4O_3$   
c)  $C_2H_2O_3$    d)  $C_6HO_{12}$
- Q15.** What are the correct coefficients (reading from left to right) when the chemical equation is balanced?  
$$\_\_PCl_3(l) + \_\_H_2O(l) \longrightarrow \_\_H_3PO_3(aq) + \_\_HCl(aq)$$
  
a) 1, 3, 1, 3   b) 1, 2, 1, 1  
c) 1, 3, 2, 1   d) 3, 6, 1, 9

Answers: 1. (c) 2. (a) 3. (a) 4. (a) 5. (d) 6. (b) 7. (d) 8. (d) 9. (b) 10. (d) 11. (c) 12. (b) 13. (d) 14. (b) 15. (a)

## Chapter 3 IN REVIEW

### Key Terms

#### Section 3.2

ionic bond (90)  
ionic compound (90)  
covalent bond (90)  
molecular compound (90)

#### Section 3.3

chemical formula (90)  
empirical formula (90)  
molecular formula (90)  
structural formula (91)  
ball-and-stick molecular model (92)  
space-filling molecular model (92)

#### Section 3.4

atomic element (92)  
molecular element (92)  
formula unit (94)  
polyatomic ion (95)

#### Section 3.5

common name (97)  
systematic name (97)  
binary compound (98)  
oxyanion (100)  
hydrate (101)

#### Section 3.6

acid (103)  
binary acid (103)  
oxyacid (104)

#### Section 3.8

formula mass (107)

#### Section 3.9

mass percent composition  
(mass percent) (109)

#### Section 3.10

empirical formula molar mass (116)

combustion analysis (117)

#### Section 3.11

chemical reaction (119)  
combustion reaction (119)  
chemical equation (119)  
reactants (119)  
products (119)  
balanced chemical equation (119)

#### Section 3.12

organic compound (123)  
hydrocarbon (124)  
alkane (124)  
alkene (124)  
alkyne (124)  
functional group (125)  
alcohol (125)  
family (126)

## Key Concepts

### Chemical Bonds (3.2)

- ▶ Chemical bonds, the forces that hold atoms together in compounds, arise from the interactions between nuclei and electrons in atoms.
- ▶ In an ionic bond, one or more electrons are *transferred* from one atom to another, forming a cation (positively charged) and an anion (negatively charged). The two ions are drawn together by the attraction between the opposite charges.
- ▶ In a covalent bond, one or more electrons are *shared* between two atoms. The atoms are held together by the attraction between their nuclei and the shared electrons.

### Representing Molecules and Compounds (3.3, 3.4)

- ▶ A compound is represented with a chemical formula, which indicates the elements present and the number of atoms of each.
- ▶ An empirical formula gives only the *relative* number of atoms, while a molecular formula gives the *actual* number of atoms present in the molecule.
- ▶ Structural formulas show how atoms are bonded together, while molecular models portray the geometry of the molecule.
- ▶ Compounds can be divided into two types: molecular compounds, formed between two or more covalently bonded nonmetals, and ionic compounds, usually formed between a metal ionically bonded to one or more nonmetals. The smallest identifiable unit of a molecular compound is a molecule, and the smallest identifiable unit of an ionic compound is a formula unit: the smallest electrically neutral collection of ions.
- ▶ Elements can also be divided into two types: molecular elements, which occur as (mostly diatomic) molecules, and atomic elements, which occur as individual atoms.

### Naming Inorganic Ionic and Molecular Compounds and Acids (3.5–3.7)

- ▶ A flowchart for naming simple inorganic compounds is provided in Section 3.7.

### Formula Mass and Mole Concept for Compounds (3.8)

- ▶ The formula mass of a compound is the sum of the atomic masses of all the atoms in the chemical formula. Like the atomic masses of elements, the formula mass characterizes the average mass of a molecule (or a formula unit).

- ▶ The mass of one mole of a compound is the molar mass of that compound and equals its formula mass (in grams).

### Chemical Composition (3.9, 3.10)

- ▶ The mass percent composition of a compound indicates each element's percentage of the total compound's mass. We can determine the mass percent composition from the compound's chemical formula and the molar masses of its elements.
- ▶ The chemical formula of a compound provides the relative number of atoms (or moles) of each element in a compound, and we can therefore use it to determine numerical relationships between moles of the compound, and moles of its constituent elements. We can extend this relationship to mass by using the molar masses of the compound and its constituent elements.
- ▶ If the mass percent composition and molar mass of a compound are known, we can determine its empirical and molecular formulas.

### Writing and Balancing Chemical Equations (3.11)

- ▶ In chemistry, we represent chemical reactions with chemical equations. The substances on the left-hand side of a chemical equation are the reactants, and the substances on the right-hand side are the products.
- ▶ Chemical equations are balanced when the number of each type of atom on the left side of the equation is equal to the number on the right side.

### Organic Compounds (3.12)

- ▶ Organic compounds are composed of carbon, hydrogen, and a few other elements such as nitrogen, oxygen, and sulfur.
- ▶ The simplest organic compounds are hydrocarbons, compounds composed of only carbon and hydrogen.
- ▶ Hydrocarbons are categorized into three types based on the bonds they contain: alkanes contain single bonds, alkenes contain double bonds, and alkynes contain triple bonds.
- ▶ All other organic compounds can be thought of as hydrocarbons with one or more functional groups—characteristic atoms or groups of atoms.
- ▶ Common functionalized hydrocarbons include alcohols, ethers, aldehydes, ketones, carboxylic acids, esters, and amines.

## Key Equations and Relationships

### Formula Mass (3.8)

$$\left( \begin{array}{c} \text{No. of atoms of 1st element} \\ \text{in chemical formula} \end{array} \times \begin{array}{c} \text{atomic mass} \\ \text{of 1st element} \end{array} \right) + \left( \begin{array}{c} \text{No. of atoms of 2nd element} \\ \text{in chemical formula} \end{array} \times \begin{array}{c} \text{atomic mass} \\ \text{of 2nd element} \end{array} \right) + \dots$$

### Mass Percent Composition (3.9)

$$\text{Mass \% of element X} = \frac{\text{mass of X in 1 mol compound}}{\text{mass of 1 mol compound}} \times 100\%$$

### Empirical Formula Molar Mass (3.10)

$$\text{Molecular formula} = n \times (\text{empirical formula})$$

$$n = \frac{\text{molar mass}}{\text{empirical formula molar mass}}$$

## Key Learning Outcomes

CHAPTER OBJECTIVES	ASSESSMENT
Writing Molecular and Empirical Formulas (3.3)	Example 3.1 For Practice 3.1 Exercises 4, 23–26
Classifying Substances as Atomic Elements, Molecular Elements, Molecular Compounds, or Ionic Compounds (3.4)	Example 3.2 For Practice 3.2 Exercises 27–32
	
Writing Formulas for Ionic Compounds (3.5)	Examples 3.3, 3.4 For Practice 3.3, 3.4 Exercises 33–36, 43, 44
Naming Ionic Compounds (3.5)	Examples 3.5, 3.6 For Practice 3.5, 3.6 For More Practice 3.5, 3.6 Exercises 37–40
	
Naming Ionic Compounds Containing Polyatomic Ions (3.5)	Example 3.7 For Practice 3.7 For More Practice 3.7 Exercises 41–44
Naming Molecular Compounds (3.6)	Example 3.8 For Practice 3.8 For More Practice 3.8 Exercises 47–50
	Examples 3.9, 3.10 For Practice 3.9, 3.10 For More Practice 3.10 Exercises 51–54
Naming Uncategorized Inorganic Compounds (3.7)	Example 3.11 For Practice 3.11 Exercises 55–58
Calculating Formula Mass (3.8)	Example 3.12 For Practice 3.12 Exercises 59, 60
Using Formula Mass to Count Molecules by Weighing (3.8)	Example 3.13 For Practice 3.13 For More Practice 3.13 Exercises 65–70
Calculating Mass Percent Composition (3.9)	Example 3.14 For Practice 3.14 For More Practice 3.14 Exercises 71–76
Using Mass Percent Composition as a Conversion Factor (3.9)	Example 3.15 For Practice 3.15 For More Practice 3.15 Exercises 77, 78
Using Chemical Formulas as Conversion Factors (3.9)	Example 3.16 For Practice 3.16 For More Practice 3.16 Exercises 83, 84
Obtaining an Empirical Formula from Experimental Data (3.10)	Examples 3.17, 3.18 For Practice 3.17, 3.18 Exercises 87–94
Calculating a Molecular Formula from an Empirical Formula and Molar Mass (3.10)	Example 3.19 For Practice 3.19 For More Practice 3.19 Exercises 95–96
Obtaining an Empirical Formula from Combustion Analysis (3.10)	Examples 3.20, 3.21 For Practice 3.20, 3.21 Exercises 97–100
Balancing Chemical Equations (3.11)	Examples 3.22, 3.23, 3.24 For Practice 3.22, 3.23, 3.24 Exercises 101–112

## EXERCISES

### Review Questions

- How do the properties of compounds compare to the properties of the elements from which the compounds are composed?
- What is a chemical bond? Explain the difference between an ionic bond and a covalent bond.
- Explain the different ways to represent compounds. Why are there so many?
- What is the difference between an empirical formula and a molecular formula?
- Define and provide an example for each of the following: atomic element, molecular element, ionic compound, molecular compound.

6. Explain how to write a formula for an ionic compound given the names of the metal and nonmetal (or polyatomic ion) in the compound.
7. Explain how to name binary ionic compounds. How do you name an ionic compound if it contains a polyatomic ion?
8. Why do the names of some ionic compounds include the charge of the metal ion while others do not?
9. Explain how to name molecular inorganic compounds.
10. How many atoms are specified by each of these prefixes: *mono-*, *di-*, *tri-*, *tetra-*, *penta-*, *hexa-*?
11. Explain how to name binary and oxyacids.
12. What is the formula mass for a compound? Why is it useful?
13. Explain how you can use the information in a chemical formula to determine how much of a particular element is present in a given amount of a compound. Provide some examples of why this might be important.
14. What is mass percent composition? Why is it useful?
15. What kinds of conversion factors are inherent in chemical formulas? Provide an example.
16. What kind of chemical formula can be obtained from experimental data showing the relative masses of the elements in a compound?
17. How can a molecular formula be obtained from an empirical formula? What additional information is required?
18. What is combustion analysis? What is it used for?
19. Which elements are normally present in organic compounds?
20. What is the difference between an alkane, an alkene, and an alkyne?
21. What are functionalized hydrocarbons? Cite an example of a functionalized hydrocarbon.
22. Write a generic formula for each of the families of organic compounds.
 

a. alcohols	e. carboxylic acids
b. ethers	f. esters
c. aldehydes	g. amines
d. ketones	

## Problems by Topic

*Note: Answers to all odd-numbered Problems, numbered in blue, can be found in Appendix III. Exercises in the Problems by Topic section are paired, with each odd-numbered problem followed by a similar even-numbered problem. Exercises in the Cumulative Problems section are also paired, but somewhat more loosely. (Challenge Problems and Conceptual Problems, because of their nature, are unpaired.)*

### Chemical Formulas and Molecular View of Elements and Compounds

23. Determine the number of each type of atom in each formula.  
a.  $\text{Mg}_3(\text{PO}_4)_2$    b.  $\text{BaCl}_2$    c.  $\text{Fe}(\text{NO}_2)_2$    d.  $\text{Ca}(\text{OH})_2$
24. Determine the number of each type of atom in each formula.  
a.  $\text{Ca}(\text{NO}_2)_2$    b.  $\text{CuSO}_4$    c.  $\text{Al}(\text{NO}_3)_3$    d.  $\text{Mg}(\text{HCO}_3)_2$
25. Write a chemical formula for each molecular model. (See Appendix IIA for color codes.)

26. Write a chemical formula for each molecular model. (See Appendix IIA for color codes.)

27. Classify each element as atomic or molecular.  
a. neon   b. fluorine   c. potassium   d. nitrogen
28. Identify the elements that have molecules as their basic units.  
a. hydrogen   b. iodine   c. lead   d. oxygen
29. Classify each compound as ionic or molecular.  
a.  $\text{CO}_2$    b.  $\text{NiCl}_2$    c.  $\text{NaI}$    d.  $\text{PCl}_3$
30. Classify each compound as ionic or molecular.  
a.  $\text{CF}_2\text{Cl}_2$    b.  $\text{CCl}_4$    c.  $\text{PtO}_2$    d.  $\text{SO}_3$

31. Based on the molecular views, classify each substance as an atomic element, a molecular element, an ionic compound, or a molecular compound.

32. Based on the molecular views, classify each substance as an atomic element, a molecular element, an ionic compound, or a molecular compound.

### Formulas and Names for Ionic Compounds

33. Write a formula for the ionic compound that forms between each pair of elements.
- calcium and oxygen
  - zinc and sulfur
  - rubidium and bromine
  - aluminum and oxygen
34. Write a formula for the ionic compound that forms between each pair of elements.
- silver and chlorine
  - sodium and sulfur
  - aluminum and sulfur
  - potassium and chlorine
35. Write a formula for the compound that forms between calcium and each polyatomic ion.
- hydroxide
  - chromate
  - phosphate
  - cyanide
36. Write a formula for the compound that forms between potassium and each polyatomic ion.
- carbonate
  - phosphate
  - hydrogen phosphate
  - acetate
37. Name each ionic compound.
- $\text{Mg}_3\text{N}_2$
  - KF
  - $\text{Na}_2\text{O}$
  - $\text{Li}_2\text{S}$
  - CsF
  - KI
38. Name each ionic compound.
- $\text{SnCl}_4$
  - $\text{PbI}_2$
  - $\text{Fe}_2\text{O}_3$
  - $\text{CuI}_2$
  - $\text{HgBr}_2$
  - $\text{CrCl}_2$
39. Give each ionic compound an appropriate name.
- SnO
  - $\text{Cr}_2\text{S}_3$
  - RbI
  - $\text{BaBr}_2$
40. Give each ionic compound an appropriate name.
- BaS
  - $\text{FeCl}_3$
  - $\text{PbI}_4$
  - $\text{SrBr}_2$
41. Name each ionic compound containing a polyatomic ion.
- $\text{CuNO}_2$
  - $\text{Mg}(\text{C}_2\text{H}_3\text{O}_2)_2$
  - $\text{Ba}(\text{NO}_3)_2$
  - $\text{Pb}(\text{C}_2\text{H}_3\text{O}_2)_2$
42. Name each ionic compound containing a polyatomic ion.
- $\text{Ba}(\text{OH})_2$
  - $\text{NH}_4\text{I}$
  - $\text{NaBrO}_4$
  - $\text{Fe}(\text{OH})_3$
43. Write the formula for each ionic compound.
- sodium hydrogen sulfite
  - lithium permanganate
  - silver nitrate
  - potassium sulfate
  - rubidium hydrogen sulfate
  - potassium hydrogen carbonate
44. Write the formula for each ionic compound.
- copper(II) chloride
  - copper(I) iodate
  - lead(II) chromate
  - calcium fluoride
  - potassium hydroxide
  - iron(II) phosphate
45. Write the name from the formula or the formula from the name for each hydrated ionic compound.
- $\text{CoSO}_4 \cdot 7 \text{H}_2\text{O}$
  - iridium(III) bromide tetrahydrate
  - $\text{Mg}(\text{BrO}_3)_2 \cdot 6 \text{H}_2\text{O}$
  - potassium carbonate dihydrate
46. Write the name from the formula or the formula from the name for each hydrated ionic compound.
- cobalt(II) phosphate octahydrate
  - $\text{BeCl}_2 \cdot 2 \text{H}_2\text{O}$
  - chromium(III) phosphate trihydrate
  - $\text{LiNO}_2 \cdot \text{H}_2\text{O}$

### Formulas and Names for Molecular Compounds and Acids

47. Name each molecular compound.
- CO
  - $\text{NI}_3$
  - $\text{SiCl}_4$
  - $\text{N}_4\text{Se}_4$
48. Name each molecular compound.
- $\text{SO}_3$
  - $\text{SO}_2$
  - $\text{BrF}_5$
  - NO

49. Write the formula for each molecular compound.
- phosphorus trichloride
  - chlorine monoxide
  - disulfur tetrafluoride
  - phosphorus pentafluoride
50. Write the formula for each molecular compound.
- boron tribromide
  - dichlorine monoxide
  - xenon tetrafluoride
  - carbon tetrabromide
51. Name each acid.
- $\text{HI}(\text{aq})$
  - $\text{HNO}_3(\text{aq})$
  - $\text{H}_2\text{CO}_3(\text{aq})$
52. Name each acid.
- $\text{HCl}(\text{aq})$
  - $\text{HClO}_2(\text{aq})$
  - $\text{H}_2\text{SO}_4(\text{aq})$
53. Write the formula for each acid.
- hydrofluoric acid
  - hydrobromic acid
  - sulfurous acid
54. Write the formula for each acid.
- phosphoric acid
  - hydrocyanic acid
  - chlorous acid

### Using the Nomenclature Flowchart

55. Refer to the nomenclature flowchart (Figure 3.11) to name each compound.
- $\text{SrCl}_2$
  - $\text{SnO}_2$
  - $\text{P}_2\text{S}_5$
  - $\text{HC}_2\text{H}_3\text{O}_2(\text{aq})$
56. Refer to the nomenclature flowchart (Figure 3.11) to name each compound.
- $\text{HNO}_2(\text{aq})$
  - $\text{B}_2\text{Cl}_2$
  - $\text{BaCl}_2$
  - $\text{CrCl}_3$
57. Refer to the nomenclature flowchart (Figure 3.11) to name each compound.
- $\text{KClO}_3$
  - $\text{I}_2\text{O}_5$
  - $\text{PbSO}_4$
58. Refer to the nomenclature flowchart (Figure 3.11) to name each compound.
- $\text{XeO}_3$
  - KClO
  - $\text{CoSO}_4$

### Formula Mass and the Mole Concept for Compounds

59. Calculate the formula mass for each compound.
- $\text{NO}_2$
  - $\text{C}_4\text{H}_{10}$
  - $\text{C}_6\text{H}_{12}\text{O}_6$
  - $\text{Cr}(\text{NO}_3)_3$
60. Calculate the formula mass for each compound.
- $\text{MgBr}_2$
  - $\text{HNO}_2$
  - $\text{CBr}_4$
  - $\text{Ca}(\text{NO}_3)_2$
61. Calculate the number of moles in each sample.
- 72.5 g  $\text{CCl}_4$
  - 12.4 g  $\text{C}_{12}\text{H}_{22}\text{O}_{11}$
  - 25.2 kg  $\text{C}_2\text{H}_2$
  - 12.3 g dinitrogen monoxide
62. Calculate the mass of each sample.
- 15.7 mol  $\text{HNO}_3$
  - $1.04 \times 10^{-3}$  mol  $\text{H}_2\text{O}_2$
  - 72.1 mmol  $\text{SO}_2$
  - 1.23 mol xenon difluoride
63. Determine the number of moles (of molecules or formula units) in each sample.
- 25.5 g  $\text{NO}_2$
  - 1.25 kg  $\text{CO}_2$
  - 38.2 g  $\text{KNO}_3$
  - 155.2 kg  $\text{Na}_2\text{SO}_4$
64. Determine the number of moles (of molecules or formula units) in each sample.
- 55.98 g  $\text{CF}_2\text{Cl}_2$
  - 23.6 kg  $\text{Fe}(\text{NO}_3)_2$
  - 0.1187 g  $\text{C}_8\text{H}_{18}$
  - 195 kg CaO
65. How many molecules are in each sample?
- 6.5 g  $\text{H}_2\text{O}$
  - 389 g  $\text{CBr}_4$
  - 22.1 g  $\text{O}_2$
  - 19.3 g  $\text{C}_8\text{H}_{10}$
66. How many molecules (or formula units) are in each sample?
- 85.26 g  $\text{CCl}_4$
  - 55.93 kg  $\text{NaHCO}_3$
  - 119.78 g  $\text{C}_4\text{H}_{10}$
  - $4.59 \times 10^5$  g  $\text{Na}_3\text{PO}_4$

67. Calculate the mass (in g) of each sample.
- $5.94 \times 10^{20}$   $\text{SO}_3$  molecules
  - $2.8 \times 10^{22}$   $\text{H}_2\text{O}$  molecules
  - 1 glucose molecule ( $\text{C}_6\text{H}_{12}\text{O}_6$ )
68. Calculate the mass (in g) of each sample.
- $4.5 \times 10^{25}$   $\text{O}_3$  molecules
  - $9.85 \times 10^{19}$   $\text{CCl}_2\text{F}_2$  molecules
  - 1 water molecule
69. A sugar crystal contains approximately  $1.8 \times 10^{17}$  sucrose ( $\text{C}_{12}\text{H}_{22}\text{O}_{11}$ ) molecules. What is its mass in mg?
70. A salt crystal has a mass of 0.12 mg. How many NaCl formula units does it contain?

### Composition of Compounds

71. Calculate the mass percent composition of carbon in each carbon-containing compound.
- $\text{CH}_4$
  - $\text{C}_2\text{H}_6$
  - $\text{C}_2\text{H}_2$
  - $\text{C}_2\text{H}_5\text{Cl}$
72. Calculate the mass percent composition of nitrogen in each nitrogen-containing compound.
- $\text{N}_2\text{O}$
  - $\text{NO}$
  - $\text{NO}_2$
  - $\text{HNO}_3$
73. Most fertilizers consist of nitrogen-containing compounds such as  $\text{NH}_3$ ,  $\text{CO}(\text{NH}_2)_2$ ,  $\text{NH}_4\text{NO}_3$ , and  $(\text{NH}_4)_2\text{SO}_4$ . Plants use the nitrogen content in these compounds for protein synthesis. Calculate the mass percent composition of nitrogen in each of the fertilizers listed. Which fertilizer has the highest nitrogen content?
74. Iron in the earth is in the form of iron ore. Common ores include  $\text{Fe}_2\text{O}_3$  (hematite),  $\text{Fe}_3\text{O}_4$  (magnetite), and  $\text{FeCO}_3$  (siderite). Calculate the mass percent composition of iron for each of these iron ores. Which ore has the highest iron content?
75. Copper(II) fluoride contains 37.42% F by mass. Calculate the mass of fluorine (in g) in 55.5 g of copper(II) fluoride.
76. Silver chloride, often used in silver plating, contains 75.27% Ag by mass. Calculate the mass of silver chloride required to plate 155 mg of pure silver.
77. The iodide ion is a dietary mineral essential to good nutrition. In countries where potassium iodide is added to salt, iodine deficiency (or goiter) has been almost completely eliminated. The recommended daily allowance (RDA) for iodine is  $150 \mu\text{g}/\text{day}$ . How much potassium iodide (76.45% I) should you consume if you want to meet the RDA?
78. The American Dental Association recommends that an adult female should consume 3.0 mg of fluoride ( $\text{F}^-$ ) per day to prevent tooth decay. If the fluoride is consumed in the form of sodium fluoride (45.24% F), what amount of sodium fluoride contains the recommended amount of fluoride?
79. Write a ratio showing the relationship between the molar amounts of each element for each compound. (See Appendix IIA for color codes.)

80. Write a ratio showing the relationship between the molar amounts of each element for each compound. (See Appendix IIA for color codes.)

81. Determine the number of moles of hydrogen atoms in each sample.
- 0.0885 mol  $\text{C}_4\text{H}_{10}$
  - 1.3 mol  $\text{CH}_4$
  - 2.4 mol  $\text{C}_6\text{H}_{12}$
  - 1.87 mol  $\text{C}_8\text{H}_{18}$
82. Determine the number of moles of oxygen atoms in each sample.
- 4.88 mol  $\text{H}_2\text{O}_2$
  - 2.15 mol  $\text{N}_2\text{O}$
  - 0.0237 mol  $\text{H}_2\text{CO}_3$
  - 24.1 mol  $\text{CO}_2$
83. Calculate mass (in grams) of sodium in 8.5 g of each sodium-containing food additive.
- NaCl (table salt)
  - $\text{Na}_3\text{PO}_4$  (sodium phosphate)
  - $\text{NaC}_7\text{H}_5\text{O}_2$  (sodium benzoate)
  - $\text{Na}_2\text{C}_6\text{H}_6\text{O}_7$  (sodium hydrogen citrate)
84. Calculate the mass (in kilograms) of chlorine in 25 kg of each chlorofluorocarbon (CFC).
- $\text{CF}_2\text{Cl}_2$
  - $\text{CFCl}_3$
  - $\text{C}_2\text{F}_3\text{Cl}_3$
  - $\text{CF}_3\text{Cl}$
85. How many fluorine atoms are present in 5.85 g of  $\text{C}_2\text{F}_4$ ?
86. How many bromine atoms are present in 35.2 g of  $\text{CH}_2\text{Br}_2$ ?

### Chemical Formulas from Experimental Data

87. A chemist decomposes samples of several compounds; the masses of their constituent elements are listed. Calculate the empirical formula for each compound.
- 1.651 g Ag, 0.1224 g O
  - 0.672 g Co, 0.569 g As, 0.486 g O
  - 1.443 g Se, 5.841 g Br
88. A chemist decomposes samples of several compounds; the masses of their constituent elements are listed. Calculate the empirical formula for each compound.
- 1.245 g Ni, 5.381 g I
  - 2.677 g Ba, 3.115 g Br
  - 2.128 g Be, 7.557 g S, 15.107 g O
89. Calculate the empirical formula for each stimulant based on its elemental mass percent composition.
- nicotine (found in tobacco leaves): C 74.03%, H 8.70%, N 17.27%
  - caffeine (found in coffee beans): C 49.48%, H 5.19%, N 28.85%, O 16.48%
90. Calculate the empirical formula for each natural flavor based on its elemental mass percent composition.
- methyl butyrate (component of apple taste and smell): C 58.80%, H 9.87%, O 31.33%
  - vanillin (responsible for the taste and smell of vanilla): C 63.15%, H 5.30%, O 31.55%
91. The elemental mass percent composition of ibuprofen (a nonsteroidal anti-inflammatory drug [NSAID]) is 75.69% C, 8.80% H, and 15.51% O. Determine the empirical formula of ibuprofen.
92. The elemental mass percent composition of ascorbic acid (vitamin C) is 40.92% C, 4.58% H, and 54.50% O. Determine the empirical formula of ascorbic acid.

93. A 0.77-mg sample of nitrogen reacts with chlorine to form 6.61 mg of the chloride. Determine the empirical formula of nitrogen chloride.
94. A 45.2-mg sample of phosphorus reacts with selenium to form 131.6 mg of the selenide. Determine the empirical formula of phosphorus selenide.
95. From the given empirical formula and molar mass, find the molecular formula of each compound.  
 a.  $C_6H_7N$ , 186.24 g/mol      b.  $C_2HCl$ , 181.44 g/mol  
 c.  $C_5H_{10}NS_2$ , 296.54 g/mol
96. From the given molar mass and empirical formula of several compounds, find the molecular formula of each compound.  
 a.  $C_4H_9$ , 114.22 g/mol      b.  $CCl_4$ , 284.77 g/mol  
 c.  $C_3H_2N$ , 312.29 g/mol
97. Combustion analysis of a hydrocarbon produces 33.01 g  $CO_2$  and 13.51 g  $H_2O$ . Calculate the empirical formula of the hydrocarbon.
98. Combustion analysis of naphthalene, a hydrocarbon used in mothballs, produces 8.80 g  $CO_2$  and 1.44 g  $H_2O$ . Calculate the empirical formula of naphthalene.
99. The foul odor of rancid butter is due largely to butyric acid, a compound containing carbon, hydrogen, and oxygen. Combustion analysis of a 4.30-g sample of butyric acid produces 8.59 g  $CO_2$  and 3.52 g  $H_2O$ . Determine the empirical formula of butyric acid.
100. Tartaric acid is the white, powdery substance that coats tart candies such as Sour Patch Kids. Combustion analysis of a 12.01-g sample of tartaric acid—which contains only carbon, hydrogen, and oxygen—produces 14.08 g  $CO_2$  and 4.32 g  $H_2O$ . Determine the empirical formula of tartaric acid.

### Writing and Balancing Chemical Equations

101. Sulfuric acid is a component of acid rain formed when gaseous sulfur dioxide pollutant reacts with gaseous oxygen and liquid water to form aqueous sulfuric acid. Write the balanced chemical equation for this reaction. (Note: this is a simplified representation of this reaction.)
102. Nitric acid is a component of acid rain that forms when gaseous nitrogen dioxide pollutant reacts with gaseous oxygen and liquid water to form aqueous nitric acid. Write the balanced chemical equation for this reaction. (Note: this is a simplified representation of this reaction.)
103. In a popular classroom demonstration, solid sodium is added to liquid water and reacts to produce hydrogen gas and aqueous sodium hydroxide. Write the balanced chemical equation for this reaction.
104. When iron rusts, solid iron reacts with gaseous oxygen to form solid iron(III) oxide. Write the balanced chemical equation for this reaction.
105. Write the balanced chemical equation for the fermentation of sucrose ( $C_{12}H_{22}O_{11}$ ) by yeasts in which the aqueous sugar reacts with water to form aqueous ethanol ( $C_2H_5OH$ ) and carbon dioxide gas.
106. Write the balanced equation for the photosynthesis reaction in which gaseous carbon dioxide and liquid water react in the presence of chlorophyll to produce aqueous glucose ( $C_6H_{12}O_6$ ) and oxygen gas.
107. Write the balanced chemical equation for each reaction.  
 a. Solid lead(II) sulfide reacts with aqueous hydrobromic acid to form solid lead(II) bromide and dihydrogen monosulfide gas.  
 b. Gaseous carbon monoxide reacts with hydrogen gas to form gaseous methane ( $CH_4$ ) and liquid water.  
 c. Aqueous hydrochloric acid reacts with solid manganese(IV) oxide to form aqueous manganese(II) chloride, liquid water, and chlorine gas.  
 d. Liquid pentane ( $C_5H_{12}$ ) reacts with gaseous oxygen to form carbon dioxide and liquid water.
108. Write the balanced chemical equation for each reaction.  
 a. Solid copper reacts with solid sulfur to form solid copper(I) sulfide.  
 b. Solid iron(III) oxide reacts with hydrogen gas to form solid iron and liquid water.  
 c. Sulfur dioxide gas reacts with oxygen gas to form sulfur trioxide gas.  
 d. Gaseous ammonia ( $NH_3$ ) reacts with gaseous oxygen to form gaseous nitrogen monoxide and gaseous water.
109. Write the balanced chemical equation for the reaction of aqueous sodium carbonate with aqueous copper(II) chloride to form solid copper(II) carbonate and aqueous sodium chloride.
110. Write the balanced chemical equation for the reaction of aqueous potassium hydroxide with aqueous iron(III) chloride to form solid iron(III) hydroxide and aqueous potassium chloride.
111. Balance each chemical equation.  
 a.  $CO_2(g) + CaSiO_3(s) + H_2O(l) \longrightarrow SiO_2(s) + Ca(HCO_3)_2(aq)$   
 b.  $Co(NO_3)_3(aq) + (NH_4)_2S(aq) \longrightarrow Co_2S_3(s) + NH_4NO_3(aq)$   
 c.  $Cu_2O(s) + C(s) \longrightarrow Cu(s) + CO(g)$   
 d.  $H_2(g) + Cl_2(g) \longrightarrow HCl(g)$
112. Balance each chemical equation.  
 a.  $Na_2S(aq) + Cu(NO_3)_2(aq) \longrightarrow NaNO_3(aq) + CuS(s)$   
 b.  $N_2H_4(l) \longrightarrow NH_3(g) + N_2(g)$   
 c.  $HCl(aq) + O_2(g) \longrightarrow H_2O(l) + Cl_2(g)$   
 d.  $FeS(s) + HCl(aq) \longrightarrow FeCl_2(aq) + H_2S(g)$

### Organic Compounds

113. Classify each compound as organic or inorganic.  
 a.  $CaCO_3$       b.  $C_4H_8$       c.  $C_4H_6O_6$       d.  $LiF$
114. Classify each compound as organic or inorganic.  
 a.  $C_8H_{18}$       b.  $CH_3NH_2$       c.  $CaO$       d.  $FeCO_3$
115. Classify each hydrocarbon as an alkane, alkene, or alkyne.  
 a.  $H_2C=CH-CH_3$   
 b.  $H_3C-CH_2-CH_3$   
 c.  $HC\equiv C-CH_3$   
 d.  $H_3C-CH_2-CH_2-CH_3$
116. Classify each hydrocarbon as an alkane, alkene, or alkyne.  
 a.  $HC\equiv CH$       b.  $H_3C-CH=CH-CH_3$   
 c.  $\begin{array}{c} CH_3 \\ | \\ H_3C-CH-CH_3 \end{array}$       d.  $H_3C-C\equiv C-CH_3$
117. Write the formula based on the name, or the name based on the formula, for each hydrocarbon.  
 a. propane      b.  $CH_3CH_2CH_3$   
 c. octane      d.  $CH_3CH_2CH_2CH_2CH_3$
118. Write the formula based on the name, or the name based on the formula, for each hydrocarbon.  
 a.  $CH_3CH_3$       b. pentane  
 c.  $CH_3CH_2CH_2CH_2CH_2CH_3$       d. heptane

**119.** Classify each organic compound as a hydrocarbon or a functionalized hydrocarbon. For functionalized hydrocarbons, identify the compound's family.

**120.** Classify each organic compound as a hydrocarbon or a functionalized hydrocarbon. For functionalized hydrocarbons, identify the compound's family.

## Cumulative Problems

**121.** How many molecules of ethanol ( $\text{C}_2\text{H}_5\text{OH}$ ) (the alcohol in alcoholic beverages) are present in 145 mL of ethanol? The density of ethanol is  $0.789 \text{ g/cm}^3$ .

**122.** A drop of water has a volume of approximately 0.05 mL. How many water molecules does it contain? The density of water is  $1.0 \text{ g/cm}^3$ .

**123.** Determine the chemical formula of each compound and then use it to calculate the mass percent composition of each constituent element.

**124.** Determine the chemical formula of each compound and then use it to calculate the mass percent composition of each constituent element.

**125.** A Freon leak in the air-conditioning system of an old car releases 25 g of  $\text{CF}_2\text{Cl}_2$  per month. What mass of chlorine does this car emit into the atmosphere each year?

**126.** A Freon leak in the air-conditioning system of a large building releases 12 kg of  $\text{CHF}_2\text{Cl}$  per month. If the leak is allowed to continue, how many kilograms of Cl will be emitted into the atmosphere each year?

**127.** A metal (M) forms a compound with the formula  $\text{MCl}_3$ . If the compound contains 65.57% Cl by mass, what is the identity of the metal?

**128.** A metal (M) forms an oxide with the formula  $\text{M}_2\text{O}$ . If the oxide contains 16.99% O by mass, what is the identity of the metal?

**129.** Estradiol is a female sexual hormone that is responsible for the maturation and maintenance of the female reproductive system. Elemental analysis of estradiol gives the following mass percent composition: C 79.37%, H 8.88%, O 11.75%. The molar mass of estradiol is  $272.37 \text{ g/mol}$ . Find the molecular formula of estradiol.

**130.** Fructose is a common sugar found in fruit. Elemental analysis of fructose gives the following mass percent composition: C 40.00%, H 6.72%, O 53.28%. The molar mass of fructose is  $180.16 \text{ g/mol}$ . Find the molecular formula of fructose.

**131.** Combustion analysis of a 13.42-g sample of equilin (which contains only carbon, hydrogen, and oxygen) produces 39.61 g  $\text{CO}_2$  and 9.01 g  $\text{H}_2\text{O}$ . The molar mass of equilin is  $268.34 \text{ g/mol}$ . Find its molecular formula.

**132.** Estrone, which contains only carbon, hydrogen, and oxygen, is a female sexual hormone in the urine of pregnant women.

Combustion analysis of a 1.893-g sample of estrone produces 5.545 g of  $\text{CO}_2$  and 1.388 g  $\text{H}_2\text{O}$ . The molar mass of estrone is  $270.36 \text{ g/mol}$ . Find its molecular formula.

**133.** Epsom salts is a hydrated ionic compound with the following formula:  $\text{MgSO}_4 \cdot x \text{H}_2\text{O}$ . A 4.93-g sample of Epsom salts is heated to drive off the water of hydration. The mass of the sample after complete dehydration is 2.41 g. Find the number of waters of hydration (x) in Epsom salts.

**134.** A hydrate of copper(II) chloride has the following formula:  $\text{CuCl}_2 \cdot x \text{H}_2\text{O}$ . The water in a 3.41-g sample of the hydrate is driven off by heating. The remaining sample has a mass of 2.69 g. Find the number of waters of hydration (x) in the hydrate.

**135.** A compound of molar mass  $177 \text{ g/mol}$  contains only carbon, hydrogen, bromine, and oxygen. Analysis reveals that the compound contains eight times as much carbon as hydrogen by mass. Find the molecular formula.

**136.** Researchers obtained the following data from experiments to find the molecular formula of benzocaine, a local anesthetic, which contains only carbon, hydrogen, nitrogen, and oxygen. Complete combustion of a 3.54-g sample of benzocaine with excess  $\text{O}_2$  forms 8.49 g of  $\text{CO}_2$  and 2.14 g  $\text{H}_2\text{O}$ . Another 2.35-g sample contains 0.199 g of N. The molar mass of benzocaine is  $165 \text{ g/mol}$ . Find the molar formula of benzocaine.

**137.** Find the total number of atoms in a sample of cocaine hydrochloride,  $\text{C}_{17}\text{H}_{22}\text{ClNO}_4$ , of mass 23.5 mg.

**138.** Vanadium forms four different oxides in which the percent by mass of vanadium is, respectively, (a) 76%, (b) 68%, (c) 61%, and (d) 56%. Determine the formula and the name of each oxide.

**139.** The chloride of an unknown metal is believed to have the formula  $\text{MCl}_3$ . A 2.395-g sample of the compound contains  $3.606 \times 10^{-2} \text{ mol Cl}$ . Find the atomic mass of M.

**140.** Write the structural formulas of three different compounds that each have the molecular formula  $\text{C}_5\text{H}_{12}$ .

**141.** A chromium-containing compound has the formula  $\text{Fe}_x\text{Cr}_y\text{O}_4$  and is 28.59% oxygen by mass. Find x and y.

**142.** A phosphorus compound that contains 34.00% phosphorus by mass has the formula  $\text{X}_3\text{P}_2$ . Identify the element X.

**143.** A particular brand of beef jerky contains 0.0552% sodium nitrite by mass and is sold in an 8.00-oz bag. What mass of sodium does the sodium nitrite contribute to the sodium content of the bag of beef jerky?

**144.** Phosphorus is obtained primarily from ores containing calcium phosphate. If a particular ore contains 57.8% calcium phosphate, what minimum mass of the ore must be processed to obtain 1.00 kg of phosphorus?

## Challenge Problems

- 145.** A mixture of NaCl and NaBr has a mass of 2.00 g and contains 0.75 g of Na. What is the mass of NaBr in the mixture?
- 146.** Three pure compounds form when 1.00-g samples of element X combine with, respectively, 0.472 g, 0.630 g, and 0.789 g of element Z. The first compound has the formula  $X_2Z_3$ . Find the empirical formulas of the other two compounds.
- 147.** A mixture of  $\text{CaCO}_3$  and  $(\text{NH}_4)_2\text{CO}_3$  is 61.9%  $\text{CO}_3$  by mass. Find the mass percent of  $\text{CaCO}_3$  in the mixture.
- 148.** A mixture of 50.0 g of S and  $1.00 \times 10^2$  g of  $\text{Cl}_2$  reacts completely to form  $\text{S}_2\text{Cl}_2$  and  $\text{SCl}_2$ . Find the mass of  $\text{S}_2\text{Cl}_2$  formed.
- 149.** Because of increasing evidence of damage to the ozone layer, chlorofluorocarbon (CFC) production was banned in 1996. However, many older cars still have air conditioners that use CFC-12 ( $\text{CF}_2\text{Cl}_2$ ). These air conditioners are recharged from stockpiled supplies of CFC-12. Suppose that 100 million automobiles each contain 1.1 kg of CFC-12 and leak 25% of their CFC-12 into the atmosphere per year. How much chlorine, in kg, is added to the atmosphere each year due to these air conditioners? (Assume two significant figures in your calculations.)
- 150.** A particular coal contains 2.55% sulfur by mass. When the coal is burned, it produces  $\text{SO}_2$  emissions, which combine with rainwater to produce sulfuric acid. Use the formula of sulfuric acid to calculate the mass percent of S in sulfuric acid. Then determine how much sulfuric acid (in metric tons) is produced by the combustion of 1.0 metric ton of this coal. (A metric ton is 1000 kg.)
- 151.** Lead is found in Earth's crust as several different lead ores. Suppose a certain rock is 38.0% PbS (galena), 25.0%  $\text{PbCO}_3$  (cerussite), and 17.4%  $\text{PbSO}_4$  (anglesite). The remainder of the rock is composed of substances containing no lead. How much of this rock (in kg) must be processed to obtain 5.0 metric tons of lead? (A metric ton is 1000 kg.)
- 152.** A 2.52-g sample of a compound containing only carbon, hydrogen, nitrogen, oxygen, and sulfur is burned in excess oxygen to yield 4.23 g of  $\text{CO}_2$  and 1.01 g of  $\text{H}_2\text{O}$ . Another sample of the same compound, of mass 4.14 g, yields 2.11 g of  $\text{SO}_3$ . A third sample, of mass 5.66 g, yields 2.27 g of  $\text{HNO}_3$ . Calculate the empirical formula of the compound.
- 153.** A compound of molar mass 229 g/mol contains only carbon, hydrogen, iodine, and sulfur. Analysis shows that a sample of the compound contains six times as much carbon as hydrogen, by mass. Calculate the molecular formula of the compound.
- 154.** The elements X and Y form a compound that is 40% X and 60% Y by mass. The atomic mass of X is twice that of Y. What is the empirical formula of the compound?
- 155.** A compound of X and Y is  $\frac{1}{3}$  X by mass. The atomic mass of element X is  $\frac{1}{3}$  the atomic mass of element Y. Find the empirical formula of the compound.
- 156.** A mixture of carbon and sulfur has a mass of 9.0 g. Complete combustion with excess  $\text{O}_2$  gives 23.3 g of a mixture of  $\text{CO}_2$  and  $\text{SO}_2$ . Find the mass of sulfur in the original mixture.

## Conceptual Problems

- 157.** When molecules are represented by molecular models, what does each sphere represent? How big is the nucleus of an atom in comparison to the sphere used to represent an atom in a molecular model?
- 158.** Without doing any calculations, determine which element in each compound has the highest mass percent composition.
- |  |                         |
|--|-------------------------|
| a. CO                                  | b. $\text{N}_2\text{O}$ |
| c. $\text{C}_6\text{H}_{12}\text{O}_6$ | d. $\text{NH}_3$        |
- 159.** Explain the problem with the following statement and correct it: "The chemical formula for ammonia ( $\text{NH}_3$ ) indicates that ammonia contains three grams of hydrogen for each gram of nitrogen."
- 160.** Explain the problem with the following statement and correct it: "When a chemical equation is balanced, the number of molecules of each type on both sides of the equation is equal."
- 161.** Without doing any calculations, arrange the elements in  $\text{H}_2\text{SO}_4$  in order of decreasing mass percent composition.
- 162.** Element A is an atomic element, and element B is a diatomic molecular element. Using circles to represent atoms of A and squares to represent atoms of B, draw molecular-level views of each element.

### Active Classroom Learning

## Questions for Group Work

Discuss these questions with the group and record your consensus answer.

- 163.** With group members playing the roles of nuclei and electrons, demonstrate the formation of an ionic bond between Na and Cl. Demonstrate the formation of the covalent bonds in  $\text{H}_2\text{O}$ .
- 164.** Create a flowchart with a series of simple questions that can be used to determine whether a chemical formula is that of an atomic element, a molecular element, a molecular compound, or an ionic compound. Use your flowchart to identify the correct category for  $\text{P}_4$ , KCl,  $\text{CH}_4$ , Ne, and  $\text{NH}_4\text{NO}_3$ .
- 165.** Have each member of your group list one similarity or difference between the naming conventions for ionic and molecular compounds.
- 166.** A compound isolated from the rind of lemons is found to be 88.14% carbon and 11.86% hydrogen by mass. How many grams of C and H are there in a 100.0-g sample of this substance? How many moles of C and H? What is the empirical formula? The molar mass is determined to be 136.26 g/mol. What is the molecular formula? Which step of the process just described does your group understand the least? Which step will be hardest for the members of your group to remember?
- 167.** Octane ( $\text{C}_8\text{H}_{18}$ ), a component of gasoline, reacts with oxygen to form carbon dioxide and water. Write the balanced chemical reaction for this process by passing a single piece of paper around your group, having each group member complete the next logical step. As you each complete your step, explain your reasoning to the group.

## Data Interpretation and Analysis

### Carbon and Fossil Fuel Consumption

- 168.** Since the 1800s, the concentration of carbon dioxide in Earth's atmosphere has been increasing (Figure a▼). The scientific consensus is that the increase in  $\text{CO}_2$  is due to fossil fuel combustion.

**▲ FIGURE a Carbon Dioxide Concentration in the Atmosphere**

Use the information provided in the figure to answer the following questions (Note that  $1 \text{ ppmv} = 1 \text{ gas volume}/1 \times 10^6 \text{ air volumes} = 1 \mu\text{L gas}/1 \text{ L air}$ ):

- Globally, in 2010 and 2012, respectively, there were about 9.20 billion metric tons and 9.60 billion metric tons of carbon in Earth's atmosphere.
    - Determine the increase in carbon in the atmosphere in units of metric tons between 2010 and 2012.
    - Determine the increase of carbon dioxide in the atmosphere in units of metric tons between 2010 and 2012.
- Figure a lists the concentration of  $\text{CO}_2$  in air in terms of parts per million by volume (ppmv).
    - Compare the volume (in mL) of  $\text{CO}_2$  in  $1.00 \text{ m}^3$  of air in 1880 to the volume (in mL) of  $\text{CO}_2$  in  $1.00 \text{ m}^3$  of air in 2014.
    - Determine the increase in volume (in mL) of  $\text{CO}_2$  in  $1.00 \text{ m}^3$  of air between 1880 and 2014.
    - What is the percent increase of  $\text{CO}_2$  in  $1.00 \text{ m}^3$  of air between 1880 and 2014?
    - Assuming that the total volume of air in the atmosphere around Earth is  $5.1 \times 10^9 \text{ km}^3$  and that the concentration of  $\text{CO}_2$  is uniform throughout the atmosphere, estimate the volume of  $\text{CO}_2$  in the atmosphere in 2014 in units of  $\text{km}^3$ .
  - Based on the information in Figure a, determine the average yearly increase in the concentration of  $\text{CO}_2$  in the atmosphere for the period 1960 to 2014. Estimate the concentration of  $\text{CO}_2$  in the atmosphere, in units of ppmv, in 2030.

## Answers to Conceptual Connections

### Types of Chemical Bonds

- 3.1** The bond is covalent because it is forming between two non-metals.

### Structural Formulas

- 3.2**  $\text{H}-\text{O}-\text{H}$

### Representing Molecules

- 3.3** The spheres represent the electron cloud of the atom. It would be nearly impossible to draw a nucleus to scale on any of the space-filling molecular models in this book—the nucleus would be too small to see.

### A Molecular View of Elements and Compounds

**3.4**

### Ionic and Molecular Compounds

- 3.5** Choice **(a)** best describes the difference between ionic and molecular compounds. Answer **(b)** is incorrect because there are no “new” forces in bonding (just rearrangements that result in lower potential energy) and because ions do not group together in pairs in the solid phase. Answer **(c)** is incorrect because the main difference between ionic and molecular compounds is the way that the atoms bond. Answer **(d)** is incorrect because ionic compounds do not contain molecules.

### Nomenclature

- 3.6** This conceptual connection addresses one of the main errors you can make in nomenclature: the failure to correctly categorize the compound. Remember that you must first determine whether the compound is an ionic compound, a molecular compound, or an acid, and then you must name it accordingly.  $\text{NCl}_3$  is a molecular compound (two or more nonmetals), and therefore in its name prefixes indicate the number of each type of atom—so  $\text{NCl}_3$  is nitrogen trichloride. The compound  $\text{AlCl}_3$ , however, is an ionic compound (metal and nonmetal), and therefore does not require prefixes—so  $\text{AlCl}_3$  is aluminum chloride.

### Molecular Models and the Size of Molecules

- 3.7** **(c)** Atomic radii range in the hundreds of picometers, while the spheres in these models have radii of about a centimeter. The scaling factor is therefore about  $10^8$  (100 million).

### Chemical Formula and Mass Percent Composition

- 3.8**  $\text{C} > \text{O} > \text{H}$  Since carbon and oxygen differ in atomic mass by only 4 amu, and since there are six carbon atoms in the formula, we can conclude that carbon constitutes the greatest fraction of the mass. Oxygen is next because its mass is 16 times that of hydrogen and there are only six hydrogen atoms for every one oxygen atom.

### Chemical Formulas and Elemental Composition

- 3.9** **(c)** The chemical formula for a compound gives relationships between *atoms* or *moles of atoms*. The chemical formula for water states that water molecules contain two H atoms to every one O atom or 2 mol H to every 1 mol  $\text{H}_2\text{O}$ . This *does not* imply a two-to-one relationship between *masses* of hydrogen and oxygen because these atoms have different masses. It also does not imply a two-to-one relationship between volumes.

### Balanced Chemical Equations

- 3.10** Both **(a)** and **(d)** are correct. When the number of atoms of each type is balanced, the sum of the masses of the substances will be the same on both sides of the equation. Since molecules change during a chemical reaction, the number of molecules is not the same on both sides, nor is the number of moles necessarily the same.

# Chemical Quantities and Aqueous Reactions

I feel sorry for people who don't know anything about chemistry. They are missing an important source of happiness.

**KEY LEARNING OUTCOMES 185**

The amount of product formed in a chemical reaction is related to the amount of reactant that reacts. This concept makes sense intuitively, but how can we describe and understand this relationship more fully? The first half of this chapter focuses on chemical stoichiometry—the numerical relationships between the amounts of reactants and products in chemical reactions. In Chapter 3, you learned how to write balanced chemical equations for chemical reactions. Here we examine more closely the meaning of those balanced equations. In the second half of this chapter, we turn to describing chemical reactions that occur in water. You have probably witnessed many of these types of reactions in your daily life because they are so common. Have you ever mixed baking soda with vinegar and observed the subsequent bubbling or noticed the hard water deposits that form on plumbing fixtures? These reactions—and many others, including those that occur within the watery environment of living cells—are aqueous chemical reactions, the subject of the second half of this chapter.

▲ The molecular models on this balance represent the reactants and products in the combustion of octane, a component of petroleum. One of the products, carbon dioxide, is the main greenhouse gas implicated in global climate change.

## 4.1 Climate Change and the Combustion of Fossil Fuels

The temperature outside my office today is a cool 48°F, lower than normal for this time of year on the California coast. However, today's "chill" pales in comparison with how cold it would be without the presence of *greenhouse gases* in the atmosphere.

► **FIGURE 4.1** The Greenhouse

**Effect** Greenhouse gases in the atmosphere act as a one-way filter. They allow visible light to pass through and warm Earth's surface, but they prevent heat energy from radiating back out into space.

**The Greenhouse Effect**

These gases act like the glass of a greenhouse, allowing sunlight to enter the atmosphere and warm Earth's surface but preventing some of the heat generated by the sunlight from escaping, as shown in Figure 4.1▲. The balance between incoming and outgoing energy from the sun determines Earth's average temperature.

If the greenhouse gases in the atmosphere were not present, more heat energy would escape, and Earth's average temperature would be about 60°F colder than it currently is. The temperature outside of my office today would be below 0°F, and even the sunniest U.S. cities would most likely be covered with snow. However, if the concentration of greenhouse gases in the atmosphere were to increase, Earth's average temperature would rise.

In recent decades scientists have become increasingly concerned because the quantity of atmospheric carbon dioxide (CO<sub>2</sub>)—Earth's most significant greenhouse gas—is rising. More CO<sub>2</sub> enhances the atmosphere's ability to hold heat and is believed to lead to *global warming*, an increase in Earth's average temperature. Since 1860, atmospheric CO<sub>2</sub> levels have risen by 38% (Figure 4.2▼), and Earth's average temperature has risen by about 1.2°F (0.7°C) (as shown in Figure 4.3▼).

Most scientists believe that the primary cause of rising atmospheric CO<sub>2</sub> concentration is the burning of fossil fuels (natural gas, petroleum, and coal), which provides 90% of our society's energy. Some people, however, have suggested that fossil fuel combustion does not significantly contribute to global warming and climate change. They argue that the amount of carbon dioxide emitted into the atmosphere by natural sources, such as volcanic eruptions, far exceeds that from fossil fuel combustion. Which group is right? One way to judge the validity of the naysayers' argument is by calculating how much carbon dioxide is emitted by fossil fuel combustion and comparing that amount to the amount released by volcanic eruptions.

The extremely cold temperatures of Mars are as much a result of its lack of atmosphere as its greater distance from the sun than Earth. Conversely, Venus is an inferno partly because its thick atmosphere is rich in greenhouse gases.

**Atmospheric Carbon Dioxide**

▲ **FIGURE 4.2** Carbon Dioxide Concentrations in the Atmosphere The rise in carbon dioxide levels is due largely to fossil fuel combustion.

**Global Temperature**

▲ **FIGURE 4.3** Global Temperature Average temperatures worldwide have risen by about 0.7°C since 1880.

## 4.2 Reaction Stoichiometry: How Much Carbon Dioxide?

### Reaction Stoichiometry

The balanced chemical equations for fossil fuel combustion reactions provide the exact relationships between the amount of fossil fuel burned and the amount of carbon dioxide emitted. In this discussion, we use octane (a component of gasoline) as a representative fossil fuel. The balanced equation for the combustion of octane is:

The balanced equation shows that 16  $\text{CO}_2$  molecules are produced for every two molecules of octane burned. We can extend this numerical relationship between molecules to the amounts in moles as follows:

**The coefficients in a chemical equation specify the relative amounts in moles of each of the substances involved in the reaction.**

In other words, from the equation, we know that 16 *moles* of  $\text{CO}_2$  are produced for every two *moles* of octane burned. The numerical relationships between chemical amounts in a balanced chemical equation are called reaction **stoichiometry**. Stoichiometry allows us to predict the amounts of products that will form in a chemical reaction based on the amounts of reactants that react. Stoichiometry also allows us to determine the amount of reactants necessary to form a given amount of product. These calculations are central to chemistry, allowing chemists to plan and carry out chemical reactions to obtain products in the desired quantities.

Stoichiometry is pronounced stoy-kee-AHM-e-tree.

### Making Pizza: The Relationships among Ingredients

The concepts of stoichiometry are similar to a cooking recipe. Calculating the amount of carbon dioxide produced by the combustion of a given amount of a fossil fuel is analogous to calculating the number of pizzas that can be made from a given amount of cheese. For example, suppose we use the following pizza recipe:

The recipe contains the numerical relationships between the pizza ingredients. It says that if we have two cups of cheese—and enough of everything else—we can make one pizza. We can write this relationship as a ratio between the cheese and the pizza:

$$2 \text{ cups cheese} : 1 \text{ pizza}$$

What if we have six cups of cheese? Assuming that we have enough of everything else, we can use the ratio as a conversion factor to calculate the number of pizzas:

$$6 \text{ cups cheese} \times \frac{1 \text{ pizza}}{2 \text{ cups cheese}} = 3 \text{ pizzas}$$

Six cups of cheese are sufficient to make three pizzas. The pizza recipe contains numerical ratios between other ingredients as well, including the crust and the tomato sauce:

$$1 \text{ crust} : 1 \text{ pizza}$$

$$5 \text{ ounces tomato sauce} : 1 \text{ pizza}$$

### Making Molecules: Mole-to-Mole Conversions

In a balanced chemical equation, we have a “recipe” for how reactants combine to form products. From our balanced equation for the combustion of octane, for example, we can write the following stoichiometric ratio:

$$2 \text{ mol C}_8\text{H}_{18} : 16 \text{ mol CO}_2$$

We can use this ratio to determine how many moles of  $\text{CO}_2$  form when a given number of moles of  $\text{C}_8\text{H}_{18}$  burns. Suppose that we burn 22.0 moles of  $\text{C}_8\text{H}_{18}$ ; how many moles of

CO<sub>2</sub> form? We use the ratio from the balanced chemical equation in the same way that we used the ratio from the pizza recipe. The ratio acts as a conversion factor between the amount in moles of the reactant (C<sub>8</sub>H<sub>18</sub>) and the amount in moles of the product (CO<sub>2</sub>):

$$22.0 \text{ mol C}_8\text{H}_{18} \times \frac{16 \text{ mol CO}_2}{2 \text{ mol C}_8\text{H}_{18}} = 176 \text{ mol CO}_2$$

The combustion of 22.0 moles of C<sub>8</sub>H<sub>18</sub> adds 176 moles of CO<sub>2</sub> to the atmosphere.

## Making Molecules: Mass-to-Mass Conversions

According to the U.S. Department of Energy, the world burned  $3.3 \times 10^{10}$  barrels of petroleum in 2013, the equivalent of approximately  $3.7 \times 10^{15}$  g of gasoline. We can estimate the mass of CO<sub>2</sub> emitted into the atmosphere from burning this much gasoline using the combustion of  $3.7 \times 10^{15}$  g octane as the representative reaction. This calculation is similar to the one we just did, except that we are now given the *mass* of octane instead of the *amount* of octane in moles. Consequently, we must first convert the mass (in grams) to the amount (in moles). The general conceptual plan for calculations in which we are given the mass of a reactant or product in a chemical reaction and asked to find the mass of a different reactant or product takes the form:

where A and B are two different substances involved in the reaction.

We use the molar mass of A to convert from the mass of A to the amount of A (in moles). We use the appropriate ratio from the balanced chemical equation to convert from the amount of A (in moles) to the amount of B (in moles). And finally, we use the molar mass of B to convert from the amount of B (in moles) to the mass of B. To calculate the mass of CO<sub>2</sub> emitted upon the combustion of  $3.7 \times 10^{15}$  g of octane, we use the following conceptual plan:

### Conceptual Plan

### Relationships Used

2 mol C<sub>8</sub>H<sub>18</sub> : 16 mol CO<sub>2</sub> (from the chemical equation)

molar mass C<sub>8</sub>H<sub>18</sub> = 114.22 g/mol

molar mass CO<sub>2</sub> = 44.01 g/mol

### Solution

We follow the conceptual plan to solve the problem, beginning with g C<sub>8</sub>H<sub>18</sub> and canceling units to arrive at g CO<sub>2</sub>:

$$3.7 \times 10^{15} \text{ g C}_8\text{H}_{18} \times \frac{1 \text{ mol C}_8\text{H}_{18}}{114.22 \text{ g C}_8\text{H}_{18}} \times \frac{16 \text{ mol CO}_2}{2 \text{ mol C}_8\text{H}_{18}} \times \frac{44.01 \text{ g CO}_2}{1 \text{ mol CO}_2} = 1.1 \times 10^{16} \text{ g CO}_2$$

The world's petroleum combustion produces  $1.1 \times 10^{16}$  g CO<sub>2</sub> ( $1.1 \times 10^{13}$  kg) per year. In comparison, volcanoes produce about  $2 \times 10^{11}$  kg CO<sub>2</sub> per year.\* In other

words, volcanoes emit only  $\frac{2 \times 10^{11} \text{ kg}}{1.1 \times 10^{13} \text{ kg}} \times 100\% = 1.8\%$  as much CO<sub>2</sub> per year as

The percentage of CO<sub>2</sub> emitted by volcanoes relative to all fossil fuels is even less than 1.8% because the combustion of coal and natural gas also emits CO<sub>2</sub>.

\*Gerlach, T. M., Present-day CO<sub>2</sub> emissions from volcanoes. *Eos, Transactions, American Geophysical Union*. **1991** 72, 249, 254–255.

petroleum combustion. The argument that volcanoes emit more carbon dioxide than fossil fuel combustion is clearly mistaken. Examples 4.1 and 4.2 provide additional practice with stoichiometric calculations.

### Example 4.1 Stoichiometry

During photosynthesis, plants convert carbon dioxide and water into glucose ( $\text{C}_6\text{H}_{12}\text{O}_6$ ) according to the reaction:

Suppose that a particular plant consumes 37.8 g of  $\text{CO}_2$  in one week. Assuming that there is more than enough water present to react with all of the  $\text{CO}_2$ , what mass of glucose (in grams) can the plant synthesize from the  $\text{CO}_2$ ?

**SORT** The problem provides the mass of carbon dioxide and asks you to find the mass of glucose that can be produced.

**GIVEN:** 37.8 g  $\text{CO}_2$

**FIND:** g  $\text{C}_6\text{H}_{12}\text{O}_6$

**STRATEGIZE** The conceptual plan follows the general pattern of mass A  $\rightarrow$  amount A (in moles)  $\rightarrow$  amount B (in moles)  $\rightarrow$  mass B. From the chemical equation, deduce the relationship between moles of carbon dioxide and moles of glucose. Use the molar masses to convert between grams and moles.

#### CONCEPTUAL PLAN

#### RELATIONSHIPS USED

molar mass  $\text{CO}_2 = 44.01 \text{ g/mol}$

$6 \text{ mol CO}_2 : 1 \text{ mol C}_6\text{H}_{12}\text{O}_6$

molar mass  $\text{C}_6\text{H}_{12}\text{O}_6 = 180.2 \text{ g/mol}$

**SOLVE** Follow the conceptual plan to solve the problem. Begin with g  $\text{CO}_2$  and use the conversion factors to arrive at g  $\text{C}_6\text{H}_{12}\text{O}_6$ .

#### SOLUTION

$$37.8 \text{ g CO}_2 \times \frac{1 \text{ mol CO}_2}{44.01 \text{ g CO}_2} \times \frac{1 \text{ mol C}_6\text{H}_{12}\text{O}_6}{6 \text{ mol CO}_2} \times \frac{180.2 \text{ g C}_6\text{H}_{12}\text{O}_6}{1 \text{ mol C}_6\text{H}_{12}\text{O}_6} = 25.8 \text{ g C}_6\text{H}_{12}\text{O}_6$$

**CHECK** The units of the answer are correct. The magnitude of the answer (25.8 g) is less than the initial mass of  $\text{CO}_2$  (37.8 g). This is reasonable because each carbon in  $\text{CO}_2$  has two oxygen atoms associated with it, while in  $\text{C}_6\text{H}_{12}\text{O}_6$  each carbon has only one oxygen atom associated with it and two hydrogen atoms, which are much lighter than oxygen. Therefore, the mass of glucose produced should be less than the mass of carbon dioxide for this reaction.

**FOR PRACTICE 4.1** Magnesium hydroxide, the active ingredient in milk of magnesia, neutralizes stomach acid, primarily HCl, according to the reaction:

What mass of HCl, in grams, is neutralized by a dose of milk of magnesia containing 3.26 g  $\text{Mg}(\text{OH})_2$ ?

### Example 4.2 Stoichiometry

Sulfuric acid ( $\text{H}_2\text{SO}_4$ ) is a component of acid rain that forms when  $\text{SO}_2$ , a pollutant, reacts with oxygen and water according to the simplified reaction:

The generation of the electricity used by a medium-sized home produces about 25 kg of  $\text{SO}_2$  per year. Assuming that there is more than enough  $\text{O}_2$  and  $\text{H}_2\text{O}$ , what mass of  $\text{H}_2\text{SO}_4$ , in kg, can form from this much  $\text{SO}_2$ ?

—Continued on the next page

—Continued

<b>SORT</b> The problem gives the mass of sulfur dioxide and asks you to find the mass of sulfuric acid.	<b>GIVEN:</b> 25 kg SO <sub>2</sub> <b>FIND:</b> kg H <sub>2</sub> SO <sub>4</sub>
<b>STRATEGIZE</b> The conceptual plan follows the standard format of mass → amount (in moles) → amount (in moles) → mass. Since the original quantity of SO <sub>2</sub> is given in kilograms, you must first convert to grams. You can deduce the relationship between moles of sulfur dioxide and moles of sulfuric acid from the chemical equation. Since the final quantity is requested in kilograms, convert to kilograms at the end.	<b>CONCEPTUAL PLAN</b>  <b>RELATIONSHIPS USED</b> 1 kg = 1000 g molar mass SO <sub>2</sub> = 64.07 g/mol 2 mol SO <sub>2</sub> : 2 mol H <sub>2</sub> SO <sub>4</sub> molar mass H <sub>2</sub> SO <sub>4</sub> = 98.09 g/mol
<b>SOLVE</b> Follow the conceptual plan to solve the problem. Begin with the given amount of SO <sub>2</sub> in kilograms and use the conversion factors to arrive at kg H <sub>2</sub> SO <sub>4</sub> .	<b>SOLUTION</b> $25 \text{ kg SO}_2 \times \frac{1000 \text{ g}}{1 \text{ kg}} \times \frac{1 \text{ mol SO}_2}{64.07 \text{ g SO}_2} \times \frac{2 \text{ mol H}_2\text{SO}_4}{2 \text{ mol SO}_2} \times \frac{98.09 \text{ g H}_2\text{SO}_4}{1 \text{ mol H}_2\text{SO}_4} \times \frac{1 \text{ kg}}{1000 \text{ g}} = 38 \text{ kg H}_2\text{SO}_4$
<b>CHECK</b> The units of the final answer are correct. The magnitude of the final answer (38 kg H <sub>2</sub> SO <sub>4</sub> ) is larger than the amount of SO <sub>2</sub> given (25 kg). This is reasonable because in the reaction each SO <sub>2</sub> molecule “gains weight” by reacting with O <sub>2</sub> and H <sub>2</sub> O.	

**FOR PRACTICE 4.2** Another component of acid rain is nitric acid, which forms when NO<sub>2</sub>, also a pollutant, reacts with oxygen and water according to the simplified equation:

The generation of the electricity used by a medium-sized home produces about 16 kg of NO<sub>2</sub> per year. Assuming that there is adequate O<sub>2</sub> and H<sub>2</sub>O, what mass of HNO<sub>3</sub>, in kg, can form from this amount of NO<sub>2</sub> pollutant?

### CONCEPTUAL CONNECTION 4.1

**Stoichiometry** Under certain conditions sodium reacts with oxygen to form sodium oxide according to the reaction:

A flask contains the amount of oxygen represented by the diagram shown at left.

Which image below best represents the amount of sodium required to completely react with all of the oxygen in the flask according to the equation?

(a)

(b)

(c)

(d)

**Stoichiometry II** Consider the generic chemical equation  $A + 3B \rightarrow 2C$ . Let circles represent molecules of A, squares represent molecules of B, and triangles represent molecules of C. If the diagram shown here represents the amount of B available for reaction, draw similar diagrams showing (a) the amount of A necessary to completely react with B, and (b) the amount of C that forms if B completely reacts.

CONCEPTUAL  
CONNECTION 4.2

## 4.3 Limiting Reactant, Theoretical Yield, and Percent Yield

Limiting Reactant, Theoretical Yield, and Percent Yield

Let's return to our pizza analogy to understand three more important concepts in reaction stoichiometry: *limiting reactant*, *theoretical yield*, and *percent yield*. Recall our pizza recipe from Section 4.2:

Suppose that we have four crusts, ten cups of cheese, and 15 ounces of tomato sauce. How many pizzas can we make?

**We have enough crusts to make:**

$$4 \text{ crusts} \times \frac{1 \text{ pizza}}{1 \text{ crust}} = 4 \text{ pizzas}$$

**We have enough cheese to make:**

$$10 \text{ cups cheese} \times \frac{1 \text{ pizza}}{2 \text{ cups cheese}} = 5 \text{ pizzas}$$

**We have enough tomato sauce to make:**

$$15 \text{ ounces tomato sauce} \times \frac{1 \text{ pizza}}{5 \text{ ounces tomato sauce}} = 3 \text{ pizzas}$$

Limiting reactant

Smallest number of pizzas

We have enough crusts for four pizzas and enough cheese for five pizzas, but enough tomato sauce for only three pizzas. Consequently, unless we get more ingredients, we can make only three pizzas. The tomato sauce *limits* how many pizzas we can make. If the pizza recipe were a chemical reaction, the tomato sauce would be the **limiting reactant**, the reactant that limits the amount of product in a chemical reaction. Notice that the limiting reactant is the reactant that makes *the least amount of product*.

The term *limiting reagent* is sometimes used in place of *limiting reactant*.

◀ The ingredient that makes the least amount of pizza determines how many pizzas you can make.

The reactants that *do not* limit the amount of product—such as the crusts and the cheese in this example—are said to be *in excess*. If this were a chemical reaction, three pizzas would be the **theoretical yield**, the maximum amount of product that can be made in a chemical reaction based on the amount of limiting reactant.

Let us carry this analogy one step further. Suppose we go on to cook our pizzas and accidentally burn one of them. Even though we theoretically have enough ingredients for three pizzas, we end up with only two. If this were a chemical reaction, the two pizzas would be our **actual yield**, the amount of product actually produced by a chemical reaction. (The actual yield is always equal to or less than the theoretical yield because a small amount of product is usually lost to other reactions or does not form during a reaction.) Finally, our **percent yield**, the percentage of the theoretical yield that was actually attained, is calculated as the ratio of the actual yield to the theoretical yield:

$$\% \text{ yield} = \frac{\text{Actual yield}}{\text{Theoretical yield}} \times 100\% = 67\%$$

Actual yield  
Theoretical yield

Since one of our pizzas burned, our percent yield for pizzas is 67%.

#### Summarizing Limiting Reactant and Yield:

- ▶ **The limiting reactant** (or **limiting reagent**) is the reactant that is completely consumed in a chemical reaction and limits the amount of product.
- ▶ **The reactant in excess** is any reactant that occurs in a quantity greater than is required to completely react with the limiting reactant.
- ▶ **The theoretical yield** is the amount of product that can be made in a chemical reaction based on the amount of limiting reactant.
- ▶ **The actual yield** is the amount of product actually produced by a chemical reaction.
- ▶ **The percent yield** is calculated as  $\frac{\text{actual yield}}{\text{theoretical yield}} \times 100\%$ .

## Calculating Limiting Reactant, Theoretical Yield, and Percent Yield

We can apply these concepts to a chemical reaction. Recall from Section 3.11 our balanced equation for the combustion of methane:

If we start out with five  $\text{CH}_4$  molecules and eight  $\text{O}_2$  molecules, what is our limiting reactant? What is our theoretical yield of carbon dioxide molecules? First we calculate the number of  $\text{CO}_2$  molecules that can be made from five  $\text{CH}_4$  molecules:

We then calculate the number of  $\text{CO}_2$  molecules that can be made from eight  $\text{O}_2$  molecules:

We have enough  $\text{CH}_4$  to make five  $\text{CO}_2$  molecules and enough  $\text{O}_2$  to make four  $\text{CO}_2$  molecules; therefore,  $\text{O}_2$  is the limiting reactant, and four  $\text{CO}_2$  molecules is the theoretical yield. The  $\text{CH}_4$  is in excess.

An alternative way to calculate the limiting reactant (which we describe here but do not use again in this book) is to pick any reactant and determine how much of the *other reactant* is necessary to completely react with it. For the reaction we just examined, we have five  $\text{CH}_4$  molecules and eight  $\text{O}_2$  molecules. Let's pick the five  $\text{CH}_4$  molecules and determine how many  $\text{O}_2$  molecules are necessary to completely react with them:

$$5 \text{CH}_4 \times \frac{2 \text{O}_2}{1 \text{CH}_4} = 10 \text{O}_2$$

Since we need ten  $\text{O}_2$  molecules to completely react with the five  $\text{CH}_4$  molecules, and since we have only eight  $\text{O}_2$  molecules, we know that the  $\text{O}_2$  is the limiting reactant. The same method can be applied by comparing the amounts of reactants in moles.

**Limiting Reactant and Theoretical Yield** Nitrogen and hydrogen gas react to form ammonia according to the reaction:

If a flask contains a mixture of reactants represented by the image shown at right, which image below best represents the mixture in the flask after the reactants have reacted as completely as possible? What is the limiting reactant? Which reactant is in excess?

### CONCEPTUAL CONNECTION 4.3

## Calculating Limiting Reactant, Theoretical Yield, and Percent Yield from Initial Reactant Masses

When working in the laboratory, we normally measure the initial quantities of reactants in grams, not in number of molecules. To find the limiting reactant and theoretical yield from initial masses, we must first convert the masses to amounts in moles. Consider the reaction:

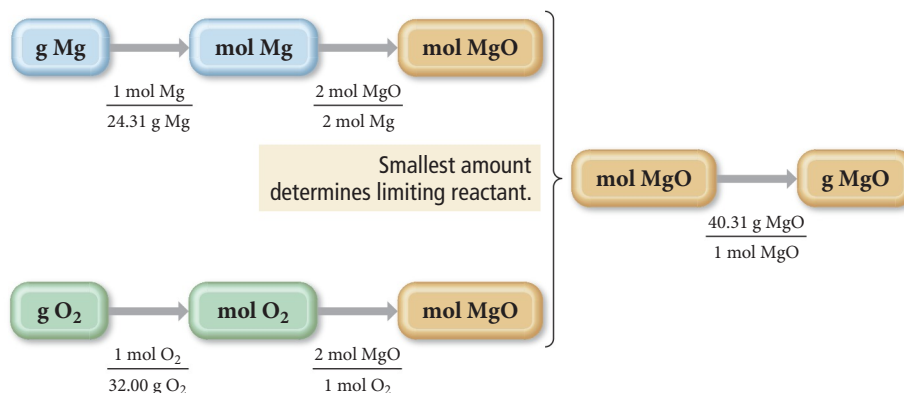

A reaction mixture contains 42.5 g Mg and 33.8 g  $\text{O}_2$ ; what is the limiting reactant and theoretical yield?

To solve this problem, we must determine which of the reactants makes the least amount of product.

**Conceptual Plan**

We can find the limiting reactant by calculating how much product can be made from each reactant. However, we are given the initial quantities in grams, and stoichiometric relationships are between moles, so we must first convert to moles. We then convert from moles of the reactant to moles of product. The reactant that makes the *least amount of product* is the limiting reactant. The conceptual plan is:

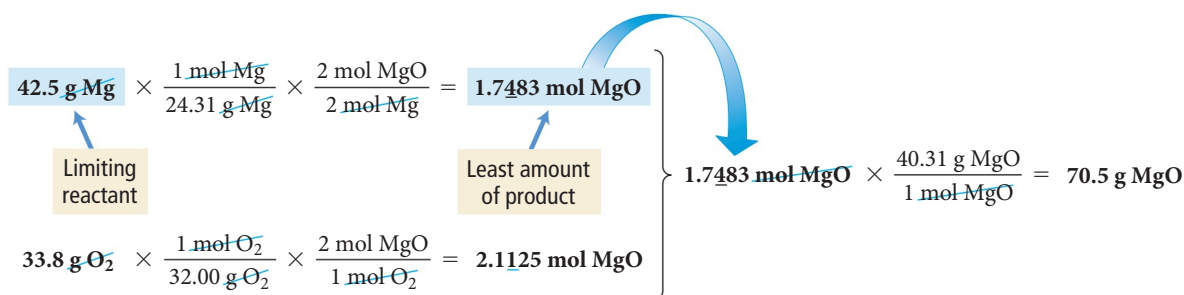

In this conceptual plan, we compare the number of moles of MgO made by each reactant and convert only the smaller amount to grams. (Alternatively, we can convert both quantities to grams and determine the limiting reactant based on the mass of the product.)

**Relationships Used**

$$\begin{aligned}\text{molar mass Mg} &= 24.31 \text{ g/mol} \\ \text{molar mass O}_2 &= 32.00 \text{ g/mol} \\ 2 \text{ mol Mg} &: 2 \text{ mol MgO} \\ 1 \text{ mol O}_2 &: 2 \text{ mol MgO} \\ \text{molar mass MgO} &= 40.31 \text{ g/mol}\end{aligned}$$

**Solution**

Beginning with the masses of each reactant, we follow the conceptual plan to calculate how much product can be made from each:

Since Mg makes the least amount of product, it is the limiting reactant, and O<sub>2</sub> is in excess. Notice that the limiting reactant is not necessarily the reactant with the least mass. In this case, the mass of O<sub>2</sub> is less than the mass of Mg, yet Mg is the limiting reactant because it makes the least amount of MgO. The theoretical yield is 70.5 g of MgO, the mass of product possible based on the limiting reactant.

Suppose that after the synthesis, the actual yield of MgO is 55.9 g. What is the percent yield? We calculate the percent yield as follows:

$$\% \text{ yield} = \frac{\text{actual yield}}{\text{theoretical yield}} \times 100\% = \frac{55.9 \text{ g}}{70.5 \text{ g}} \times 100\% = 79.3\%$$

**Example 4.3** Limiting Reactant and Theoretical Yield

Ammonia,  $\text{NH}_3$ , can be synthesized by the reaction:

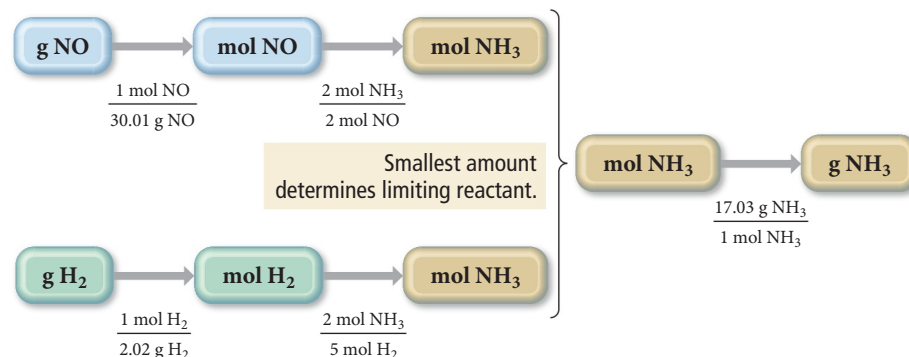

Starting with 86.3 g NO and 25.6 g  $\text{H}_2$ , find the theoretical yield of ammonia in grams.

**SORT** You are given the mass of each reactant in grams and asked to find the theoretical yield of a product.

**GIVEN:** 86.3 g NO, 25.6 g  $\text{H}_2$

**FIND:** theoretical yield of  $\text{NH}_3(g)$

**STRATEGIZE** Determine which reactant makes the least amount of product by converting from grams of each reactant to moles of the reactant to moles of the product. Use molar masses to convert between grams and moles and use the stoichiometric relationships (from the chemical equation) to convert between moles of reactant and moles of product. Remember that the reactant that makes *the least amount of product* is the limiting reactant. Convert the number of moles of product obtained using the limiting reactant to grams of product.

**CONCEPTUAL PLAN****RELATIONSHIPS USED**

molar mass NO = 30.01 g/mol

molar mass  $\text{H}_2$  = 2.02 g/mol

2 mol NO : 2 mol  $\text{NH}_3$  (from chemical equation)

5 mol  $\text{H}_2$  : 2 mol  $\text{NH}_3$  (from chemical equation)

molar mass  $\text{NH}_3$  = 17.03 g/mol

**SOLVE** Beginning with the given mass of each reactant, calculate the amount of product that can be made in moles. Convert the amount of product made by the limiting reactant to grams—this is the theoretical yield.

**SOLUTION**

**CHECK** The units of the answer (g  $\text{NH}_3$ ) are correct. The magnitude (49.0 g) seems reasonable given that 86.3 g NO is the limiting reactant. NO contains one oxygen atom per nitrogen atom and  $\text{NH}_3$  contains three hydrogen atoms per nitrogen atom. Since three hydrogen atoms have less mass than one oxygen atom, it is reasonable that the mass of  $\text{NH}_3$  obtained is less than the mass of NO.

**FOR PRACTICE 4.3** Ammonia can also be synthesized by the reaction:

What is the theoretical yield of ammonia, in kg, that we can synthesize from 5.22 kg of  $\text{H}_2$  and 31.5 kg of  $\text{N}_2$ ?

**Example 4.4** Limiting Reactant and Theoretical Yield

We can obtain titanium metal from its oxide according to the following balanced equation:

When 28.6 kg of C reacts with 88.2 kg of  $\text{TiO}_2$ , 42.8 kg of Ti is produced. Find the limiting reactant, theoretical yield (in kg), and percent yield.

**SORT** You are given the mass of each reactant and the mass of product formed. You are asked to find the limiting reactant, theoretical yield, and percent yield.

**STRATEGIZE** Determine which of the reactants makes the least amount of product by converting from kilograms of each reactant to moles of product. Convert between grams and moles using molar mass. Convert between moles of reactant and moles of product using the stoichiometric relationships derived from the chemical equation. Remember that the reactant that makes the *least amount of product* is the limiting reactant.

Determine the theoretical yield (in kilograms) by converting the number of moles of product obtained with the limiting reactant to kilograms of product.

**SOLVE** Beginning with the actual amount of each reactant, calculate the amount of product that can be made in moles. Convert the amount of product made by the limiting reactant to kilograms—this is the theoretical yield.

Calculate the percent yield by dividing the actual yield (42.8 kg Ti) by the theoretical yield.

**GIVEN:** 28.6 kg C, 88.2 kg  $\text{TiO}_2$ , 42.8 kg Ti produced

**FIND:** limiting reactant, theoretical yield, % yield

**CONCEPTUAL PLAN****RELATIONSHIPS USED**

$$1000 \text{ g} = 1 \text{ kg}$$

$$\text{molar mass of C} = 12.01 \text{ g/mol}$$

$$\text{molar mass of TiO}_2 = 79.87 \text{ g/mol}$$

$$1 \text{ mol TiO}_2 : 1 \text{ mol Ti}$$

$$2 \text{ mol C} : 1 \text{ mol Ti}$$

$$\text{molar mass of Ti} = 47.87 \text{ g/mol}$$

**SOLUTION**

$$\begin{aligned} & 28.6 \text{ kg C} \times \frac{1000 \text{ g}}{1 \text{ kg}} \times \frac{1 \text{ mol C}}{12.01 \text{ g C}} \times \frac{1 \text{ mol Ti}}{2 \text{ mol C}} = 1.1907 \times 10^3 \text{ mol Ti} \\ & \text{Limiting reactant} \quad \text{Least amount of product} \\ & 88.2 \text{ kg TiO}_2 \times \frac{1000 \text{ g}}{1 \text{ kg}} \times \frac{1 \text{ mol TiO}_2}{79.87 \text{ g TiO}_2} \times \frac{1 \text{ mol Ti}}{1 \text{ mol TiO}_2} = 1.1043 \times 10^3 \text{ mol Ti} \\ & 1.1043 \times 10^3 \text{ mol Ti} \times \frac{47.87 \text{ g Ti}}{1 \text{ mol Ti}} \times \frac{1 \text{ kg}}{1000 \text{ g}} = 52.9 \text{ kg Ti} \end{aligned}$$

Since  $\text{TiO}_2$  makes the least amount of product, it is the limiting reactant, and 52.9 kg Ti is the theoretical yield.

$$\% \text{ yield} = \frac{\text{actual yield}}{\text{theoretical yield}} \times 100\% = \frac{42.8 \text{ kg}}{52.9 \text{ kg}} \times 100\% = 80.9\%$$

**CHECK** The theoretical yield has the correct units (kg Ti) and has a reasonable magnitude compared to the mass of  $\text{TiO}_2$ . Since Ti has a lower molar mass than  $\text{TiO}_2$ , the amount of Ti made from  $\text{TiO}_2$  should have a lower mass. The percent yield is reasonable (under 100% as it should be).

**FOR PRACTICE 4.4** Mining companies use this reaction to obtain iron from iron ore:

The reaction of 167 g  $\text{Fe}_2\text{O}_3$  with 85.8 g CO produces 72.3 g Fe. Determine the limiting reactant, theoretical yield, and percent yield.

CONCEPTUAL  
CONNECTION 4.4

**Reactant in Excess** Nitrogen dioxide reacts with water to form nitric acid and nitrogen monoxide according to the equation:

Suppose that 5 mol  $\text{NO}_2$  and 1 mol  $\text{H}_2\text{O}$  combine and react completely. How many moles of the reactant in excess are present after the reaction has completed?

## 4.4 Solution Concentration and Solution Stoichiometry

The reactions that occur in lakes, streams, and oceans, as well as the reactions that occur in every cell within our bodies, take place in water. Chemical reactions involving reactants dissolved in water are among the most common and important. A homogeneous mixture of two substances—such as salt and water—is a **solution**. The majority component of the mixture is the **solvent**, and the minority component is the **solute**. An **aqueous solution** is one in which water acts as the solvent. In this section, we first examine how to quantify the concentration of a solution (the amount of solute relative to solvent) and then turn to applying the principles of stoichiometry, which we discussed in the previous section, to reactions occurring in solution.

### Solution Concentration

The amount of solute in a solution is variable. For example, we can add just a little salt to water to make a **dilute solution**, one that contains a small amount of solute relative to the solvent, or we can add a lot of salt to water to make a **concentrated solution**, one that contains a large amount of solute relative to the solvent (Figure 4.4▼). A common way to express solution concentration is **molarity (M)**, the amount of solute (in moles) divided by the volume of solution (in liters):

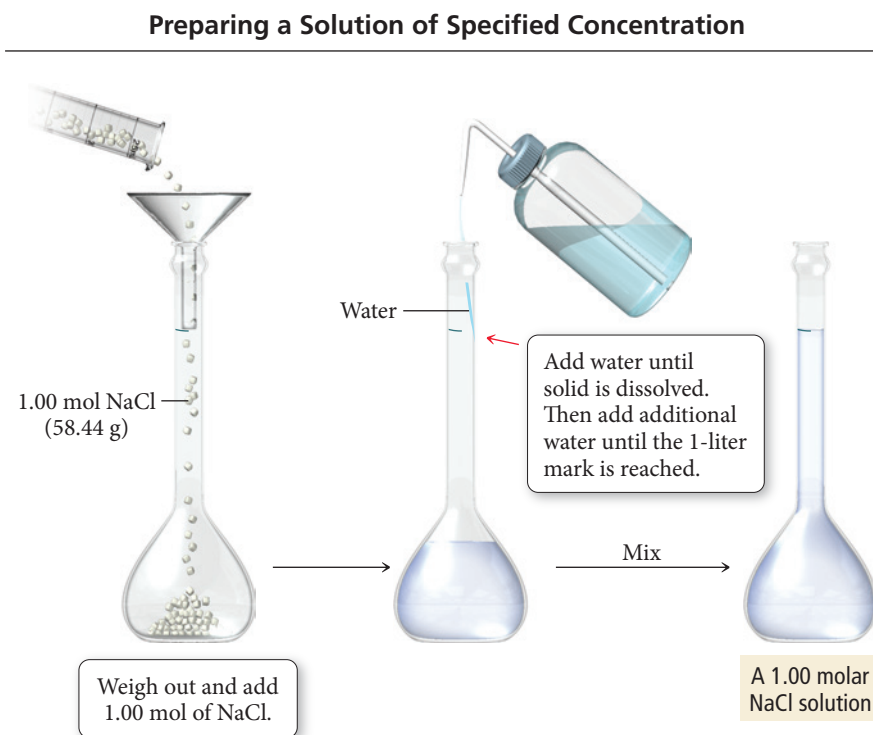

$$\text{Molarity (M)} = \frac{\text{amount of solute (in mol)}}{\text{volume of solution (in L)}}$$

Notice that molarity is a ratio of the amount of solute per liter of *solution*, not per liter of solvent. To make an aqueous solution of a specified molarity, we usually put the solute into a flask and then add water to reach the desired volume of solution. For example,

◀ **FIGURE 4.4 Concentrated and Dilute Solutions** A concentrated solution contains a relatively large amount of solute relative to solvent. A dilute solution contains a relatively small amount of solute relative to solvent.

► **FIGURE 4.5** Preparing a 1 Molar NaCl Solution

to make 1 L of a 1 M NaCl solution, we add 1 mol of NaCl to a flask and then add enough water to make 1 L of solution (Figure 4.5▲). We *do not* combine 1 mol of NaCl with 1 L of water because the resulting solution would have a total volume different from 1 L and therefore a molarity different than 1 M. To calculate molarity, divide the amount of the solute in moles by the volume of the solution (solute *and* solvent) in liters, as shown in Example 4.5.

### Example 4.5 Calculating Solution Concentration

What is the molarity of a solution containing 25.5 g KBr dissolved in enough water to make 1.75 L of solution?

**SORT** You are given the mass of KBr and the volume of a solution and asked to find its molarity.

**GIVEN:** 25.5 g KBr, 1.75 L of solution

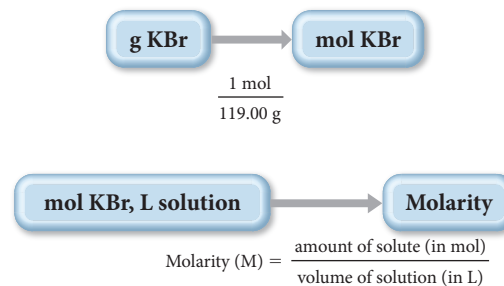

**FIND:** molarity (M)

**STRATEGIZE** When formulating the conceptual plan, think about the definition of molarity, the amount of solute *in moles* per liter of solution.

You are given the mass of KBr, so first use the molar mass of KBr to convert from g KBr to mol KBr.

Then use the number of moles of KBr and liters of solution to find the molarity.

#### CONCEPTUAL PLAN

#### RELATIONSHIPS USED

molar mass of KBr = 119.00 g/mol

**SOLVE** Follow the conceptual plan. Begin with g KBr and convert to mol KBr; then use mol KBr and L solution to calculate molarity.

**SOLUTION**

$$25.5 \text{ g KBr} \times \frac{1 \text{ mol KBr}}{119.00 \text{ g KBr}} = 0.21429 \text{ mol KBr}$$

$$\text{molarity (M)} = \frac{\text{amount of solute (in mol)}}{\text{volume of solution (in L)}}$$

$$= \frac{0.21429 \text{ mol KBr}}{1.75 \text{ L solution}}$$

$$= 0.122 \text{ M}$$

**CHECK** The units of the answer (M) are correct. The magnitude is reasonable since common solutions range in concentration from 0 to about 18 M. Concentrations significantly above 18 M are suspect and should be double-checked.

**FOR PRACTICE 4.5** Calculate the molarity of a solution made by adding 45.4 g of  $\text{NaNO}_3$  to a flask and dissolving it with water to create a total volume of 2.50 L.

**FOR MORE PRACTICE 4.5** What mass of KBr (in grams) do you need to make 250.0 mL of a 1.50 M KBr solution?

## Using Molarity in Calculations

We can use the molarity of a solution as a conversion factor between moles of the solute and liters of the solution. For example, a 0.500 M NaCl solution contains 0.500 moles NaCl for every liter of solution:

This conversion factor converts from liters solution to mole NaCl. If we want to convert in the other direction, we invert the conversion factor:

Example 4.6 illustrates how to use molarity in this way.

### Example 4.6 Using Molarity in Calculations

How many liters of a 0.125 M NaOH solution contain 0.255 mol of NaOH?

**SORT** You are given the concentration of a NaOH solution. You are asked to find the volume of the solution that contains a given amount (in moles) of NaOH.

**GIVEN:** 0.125 M NaOH solution, 0.255 mol NaOH

**FIND:** volume of NaOH solution (in L)

**STRATEGIZE** The conceptual plan begins with mol NaOH and shows the conversion to L of solution using molarity as a conversion factor.

**CONCEPTUAL PLAN**

**RELATIONSHIPS USED**  $0.125 \text{ M NaOH} = \frac{0.125 \text{ mol NaOH}}{1 \text{ L solution}}$

—Continued on the next page

—Continued

**SOLVE** Follow the conceptual plan. Begin with mol NaOH and convert to L solution.

**SOLUTION**

$$0.255 \text{ mol NaOH} \times \frac{1 \text{ L solution}}{0.125 \text{ mol NaOH}} = 2.04 \text{ L solution}$$

**CHECK** The units of the answer (L) are correct. The magnitude is reasonable because the solution contains 0.125 mol per liter. Therefore, roughly 2 L contains the given amount of moles (0.255 mol).

**FOR PRACTICE 4.6** How many grams of sucrose ( $\text{C}_{12}\text{H}_{22}\text{O}_{11}$ ) are in 1.55 L of 0.758 M sucrose solution?

**FOR MORE PRACTICE 4.6** How many mL of a 0.155 M KCl solution contain 2.55 g KCl?

## CONCEPTUAL CONNECTION 4.5

**Solutions** If we dissolve 25 g of salt in 251 g of water, what is the mass of the resulting solution?

- (a) 251 g      (b) 276 g      (c) 226 g

When diluting acids, always add the concentrated acid to the water. Never add water to concentrated acid solutions, as the heat generated may cause the concentrated acid to splatter and burn your skin.

## Solution Dilution

To save space in storerooms, laboratories often store solutions in concentrated forms called **stock solutions**. For example, hydrochloric acid is frequently stored as a 12 M stock solution. However, many lab procedures call for much less concentrated hydrochloric acid solutions, so we must dilute the stock solution to the required concentration. How do we know how much of the stock solution to use? The easiest way to solve dilution problems is to use the following dilution equation:

$$M_1 V_1 = M_2 V_2 \quad [4.1]$$

where  $M_1$  and  $V_1$  are the molarity and volume of the initial concentrated solution, and  $M_2$  and  $V_2$  are the molarity and volume of the final diluted solution. This equation works because the molarity multiplied by the volume gives the number of moles of solute, which is the same in both solutions.

$$M_1 V_1 = M_2 V_2$$

$$\text{mol}_1 = \text{mol}_2$$

In other words, the number of moles of solute does not change when we dilute a solution.

For example, suppose a laboratory procedure calls for 3.00 L of a 0.500 M  $\text{CaCl}_2$  solution. How should we prepare this solution from a 10.0 M stock solution? We solve Equation 4.1 for  $V_1$ , the volume of the stock solution required for the dilution, and then substitute in the correct values to calculate it.

$$M_1 V_1 = M_2 V_2$$

$$V_1 = \frac{M_2 V_2}{M_1}$$

$$= \frac{0.500 \text{ mol/L} \times 3.00 \text{ L}}{10.0 \text{ mol/L}}$$

$$= 0.150 \text{ L}$$

Consequently, we make the solution by diluting 0.150 L of the stock solution to a total volume of 3.00 L ( $V_2$ ). The resulting solution will be 0.500 M in  $\text{CaCl}_2$  (Figure 4.6▶).

## Diluting a Solution

$$M_1 V_1 = M_2 V_2$$

$$\frac{10.0 \text{ mol}}{\cancel{\text{L}}} \times 0.150 \cancel{\text{L}} = \frac{0.500 \text{ mol}}{\cancel{\text{L}}} \times 3.00 \cancel{\text{L}}$$

$$1.50 \text{ mol} = 1.50 \text{ mol}$$

◀ **FIGURE 4.6** Preparing 3.00 L of 0.500 M  $\text{CaCl}_2$  from a 10.0 M Stock Solution

### Example 4.7 Solution Dilution

To what volume should you dilute 0.200 L of a 15.0 M NaOH solution to obtain a 3.00 M NaOH solution?

**SORT** You are given the initial volume, initial concentration, and final concentration of a solution. You need to determine the final volume.

**GIVEN:**

$$V_1 = 0.200 \text{ L}$$

$$M_1 = 15.0 \text{ M}$$

$$M_2 = 3.00 \text{ M}$$

**FIND:**  $V_2$

**STRATEGIZE** Equation 4.1 relates the initial and final volumes and concentrations for solution dilution problems. You are asked to find  $V_2$ . The other quantities ( $V_1$ ,  $M_1$ , and  $M_2$ ) are all given in the problem.

**CONCEPTUAL PLAN**

**RELATIONSHIPS USED**

$$M_1 V_1 = M_2 V_2$$

—Continued on the next page

—Continued

**SOLVE** Begin with the solution dilution equation and solve it for  $V_2$ .Substitute in the required quantities and calculate  $V_2$ .Make the solution by diluting 0.200 L of the stock solution to a total volume of 1.00 L ( $V_2$ ). The resulting solution will have a concentration of 3.00 M.**SOLUTION**  $M_1 V_1 = M_2 V_2$ 

$$\begin{aligned}
 V_2 &= \frac{M_1 V_1}{M_2} \\
 &= \frac{15.0 \text{ mol/L} \times 0.200 \text{ L}}{3.00 \text{ mol/L}} \\
 &= 1.00 \text{ L}
 \end{aligned}$$

**CHECK** The final units (L) are correct. The magnitude of the answer is reasonable because the solution is diluted from 15.0 M to 3.00 M, a factor of five. Therefore, the volume should increase by a factor of five.**FOR PRACTICE 4.7** To what volume (in mL) should you dilute 100.0 mL of a 5.00 M  $\text{CaCl}_2$  solution to obtain a 0.750 M  $\text{CaCl}_2$  solution?**FOR MORE PRACTICE 4.7** What volume of a 6.00 M  $\text{NaNO}_3$  solution should you use to make 0.525 L of a 1.20 M  $\text{NaNO}_3$  solution?**CONCEPTUAL CONNECTION 4.6****Solution Dilution** The image shown at left represents a small volume within 500 mL of aqueous ethanol ( $\text{CH}_3\text{CH}_2\text{OH}$ ) solution. (The water molecules have been omitted for clarity.)

Which image below best represents the same volume of the solution after we add an additional 500 mL of water?

(a)

(b)

(c)

**Solution Stoichiometry**

In Section 4.2 we discussed how we can use the coefficients in chemical equations as conversion factors between the amounts of reactants (in moles) and the amounts of products (in moles). In aqueous reactions, quantities of reactants and products are often specified in terms of volumes and concentrations. We can use the volume and concentration of a reactant or product to calculate its amount in moles. We can then use the stoichiometric coefficients in the chemical equation to convert to the amount of another reactant or product in moles. The general conceptual plan for these kinds of calculations begins with the volume of a reactant or product:

We make the conversions between solution volumes and amounts of solute in moles using the molarities of the solutions. We make the conversions between amounts in moles of A and B using the stoichiometric coefficients from the balanced chemical equation. Example 4.8 demonstrates solution stoichiometry.

**Example 4.8** Solution Stoichiometry

What volume (in L) of 0.150 M KCl solution will completely react with 0.150 L of a 0.175 M  $\text{Pb}(\text{NO}_3)_2$  solution according to the following balanced chemical equation?

**SORT** You are given the volume and concentration of a  $\text{Pb}(\text{NO}_3)_2$  solution. You are asked to find the volume of KCl solution (of a given concentration) required to react with it.

**GIVEN:** 0.150 L of  $\text{Pb}(\text{NO}_3)_2$  solution, 0.175 M  $\text{Pb}(\text{NO}_3)_2$  solution, 0.150 M KCl solution

**FIND:** volume KCl solution (in L)

**STRATEGIZE** The conceptual plan has the form: volume A  $\rightarrow$  amount A (in moles)  $\rightarrow$  amount B (in moles)  $\rightarrow$  volume B. Use the molar concentrations of the KCl and  $\text{Pb}(\text{NO}_3)_2$  solutions as conversion factors between the number of moles of reactants in these solutions and their volumes. Use the stoichiometric coefficients from the balanced equation to convert between number of moles of  $\text{Pb}(\text{NO}_3)_2$  and number of moles of KCl.

**CONCEPTUAL PLAN****RELATIONSHIPS USED**

$$M \text{Pb}(\text{NO}_3)_2 = \frac{0.175 \text{ mol Pb}(\text{NO}_3)_2}{1 \text{ L Pb}(\text{NO}_3)_2 \text{ solution}}$$

$$M \text{KCl} = \frac{0.150 \text{ mol KCl}}{1 \text{ L KCl solution}}$$

**SOLVE** Begin with L  $\text{Pb}(\text{NO}_3)_2$  solution and follow the conceptual plan to arrive at L KCl solution.

**SOLUTION**

$$0.150 \text{ L Pb}(\text{NO}_3)_2 \text{ solution} \times \frac{0.175 \text{ mol Pb}(\text{NO}_3)_2}{1 \text{ L Pb}(\text{NO}_3)_2 \text{ solution}} \times \frac{2 \text{ mol KCl}}{1 \text{ mol Pb}(\text{NO}_3)_2} \times \frac{1 \text{ L KCl solution}}{0.150 \text{ mol KCl}} = 0.350 \text{ L KCl solution}$$

**CHECK** The final units (L KCl solution) are correct. The magnitude (0.350 L) is reasonable because the reaction stoichiometry requires 2 mol of KCl per mole of  $\text{Pb}(\text{NO}_3)_2$ . Since the concentrations of the two solutions are not very different (0.150 M compared to 0.175 M), the volume of KCl required is roughly two times the 0.150 L of  $\text{Pb}(\text{NO}_3)_2$  given in the problem.

**FOR PRACTICE 4.8** What volume (in mL) of a 0.150 M  $\text{HNO}_3$  solution will completely react with 35.7 mL of a 0.108 M  $\text{Na}_2\text{CO}_3$  solution according to the following balanced chemical equation?

**FOR MORE PRACTICE 4.8** In the previous reaction, what mass (in grams) of carbon dioxide forms?

**Solution Stoichiometry** Consider the reaction:

What is the limiting reactant if you mix equal volumes of a 1 M solution of A and a 1 M solution of B?

**CONCEPTUAL CONNECTION 4.7**

## Solute and Solvent Interactions

**▲ FIGURE 4.7 Solute and Solvent Interactions** When a solid is put into a solvent, the interactions between solvent and solute particles compete with the interactions between the solute particles themselves.

**▲ FIGURE 4.8 Charge Distribution in a Water Molecule** An uneven distribution of electrons within the water molecule causes the oxygen side of the molecule to have a partial negative charge and the hydrogen side to have a partial positive charge.

## 4.5 Types of Aqueous Solutions and Solubility

Consider two familiar aqueous solutions: salt water and sugar water. Salt water is a homogeneous mixture of  $\text{NaCl}$  and  $\text{H}_2\text{O}$ , and sugar water is a homogeneous mixture of  $\text{C}_{12}\text{H}_{22}\text{O}_{11}$  and  $\text{H}_2\text{O}$ . You may have made these solutions yourself by adding table salt or sugar to water. As you stir either of these two substances into the water, the substance seems to disappear. However, you know that the original substance is still present because the mixture tastes salty or sweet. How do solids such as salt and sugar dissolve in water?

When a solid is put into a liquid solvent, the attractive forces that hold the solid together (the solute-solute interactions) compete with the attractive forces between the solvent molecules and the particles that compose the solid (the solvent-solute interactions), as shown in Figure 4.7◀. For example, when sodium chloride is put into water, there is a competition between the attraction of  $\text{Na}^+$  cations and  $\text{Cl}^-$  anions to each other (due to their opposite charges) and the attraction of  $\text{Na}^+$  and  $\text{Cl}^-$  to water molecules. The attraction of  $\text{Na}^+$  and  $\text{Cl}^-$  to water is based on the *polar nature* of the water molecule. For reasons we discuss later in this book (Section 9.6), the oxygen atom in water is electron-rich, giving it a partial negative charge ( $\delta^-$ ), as shown in Figure 4.8◀. The hydrogen atoms, in contrast, are electron-poor, giving them a partial positive charge ( $\delta^+$ ). As a result, the positively charged sodium ions are strongly attracted to the oxygen side of the water molecule (which has a partial negative charge), and the negatively charged chloride ions are attracted to the hydrogen side of the water molecule (which has a partial positive charge), as shown in Figure 4.9▼. In the case of  $\text{NaCl}$ , the attraction between the separated ions and the water molecules overcomes the attraction of sodium and chloride ions to each other, and the sodium chloride dissolves in the water (Figure 4.10▼).

### Electrolyte and Nonelectrolyte Solutions

As Figure 4.11► illustrates, a salt solution conducts electricity while a sugar solution does not. The difference between the ways that salt (an ionic compound) and sugar (a molecular compound) dissolve in water illustrates a fundamental difference between types of

#### Dissolution of an Ionic Compound

**▲ FIGURE 4.10 Sodium Chloride Dissolving in Water** The attraction between water molecules and the ions of sodium chloride causes  $\text{NaCl}$  to dissolve in the water.

#### Interactions in a Sodium Chloride Solution

**▲ FIGURE 4.9 Solute and Solvent Interactions in a Sodium Chloride Solution** When sodium chloride is put into water, the attraction of  $\text{Na}^+$  and  $\text{Cl}^-$  ions to water molecules competes with the attraction between the oppositely charged ions themselves.

## Electrolyte and Nonelectrolyte Solutions

◀ **FIGURE 4.11 Electrolyte and Nonelectrolyte Solutions** A solution of salt (an electrolyte) conducts electrical current. A solution of sugar (a nonelectrolyte) does not.

solutions. Ionic compounds such as the sodium chloride in the previous example dissociate into their component ions when they dissolve in water. An NaCl solution, represented as  $\text{NaCl}(aq)$ , does not contain any NaCl units, but rather dissolved  $\text{Na}^+$  ions and  $\text{Cl}^-$  ions. The dissolved ions act as charge carriers, allowing the solution to conduct electricity. Substances that dissolve in water to form solutions that conduct electricity are **electrolytes**. Substances such as sodium chloride that completely dissociate into ions when they dissolve in water are **strong electrolytes**, and the resulting solutions are *strong electrolyte solutions*.

In contrast to sodium chloride, sugar is a molecular compound. Most molecular compounds—with the important exception of acids, which we discuss shortly—dissolve in water as intact molecules. Sugar dissolves because the attraction between sugar molecules and water molecules (shown in Figure 4.12 ▼) overcomes the attraction of sugar molecules to each other (Figure 4.13 ▼). So unlike a sodium chloride solution

## Sugar Solution

## Interactions between Sugar and Water Molecules

▲ **FIGURE 4.12 Sugar and Water Interactions** Partial charges on sugar molecules and water molecules (which we will discuss more fully in Chapter 11) result in attractions between the sugar molecules and water molecules.

▲ **FIGURE 4.13 A Sugar Solution** Sugar dissolves because the attractions between sugar molecules and water molecules, which both contain a distribution of electrons that results in partial positive and partial negative charges, overcome the attractions between sugar molecules to each other.

Unlike soluble ionic compounds, which contain ions and therefore *dissociate* in water, acids are molecular compounds that *ionize* in water.

(which is composed of dissociated ions), a sugar solution is composed of intact  $\text{C}_{12}\text{H}_{22}\text{O}_{11}$  molecules homogeneously mixed with the water molecules. Compounds such as sugar that do not dissociate into ions when dissolved in water are called **nonelectrolytes**, and the resulting solutions—called *nonelectrolyte solutions*—do not conduct electricity.

Acids, which we introduced in Section 3.6, are molecular compounds, but they do ionize—form ions—when they dissolve in water. Hydrochloric acid (HCl) is a molecular compound that ionizes into  $\text{H}^+$  and  $\text{Cl}^-$  when it dissolves in water. HCl is an example of a **strong acid**, one that completely ionizes in solution. Since strong acids completely ionize in solution, they are also strong electrolytes. We represent the complete ionization of a strong acid with a single reaction arrow between the acid and its ionized form:

Many acids are **weak acids**; they do not completely ionize in water. For example, acetic acid ( $\text{HC}_2\text{H}_3\text{O}_2$ ), the acid in vinegar, is a weak acid. A solution of a weak acid is composed mostly of the nonionized acid—only a small percentage of the acid molecules ionize. We represent the partial ionization of a weak acid with opposing half arrows between the reactants and products:

Weak acids are **weak electrolytes**, and the resulting solutions—called *weak electrolyte solutions*—conduct electricity only weakly. Figure 4.14 summarizes the electrolytic properties of solutions.

## The Solubility of Ionic Compounds

As we have just discussed, when an ionic compound dissolves in water, the resulting solution contains not the intact ionic compound itself, but its component ions dissolved in water. However, not all ionic compounds dissolve in water. If we add  $\text{AgCl}$  to

▼ FIGURE 4.14 Electrolytic Properties of Solutions

### Electrolytic Properties of Solutions

water, for example, it remains solid and appears as a white powder at the bottom of the water.

In general, a compound is termed **soluble** if it dissolves in water and **insoluble** if it does not. However, these classifications are a bit of an oversimplification. (In reality, solubility is a continuum and even “insoluble” compounds dissolve to some extent, though usually orders of magnitude less than soluble compounds.) For example, silver nitrate is soluble. If we mix solid  $\text{AgNO}_3$  with water, it dissolves and forms a strong electrolyte solution. Silver chloride, as we just saw, is almost completely insoluble. If we mix solid  $\text{AgCl}$  with water, virtually all of it remains as a solid within the liquid water.

Whether a particular compound is soluble or insoluble depends on several factors. In Section 12.3, we will examine more closely the energy changes associated with solution formation. For now, we can follow a set of empirical rules that chemists have inferred from observations on many ionic compounds. Table 4.1 summarizes these *solubility rules*.

The solubility rules state that compounds containing the sodium ion are soluble. That means that compounds such as  $\text{NaBr}$ ,  $\text{NaNO}_3$ ,  $\text{Na}_2\text{SO}_4$ ,  $\text{NaOH}$ , and  $\text{Na}_2\text{CO}_3$  all dissolve in water to form strong electrolyte solutions. Similarly, the solubility rules state that compounds containing the  $\text{NO}_3^-$  ion are soluble. That means that compounds such as  $\text{AgNO}_3$ ,  $\text{Pb}(\text{NO}_3)_2$ ,  $\text{NaNO}_3$ ,  $\text{Ca}(\text{NO}_3)_2$ , and  $\text{Sr}(\text{NO}_3)_2$  all dissolve in water to form strong electrolyte solutions.

Notice that when compounds containing polyatomic ions such as  $\text{NO}_3^-$  dissolve, the polyatomic ions dissolve as intact units.

The solubility rules also state that, with some exceptions, compounds containing the  $\text{CO}_3^{2-}$  ion are insoluble. Therefore, compounds such as  $\text{CuCO}_3$ ,  $\text{CaCO}_3$ ,  $\text{SrCO}_3$ , and  $\text{FeCO}_3$  do not dissolve in water. Note that the solubility rules contain many exceptions. For example, compounds containing  $\text{CO}_3^{2-}$  are soluble when paired with  $\text{Li}^+$ ,  $\text{Na}^+$ ,  $\text{K}^+$ , or  $\text{NH}_4^+$ . Thus  $\text{Li}_2\text{CO}_3$ ,  $\text{Na}_2\text{CO}_3$ ,  $\text{K}_2\text{CO}_3$ , and  $(\text{NH}_4)_2\text{CO}_3$  are all soluble.

▲  $\text{AgCl}$  does not dissolve in water; it remains as a white powder at the bottom of the beaker.

**TABLE 4.1 Solubility Rules for Ionic Compounds in Water**

Compounds Containing the Following Ions Are Generally Soluble	Exceptions
$\text{Li}^+$ , $\text{Na}^+$ , $\text{K}^+$ , and $\text{NH}_4^+$	None
$\text{NO}_3^-$ and $\text{C}_2\text{H}_3\text{O}_2^-$	None
$\text{Cl}^-$ , $\text{Br}^-$ , and $\text{I}^-$	When these ions pair with $\text{Ag}^+$ , $\text{Hg}_2^{2+}$ , or $\text{Pb}^{2+}$ , the resulting compounds are insoluble.
$\text{SO}_4^{2-}$	When $\text{SO}_4^{2-}$ pairs with $\text{Sr}^{2+}$ , $\text{Ba}^{2+}$ , $\text{Pb}^{2+}$ , $\text{Ag}^+$ , or $\text{Ca}^{2+}$ , the resulting compound is insoluble.
Compounds Containing the Following Ions Are Generally Insoluble	Exceptions
$\text{OH}^-$ and $\text{S}^{2-}$	When these ions pair with $\text{Li}^+$ , $\text{Na}^+$ , $\text{K}^+$ , or $\text{NH}_4^+$ , the resulting compounds are soluble.
	When $\text{S}^{2-}$ pairs with $\text{Ca}^{2+}$ , $\text{Sr}^{2+}$ , or $\text{Ba}^{2+}$ , the resulting compound is soluble.
	When $\text{OH}^-$ pairs with $\text{Ca}^{2+}$ , $\text{Sr}^{2+}$ , or $\text{Ba}^{2+}$ , the resulting compound is slightly soluble.
$\text{CO}_3^{2-}$ and $\text{PO}_4^{3-}$	When these ions pair with $\text{Li}^+$ , $\text{Na}^+$ , $\text{K}^+$ , or $\text{NH}_4^+$ , the resulting compounds are soluble.

**Example 4.9** Predicting Whether an Ionic Compound Is Soluble

Predict whether each compound is soluble or insoluble.

- (a)  $\text{PbCl}_2$       (b)  $\text{CuCl}_2$       (c)  $\text{Ca}(\text{NO}_3)_2$       (d)  $\text{BaSO}_4$

**SOLUTION**

- (a) Insoluble. Compounds containing  $\text{Cl}^-$  are normally soluble, but  $\text{Pb}^{2+}$  is an exception.  
 (b) Soluble. Compounds containing  $\text{Cl}^-$  are normally soluble and  $\text{Cu}^{2+}$  is not an exception.  
 (c) Soluble. Compounds containing  $\text{NO}_3^-$  are always soluble.  
 (d) Insoluble. Compounds containing  $\text{SO}_4^{2-}$  are normally soluble, but  $\text{Ba}^{2+}$  is an exception.

**FOR PRACTICE 4.9** Predict whether each compound is soluble or insoluble.

- (a)  $\text{NiS}$       (b)  $\text{Mg}_3(\text{PO}_4)_2$       (c)  $\text{Li}_2\text{CO}_3$       (d)  $\text{NH}_4\text{Cl}$

## Reactions in Solution

**4.6** Precipitation Reactions

Have you ever taken a bath in hard water? Hard water contains dissolved ions such as  $\text{Ca}^{2+}$  and  $\text{Mg}^{2+}$  that diminish the effectiveness of soap. These ions react with soap to form a gray curd that may appear as a “bathtub ring” after you drain the tub. Hard water is particularly troublesome when washing clothes. Consider how your white shirt would look covered with the gray curd from the bathtub and you can understand the problem. Consequently, most laundry detergents include substances designed to remove  $\text{Ca}^{2+}$  and  $\text{Mg}^{2+}$  from the laundry mixture. The most common substance used for this purpose is sodium carbonate, which dissolves in water to form sodium cations ( $\text{Na}^+$ ) and carbonate ( $\text{CO}_3^{2-}$ ) anions:

Sodium carbonate is soluble, but calcium carbonate and magnesium carbonate are not (see the solubility rules in Table 4.1). Consequently, the carbonate anions react with dissolved  $\text{Mg}^{2+}$  and  $\text{Ca}^{2+}$  ions in hard water to form solids that *precipitate* from (or come out of) solution:

The precipitation of these ions prevents their reaction with the soap, eliminating curd and preventing white shirts from turning gray.

The reactions between  $\text{CO}_3^{2-}$  and  $\text{Mg}^{2+}$  and  $\text{Ca}^{2+}$  are examples of **precipitation reactions**, reactions in which a solid or **precipitate** forms when we mix two solutions. Precipitation reactions are common in chemistry. As another example, consider potassium iodide and lead(II) nitrate, which form colorless, strong electrolyte solutions when dissolved in water separately. When the two solutions are combined, however, a brilliant yellow precipitate forms (Figure 4.15▶). We describe this precipitation reaction with the following chemical equation:

Precipitation reactions do not always occur when two aqueous solutions are mixed. For example, if we combine solutions of  $\text{KI}(aq)$  and  $\text{NaCl}(aq)$ , nothing happens (Figure 4.16▶, on page 164):

The key to predicting precipitation reactions is to understand that *only insoluble compounds form precipitates*. In a precipitation reaction, two solutions containing soluble compounds combine and an insoluble compound precipitates. Consider the precipitation reaction described previously:

▲ The reaction of ions in hard water with soap produces a gray curd that is visible after you drain the bathwater.

## Precipitation Reaction

When a potassium iodide solution is mixed with a lead(II) nitrate solution, a yellow lead(II) iodide precipitate forms.

**FIGURE 4.15 Precipitation of Lead(II) Iodide** When a potassium iodide solution is mixed with a lead(II) nitrate solution, a yellow lead(II) iodide precipitate forms.

KI and  $\text{Pb}(\text{NO}_3)_2$  are both soluble, but the precipitate,  $\text{PbI}_2$ , is insoluble. Before mixing,  $\text{KI}(aq)$  and  $\text{Pb}(\text{NO}_3)_2(aq)$  are both dissociated in their respective solutions:

The instant that the solutions come into contact, all four ions are present:

Now, new compounds—one or both of which might be insoluble—are possible. Specifically, the cation from either compound can pair with the anion from the other to form possibly insoluble products:

If the possible products are both soluble, no reaction occurs and no precipitate forms. If one or both of the possible products are insoluble, a precipitation reaction occurs. In this case, KNO<sub>3</sub> is soluble, but PbI<sub>2</sub> is insoluble. Consequently, PbI<sub>2</sub> precipitates.

To predict whether a precipitation reaction will occur when two solutions are mixed and to write an equation for the reaction, we use the procedure that follows. The steps are outlined in the left column, and two examples illustrating how to apply the procedure are shown in the center and right columns.

► **FIGURE 4.16 No Precipitation**

When a potassium iodide solution is mixed with a sodium chloride solution, no reaction occurs.

## Procedure for...

## Writing Equations for Precipitation Reactions

1. Write the formulas of the two compounds being mixed as reactants in a chemical equation.

2. Below the equation, write the formulas of the products that could form from the reactants. Obtain these by combining the cation from each reactant with the anion from the other. Make sure to write correct formulas for these ionic compounds using the procedure demonstrated in Section 3.5.

3. Refer to the solubility rules to determine whether any of the possible products are insoluble.

4. If all of the possible products are soluble, there is no precipitate. Write "NO REACTION" after the arrow.

5. If any of the possible products are insoluble, write their formulas as the products of the reaction, using (s) to indicate solid. Include an (aq) to indicate aqueous after any soluble products.

6. Balance the equation. Remember to adjust only coefficients, not subscripts.

## Example 4.10

## Writing Equations for Precipitation Reactions

Write an equation for the precipitation reaction that occurs (if any) when solutions of potassium carbonate and nickel(II) chloride are mixed.

KCl is soluble. (Compounds containing  $\text{Cl}^-$  are usually soluble and  $\text{K}^+$  is not an exception.)

$\text{NiCO}_3$  is insoluble. (Compounds containing  $\text{CO}_3^{2-}$  are usually insoluble and  $\text{Ni}^{2+}$  is not an exception.)

Since this example has an insoluble product, we proceed to the next step.

**FOR PRACTICE 4.10** Write an equation for the precipitation reaction that occurs (if any) when solutions of ammonium chloride and iron(III) nitrate mix.

## Example 4.11

## Writing Equations for Precipitation Reactions

Write an equation for the precipitation reaction that occurs (if any) when solutions of sodium nitrate and lithium sulfate are mixed.

$\text{LiNO}_3$  is soluble. (Compounds containing  $\text{NO}_3^-$  are soluble and  $\text{Li}^+$  is not an exception.)

$\text{Na}_2\text{SO}_4$  is soluble. (Compounds containing  $\text{SO}_4^{2-}$  are generally soluble and  $\text{Na}^+$  is not an exception.)

Since this example has no insoluble product, there is no reaction.

**FOR PRACTICE 4.11** Write an equation for the precipitation reaction that occurs (if any) when solutions of sodium hydroxide and copper(II) bromide mix.

## CONCEPTUAL CONNECTION 4.8

**Precipitation Reactions** Consider the generic ionic compounds with the formulas AX and BY and the following solubility rules:

AX soluble; BY soluble; AY soluble; BX insoluble

Let circles represent  $A^+$  ions; squares represent  $B^+$  ions; triangles represent  $X^-$  ions; and diamonds represent  $Y^-$  ions. We represent solutions of the two compounds (AX and BY) as follows:

Draw a molecular-level representation showing the result of mixing the two solutions and write an equation to represent the reaction.

## 4.7 Representing Aqueous Reactions: Molecular, Ionic, and Complete Ionic Equations

Consider the following equation for a precipitation reaction:

This equation is a **molecular equation**, an equation showing the complete neutral formulas for each compound in the reaction as if they existed as molecules. In actual solutions of soluble ionic compounds, dissolved substances are present as ions. We can write equations for reactions occurring in aqueous solution in a way that better shows the dissociated nature of dissolved ionic compounds. For example, we can rewrite the previous equation as:

Equations such as this, which list all of the ions present as either reactants or products in a chemical reaction, are **complete ionic equations**. Strong electrolytes are always represented as their component ions in ionic equations—weak electrolytes are not.

Notice that in the complete ionic equation, some of the ions in solution appear unchanged on both sides of the equation. These ions are called **spectator ions** because they do not participate in the reaction.

To simplify the equation and to show more clearly what is happening, we can omit spectator ions:

Equations that show only the species that actually change during the reaction are **net ionic equations**.

As another example, consider the reaction between  $\text{HCl}(aq)$  and  $\text{KOH}(aq)$ :

Since  $\text{HCl}$ ,  $\text{KOH}$ , and  $\text{KCl}$  all exist in solution primarily as independent ions, the complete ionic equation is:

To write the net ionic equation, we remove the spectator ions, those that are unchanged on both sides of the equation:

Spectator ions

The net ionic equation is  $\text{H}^+(aq) + \text{OH}^-(aq) \longrightarrow \text{H}_2\text{O}(l)$ .

#### Summarizing Aqueous Equations:

- ▶ A **molecular equation** is a chemical equation showing the complete, neutral formulas for every compound in a reaction.
- ▶ A **complete ionic equation** is a chemical equation showing all of the species as they are actually present in solution.
- ▶ A **net ionic equation** is an equation showing only the species that actually change during the reaction.

### Example 4.12 Writing Complete Ionic and Net Ionic Equations

Write complete ionic and net ionic equations for each reaction.

#### SOLUTION

- (a) Write the complete ionic equation by separating aqueous ionic compounds into their constituent ions. The  $\text{Sr}_3(\text{PO}_4)_2(s)$ , precipitating as a solid, remains as one unit.

Write the net ionic equation by eliminating the spectator ions, those that do not change from one side of the reaction to the other.

#### Complete ionic equation:

#### Net ionic equation:

- (b) Write the complete ionic equation by separating aqueous ionic compounds into their constituent ions. Do not separate  $\text{HC}_2\text{H}_3\text{O}_2(aq)$  because it is a weak electrolyte.

Write the net ionic equation by eliminating the spectator ions.

#### Complete ionic equation:

#### Net ionic equation:

**FOR PRACTICE 4.12** Write the complete ionic equation and net ionic equation for the following reaction:

## 4.8 Acid-Base and Gas-Evolution Reactions

Two other important classes of reactions that occur in aqueous solution are acid-base reactions and gas-evolution reactions. In an **acid-base reaction** (also called a **neutralization reaction**), an acid reacts with a base and the two neutralize each other, producing water (or in some cases a weak electrolyte). In a **gas-evolution reaction**, a gas forms, resulting in bubbling. In both cases, as in precipitation reactions, the

▲ Gas-evolution reactions, such as the reaction of hydrochloric acid (HCl) with limestone (CaCO<sub>3</sub>), typically produce CO<sub>2</sub>; bubbling occurs as the gas is released.

▲ **FIGURE 4.17 The Hydronium Ion** Protons normally associate with water molecules in solution to form H<sub>3</sub>O<sup>+</sup> ions, which in turn interact with other water molecules.

▲ These household substances all contain acids.

reactions occur when the anion from one reactant combines with the cation of the other. Many gas-evolution reactions are also acid–base reactions.

## Acid–Base Reactions

Our stomachs contain hydrochloric acid (HCl), which acts in the digestion of food. Certain foods or stress, however, can increase the stomach's acidity to uncomfortable levels, causing acid stomach or heartburn. Antacids are over-the-counter medicines that work by reacting with and neutralizing stomach acid. Antacids employ different *bases*—substances that produce hydroxide (OH<sup>−</sup>) ions in water—as neutralizing agents. Milk of magnesia, for example, contains Mg(OH)<sub>2</sub> and Mylanta contains Al(OH)<sub>3</sub>. All antacids, regardless of the base they employ, have the same effect of neutralizing stomach acid and relieving heartburn through *acid–base reactions*.

Recall from Chapter 3 that an acid forms H<sup>+</sup> ions in solution, and we just saw that a base is a substance that produces OH<sup>−</sup> ions in solution. More formally:

- Acid: Substance that produces H<sup>+</sup> ions in aqueous solution
- Base: Substance that produces OH<sup>−</sup> ions in aqueous solution

These definitions of acids and bases, called the **Arrhenius definitions**, are named after Swedish chemist Svante Arrhenius (1859–1927). In Chapter 15, we will learn more general definitions of acids and bases, but these definitions are sufficient to describe neutralization reactions.

According to the Arrhenius definition, HCl is an acid because it produces H<sup>+</sup> ions in solution:

An H<sup>+</sup> ion is a bare proton. In solution bare protons normally associate with water molecules to form **hydronium ions** (Figure 4.17◀):

Chemists use H<sup>+</sup>(aq) and H<sub>3</sub>O<sup>+</sup>(aq) interchangeably to mean the same thing—a hydronium ion. The chemical equation for the ionization of HCl and other acids is often written to show the association of the proton with a water molecule to form the hydronium ion:

As we discussed in Section 4.5, some acids are weak acids—they do not completely ionize in solution. We represent the partial ionization of a weak acid with opposing half arrows.

Some acids—called **polyprotic acids**—contain more than one ionizable proton and release them sequentially. For example, sulfuric acid, H<sub>2</sub>SO<sub>4</sub>, is a **diprotic acid**. It is strong in its first ionizable proton, but weak in its second:

According to the Arrhenius definition, NaOH is a base because it produces OH<sup>−</sup> ions in solution:

In analogy to diprotic acids, some bases such as Sr(OH)<sub>2</sub> produce two moles of OH<sup>−</sup> per mole of the base:

Table 4.2 lists common acids and bases. You can find acids and bases in many everyday substances. Foods such as citrus fruits and vinegar contain acids. Soap, baking soda, and milk of magnesia all contain bases.

When we mix an acid and a base, the H<sup>+</sup>(aq) from the acid—whether it is weak or strong—combines with the OH<sup>−</sup>(aq) from the base to form H<sub>2</sub>O(l) (Figure 4.18▶). Consider the reaction between hydrochloric acid and sodium hydroxide:

**TABLE 4.2** Some Common Acids and Bases

Name of Acid	Formula	Name of Base	Formula
Hydrochloric acid	HCl	Sodium hydroxide	NaOH
Hydrobromic acid	HBr	Lithium hydroxide	LiOH
Hydroiodic acid	HI	Potassium hydroxide	KOH
Nitric acid	HNO <sub>3</sub>	Calcium hydroxide	Ca(OH) <sub>2</sub>
Sulfuric acid	H <sub>2</sub> SO <sub>4</sub>	Barium hydroxide	Ba(OH) <sub>2</sub>
Perchloric acid	HClO <sub>4</sub>	Ammonia*	NH <sub>3</sub> (weak base)
Formic acid	HCHO <sub>2</sub> (weak acid)		
Acetic acid	HC <sub>2</sub> H <sub>3</sub> O <sub>2</sub> (weak acid)		
Hydrofluoric acid	HF (weak acid)		

\*Ammonia does not contain OH<sup>−</sup>, but it produces OH<sup>−</sup> in a reaction with water that occurs only to a small extent:  $\text{NH}_3(\text{aq}) + \text{H}_2\text{O}(\text{l}) \rightleftharpoons \text{NH}_4^+(\text{aq}) + \text{OH}^-(\text{aq})$ .

▲ Many common household products contain bases.

### Acid–Base Reaction

The reaction between hydrochloric acid and sodium hydroxide forms water and a salt, sodium chloride, which remains dissolved in the solution.

◀ **FIGURE 4.18 Acid–Base Reaction** The reaction between hydrochloric acid and sodium hydroxide forms water and a salt, sodium chloride, which remains dissolved in the solution.

The word *salt* in this sense applies to any ionic compound and is therefore more general than the common usage, which refers only to table salt (NaCl).

Acid–base reactions generally form water and an ionic compound—called a **salt**—that usually remains dissolved in the solution. The net ionic equation for acid–base reactions involving a strong acid is:

However, if the acid is a weak acid, the net ionic equation is slightly different. For example, consider the acid–base equation between hydrofluoric acid and sodium hydroxide:

The complete ionic equation and the net ionic equation for this reaction are:

Notice that, since HF is a weak acid, we do not show it as ionized in the ionic equations.

Another example of an acid–base reaction is the reaction between sulfuric acid and potassium hydroxide:

Again, notice the pattern of acid and base reacting to form water and a salt.

When writing equations for acid–base reactions, write the formula of the salt using the procedure for writing formulas of ionic compounds demonstrated in Section 3.5.

### Example 4.13 Writing Equations for Acid–Base Reactions Involving a Strong Acid

Write a molecular and net ionic equation for the reaction between aqueous HI and aqueous Ba(OH)<sub>2</sub>.

**SOLUTION** First identify these substances as an acid and a base. Begin by writing the unbalanced equation in which the acid and the base combine to form water and a salt.

Next, balance the equation; this is the molecular equation.

Write the net ionic equation by removing the spectator ions.

**FOR PRACTICE 4.13** Write a molecular and a net ionic equation for the reaction that occurs between aqueous HBr and aqueous LiOH.

### Example 4.14 Writing Equations for Acid–Base Reactions Involving a Weak Acid

Write a molecular equation, ionic equation, and net ionic equation for the reaction between aqueous acetic acid (HC<sub>2</sub>H<sub>3</sub>O<sub>2</sub>) and aqueous potassium hydroxide (KOH).

**SOLUTION** Begin by writing the molecular equation in which the acid and the base combine to form water and a salt. (The equation is already balanced.)

Write the complete ionic equation by separating aqueous ionic compounds into their constituent ions. Do not separate HC<sub>2</sub>H<sub>3</sub>O<sub>2</sub>(aq) because it is a weak acid (and a weak electrolyte).

Write the net ionic equation by eliminating the spectator ions.

**Net ionic equation:**

**FOR PRACTICE 4.14** Write the net ionic equation for the reaction between  $\text{HCHO}_2$  (a weak acid) and  $\text{NaOH}$ .

### Acid–Base Titrations

We can apply the principles of acid–base neutralization and stoichiometry to a common laboratory procedure called a *titration*. In a **titration**, a substance in a solution of known concentration is reacted with another substance in a solution of unknown concentration. For example, consider the following acid–base reaction:

The net ionic equation for this reaction eliminates the spectator ions:

Suppose we have an  $\text{HCl}$  solution represented by the molecular diagram shown at right (we have omitted the  $\text{Cl}^-$  ions and the  $\text{H}_2\text{O}$  molecules not involved in the reaction from this representation for clarity).

In titrating this sample, we slowly add a solution of known  $\text{OH}^-$  concentration, as shown in the molecular diagrams in Figure 4.19. As we add the  $\text{OH}^-$ , it reacts with and neutralizes the  $\text{H}^+$ , forming water. At the **equivalence point**—the point in the titration when the number of moles of  $\text{OH}^-$  added equals the number of moles of  $\text{H}^+$  initially in solution—the titration is complete. The equivalence point is typically signaled by an **indicator**, a dye whose color depends on the acidity or basicity of the solution (Figure 4.20, on the next page).

### Acid–Base Titration

**FIGURE 4.19** Acid–Base Titration

► **FIGURE 4.20 Titration** In this titration, NaOH is added to a dilute HCl solution. When the NaOH and HCl reach stoichiometric proportions (the equivalence point), the phenolphthalein indicator changes color to pink.

Indicator in Titration

We cover acid–base titrations and indicators in more detail in Chapter 17. In most laboratory titrations, the concentration of one of the reactant solutions is unknown, and the concentration of the other is precisely known. By carefully measuring the volume of each solution required to reach the equivalence point, we can determine the concentration of the unknown solution, as demonstrated in Example 4.15.

### Example 4.15 Acid–Base Titration

The titration of 10.00 mL of HCl solution of unknown concentration requires 12.54 mL of a 0.100 M NaOH solution to reach the equivalence point. What is the concentration of the unknown HCl solution in M?

**SORT** You are given the volume and concentration of NaOH solution required to titrate a given volume of HCl solution. You are asked to find the concentration of the HCl solution.

**STRATEGIZE** Since this problem involves an acid–base neutralization reaction between HCl and NaOH, start by writing the balanced equation, using the techniques covered earlier in this section.

The first part of the conceptual plan has the form volume A  $\rightarrow$  moles A  $\rightarrow$  moles B. The concentration of the NaOH solution is a conversion factor between moles and volume of NaOH. The balanced equation provides the relationship between number of moles of NaOH and number of moles of HCl.

In the second part of the conceptual plan, use the number of moles of HCl (from the first part) and the volume of HCl solution (given) to calculate the molarity of the HCl solution.

**GIVEN:** 12.54 mL of NaOH solution, 0.100 M NaOH solution, 10.00 mL of HCl solution

**FIND:** concentration of HCl solution

#### CONCEPTUAL PLAN

#### RELATIONSHIPS USED

$$1 \text{ L} = 1000 \text{ mL}$$

$$M(\text{NaOH}) = \frac{0.100 \text{ mol NaOH}}{\text{L NaOH}}$$

$$1 \text{ mol HCl} : 1 \text{ mol NaOH}$$

$$\text{Molarity (M)} = \frac{\text{moles of solute (mol)}}{\text{volume of solution (L)}}$$

**SOLVE** In the first part of the solution, determine the number of moles of HCl in the unknown solution.

In the second part of the solution, divide the number of moles of HCl by the volume of the HCl solution in L. 10.00 mL is equivalent to 0.01000 L.

**SOLUTION**

$$12.54 \text{ mL NaOH} \times \frac{1 \text{ L}}{1000 \text{ mL}} \times \frac{0.100 \text{ mol NaOH}}{1 \text{ L NaOH}} \times \frac{1 \text{ mol HCl}}{1 \text{ mol NaOH}} = 1.25 \times 10^{-3} \text{ mol HCl}$$

$$\text{Molarity} = \frac{1.25 \times 10^{-3} \text{ mol HCl}}{0.01000 \text{ L}} = 0.125 \text{ M HCl}$$

**CHECK** The units of the answer (M HCl) are correct. The magnitude of the answer (0.125 M) is reasonable because it is similar to the molarity of the NaOH solution, as expected from the reaction stoichiometry (1 mol HCl reacts with 1 mol NaOH) and the similar volumes of NaOH and HCl.

**FOR PRACTICE 4.15** The titration of a 20.0-mL sample of an  $\text{H}_2\text{SO}_4$  solution of unknown concentration requires 22.87 mL of a 0.158 M KOH solution to reach the equivalence point. What is the concentration of the unknown  $\text{H}_2\text{SO}_4$  solution?

**FOR MORE PRACTICE 4.15** What volume (in mL) of 0.200 M NaOH do we need to titrate 35.00 mL of 0.140 M HBr to the equivalence point?

## Gas-Evolution Reactions

In a *gas-evolution reaction*, two aqueous solutions mix to form a gaseous product that bubbles out of solution. Some gas-evolution reactions form a gaseous product directly when the cation of one reactant combines with the anion of the other. For example, when sulfuric acid reacts with lithium sulfide, dihydrogen sulfide gas forms:

Other gas-evolution reactions often form an intermediate product that then decomposes (breaks down into simpler substances) to form a gas. For example, when aqueous hydrochloric acid is mixed with aqueous sodium bicarbonate, the following reaction occurs (Figure 4.21►, on the next page):

The intermediate product,  $\text{H}_2\text{CO}_3$ , is not stable and decomposes into  $\text{H}_2\text{O}$  and gaseous  $\text{CO}_2$ . Other important gas-evolution reactions form either  $\text{H}_2\text{SO}_3$  or  $\text{NH}_4\text{OH}$  as intermediate products:

Table 4.3 lists the main types of compounds that form gases in aqueous reactions, as well as the gases formed.

Many gas-evolution reactions such as this one are also acid–base reactions. In Chapter 16 we will learn how ions such as  $\text{CO}_3^{2-}$  act as bases in aqueous solution.

The intermediate product  $\text{NH}_4\text{OH}$  provides a convenient way to think about this reaction, but the extent to which it actually forms is debatable.

**TABLE 4.3** Types of Compounds That Undergo Gas-Evolution Reactions

Reactant Type	Intermediate Product	Gas Evolved	Example
Sulfides	None	$\text{H}_2\text{S}$	$2 \text{HCl}(aq) + \text{K}_2\text{S}(aq) \longrightarrow \text{H}_2\text{S}(g) + 2 \text{KCl}(aq)$
Carbonates and bicarbonates	$\text{H}_2\text{CO}_3$	$\text{CO}_2$	$2 \text{HCl}(aq) + \text{K}_2\text{CO}_3(aq) \longrightarrow \text{H}_2\text{O}(l) + \text{CO}_2(g) + 2 \text{KCl}(aq)$
Sulfites and bisulfites	$\text{H}_2\text{SO}_3$	$\text{SO}_2$	$2 \text{HCl}(aq) + \text{K}_2\text{SO}_3(aq) \longrightarrow \text{H}_2\text{O}(l) + \text{SO}_2(g) + 2 \text{KCl}(aq)$
Ammonium	$\text{NH}_4\text{OH}$	$\text{NH}_3$	$\text{NH}_4\text{Cl}(aq) + \text{KOH}(aq) \longrightarrow \text{H}_2\text{O}(l) + \text{NH}_3(g) + \text{KCl}(aq)$

► **FIGURE 4.21** Gas-Evolution

**Reaction** When aqueous hydrochloric acid is mixed with aqueous sodium bicarbonate, gaseous  $\text{CO}_2$  bubbles out of the reaction mixture.

**Gas-Evolution Reaction**

When aqueous sodium bicarbonate is mixed with aqueous hydrochloric acid, gaseous  $\text{CO}_2$  bubbles are the result of the reaction.

**Example 4.16** Writing Equations for Gas-Evolution Reactions

Write a molecular equation for the gas-evolution reaction that occurs when you mix aqueous nitric acid and aqueous sodium carbonate.

Begin by writing an unbalanced equation in which the cation of each reactant combines with the anion of the other.

You must then recognize that  $\text{H}_2\text{CO}_3(aq)$  decomposes into  $\text{H}_2\text{O}(l)$  and  $\text{CO}_2(g)$  and write these products into the equation.

Finally, balance the equation.

**FOR PRACTICE 4.16** Write a molecular equation for the gas-evolution reaction that occurs when you mix aqueous hydrobromic acid and aqueous potassium sulfite.

**FOR MORE PRACTICE 4.16** Write a net ionic equation for the reaction that occurs when you mix hydroiodic acid with calcium sulfide.

## 4.9 Oxidation–Reduction Reactions

**Oxidation–reduction reactions** or **redox reactions** are reactions in which electrons transfer from one reactant to the other. The rusting of iron, the bleaching of hair, and the production of electricity in batteries involve redox reactions. Many redox reactions involve the reaction of a substance with oxygen (Figure 4.22▼).

Oxidation–reduction reactions are covered in more detail in Chapter 19.

### Oxidation–Reduction Reaction

▲ **FIGURE 4.22 Oxidation–Reduction Reaction** The hydrogen in the balloon reacts with oxygen upon ignition to form gaseous water (which is dispersed in the flame).

However, redox reactions need not involve oxygen. Consider, for example, the reaction between sodium and chlorine to form sodium chloride (NaCl), depicted in Figure 4.23►, on the next page:

This reaction is similar to the reaction between sodium and oxygen, which forms sodium oxide:

In both cases, a metal (which has a tendency to lose electrons) reacts with a nonmetal (which has a tendency to gain electrons). And in both cases, metal atoms lose electrons to nonmetal atoms. A fundamental definition of **oxidation** is the loss of electrons, and a fundamental definition of **reduction** is the gain of electrons.

The transfer of electrons does not need to be a *complete* transfer (as occurs in the formation of an ionic compound) for the reaction to qualify as oxidation–reduction. For example, consider the reaction between hydrogen gas and chlorine gas:

Even though hydrogen chloride is a molecular compound with a covalent bond, and even though the hydrogen has not completely transferred its electron to chlorine during

The reaction between sodium and oxygen forms other oxides as well.

Helpful Mnemonic: O I L R I G—  
Oxidation Is Loss; Reduction Is Gain.

The ability of an element to attract electrons in a chemical bond is called electronegativity. We cover electronegativity in more detail in Section 9.6.

## Oxidation–Reduction Reaction without Oxygen

Electrons are transferred from sodium to chlorine, forming sodium chloride.  
Sodium is oxidized and chlorine is reduced.

▲ **FIGURE 4.23** Oxidation–Reduction without Oxygen When sodium reacts with chlorine, electrons transfer from the sodium to the chlorine, resulting in the formation of sodium chloride. In this redox reaction, sodium is oxidized and chlorine is reduced.

Hydrogen loses electron density (oxidation) and chlorine gains electron density (reduction).

▲ **FIGURE 4.24** Redox with Partial Electron Transfer When hydrogen bonds to chlorine, the electrons are unevenly shared, resulting in an increase of electron density (reduction) for chlorine and a decrease in electron density (oxidation) for hydrogen.

the reaction, we can see from the electron density diagrams (Figure 4.24) that hydrogen has lost some of its electron density—it has *partially* transferred its electron to chlorine. In the reaction, hydrogen is oxidized and chlorine is reduced and, therefore, this is a redox reaction.

## Oxidation States

Identifying whether or not a reaction between a metal and a nonmetal is a redox reaction is fairly straightforward because of ion formation. But how do we identify redox reactions that occur between nonmetals? Chemists have devised a scheme to track electrons before and after a chemical reaction. In this scheme—which is like book-keeping for electrons—each shared electron is assigned to the atom that attracts the electrons most strongly. Then a number, called the **oxidation state** or **oxidation number**, is given to each atom based on the electron assignments. In other words, the oxidation number of an atom in a compound is the “charge” it would have if all shared electrons were assigned to the atom with the greatest attraction for those electrons.

For example, consider HCl. Since chlorine attracts electrons more strongly than hydrogen, we assign the two shared electrons in the bond to chlorine; then H (which has lost an electron in our assignment) has an oxidation state of +1, and Cl (which has gained one electron in our assignment) has an oxidation state of −1. Notice that in contrast to ionic charges, which are usually written with the sign of the charge *after* the magnitude (1+ and 1−, for example), oxidation states are written with the sign of the charge *before* the magnitude (+1 and −1, for example). We use the following rules to assign oxidation states to atoms in elements, ions, and compounds.

### Rules for Assigning Oxidation States

(These rules are hierarchical. If any two rules conflict, follow the rule that is higher on the list.)

- The oxidation state of an atom in a free element is 0.
- The oxidation state of a monoatomic ion is equal to its charge.
- The sum of the oxidation states of all atoms in:
  - A neutral molecule or formula unit is 0.
  - An ion is equal to the charge of the ion.
- In their compounds, metals have positive oxidation states.
  - Group 1A metals *always* have an oxidation state of +1.
  - Group 2A metals *always* have an oxidation state of +2.

- In their compounds, nonmetals are assigned oxidation states according to the table shown here. Entries at the top of the table take precedence over entries at the bottom of the table.

When assigning oxidation states, keep these points in mind:

- The oxidation state of any given element generally depends on what other elements are present in the compound. (The exceptions are the group 1A and 2A metals, which are *always* +1 and +2, respectively.)
- Rule 3 must always be followed. Therefore, when following the hierarchy shown in rule 5, give priority to the element(s) highest on the list and then assign the oxidation state of the element lowest on the list using rule 3.
- When assigning oxidation states to elements that are not covered by rules 4 and 5 (such as carbon), use rule 3 to deduce their oxidation state once all other oxidation states have been assigned.

### Examples

Do not confuse oxidation state with ionic charge. Unlike ionic charge—which is a real property of an ion—the oxidation state of an atom is merely a theoretical (but useful) construct.

Nonmetal	Oxidation State	Example
Fluorine	−1	MgF <sub>2</sub> −1 ox state
Hydrogen	+1	H <sub>2</sub> O +1 ox state
Oxygen	−2	CO <sub>2</sub> −2 ox state
Group 7A	−1	CCl <sub>4</sub> −1 ox state
Group 6A	−2	H <sub>2</sub> S −2 ox state
Group 5A	−3	NH <sub>3</sub> −3 ox state

### Example 4.17 Assigning Oxidation States

Assign an oxidation state to each atom in each element, ion, or compound.

(a) Cl<sub>2</sub>      (b) Na<sup>+</sup>      (c) KF      (d) CO<sub>2</sub>      (e) SO<sub>4</sub><sup>2−</sup>      (f) K<sub>2</sub>O<sub>2</sub>

#### SOLUTION

Since Cl<sub>2</sub> is a free element, the oxidation state of both Cl atoms is 0 (rule 1).

Since Na<sup>+</sup> is a monoatomic ion, the oxidation state of the Na<sup>+</sup> ion is +1 (rule 2).

The oxidation state of K is +1 (rule 4). The oxidation state of F is −1 (rule 5). Since this is a neutral compound, the sum of the oxidation states is 0.

—Continued on the next page

—Continued

<p>The oxidation state of oxygen is <math>-2</math> (rule 5). The oxidation state of carbon must be deduced using rule 3, which says that the sum of the oxidation states of all the atoms must be 0.</p>	<p><b>(d)</b> <math>\text{CO}_2</math>  <math>(\text{C ox state}) + 2(\text{O ox state}) = 0</math>  <math>(\text{C ox state}) + 2(-2) = 0</math>  <math>(\text{C ox state}) = +4</math>  <math>\text{CO}_2</math>  <math>+4 - 2</math>  sum: <math>+4 + 2(-2) = 0</math></p>
<p>The oxidation state of oxygen is <math>-2</math> (rule 5). You would ordinarily expect the oxidation state of S to be <math>-2</math> (rule 5). However, if that were the case, the sum of the oxidation states would not equal the charge of the ion. Since O is higher on the list than S, it takes priority and you calculate the oxidation state of sulfur by setting the <i>sum</i> of all of the oxidation states equal to <math>-2</math> (the charge of the ion).</p>	<p><b>(e)</b> <math>\text{SO}_4^{2-}</math>  <math>(\text{S ox state}) + 4(\text{O ox state}) = -2</math>  <math>(\text{S ox state}) + 4(-2) = -2</math>  <math>\text{S ox state} = +6</math>  <math>\text{SO}_4^{2-}</math>  <math>+6 - 2</math>  sum: <math>+6 + 4(-2) = -2</math></p>
<p>The oxidation state of potassium is <math>+1</math> (rule 4). You would ordinarily expect the oxidation state of O to be <math>-2</math> (rule 5), but rule 4 takes priority, and you deduce the oxidation state of O by setting the sum of all of the oxidation states equal to 0.</p>	<p><b>(f)</b> <math>\text{K}_2\text{O}_2</math>  <math>2(\text{K ox state}) + 2(\text{O ox state}) = 0</math>  <math>2(+1) + 2(\text{O ox state}) = 0</math>  <math>\text{O ox state} = -1</math>  <math>\text{K}_2\text{O}_2</math>  <math>+1 - 1</math>  sum: <math>2(+1) + 2(-1) = 0</math></p>
<p><b>FOR PRACTICE 4.17</b> Assign an oxidation state to each atom in each element, ion, or compound.</p> <p><b>(a)</b> Cr      <b>(b)</b> <math>\text{Cr}^{3+}</math>      <b>(c)</b> <math>\text{CCl}_4</math>      <b>(d)</b> <math>\text{SrBr}_2</math>      <b>(e)</b> <math>\text{SO}_3</math>      <b>(f)</b> <math>\text{NO}_3^-</math></p>	

In most cases, oxidation states are positive or negative integers; however, on occasion an atom within a compound can have a fractional oxidation state. Consider  $\text{KO}_2$ . The oxidation states are assigned as follows:

In  $\text{KO}_2$ , oxygen has a  $-\frac{1}{2}$  oxidation state. Although this seems unusual, it is accepted because oxidation states are merely an imposed electron bookkeeping scheme, not an actual physical quantity.

## CONCEPTUAL CONNECTION 4.9

**Oxidation Numbers in Polyatomic Ions** Which statement best describes the *difference* between the *charge* of a polyatomic ion and the *oxidation states* of its constituent atoms? (For example, the charge of  $\text{NO}_3^-$  is  $1-$ , and the oxidation states of its atoms are  $+5$  for the nitrogen atom and  $-2$  for each oxygen atom.)

- (a)** The charge of a polyatomic ion is a property of the entire ion, while the oxidation states are assigned to each individual atom.
- (b)** The oxidation state of the ion is the same as its charge.
- (c)** The charge of a polyatomic ion is not a real physical property, while the oxidation states of atoms are actual physical properties.

## Identifying Redox Reactions

We can use oxidation states to identify redox reactions, even between nonmetals. For example, is the following reaction between carbon and sulfur a redox reaction?

If so, what element is oxidized? What element is reduced? We can use the oxidation state rules to assign oxidation states to all elements on both sides of the equation.

Carbon changes from an oxidation state of 0 to an oxidation state of +4. In terms of our electron bookkeeping scheme (the assigned oxidation state), carbon *loses electrons* and is *oxidized*. Sulfur changes from an oxidation state of 0 to an oxidation state of −2. In terms of our electron bookkeeping scheme, sulfur *gains electrons* and is *reduced*. In terms of oxidation states, oxidation and reduction are defined as follows:

- Oxidation: An increase in oxidation state
- Reduction: A decrease in oxidation state

Remember that a reduction is a *reduction* in oxidation state.

### Example 4.18 Using Oxidation States to Identify Oxidation and Reduction

Use oxidation states to identify the element that is oxidized and the element that is reduced in the following redox reaction:

#### SOLUTION

Begin by assigning oxidation states to each atom in the reaction.

Since Mg increased in oxidation state, it was oxidized. Since H decreased in oxidation state, it was reduced.

**FOR PRACTICE 4.18** Use oxidation states to identify the element that is oxidized and the element that is reduced in the following redox reaction:

**FOR MORE PRACTICE 4.18** Determine whether or not each reaction is a redox reaction. If the reaction is a redox reaction, identify which element is oxidized and which is reduced.

- $\text{Hg}_2(\text{NO}_3)_2(aq) + 2\text{KBr}(aq) \longrightarrow \text{Hg}_2\text{Br}_2(s) + 2\text{KNO}_3(aq)$
- $4\text{Al}(s) + 3\text{O}_2(g) \longrightarrow 2\text{Al}_2\text{O}_3(s)$
- $\text{CaO}(s) + \text{CO}_2(g) \longrightarrow \text{CaCO}_3(s)$

Notice that *oxidation and reduction must occur together*. If one substance loses electrons (oxidation), then another substance must gain electrons (reduction). A substance that causes the oxidation of another substance is an **oxidizing agent**. Oxygen, for example, is an excellent oxidizing agent. In a redox reaction, *the oxidizing agent is always reduced*. A substance that causes the reduction of another substance is a **reducing agent**. Hydrogen, for example, and group 1A and group 2A metals (because of their tendency to lose electrons) are excellent reducing agents. In a redox reaction, *the reducing agent is always oxidized*.

In Section 19.2 you will learn more about redox reactions, including how to balance them. For now, be able to identify redox reactions, as well as oxidizing and reducing agents, according to the following guidelines.

*Redox reactions:*

- Any reaction in which there is a change in the oxidation states of atoms in going from reactants to products.

*In a redox reaction:*

- The oxidizing agent oxidizes another substance (and is itself reduced).
- The reducing agent reduces another substance (and is itself oxidized).

**Example 4.19** Identifying Redox Reactions, Oxidizing Agents, and Reducing Agents

Determine whether each reaction is an oxidation–reduction reaction. For each oxidation–reduction reaction, identify the oxidizing agent and the reducing agent.

**SOLUTION**

*This is a redox reaction* because magnesium increases in oxidation number (oxidation) and oxygen decreases in oxidation number (reduction).

*This is not a redox reaction* because none of the atoms undergo a change in oxidation number.

*This is a redox reaction* because zinc increases in oxidation number (oxidation) and iron decreases in oxidation number (reduction).

**FOR PRACTICE 4.19** Determine whether or not each reaction is a redox reaction. For each redox reaction, identify the oxidizing agent and the reducing agent.

**CONCEPTUAL CONNECTION 4.10****Oxidation and Reduction** Which statement is true?

- A redox reaction involves *either* the transfer of an electron *or* a change in the oxidation state of an element.
- If any of the reactants or products in a reaction contain oxygen, the reaction is a redox reaction.
- In a reaction, oxidation can occur independently of reduction.
- In a redox reaction, any increase in the oxidation state of a reactant must be accompanied by a decrease in the oxidation state of a reactant.

## Chemistry IN YOUR DAY | Bleached Blonde

**H**ave you ever bleached your hair? Most home kits for hair bleaching contain hydrogen peroxide ( $\text{H}_2\text{O}_2$ ), an excellent oxidizing agent. When applied to hair, hydrogen peroxide oxidizes melanin, the dark pigment that gives hair its color. Once melanin is oxidized, it no longer imparts a dark color, leaving the hair with the familiar bleached look. Hydrogen peroxide also oxidizes other components of hair. For example, protein molecules in hair contain  $\text{—SH}$  groups called thiols. Hydrogen peroxide oxidizes these thiol groups to sulfonic acid groups,  $\text{—SO}_3\text{H}$ . The oxidation of thiol groups to sulfonic acid groups causes changes in the proteins that compose hair, making the hair more brittle and more likely to tangle. Consequently, people with heavily bleached hair generally use conditioners, which contain compounds that form thin, lubricating coatings on individual hair shafts. These coatings prevent tangling and make hair softer and more manageable.

### QUESTION

The following is a reaction of hydrogen peroxide with an alkene:

Can you see why this reaction is a redox reaction? Can you identify the oxidizing and reducing agents?

▲ The bleaching of hair involves a redox reaction in which melanin—the main pigment in hair—is oxidized.

## Combustion Reactions

We encountered combustion reactions, a type of redox reaction, in the opening section of this chapter. Combustion reactions are important because most of our society's energy is derived from them (Figure 4.25▼).

As we discussed in Section 4.1, *combustion reactions* are characterized by the reaction of a substance with  $\text{O}_2$  to form one or more oxygen-containing compounds, often including water. Combustion reactions also emit heat. For example, as we saw earlier in this chapter, natural gas ( $\text{CH}_4$ ) reacts with oxygen to form carbon dioxide and water:

◀ **FIGURE 4.25 U.S. Energy Consumption** About 82% of the energy the United States uses is produced by combustion reactions. Source: U.S. Energy Information Administration. *Annual Energy Review*. 2014.

In this reaction, carbon is oxidized and oxygen is reduced. Ethanol, the alcohol in alcoholic beverages, also reacts with oxygen in a combustion reaction to form carbon dioxide and water:

Compounds containing carbon and hydrogen—or carbon, hydrogen, and oxygen—always form carbon dioxide and water upon complete combustion. Other combustion reactions include the reaction of carbon with oxygen to form carbon dioxide:

and the reaction of hydrogen with oxygen to form water:

### Example 4.20 Writing Equations for Combustion Reactions

Write a balanced equation for the combustion of liquid methyl alcohol ( $\text{CH}_3\text{OH}$ ).

#### SOLUTION

Begin by writing an unbalanced equation showing the reaction of  $\text{CH}_3\text{OH}$  with  $\text{O}_2$  to form  $\text{CO}_2$  and  $\text{H}_2\text{O}$ .

Balance the equation using the guidelines in Section 3.10.

**FOR PRACTICE 4.20** Write a balanced equation for the complete combustion of liquid  $\text{C}_2\text{H}_5\text{SH}$ .

## Self-Assessment Quiz

- Q1.** Manganese(IV) oxide reacts with aluminum to form elemental manganese and aluminum oxide:

What mass of Al is required to completely react with 25.0 g  $\text{MnO}_2$ ?

- a) 7.76 g Al                      b) 5.82 g Al  
c) 33.3 g Al                      d) 10.3 g Al

- Q2.** Sodium and chlorine react to form sodium chloride:

What is the theoretical yield of sodium chloride for the reaction of 55.0 g Na with 67.2 g  $\text{Cl}_2$ ?

- a)  $1.40 \times 10^2$  g NaCl              b) 111 g NaCl  
c) 55.4 g NaCl                      d) 222 g NaCl

- Q3.** Sulfur and fluorine react to form sulfur hexafluoride:

If 50.0 g S is allowed to react as completely as possible with 105.0 g  $\text{F}_2$ , what mass of the excess reactant is left?

- a) 20.5 g S                      b) 45.7 g  $\text{F}_2$   
c) 15.0 g S                      d) 36.3 g  $\text{F}_2$

- Q4.** A reaction has a theoretical yield of 45.8 g. When the reaction is carried out, 37.2 g of the product is obtained. What is the percent yield?

- a) 55.1%                      b) 44.8%  
c) 123%                      d) 81.2%

- Q5.** What is the molarity of a solution containing 55.8 g of  $\text{MgCl}_2$  dissolved in 1.00 L of solution?

- a) 55.8 M                      b) 1.71 M  
c) 0.586 M                      d) 0.558 M

- Q6.** What mass (in grams) of  $\text{Mg}(\text{NO}_3)_2$  is present in 145 mL of a 0.150 M solution of  $\text{Mg}(\text{NO}_3)_2$ ?

- a) 3.23 g                      b) 0.022 g  
c) 1.88 g                      d) 143 g

- Q7.** What volume of a 1.50 M HCl solution should you use to prepare 2.00 L of a 0.100 M HCl solution?

- a) 0.300 L                      b) 0.133 L  
c) 30.0 L                      d) 2.00 L

- Q8.** Potassium iodide reacts with lead(II) nitrate in the following precipitation reaction:

What minimum volume of 0.200 M potassium iodide solution is required to completely precipitate all of the lead in 155.0 mL of a 0.112 M lead(II) nitrate solution?

- a) 348 mL                      b) 86.8 mL  
c) 174 mL                      d) 43.4 mL

**Q9.** Which solution forms a precipitate when mixed with a solution of aqueous  $\text{Na}_2\text{CO}_3$ ?

- a)  $\text{KNO}_3(aq)$                       b)  $\text{NaBr}(aq)$   
c)  $\text{NH}_4\text{Cl}(aq)$                       d)  $\text{CuCl}_2(aq)$

**Q10.** What is the net ionic equation for the reaction that occurs when aqueous solutions of  $\text{KOH}$  and  $\text{SrCl}_2$  are mixed?

- a)  $\text{K}^+(aq) + \text{Cl}^-(aq) \longrightarrow \text{KCl}(s)$   
b)  $\text{Sr}^{2+}(aq) + 2\text{OH}^-(aq) \longrightarrow \text{Sr}(\text{OH})_2(s)$   
c)  $\text{H}^+(aq) + \text{OH}^-(aq) \longrightarrow \text{H}_2\text{O}(l)$   
d) None of the above because no reaction occurs

**Q11.** What is the net ionic equation for the reaction that occurs when aqueous solutions of  $\text{KOH}$  and  $\text{HNO}_3$  are mixed?

- a)  $\text{K}^+(aq) + \text{NO}_3^-(aq) \longrightarrow \text{KNO}_3(s)$   
b)  $\text{NO}_3^-(aq) + \text{OH}^-(aq) \longrightarrow \text{NO}_3\text{OH}(s)$   
c)  $\text{H}^+(aq) + \text{OH}^-(aq) \longrightarrow \text{H}_2\text{O}(l)$   
d) None of the above because no reaction occurs.

**Q12.** What is the net ionic equation for the reaction that occurs when aqueous solutions of  $\text{KHCO}_3$  and  $\text{HBr}$  are mixed?

- a)  $\text{K}^+(aq) + \text{C}_2\text{H}_3\text{O}_2^-(aq) \longrightarrow \text{KC}_2\text{H}_3\text{O}_2(s)$   
b)  $\text{H}^+(aq) + \text{HCO}_3^-(aq) \longrightarrow \text{CO}_2(g) + \text{H}_2\text{O}(l)$   
c)  $\text{H}^+(aq) + \text{OH}^-(aq) \longrightarrow \text{H}_2\text{O}(l)$   
d) None of the above because no reaction occurs.

**Q13.** What is the oxidation state of carbon in  $\text{CO}_3^{2-}$ ?

- a) +4                                      b) +3  
c) -3                                      d) -2

**Q14.** Sodium reacts with water according to the reaction:

Identify the oxidizing agent.

- a)  $\text{Na}(s)$                                       b)  $\text{H}_2\text{O}(l)$   
c)  $\text{NaOH}(aq)$                               d)  $\text{H}_2(g)$

**Q15.** Identify the correct balanced equation for the combustion of propane ( $\text{C}_3\text{H}_8$ ).

- a)  $\text{C}_3\text{H}_8(g) \longrightarrow 4\text{H}_2(g) + 3\text{C}(s)$   
b)  $\text{C}_3\text{H}_8(g) + 5\text{O}_2(g) \longrightarrow 4\text{H}_2\text{O}(g) + 3\text{CO}_2(g)$   
c)  $\text{C}_3\text{H}_8(g) + 3\text{O}_2(g) \longrightarrow 4\text{H}_2\text{O}(g) + 3\text{CO}_2(g)$   
d)  $2\text{C}_3\text{H}_8(g) + 9\text{O}_2(g) \longrightarrow 6\text{H}_2\text{CO}_3(g) + 2\text{H}_2(g)$

Answers: 1. (d) 2. (b) 3. (a) 4. (d) 5. (c) 6. (a) 7. (b) 8. (c) 9. (d) 10. (b) 11. (c) 12. (b) 13. (a) 14. (b) 15. (b)

## Key Concepts

### Climate Change and the Combustion of Fossil Fuels (4.1)

- ▶ Greenhouse gases warm Earth by trapping some of the sunlight that penetrates Earth's atmosphere. Global warming, resulting from rising atmospheric carbon dioxide levels, is potentially harmful.
- ▶ The largest atmospheric carbon dioxide source is the burning of fossil fuels. This can be verified by reaction stoichiometry.

### Reaction Stoichiometry (4.2)

- ▶ Reaction stoichiometry refers to the numerical relationships between the reactants and products in a balanced chemical equation.
- ▶ Reaction stoichiometry allows us to predict, for example, the amount of product that can be formed for a given amount of reactant, or how much of one reactant is required to react with a given amount of another.

### Limiting Reactant, Theoretical Yield, and Percent Yield (4.3)

- ▶ When a chemical reaction actually occurs, the reactants are usually not present in the exact stoichiometric ratios specified by the balanced chemical equation. The limiting reactant is the one that is available in the smallest stoichiometric quantity—it will be completely consumed in the reaction, and it limits the amount of product that can be made.
- ▶ Any reactant that does not limit the amount of product is in excess.
- ▶ The amount of product that can be made from the limiting reactant is the theoretical yield.
- ▶ The actual yield—always equal to or less than the theoretical yield—is the amount of product that is actually made when the reaction is carried out.
- ▶ The percentage of the theoretical yield that is actually produced when the reaction is carried out is the percent yield.

### Solution Concentration and Stoichiometry (4.4)

- ▶ An aqueous solution is a homogeneous mixture of water (the solvent) with another substance (the solute).
- ▶ We express the concentration of a solution in molarity, the number of moles of solute per liter of solution.
- ▶ We can use the molarities and volumes of reactant solutions to predict the amount of product that forms in an aqueous reaction.

### Aqueous Solutions and Precipitation Reactions (4.5, 4.6)

- ▶ Solutes that completely dissociate (or completely ionize in the case of the strong acids) to ions in solution are strong electrolytes and their solutions are good conductors of electricity.

- ▶ Solutes that only partially dissociate (or partially ionize) are weak electrolytes.
- ▶ Solutes that do not dissociate (or ionize) are nonelectrolytes.
- ▶ A substance that dissolves in water to form a solution is soluble.
- ▶ In a precipitation reaction, we mix two aqueous solutions and a solid (precipitate) forms.
- ▶ The solubility rules are an empirical set of guidelines that help predict the solubilities of ionic compounds; these rules are especially useful when determining whether or not a precipitate will form.

### Equations for Aqueous Reactions (4.7)

- ▶ We can represent an aqueous reaction with a molecular equation, which shows the complete neutral formula for each compound in the reaction.
- ▶ We can also represent an aqueous reaction with a complete ionic equation, which shows the dissociated nature of the aqueous ionic compounds.
- ▶ A third representation of an aqueous reaction is the net ionic equation, in which the spectator ions—those that do not change in the course of the reaction—are left out of the equation.

### Acid-Base and Gas-Evolution Reactions (4.8)

- ▶ In an acid-base reaction, an acid, a substance that produces  $H^+$  in solution, reacts with a base, a substance that produces  $OH^-$  in solution, and the two neutralize each other, producing water (or in some cases a weak electrolyte).
- ▶ An acid-base titration is a laboratory procedure in which a reaction is carried to its equivalence point—the point at which the reactants are in exact stoichiometric proportions; titrations are useful in determining the concentrations of unknown solutions.
- ▶ In gas-evolution reactions, two aqueous solutions combine and a gas is produced.

### Oxidation-Reduction Reactions (4.9)

- ▶ In oxidation-reduction reactions, one substance transfers electrons to another substance.
- ▶ In oxidation-reduction reactions, the substance that loses electrons is oxidized and the substance that gains them is reduced.
- ▶ An oxidation state is a fictitious charge given to each atom in an oxidation-reduction reaction by assigning all shared electrons to the atom with the greater attraction for those electrons. An oxidation state is an imposed electronic bookkeeping scheme, not an actual physical state.
- ▶ The oxidation state of an atom increases upon oxidation and decreases upon reduction.
- ▶ A combustion reaction is a specific type of oxidation-reduction reaction in which a substance reacts with oxygen, emitting heat and forming one or more oxygen-containing products.

## Key Equations and Relationships

Mass-to-Mass Conversion: Stoichiometry (4.2)

mass A  $\longrightarrow$  amount A (in moles)  $\longrightarrow$   
amount B (in moles)  $\longrightarrow$  mass B

Percent Yield (4.3)

$$\% \text{ yield} = \frac{\text{actual yield}}{\text{theoretical yield}} \times 100\%$$

Molarity (M): Solution Concentration (4.4)

$$M = \frac{\text{amount of solute (in mol)}}{\text{volume of solution (in L)}}$$

Solution Dilution (4.4)

$$M_1V_1 = M_2V_2$$

Solution Stoichiometry (4.4)

volume A  $\longrightarrow$  amount A (in moles)  $\longrightarrow$   
amount B (in moles)  $\longrightarrow$  volume B

## Key Learning Outcomes

CHAPTER OBJECTIVES	ASSESSMENT
Calculations Involving the Stoichiometry of a Reaction (4.2)	Examples 4.1, 4.2 For Practice 4.1, 4.2 Exercises 31–36
Determining the Limiting Reactant and Calculating Theoretical and Percent Yield (4.3)	Examples 4.3, 4.4 For Practice 4.3, 4.4 Exercises 41–51
Calculating and Using Molarity as a Conversion Factor (4.4)	Examples 4.5, 4.6 For Practice 4.5, 4.6 For More Practice 4.5, 4.6 Exercises 53–60
Determining Solution Dilutions (4.4)	Example 4.7 For Practice 4.7 For More Practice 4.7 Exercises 63, 64
Using Solution Stoichiometry to Find Volumes and Amounts (4.4)	Example 4.8 For Practice 4.8 For More Practice 4.8 Exercises 65–67
Predicting Whether a Compound Is Soluble (4.5)	Example 4.9 For Practice 4.9 Exercises 73, 74
Writing Equations for Precipitation Reactions (4.6)	Examples 4.10, 4.11 For Practice 4.10, 4.11 Exercises 75–78
Writing Complete Ionic and Net Ionic Equations (4.7)	Example 4.12 For Practice 4.12 For More Practice 4.12 Exercises 79, 80
Writing Equations for Acid–Base Reactions (4.8)	Example 4.13 For Practice 4.13 Exercises 83, 84
Calculations Involving Acid–Base Titrations (4.8)	Example 4.15 For Practice 4.15 For More Practice 4.15 Exercises 89, 90

## Writing Equations for Gas-Evolution Reactions (4.8)

Example 4.16 For Practice 4.16 For More Practice 4.16  
Exercises 91, 92

## Assigning Oxidation States (4.9)

Example 4.17 For Practice 4.17 Exercises 93–96

## Identifying Redox Reactions, Oxidizing Agents, and Reducing Agents Using Oxidation States (4.9)

Examples 4.18, 4.19 For Practice 4.18, 4.19  
For More Practice 4.18 Exercises 97, 98

## Writing Equations for Combustion Reactions (4.9)

Example 4.20 For Practice 4.20 Exercises 99, 100

## EXERCISES

## Review Questions

- What is reaction stoichiometry? What is the significance of the coefficients in a balanced chemical equation?
- In a chemical reaction, what is the limiting reactant? The theoretical yield? The percent yield? What do we mean when we say a reactant is in excess?
- We typically calculate the percent yield using the actual yield and theoretical yield in units of mass (grams or kilograms). Would the percent yield be different if the actual yield and theoretical yield were in units of amount (moles)?
- What is an aqueous solution? What is the difference between the solute and the solvent?
- What is molarity? How is it useful?
- Explain how a strong electrolyte, a weak electrolyte, and a non-electrolyte differ.
- Explain the difference between a strong acid and a weak acid.
- What does it mean for a compound to be soluble? Insoluble?
- What are the solubility rules? How are they useful?
- What are the cations and anions whose compounds are usually soluble? What are the exceptions? What are the anions whose compounds are mostly insoluble? What are the exceptions?
- What is a precipitation reaction? Give an example.
- How can you predict whether a precipitation reaction will occur upon mixing two aqueous solutions?
- Explain how a molecular equation, a complete ionic equation, and a net ionic equation differ.
- What is the Arrhenius definition of an acid? A base?
- What is an acid–base reaction? Give an example.
- Explain the principles behind an acid–base titration. What is an indicator?
- What is a gas-evolution reaction? Give an example.
- What reactant types give rise to gas-evolution reactions?
- What is an oxidation–reduction reaction? Give an example.
- What are oxidation states?
- How can oxidation states be used to identify redox reactions?
- What happens to a substance when it becomes oxidized? Reduced?
- In a redox reaction, which reactant is the oxidizing agent? The reducing agent?
- What is a combustion reaction? Why are they important? Give an example.

## Problems by Topic

## Reaction Stoichiometry

25. Consider the unbalanced equation for the combustion of hexane:

Balance the equation and determine how many moles of  $\text{O}_2$  are required to react completely with 7.2 moles of  $\text{C}_6\text{H}_{14}$ .

26. Consider the unbalanced equation for the neutralization of acetic acid:

Balance the equation and determine how many moles of  $\text{Ba}(\text{OH})_2$  are required to completely neutralize 0.461 mole of  $\text{HC}_2\text{H}_3\text{O}_2$ .

27. Calculate how many moles of  $\text{NO}_2$  form when each quantity of reactant completely reacts.

- a. 2.5 mol  $\text{N}_2\text{O}_5$                       b. 6.8 mol  $\text{N}_2\text{O}_5$   
c. 15.2 g  $\text{N}_2\text{O}_5$                       d. 2.87 kg  $\text{N}_2\text{O}_5$

28. Calculate how many moles of  $\text{NH}_3$  form when each quantity of reactant completely reacts.

- a. 2.6 mol  $\text{N}_2\text{H}_4$                       b. 3.55 mol  $\text{N}_2\text{H}_4$   
c. 65.3 g  $\text{N}_2\text{H}_4$                       d. 4.88 kg  $\text{N}_2\text{H}_4$

29. Consider the balanced equation:

Complete the table showing the appropriate number of moles of reactants and products. If the number of moles of a *reactant* is provided, fill in the required amount of the other reactant, as well as the moles of each product that forms. If the number of moles of a *product* is provided, fill in the required amount of each reactant to make that amount of product, as well as the amount of the other product that forms.

Mol SiO <sub>2</sub>	Mol C	Mol SiC	Mol CO
3	_____	_____	_____
_____	6	_____	_____
_____	_____	_____	10
2.8	_____	_____	_____
_____	1.55	_____	_____

30. Consider the balanced equation:

Complete the table showing the appropriate number of moles of reactants and products. If the number of moles of a *reactant* is provided, fill in the required amount of the other reactant, as well as the moles of each product that forms. If the number of moles of a *product* is provided, fill in the required amount of each reactant to make that amount of product, as well as the amount of the other product that forms.

Mol N <sub>2</sub> H <sub>4</sub>	Mol N <sub>2</sub> O <sub>4</sub>	Mol N <sub>2</sub>	Mol H <sub>2</sub> O
2	_____	_____	_____
_____	5	_____	_____
_____	_____	_____	10
2.5	_____	_____	_____
_____	4.2	_____	_____
_____	_____	11.8	_____

31. Hydrobromic acid dissolves solid iron according to the reaction:

What mass of HBr (in g) do you need to dissolve a 3.2-g pure iron bar on a padlock? What mass of H<sub>2</sub> would the complete reaction of the iron bar produce?

32. Sulfuric acid dissolves aluminum metal according to the reaction:

Suppose you want to dissolve an aluminum block with a mass of 15.2 g. What minimum mass of H<sub>2</sub>SO<sub>4</sub> (in g) do you need? What mass of H<sub>2</sub> gas (in g) does the complete reaction of the aluminum block produce?

33. For each of the reactions, calculate the mass (in grams) of the product that forms when 3.67 g of the underlined reactant completely reacts. Assume that there is more than enough of the other reactant.

- $\text{Ba}(s) + \text{Cl}_2(g) \longrightarrow \text{BaCl}_2(s)$
- $\text{CaO}(s) + \text{CO}_2(g) \longrightarrow \text{CaCO}_3(s)$
- $2 \text{Mg}(s) + \text{O}_2(g) \longrightarrow 2 \text{MgO}(s)$
- $4 \text{Al}(s) + 3 \text{O}_2(g) \longrightarrow 2 \text{Al}_2\text{O}_3(s)$

34. For each of the reactions, calculate the mass (in grams) of the product that forms when 15.39 g of the underlined reactant completely reacts. Assume that there is more than enough of the other reactant.

- $2 \text{K}(s) + \text{Cl}_2(g) \longrightarrow 2 \text{KCl}(s)$
- $2 \text{K}(s) + \text{Br}_2(l) \longrightarrow 2 \text{KBr}(s)$
- $4 \text{Cr}(s) + 3 \text{O}_2(g) \longrightarrow 2 \text{Cr}_2\text{O}_3(s)$
- $2 \text{Sr}(s) + \text{O}_2(g) \longrightarrow 2 \text{SrO}(s)$

35. For each of the acid–base reactions, calculate the mass (in grams) of each acid necessary to completely react with and neutralize 4.85 g of the base.

- $\text{HCl}(aq) + \text{NaOH}(aq) \longrightarrow \text{H}_2\text{O}(l) + \text{NaCl}(aq)$
- $2 \text{HNO}_3(aq) + \text{Ca}(\text{OH})_2(aq) \longrightarrow 2 \text{H}_2\text{O}(l) + \text{Ca}(\text{NO}_3)_2(aq)$
- $\text{H}_2\text{SO}_4(aq) + 2 \text{KOH}(aq) \longrightarrow 2 \text{H}_2\text{O}(l) + \text{K}_2\text{SO}_4(aq)$

36. For each precipitation reaction, calculate how many grams of the first reactant are necessary to completely react with 55.8 g of the second reactant.

- $2 \text{KI}(aq) + \text{Pb}(\text{NO}_3)_2(aq) \longrightarrow \text{PbI}_2(s) + 2 \text{KNO}_3(aq)$
- $\text{Na}_2\text{CO}_3(aq) + \text{CuCl}_2(aq) \longrightarrow \text{CuCO}_3(s) + 2 \text{NaCl}(aq)$
- $\text{K}_2\text{SO}_4(aq) + \text{Sr}(\text{NO}_3)_2(aq) \longrightarrow \text{SrSO}_4(s) + 2 \text{KNO}_3(aq)$

### Limiting Reactant, Theoretical Yield, and Percent Yield

37. Find the limiting reactant for each initial amount of reactants.

- 2 mol Na, 2 mol Br<sub>2</sub>
- 1.8 mol Na, 1.4 mol Br<sub>2</sub>
- 2.5 mol Na, 1 mol Br<sub>2</sub>
- 12.6 mol Na, 6.9 mol Br<sub>2</sub>

38. Find the limiting reactant for each initial amount of reactants.

- 1 mol Al, 1 mol O<sub>2</sub>
- 4 mol Al, 2.6 mol O<sub>2</sub>
- 16 mol Al, 13 mol O<sub>2</sub>
- 7.4 mol Al, 6.5 mol O<sub>2</sub>

39. Consider the reaction:

Each molecular diagram represents an initial mixture of reactants. Which mixture produces the greatest amount of products? How many molecules of Cl<sub>2</sub> form from the reaction mixture that produces the greatest amount of products?

40. Consider the reaction:

Each of the molecular diagrams represents an initial mixture of the reactants. Which reaction mixture produces the greatest amount of products? How many CO<sub>2</sub> molecules form from the reaction mixture that produces the greatest amount of products?

41. Calculate the theoretical yield of the product (in moles) for each initial amount of reactants.

- a. 4 mol Ti, 4 mol Cl<sub>2</sub>      b. 7 mol Ti, 17 mol Cl<sub>2</sub>  
c. 12.4 mol Ti, 18.8 mol Cl<sub>2</sub>
42. Calculate the theoretical yield of product (in moles) for each initial amount of reactants.
- $$3 \text{Mn(s)} + 2 \text{O}_2(\text{g}) \longrightarrow \text{Mn}_3\text{O}_4(\text{s})$$
- a. 3 mol Mn, 3 mol O<sub>2</sub>      b. 4 mol Mn, 7 mol O<sub>2</sub>  
c. 27.5 mol Mn, 43.8 mol O<sub>2</sub>
43. Zinc sulfide reacts with oxygen according to the reaction:
- $$2 \text{ZnS(s)} + 3 \text{O}_2(\text{g}) \longrightarrow 2 \text{ZnO(s)} + 2 \text{SO}_2(\text{g})$$
- A reaction mixture initially contains 4.2 mol ZnS and 6.8 mol O<sub>2</sub>. Once the reaction has occurred as completely as possible, what amount (in moles) of the excess reactant remains?

44. Iron(II) sulfide reacts with hydrochloric acid according to the reaction:

A reaction mixture initially contains 0.223 mol FeS and 0.652 mol HCl. Once the reaction has occurred as completely as possible, what amount (in moles) of the excess reactant remains?

45. For the reaction shown, calculate the theoretical yield of product (in grams) for each initial amount of reactants.

- a. 2.0 g Al, 2.0 g Cl<sub>2</sub>      b. 7.5 g Al, 24.8 g Cl<sub>2</sub>  
c. 0.235 g Al, 1.15 g Cl<sub>2</sub>
46. For the reaction shown, calculate the theoretical yield of the product (in grams) for each initial amount of reactants.

- a. 5.0 g Ti, 5.0 g F<sub>2</sub>      b. 2.4 g Ti, 1.6 g F<sub>2</sub>  
c. 0.233 g Ti, 0.288 g F<sub>2</sub>
47. Iron(III) oxide reacts with carbon monoxide according to the equation:

A reaction mixture initially contains 22.55 g Fe<sub>2</sub>O<sub>3</sub> and 14.78 g CO. Once the reaction has occurred as completely as possible, what mass (in g) of the excess reactant remains?

48. Elemental phosphorus reacts with chlorine gas according to the equation:

A reaction mixture initially contains 45.69 g P<sub>4</sub> and 131.3 g Cl<sub>2</sub>. Once the reaction has occurred as completely as possible, what mass (in g) of the excess reactant remains?

49. Lead ions can be precipitated from solution with KCl according to the reaction:

When 28.5 g KCl is added to a solution containing 25.7 g Pb<sup>2+</sup>, a PbCl<sub>2</sub> precipitate forms. The precipitate is filtered and dried and found to have a mass of 29.4 g. Determine the limiting reactant, theoretical yield of PbCl<sub>2</sub>, and percent yield for the reaction.

50. Magnesium oxide can be made by heating magnesium metal in the presence of oxygen. The balanced equation for the reaction is:

When 10.1 g of Mg reacts with 10.5 g O<sub>2</sub>, 11.9 g MgO is collected. Determine the limiting reactant, theoretical yield, and percent yield for the reaction.

51. Urea (CH<sub>4</sub>N<sub>2</sub>O) is a common fertilizer that is synthesized by the reaction of ammonia (NH<sub>3</sub>) with carbon dioxide:

In an industrial synthesis of urea, a chemist combines 136.4 kg of ammonia with 211.4 kg of carbon dioxide and obtains 168.4 kg of urea. Determine the limiting reactant, theoretical yield of urea, and percent yield for the reaction.

52. Many computer chips are manufactured from silicon, which occurs in nature as SiO<sub>2</sub>. When SiO<sub>2</sub> is heated to melting, it reacts with solid carbon to form liquid silicon and carbon monoxide gas. In an industrial preparation of silicon, 155.8 kg of SiO<sub>2</sub> reacts with 78.3 kg of carbon to produce 66.1 kg of silicon. Determine the limiting reactant, theoretical yield, and percent yield for the reaction.

### Solution Concentration and Solution Stoichiometry

53. Calculate the molarity of each solution.
- a. 3.25 mol of LiCl in 2.78 L solution  
b. 28.33 g C<sub>6</sub>H<sub>12</sub>O<sub>6</sub> in 1.28 L of solution  
c. 32.4 mg NaCl in 122.4 mL of solution
54. Calculate the molarity of each solution.
- a. 0.38 mol of LiNO<sub>3</sub> in 6.14 L of solution  
b. 72.8 g C<sub>2</sub>H<sub>6</sub>O in 2.34 L of solution  
c. 12.87 mg KI in 112.4 mL of solution
55. What is the molarity of NO<sub>3</sub><sup>−</sup> in each solution?
- a. 0.150 M KNO<sub>3</sub>      b. 0.150 M Ca(NO<sub>3</sub>)<sub>2</sub>  
c. 0.150 M Al(NO<sub>3</sub>)<sub>3</sub>
56. What is the molarity of Cl<sup>−</sup> in each solution?
- a. 0.200 M NaCl      b. 0.150 M SrCl<sub>2</sub>  
c. 0.100 M AlCl<sub>3</sub>
57. How many moles of KCl are contained in each solution?
- a. 0.556 L of a 2.3 M KCl solution  
b. 1.8 L of a 0.85 M KCl solution  
c. 114 mL of a 1.85 M KCl solution
58. What volume of 0.200 M ethanol solution contains each amount in moles of ethanol?
- a. 0.45 mol ethanol      b. 1.22 mol ethanol  
c. 1.2 × 10<sup>−2</sup> mol ethanol
59. A laboratory procedure calls for making 400.0 mL of a 1.1 M NaNO<sub>3</sub> solution. What mass of NaNO<sub>3</sub> (in g) is needed?
60. A chemist wants to make 5.5 L of a 0.300 M CaCl<sub>2</sub> solution. What mass of CaCl<sub>2</sub> (in g) should the chemist use?
61. If 123 mL of a 1.1 M glucose solution is diluted to 500.0 mL, what is the molarity of the diluted solution?
62. If 3.5 L of a 4.8 M SrCl<sub>2</sub> solution is diluted to 45 L, what is the molarity of the diluted solution?
63. To what volume should you dilute 50.0 mL of a 12 M stock HNO<sub>3</sub> solution to obtain a 0.100 M HNO<sub>3</sub> solution?
64. To what volume should you dilute 25 mL of a 10.0 M H<sub>2</sub>SO<sub>4</sub> solution to obtain a 0.150 M H<sub>2</sub>SO<sub>4</sub> solution?
65. Consider the precipitation reaction:
- $$2 \text{Na}_3\text{PO}_4(\text{aq}) + 3 \text{CuCl}_2(\text{aq}) \longrightarrow \text{Cu}_3(\text{PO}_4)_2(\text{s}) + 6 \text{NaCl(aq)}$$
- What volume of 0.175 M Na<sub>3</sub>PO<sub>4</sub> solution is necessary to completely react with 95.4 mL of 0.102 M CuCl<sub>2</sub>?

66. Consider the reaction:

What volume of 0.150 M  $\text{Li}_2\text{S}$  solution is required to completely react with 125 mL of 0.150 M  $\text{Co}(\text{NO}_3)_2$ ?

67. What is the minimum amount of 6.0 M  $\text{H}_2\text{SO}_4$  necessary to produce 25.0 g of  $\text{H}_2(g)$  according to the reaction between aluminum and sulfuric acid?

68. What is the molarity of  $\text{ZnCl}_2$  that forms when 25.0 g of zinc completely reacts with  $\text{CuCl}_2$  according to the following reaction? Assume a final volume of 275 mL.

69. A 25.0-mL sample of a 1.20 M potassium chloride solution is mixed with 15.0 mL of a 0.900 M lead(II) nitrate solution and this precipitation reaction occurs:

The solid  $\text{PbCl}_2$  is collected, dried, and found to have a mass of 2.45 g. Determine the limiting reactant, the theoretical yield, and the percent yield.

70. A 55.0-mL sample of a 0.102 M potassium sulfate solution is mixed with 35.0 mL of a 0.114 M lead(II) acetate solution and this precipitation reaction occurs:

The solid  $\text{PbSO}_4$  is collected, dried, and found to have a mass of 1.01 g. Determine the limiting reactant, the theoretical yield, and the percent yield.

### Types of Aqueous Solutions and Solubility

71. For each compound (all water soluble), would you expect the resulting aqueous solution to conduct electrical current?  
a.  $\text{CsCl}$       b.  $\text{CH}_3\text{OH}$       c.  $\text{Ca}(\text{NO}_3)_2$       d.  $\text{C}_6\text{H}_{12}\text{O}_6$
72. Classify each compound as a strong electrolyte or nonelectrolyte.  
a.  $\text{MgBr}_2$       b.  $\text{C}_{12}\text{H}_{22}\text{O}_{11}$       c.  $\text{Na}_2\text{CO}_3$       d.  $\text{KOH}$
73. Determine whether each compound is soluble or insoluble. If the compound is soluble, list the ions present in solution.  
a.  $\text{AgNO}_3$       b.  $\text{Pb}(\text{C}_2\text{H}_3\text{O}_2)_2$       c.  $\text{KNO}_3$       d.  $(\text{NH}_4)_2\text{S}$
74. Determine whether each compound is soluble or insoluble. If the compound is soluble, list the ions present in solution.  
a.  $\text{AgI}$       b.  $\text{Cu}_3(\text{PO}_4)_2$       c.  $\text{CoCO}_3$       d.  $\text{K}_3\text{PO}_4$

### Precipitation Reactions

75. Complete and balance each equation. If no reaction occurs, write "NO REACTION."  
a.  $\text{LiI}(aq) + \text{BaS}(aq) \longrightarrow$   
b.  $\text{KCl}(aq) + \text{CaS}(aq) \longrightarrow$   
c.  $\text{CrBr}_2(aq) + \text{Na}_2\text{CO}_3(aq) \longrightarrow$   
d.  $\text{NaOH}(aq) + \text{FeCl}_3(aq) \longrightarrow$
76. Complete and balance each equation. If no reaction occurs, write "NO REACTION."  
a.  $\text{NaNO}_3(aq) + \text{KCl}(aq) \longrightarrow$   
b.  $\text{NaCl}(aq) + \text{Hg}_2(\text{C}_2\text{H}_3\text{O}_2)_2(aq) \longrightarrow$   
c.  $(\text{NH}_4)_2\text{SO}_4(aq) + \text{SrCl}_2(aq) \longrightarrow$   
d.  $\text{NH}_4\text{Cl}(aq) + \text{AgNO}_3(aq) \longrightarrow$
77. Write a molecular equation for the precipitation reaction that occurs (if any) when each pair of aqueous solutions is mixed. If no reaction occurs, write "NO REACTION."

- a. potassium carbonate and lead(II) nitrate  
b. lithium sulfate and lead(II) acetate  
c. copper(II) nitrate and magnesium sulfide  
d. strontium nitrate and potassium iodide

78. Write a molecular equation for the precipitation reaction that occurs (if any) when each pair of aqueous solutions is mixed. If no reaction occurs, write "NO REACTION."

- a. sodium chloride and lead(II) acetate  
b. potassium sulfate and strontium iodide  
c. cesium chloride and calcium sulfide  
d. chromium(III) nitrate and sodium phosphate

### Ionic and Net Ionic Equations

79. Write balanced complete ionic and net ionic equations for each reaction.  
a.  $\text{HCl}(aq) + \text{LiOH}(aq) \longrightarrow \text{H}_2\text{O}(l) + \text{LiCl}(aq)$   
b.  $\text{MgS}(aq) + \text{CuCl}_2(aq) \longrightarrow \text{CuS}(s) + \text{MgCl}_2(aq)$   
c.  $\text{NaOH}(aq) + \text{HC}_2\text{H}_3\text{O}_2(aq) \longrightarrow \text{H}_2\text{O}(l) + \text{NaC}_2\text{H}_3\text{O}_2(aq)$   
d.  $\text{Na}_3\text{PO}_4(aq) + \text{NiCl}_2(aq) \longrightarrow \text{Ni}_3(\text{PO}_4)_2(s) + \text{NaCl}(aq)$
80. Write balanced complete ionic and net ionic equations for each reaction.  
a.  $\text{K}_2\text{SO}_4(aq) + \text{CaI}_2(aq) \longrightarrow \text{CaSO}_4(s) + \text{KI}(aq)$   
b.  $\text{NH}_4\text{Cl}(aq) + \text{NaOH}(aq) \longrightarrow \text{H}_2\text{O}(l) + \text{NH}_3(g) + \text{NaCl}(aq)$   
c.  $\text{AgNO}_3(aq) + \text{NaCl}(aq) \longrightarrow \text{AgCl}(s) + \text{NaNO}_3(aq)$   
d.  $\text{HC}_2\text{H}_3\text{O}_2(aq) + \text{K}_2\text{CO}_3(aq) \longrightarrow$   
 $\text{H}_2\text{O}(l) + \text{CO}_2(g) + \text{KC}_2\text{H}_3\text{O}_2(aq)$
81. Mercury(I) ions ( $\text{Hg}_2^{2+}$ ) can be removed from solution by precipitation with  $\text{Cl}^-$ . Suppose that a solution contains aqueous  $\text{Hg}_2(\text{NO}_3)_2$ . Write complete ionic and net ionic equations for the reaction of aqueous  $\text{Hg}_2(\text{NO}_3)_2$  with aqueous sodium chloride to form solid  $\text{Hg}_2\text{Cl}_2$  and aqueous sodium nitrate.
82. Lead(II) ions can be removed from solution by precipitation with sulfate ions. Suppose that a solution contains lead(II) nitrate. Write complete ionic and net ionic equations for the reaction of aqueous lead(II) nitrate with aqueous potassium sulfate to form solid lead(II) sulfate and aqueous potassium nitrate.

### Acid-Base and Gas-Evolution Reactions

83. Write balanced molecular and net ionic equations for the reaction between hydrobromic acid and potassium hydroxide.
84. Write balanced molecular and net ionic equations for the reaction between nitric acid and calcium hydroxide.
85. Complete and balance each acid-base equation.  
a.  $\text{H}_2\text{SO}_4(aq) + \text{Ca}(\text{OH})_2(aq) \longrightarrow$   
b.  $\text{HClO}_4(aq) + \text{KOH}(aq) \longrightarrow$   
c.  $\text{H}_2\text{SO}_4(aq) + \text{NaOH}(aq) \longrightarrow$
86. Complete and balance each acid-base equation.  
a.  $\text{HI}(aq) + \text{LiOH}(aq) \longrightarrow$   
b.  $\text{HC}_2\text{H}_3\text{O}_2(aq) + \text{Ca}(\text{OH})_2(aq) \longrightarrow$   
c.  $\text{HCl}(aq) + \text{Ba}(\text{OH})_2(aq) \longrightarrow$
87. Write balanced complete ionic and net ionic equations for each acid-base reaction.  
a.  $\text{HBr}(aq) + \text{NaOH}(aq) \longrightarrow$   
b.  $\text{HF}(aq) + \text{NaOH}(aq) \longrightarrow$   
c.  $\text{HC}_2\text{H}_3\text{O}_2(aq) + \text{RbOH}(aq) \longrightarrow$
88. Write balanced complete ionic and net ionic equations for each acid-base reaction.  
a.  $\text{HI}(aq) + \text{RbOH}(aq) \longrightarrow$   
b.  $\text{HCHO}_2(aq) + \text{NaOH}(aq) \longrightarrow$   
c.  $\text{HC}_2\text{H}_3\text{O}_2(aq) + \text{LiOH}(aq) \longrightarrow$

89. A 25.00-mL sample of an unknown  $\text{HClO}_4$  solution requires titration with 22.62 mL of 0.2000 M  $\text{NaOH}$  to reach the equivalence point. What is the concentration of the unknown  $\text{HClO}_4$  solution? The neutralization reaction is

90. A 30.00-mL sample of an unknown  $\text{H}_3\text{PO}_4$  solution is titrated with a 0.100 M  $\text{NaOH}$  solution. The equivalence point is reached when 26.38 mL of  $\text{NaOH}$  solution is added. What is the concentration of the unknown  $\text{H}_3\text{PO}_4$  solution? The neutralization reaction is

91. Complete and balance each gas-evolution equation.

92. Complete and balance each gas-evolution equation.

### Oxidation–Reduction and Combustion

93. Assign oxidation states to each atom in each element, ion, or compound.

94. Assign oxidation states to each atom in each element, ion, or compound.

95. What is the oxidation state of Cr in each compound?

96. What is the oxidation state of Cl in each ion?

97. Determine whether each reaction is a redox reaction. For each redox reaction, identify the oxidizing agent and the reducing agent.

98. Determine whether each reaction is a redox reaction. For each redox reaction, identify the oxidizing agent and the reducing agent.

99. Complete and balance each combustion reaction equation.

100. Complete and balance each combustion reaction equation:

## Cumulative Problems

101. The density of a 20.0% by mass ethylene glycol ( $\text{C}_2\text{H}_6\text{O}_2$ ) solution in water is 1.03 g/mL. Find the molarity of the solution.

102. Find the percent by mass of sodium chloride in a 1.35 M  $\text{NaCl}$  solution. The density of the solution is 1.05 g/mL.

103. People sometimes use sodium bicarbonate as an antacid to neutralize excess hydrochloric acid in an upset stomach. What mass of hydrochloric acid (in grams) can 2.5 g of sodium bicarbonate neutralize? (Hint: Begin by writing a balanced equation for the reaction between aqueous sodium bicarbonate and aqueous hydrochloric acid.)

104. Toilet bowl cleaners often contain hydrochloric acid, which dissolves the calcium carbonate deposits that accumulate within a toilet bowl. What mass of calcium carbonate (in grams) can 3.8 g of  $\text{HCl}$  dissolve? (Hint: Begin by writing a balanced equation for the reaction between hydrochloric acid and calcium carbonate.)

105. The combustion of gasoline produces carbon dioxide and water. Assume gasoline to be pure octane ( $\text{C}_8\text{H}_{18}$ ) and calculate the mass (in kg) of carbon dioxide that is added to the atmosphere per 1.0 kg of octane burned. (Hint: Begin by writing a balanced equation for the combustion reaction.)

106. Many home barbecues are fueled with propane gas ( $\text{C}_3\text{H}_8$ ). What mass of carbon dioxide (in kg) is produced upon the complete combustion of 18.9 L of propane (approximate contents of one 5-gallon tank)? Assume that the density of the liquid

propane in the tank is 0.621 g/mL. (Hint: Begin by writing a balanced equation for the combustion reaction.)

107. Aspirin can be made in the laboratory by reacting acetic anhydride ( $\text{C}_4\text{H}_6\text{O}_3$ ) with salicylic acid ( $\text{C}_7\text{H}_6\text{O}_3$ ) to form aspirin ( $\text{C}_9\text{H}_8\text{O}_4$ ) and acetic acid ( $\text{C}_2\text{H}_4\text{O}_2$ ). The balanced equation is:

In a laboratory synthesis, a student begins with 3.00 mL of acetic anhydride (density = 1.08 g/mL) and 1.25 g of salicylic acid. Once the reaction is complete, the student collects 1.22 g of aspirin. Determine the limiting reactant, theoretical yield of aspirin, and percent yield for the reaction.

108. The combustion of liquid ethanol ( $\text{C}_2\text{H}_5\text{OH}$ ) produces carbon dioxide and water. After 4.62 mL of ethanol (density = 0.789 g/mL) is allowed to burn in the presence of 15.55 g of oxygen gas, 3.72 mL of water (density = 1.00 g/mL) is collected. Determine the limiting reactant, theoretical yield of  $\text{H}_2\text{O}$ , and percent yield for the reaction. (Hint: Write a balanced equation for the combustion of ethanol.)

109. A loud classroom demonstration involves igniting a hydrogen-filled balloon. The hydrogen within the balloon reacts explosively with oxygen in the air to form water. If the balloon is filled with a mixture of hydrogen and oxygen, the explosion is even louder than if the balloon is filled only with hydrogen—the intensity of the explosion depends on the relative amounts of oxygen and hydrogen within the balloon. Look at the molecular views representing different amounts of hydrogen and oxygen in four

different balloons. Based on the balanced chemical equation, which balloon will make the loudest explosion?

- 110.** A hydrochloric acid solution will neutralize a sodium hydroxide solution. Look at the molecular views showing one beaker of HCl and four beakers of NaOH. Which NaOH beaker will just neutralize the HCl beaker? Begin by writing a balanced chemical equation for the neutralization reaction.

- 111.** Predict the products and write a balanced molecular equation for each reaction. If no reaction occurs, write "NO REACTION."
- $\text{HCl}(aq) + \text{Hg}_2(\text{NO}_3)_2(aq) \longrightarrow$
  - $\text{KHSO}_3(aq) + \text{HNO}_3(aq) \longrightarrow$
  - aqueous ammonium chloride and aqueous lead(II) nitrate
  - aqueous ammonium chloride and aqueous calcium hydroxide
- 112.** Predict the products and write a balanced molecular equation for each reaction. If no reaction occurs, write "NO REACTION."
- $\text{H}_2\text{SO}_4(aq) + \text{HNO}_3(aq) \longrightarrow$
  - $\text{Cr}(\text{NO}_3)_3(aq) + \text{LiOH}(aq) \longrightarrow$
  - liquid pentanol ( $\text{C}_5\text{H}_{12}\text{O}$ ) and gaseous oxygen
  - aqueous strontium sulfide and aqueous copper(II) sulfate
- 113.** Hard water often contains dissolved  $\text{Ca}^{2+}$  and  $\text{Mg}^{2+}$  ions. One way to soften water is to add phosphates. The phosphate ion forms insoluble precipitates with calcium and magnesium ions, removing them from solution. A solution is 0.050 M in calcium chloride and 0.085 M in magnesium nitrate. What mass of sodium phosphate would you add to 1.5 L of this solution to completely eliminate the hard water ions? Assume complete reaction.
- 114.** An acid solution is 0.100 M in HCl and 0.200 M in  $\text{H}_2\text{SO}_4$ . What volume of a 0.150 M KOH solution would completely neutralize all the acid in 500.0 mL of this solution?
- 115.** Find the mass of barium metal (in grams) that must react with  $\text{O}_2$  to produce enough barium oxide to prepare 1.0 L of a 0.10 M solution of  $\text{OH}^-$ .

- 116.** A solution contains  $\text{Cr}^{3+}$  ions and  $\text{Mg}^{2+}$  ions. The addition of 1.00 L of 1.51 M NaF solution causes the complete precipitation of these ions as  $\text{CrF}_3(s)$  and  $\text{MgF}_2(s)$ . The total mass of the precipitate is 49.6 g. Find the mass of  $\text{Cr}^{3+}$  in the original solution.
- 117.** The nitrogen in sodium nitrate and in ammonium sulfate is available to plants as fertilizer. Which is the more economical source of nitrogen, a fertilizer containing 30.0% sodium nitrate by weight and costing \$9.00 per 100 lb or one containing 20.0% ammonium sulfate by weight and costing \$8.10 per 100 lb?
- 118.** Find the volume of 0.110 M hydrochloric acid necessary to react completely with 1.52 g  $\text{Al}(\text{OH})_3$ .
- 119.** Treatment of gold metal with  $\text{BrF}_3$  and KF produces  $\text{Br}_2$  and  $\text{KAuF}_4$ , a salt of gold. Identify the oxidizing agent and the reducing agent in this reaction. Find the mass of the gold salt that forms when a 73.5-g mixture of equal masses of all three reactants is prepared.
- 120.** We prepare a solution by mixing 0.10 L of 0.12 M sodium chloride with 0.23 L of a 0.18 M  $\text{MgCl}_2$  solution. What volume of a 0.20 M silver nitrate solution do we need to precipitate all the  $\text{Cl}^-$  ion in the solution as  $\text{AgCl}$ ?
- 121.** A solution contains one or more of the following ions:  $\text{Ag}^+$ ,  $\text{Ca}^{2+}$ , and  $\text{Cu}^{2+}$ . When you add sodium chloride to the solution, no precipitate forms. When you add sodium sulfate to the solution, a white precipitate forms. You filter off the precipitate and add sodium carbonate to the remaining solution, producing another precipitate. Which ions were present in the original solution? Write net ionic equations for the formation of each of the precipitates observed.
- 122.** A solution contains one or more of the following ions:  $\text{Hg}_2^{2+}$ ,  $\text{Ba}^{2+}$ , and  $\text{Fe}^{2+}$ . When you add potassium chloride to the solution, a precipitate forms. The precipitate is filtered off, and you add potassium sulfate to the remaining solution, producing no precipitate. When you add potassium carbonate to the remaining solution, a precipitate forms. Which ions were present in the original solution? Write net ionic equations for the formation of each of the precipitates observed.
- 123.** The reaction of  $\text{NH}_3$  and  $\text{O}_2$  forms NO and water. The NO can be used to convert  $\text{P}_4$  to  $\text{P}_4\text{O}_6$ , forming  $\text{N}_2$  in the process. The  $\text{P}_4\text{O}_6$  can be treated with water to form  $\text{H}_3\text{PO}_3$ , which forms  $\text{PH}_3$  and  $\text{H}_3\text{PO}_4$  when heated. Find the mass of  $\text{PH}_3$  that forms from the reaction of 1.00 g of  $\text{NH}_3$ .
- 124.** An important reaction that takes place in a blast furnace during the production of iron is the formation of iron metal and  $\text{CO}_2$  from  $\text{Fe}_2\text{O}_3$  and CO. Determine the mass of  $\text{Fe}_2\text{O}_3$  required to form 910 kg of iron. Determine the amount of  $\text{CO}_2$  that forms in this process.
- 125.** A liquid fuel mixture contains 30.35% hexane ( $\text{C}_6\text{H}_{14}$ ), 15.85% heptane ( $\text{C}_7\text{H}_{16}$ ), and the rest octane ( $\text{C}_8\text{H}_{18}$ ). What maximum mass of carbon dioxide is produced by the complete combustion of 10.0 kg of this fuel mixture?
- 126.** Titanium occurs in the magnetic mineral ilmenite ( $\text{FeTiO}_3$ ), which is often found mixed with sand. The ilmenite can be separated from the sand with magnets. The titanium can then be extracted from the ilmenite by the following set of reactions:
- $$\text{FeTiO}_3(s) + 3 \text{Cl}_2(g) + 3 \text{C}(s) \longrightarrow 3 \text{CO}(g) + \text{FeCl}_2(s) + \text{TiCl}_4(g)$$
- $$\text{TiCl}_4(g) + 2 \text{Mg}(s) \longrightarrow 2 \text{MgCl}_2(l) + \text{Ti}(s)$$

Suppose that an ilmenite-sand mixture contains 22.8% ilmenite by mass and that the first reaction is carried out with a 90.8% yield. If the second reaction is carried out with an 85.9% yield, what mass of titanium can be obtained from 1.00 kg of the ilmenite-sand mixture?

## Challenge Problems

- 127.** A mixture of  $\text{C}_3\text{H}_8$  and  $\text{C}_2\text{H}_2$  has a mass of 2.0 g. It is burned in excess  $\text{O}_2$  to form a mixture of water and carbon dioxide that contains 1.5 times as many moles of  $\text{CO}_2$  as of water. Find the mass of  $\text{C}_2\text{H}_2$  in the original mixture.
- 128.** A mixture of 20.6 g of P and 79.4 g of  $\text{Cl}_2$  reacts completely to form  $\text{PCl}_3$  and  $\text{PCl}_5$  as the only products. Find the mass of  $\text{PCl}_3$  that forms.
- 129.** A solution contains  $\text{Ag}^+$  and  $\text{Hg}^{2+}$  ions. The addition of 0.100 L of 1.22 M NaI solution is just enough to precipitate all the ions as  $\text{AgI}$  and  $\text{HgI}_2$ . The total mass of the precipitate is 28.1 g. Find the mass of  $\text{AgI}$  in the precipitate.
- 130.** The water in lakes that have been acidified by acid rain ( $\text{HNO}_3$  and  $\text{H}_2\text{SO}_4$ ) can be neutralized by a process called liming, in which limestone ( $\text{CaCO}_3$ ) is added to the acidified water. What mass of limestone (in kg) would completely neutralize a 15.2 billion-liter lake that is  $1.8 \times 10^{-5}$  M in  $\text{H}_2\text{SO}_4$  and  $8.7 \times 10^{-6}$  M in  $\text{HNO}_3$ ?
- 131.** Recall from Section 4.6 that sodium carbonate is often added to laundry detergents to soften hard water and make the detergent more effective. Suppose that a particular detergent mixture is designed to soften hard water that is  $3.5 \times 10^{-3}$  M in  $\text{Ca}^{2+}$  and  $1.1 \times 10^{-3}$  M in  $\text{Mg}^{2+}$  and that the average capacity of a washing machine is 19.5 gallons of water. If the detergent requires using 0.65 kg detergent per load of laundry, what percentage (by mass) of the detergent should be sodium carbonate in order to completely precipitate all of the calcium and magnesium ions in an average load of laundry water?
- 132.** Lead poisoning is a serious condition resulting from the ingestion of lead in food, water, or other environmental sources. It affects the central nervous system, leading to a variety of symptoms such as distractibility, lethargy, and loss of motor coordination. Lead poisoning is treated with chelating agents, substances that bind to metal ions, allowing them to

be eliminated in the urine. A modern chelating agent used for this purpose is succimer ( $\text{C}_4\text{H}_6\text{O}_4\text{S}_2$ ). Suppose you are trying to determine the appropriate dose for succimer treatment of lead poisoning. What minimum mass of succimer (in mg) is needed to bind all of the lead in a patient's bloodstream? Assume that patient blood lead levels are  $45 \mu\text{g/dL}$ , that total blood volume is 5.0 L, and that 1 mol of succimer binds 1 mol of lead.

- 133.** A particular kind of emergency breathing apparatus—often placed in mines, caves, or other places where oxygen might become depleted or where the air might become poisoned—works via the following chemical reaction:

Notice that the reaction produces  $\text{O}_2$ , which can be breathed, and absorbs  $\text{CO}_2$ , a product of respiration. Suppose you work for a company interested in producing a self-rescue breathing apparatus (based on the given reaction) that would allow the user to survive for 10 minutes in an emergency situation. What are the important chemical considerations in designing such a unit? Estimate how much  $\text{KO}_2$  would be required for the apparatus. (Find any necessary additional information—such as human breathing rates—from appropriate sources. Assume that normal air is 20% oxygen.)

- 134.** Metallic aluminum reacts with  $\text{MnO}_2$  at elevated temperatures to form manganese metal and aluminum oxide. A mixture of the two reactants is 67.2% mole percent Al. Find the theoretical yield (in grams) of manganese from the reaction of 250 g of this mixture.
- 135.** Hydrolysis of the compound  $\text{B}_5\text{H}_9$  forms boric acid,  $\text{H}_3\text{BO}_3$ . Fusion of boric acid with sodium oxide forms a borate salt,  $\text{Na}_2\text{B}_4\text{O}_7$ . Without writing complete equations, find the mass (in grams) of  $\text{B}_5\text{H}_9$  required to form 151 g of the borate salt by this reaction sequence.

## Conceptual Problems

- 136.** Consider the reaction:

The molar mass of K is 39.10 g/mol, and that of  $\text{O}_2$  is 32.00 g/mol. Without doing any calculations, pick the conditions under which potassium is the limiting reactant and explain your reasoning.

- a. 170 g K, 31 g  $\text{O}_2$       b. 16 g K, 2.5 g  $\text{O}_2$   
c. 165 kg K, 28 kg  $\text{O}_2$       d. 1.5 g K, 0.38 g  $\text{O}_2$
- 137.** Consider the reaction:

A reaction mixture initially contains 5 moles of NO and 10 moles of  $\text{H}_2$ . Without doing any calculations, determine which set of amounts best represents the mixture after the reactants have reacted as completely as possible. Explain your reasoning.

- a. 1 mol NO, 0 mol  $\text{H}_2$ , 4 mol  $\text{NH}_3$ , 4 mol  $\text{H}_2\text{O}$   
b. 0 mol NO, 1 mol  $\text{H}_2$ , 5 mol  $\text{NH}_3$ , 5 mol  $\text{H}_2\text{O}$   
c. 3 mol NO, 5 mol  $\text{H}_2$ , 2 mol  $\text{NH}_3$ , 2 mol  $\text{H}_2\text{O}$   
d. 0 mol NO, 0 mol  $\text{H}_2$ , 4 mol  $\text{NH}_3$ , 4 mol  $\text{H}_2\text{O}$

- 138.** The following circle represents 1.0 liter of a solution with a solute concentration of 1 M:

Explain what you would add (the amount of solute or volume of solvent) to the solution to obtain a solution represented by each diagram:

(a)

(b)

(c)

139. Consider the reaction:

Consider also this representation of an initial mixture of  $\text{N}_2\text{H}_4$  and  $\text{N}_2\text{O}_4$ :

Which diagram best represents the reaction mixture after the reactants have reacted as completely as possible?

(a)

(b)

(c)

140. Consider the generic ionic compounds with the formulas  $\text{A}_2\text{X}$  and  $\text{BY}_2$  and the following solubility rules:

$\text{A}_2\text{X}$  soluble;  $\text{BY}_2$  soluble;  $\text{AY}$  insoluble;  $\text{BX}$  soluble.

Assume  $\text{A}^+$  ions are circles,  $\text{B}^{2+}$  ions are squares,  $\text{X}^{2-}$  ions are triangles, and  $\text{Y}^-$  ions are diamonds. Solutions of the two compounds ( $\text{A}_2\text{X}$  and  $\text{BY}_2$ ) are represented as follows:

Draw a molecular-level representation showing the result of mixing the two given solutions and write an equation to represent the reaction.

### Active Classroom Learning

## Questions for Group Work

Discuss these questions with the group and record your consensus answer.

141. Imagine you mix 16.05 g of methane ( $\text{CH}_4$ ) gas and 96.00 g of oxygen ( $\text{O}_2$ ) gas and then ignite the mixture. After a bright flash and a loud bang, some water droplets form on the inside of the reaction vessel.

- Write the balanced chemical reaction for the combustion of methane.
- Depict the process that occurred in the vessel using circles to represent atoms. Represent carbon with black circles, hydrogen with white circles, and oxygen with gray circles. Let one circle (or one molecule made of circles bonded together) represent exactly one mole.
- How many moles of water can you make? How many moles of carbon dioxide?
- Will anything be left over? What? How much?
- Identify the following: limiting reagent, excess reagent, and theoretical yield.

142. Write a detailed set of instructions for making two solutions: (1) 100 mL of 12 M NaOH from solid sodium hydroxide and (2) 1.00 L of 0.1 M NaOH from your first solution. You have in your lab: volumetric flasks marked to contain 100.0 mL and 1.000 L, a graduated cylinder, and a balance.

143. Review the solubility rules. Without referring back to the rules, have each group member list two ionic compounds that are expected to be soluble and two that are expected to be insoluble. Include at least one exception. Check the work of the other members of your group.

144. Define and give an example of each of the following classes of reactions: precipitation, acid-base, gas evolution, redox (non-combustion), and combustion. Each group member can do one, and then present his or her reaction to the group.

145. Using group members to represent atoms, ions, or electrons, act out the reaction  $\text{Zn}(s) + \text{Fe}^{2+}(aq) \longrightarrow \text{Zn}^{2+}(aq) + \text{Fe}(s)$ . Which group member is oxidized? Which is reduced? Which is the oxidizing agent? Which is the reducing agent?

Data Interpretation and Analysis

Fluoride in Drinking Water

146. In most communities in the United States, fluoride ions are added to public drinking water to help reduce dental caries (cavities in teeth). Fluoride ions in water react with calcium hydroxyapatite, a chemical component of teeth, to form hydroxyfluorapatite according to this reaction:

Hydroxyfluorapatite reduces the rate of demineralization of tooth enamel; demineralization can lead to dental caries. However, too much fluoride in drinking water can cause dental fluorosis and/or enamel fluorosis, which stain teeth. Figure a lists the 1962 recommended and maximum fluoride ion concentration for drinking water in the United States as a function of annual average air temperature.

Annual average of maximum daily air temperatures (°C)	Recommended fluoride Concentration (mg/L)			Maximum allowable fluoride concentration (mg/L)
	Lower	Optimum	Upper	
10.0–12.0	0.9	1.2	1.7	2.4
12.1–14.6	0.8	1.1	1.5	2.2
14.7–17.7	0.8	1.0	1.3	2.0
17.8–21.4	0.7	0.9	1.2	1.8
21.5–26.3	0.7	0.8	1.0	1.6
26.4–31.5	0.6	0.7	0.8	1.4

Source: <http://water.epa.gov/drink/contaminants/basicinformation/fluoride.cfm>

▲ FIGURE a Recommended and Maximum Allowable Fluoride Concentration for U.S. Drinking Water

A 1994 World Health Organization committee recommended an optimal level of fluoride in drinking water from 0.5 to 1.0 mg/L (milligrams per liter), depending on climate region. Municipalities typically use three commercially available compounds to add fluoride ions to public drinking water. Figure b lists the three compounds containing fluoride ions along with their molar mass, percent fluoride in the pure compound, and percent pure compound in the commercial product.

		Molar Mass	% F-	% Pure Compound in the Commercial Product
NaF	Sodium fluoride	42	45	98
Na2SiF6	Sodium fluorosilicate	188	61	98
H2SiF6	Fluorosilicic acid	144	79	25

▲ FIGURE b Percentage (by mass) of Fluoride Ion in Fluoride Compounds

Use the information provided in the figures to answer the following questions:

- a. Sodium fluoride (NaF) and sodium fluorosilicate (Na2SiF6) are commercially available in 100.0-lb bags. Calculate the mass, in kg, of fluoride ion in a 100.0-lb bag for each of these two compounds.
- b. The density of fluorosilicic acid (H2SiF6) is related to its percent by weight as shown in Figure c.

▲ FIGURE c Density of Fluorosilicic Acid at 20 °C  
Source: <http://www.ml2rconsultancy.com/Pages/H2SiF6DATA.aspx>

- i. Calculate the mass, in kg, of fluoride ion in 100.0 lbs of 25.0 % (weight/weight) commercial fluorosilicic acid. For a mixture of two components, A and B, the % (weight/weight) means the weight of component A (lbs.) in the total weight (lbs.) of the contents = weight of A + weight of B.
- ii. Calculate the molarity of the dilute (25.0% weight/weight) fluorosilicic acid.
- c. A public water treatment plant located in a region with an annual average maximum temperature of 16.0 °C uses fluorosilicic acid to treat 50,000 gallons of water per day (5.00 × 10<sup>4</sup> gallons).
  - i. Calculate the amount of fluoride ions that must be added to the water, in kg, in order to meet the optimum amount of fluoride.
  - ii. How much 25.0 % commercial fluorosilicic acid in kg must be added to 50,000 gallons of water in order to fluoridate at the optimum level?
- d. The U.S. Institute of Medicine has established a maximum daily intake of fluoride of 4 mg F<sup>-</sup>/day for adults. Fluoridated drinking water provides about 75% of an adult’s daily fluoride, assuming the adult is consuming mostly public water.
  - i. If a community is located in a cold climate (10.0–12.0 °C) and the water has the optimum level of fluoride ions, calculate the mg of fluoride ion present in one glass of water. (Note that: 1 glass = 12.0 ounces of water = 0.355 liters.)
  - ii. A public water treatment plant located in a hot climate has a lower fluoride ion concentration in the drinking water compared to the water from a public water treatment plant located in a colder climate. Both meet the recommended daily F<sup>-</sup> guideline. Explain how this is possible.

- e. If you were in charge of fluoridating the public water supply in your community, which compound would you use, how much would you need, and what would it cost? Refer to Figure d ▼ to answer this question. Assume you need to treat 50,000 gallons of water per day.

		2015 Price	% Pure Compound in the Commercial Product
NaF	Sodium fluoride	\$85.60/kg	98
Na <sub>2</sub> SiF <sub>6</sub>	Sodium fluorosilicate	\$89.60/kg	98
H <sub>2</sub> SiF <sub>6</sub>	Fluorosilicic acid	\$52.80/L	25

▲ **FIGURE d** Commercial Price of Fluoride Compounds

- f. Under certain conditions, fluoride ions react with the calcium hydroxyapatite in teeth according to this reaction:

If this reaction occurs, how would this influence the amount of fluoridation required in public drinking water and the cost?

- g. On April 27, 2015, the U.S. Department of Health and Human Services recommended decreasing the amount of fluoride added to drinking water by about 40% for all regions of the country. For example, communities located in the 17.8–21.4 °C annual average air temperature range should now have a maximum of 0.7 milligram of fluoride per liter of water instead of the long-standing recommended maximum of 1.2 milligrams of fluoride per liter. Explain how this new standard impacts your answers to parts e and f.

## Answers to Conceptual Connections

### Stoichiometry

- 4.1 (c) Since each O<sub>2</sub> molecule reacts with 4 Na atoms, 12 Na atoms are required to react with 3 O<sub>2</sub> molecules.

### Stoichiometry II

4.2

### Limiting Reactant and Theoretical Yield

- 4.3 (c) Nitrogen is the limiting reactant, and there is enough nitrogen to make four NH<sub>3</sub> molecules. Hydrogen is in excess, and two hydrogen molecules remain after the reactants have reacted as completely as possible.

### Reactant in Excess

- 4.4 The limiting reactant is the 1 mol H<sub>2</sub>O, which is completely consumed. The 1 mol of H<sub>2</sub>O requires 3 mol of NO<sub>2</sub> to completely react; therefore, 2 mol NO<sub>2</sub> remain after the reaction is complete.

### Solutions

- 4.5 (b) The mass of a solution is equal to the mass of the solute plus the mass of the solvent. Although the solute seems to disappear, it really does not, and its mass becomes part of the mass of the solution, in accordance with the law of mass conservation.

### Solution Dilution

- 4.6 (c) Since the volume has doubled, the concentration is halved, so the same volume should contain half as many solute molecules.

### Solution Stoichiometry

- 4.7 A is the limiting reactant. You have equal amounts of both reactants, but the reaction requires twice as much of A as B.

### Precipitation Reactions

4.8

### Oxidation Numbers in Polyatomic Ions

- 4.9 (a) The charge of a polyatomic ion is the charge associated with the ion as a whole. The oxidation states of the individual atoms must sum to the charge of the ion, but they are assigned to the individual atoms themselves. Answer (b) is incorrect because oxidation state and charge are not identical, even though the charge of a monoatomic ion is equal to its oxidation state. Answer (c) is incorrect because charge is a physical property of ions. Conversely, the oxidation states of atoms are not real physical properties, but an imposed electron bookkeeping scheme.

### Oxidation and Reduction

- 4.10 (d) Since oxidation and reduction must occur together, an increase in the oxidation state of a reactant is always accompanied by a decrease in the oxidation state of a reactant.

# Gases

So many of the properties of matter, especially when in the gaseous form, can be deduced from the hypothesis that their minute parts are in rapid motion, the velocity increasing with the temperature, that the precise nature of this motion becomes a subject of rational curiosity.

**5.10** Real Gases: The Effects of Size and Intermolecular Forces 232

KEY LEARNING OUTCOMES 238

**H**uman beings can survive for weeks without food, days without water, but only minutes without air. Fortunately, we live at the bottom of a vast ocean of air, held to Earth by gravity. We inhale a lungful of this air every few seconds, keep some of the molecules for our own uses, add some molecules that our bodies no longer need, and exhale the mixture back into the surrounding air. The air around us is matter in the gaseous state. What are the fundamental properties of these gases? What laws describe their behavior? What theory explains these properties and laws? Recall that the scientific approach (see Section 1.2) proceeds in this way—from observations to laws to theories—exactly the way we will proceed in this chapter. The gaseous state is the simplest and best-understood state of matter. In this chapter, we examine that state.

▲ A pressurized suit protected Felix Baumgartner from the vacuum of space during his record-breaking skydive. Any significant damage to the suit carried the risk of uncontrolled decompression, which would likely result in Baumgartner's death.

## 5.1 Supersonic Skydiving and the Risk of Decompression

On October 14, 2012, just after midday in New Mexico, Austrian daredevil Felix Baumgartner stepped into the dark void of space 24 miles (38.6 km) above the Earth's surface. Baumgartner's 20-minute journey back to the desert floor broke the sound barrier and shattered the previous skydiving record of 19.5 miles (31.4 km).

When Baumgartner stepped into space, he was protected from the surrounding vacuum by a pressurized suit. The suit contained air at a pressure similar to that found on

### ▲ FIGURE 5.1 Gas Pressure

Pressure is the force per unit area exerted by gas molecules colliding with the surfaces around them.

### Pressure and Density

### ▲ FIGURE 5.2 Pressure and Particle Density

A low density of gas particles results in low pressure. A high density of gas particles results in high pressure.

the surface of Earth. **Pressure** is the force exerted per unit area by gas particles as they strike the surfaces around them (Figure 5.1). Just as a ball exerts a force when it bounces against a wall, so a gaseous atom or molecule exerts a force when it collides with a surface. The result of these collisions is pressure—a constant force on the surfaces exposed to any gas. The total pressure exerted by a gas depends on several factors, including the concentration of gas particles in the sample; the lower the concentration, the lower the pressure. At 24 miles (38.6 km) above the Earth's surface, the concentration of gas particles is much lower than it is at sea level; consequently, the pressure at that high altitude is very low. Without the pressurized suit, Baumgartner could not have survived the space-like conditions.

One of the primary risks that Baumgartner faced while in space was uncontrolled decompression. Any significant damage to his suit could have caused the air within the suit to escape, resulting in a large pressure drop. While the effects of a large pressure drop are sometimes exaggerated—for example, one urban myth claims that a person can explode—they are nonetheless lethal. If a pressure drop had occurred fast enough, a large pressure difference would have quickly developed between the air in Baumgartner's lungs and the surrounding vacuum. The pressure difference would have caused his lungs to expand too much, resulting in severe lung damage. Fortunately, Baumgartner's suit worked just as it was designed to do, and he plunged safely back to Earth.

## 5.2 Pressure: The Result of Molecular Collisions

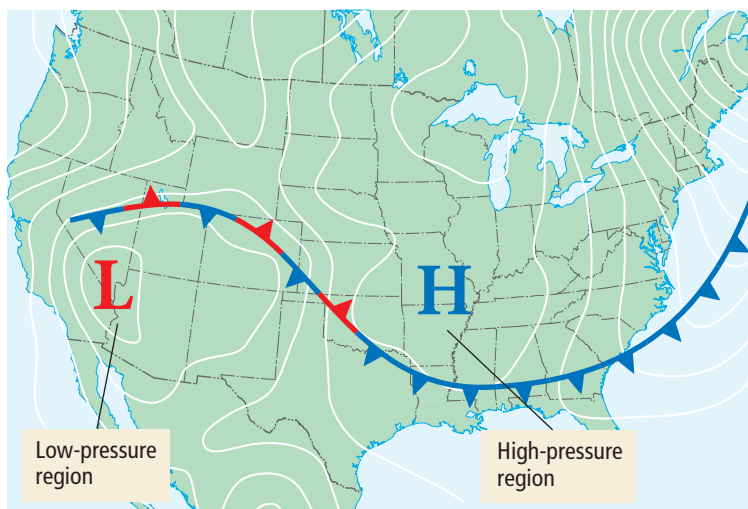

Air can hold up a jumbo jet or knock down a building. How? As we discussed in Section 5.1, air contains gaseous atoms and molecules in constant motion. The particles collide with each other and with the surfaces around them. Each collision exerts only a small force, but when the forces of the many particles are summed, they quickly add up. The result of the constant collisions between the atoms or molecules in a gas and the surfaces around them is *pressure*. Because of pressure, we can drink from straws, inflate basketballs, and breathe. Variation in pressure in Earth's atmosphere creates wind, and changes in pressure help us to predict weather. Pressure is all around us and inside of us.

The pressure that a gas sample exerts is the *force* that results from the collisions of gas particles divided by the *area* of the surface with which they collide:

$$\text{Pressure} = \frac{\text{force}}{\text{area}} = \frac{F}{A} \quad [5.1]$$

The pressure exerted by a gas sample, therefore, depends on the number of gas particles in a given volume—the fewer the gas particles, the lower the force per unit area and the lower the pressure (Figure 5.2). Since the number of gas particles in a given volume

► Pressure variations in Earth's atmosphere create wind and weather. The H on this map indicates a region of high pressure, usually associated with clear weather. The L indicates a region of low pressure, usually associated with unstable weather.

generally decreases with increasing altitude, *pressure decreases with increasing altitude*. Above 30,000 ft, for example, where most commercial airplanes fly, the pressure is so low that a person could pass out due to a lack of oxygen. For this reason, most airplane cabins are artificially pressurized.

You may sometimes feel the effect of a drop in pressure as a brief pain in your ears. This pain arises within the air-containing cavities in your ear (Figure 5.3▶). When you ascend to a higher altitude, the external pressure (the pressure that surrounds you) drops, while the pressure within your ear cavities (the internal pressure) remains the same. This creates an imbalance—the greater internal pressure forces your eardrum to bulge outward, causing pain. With time, and with the help of a yawn or two, the excess air within your ear's cavities escapes, equalizing the internal and external pressure and relieving the pain.

## Pressure Units

We measure pressure in several different units. A common unit of pressure, the **millimeter of mercury (mmHg)**, originates from how pressure is measured with a **barometer** (Figure 5.4▼). A barometer is an evacuated glass tube, the tip of which is submerged in a pool of mercury (Hg). Atmospheric pressure on the liquid mercury's surface forces the mercury upward into the evacuated tube. Because mercury is so dense (13.5 times more dense than water), atmospheric pressure can support a column of Hg that is only about 0.760 m or 760 mm (about 30 in) tall. (By contrast, atmospheric pressure can support a column of water that is about 10.3 m tall.) This makes a column of mercury a convenient way to measure pressure.

In a barometer, when the atmospheric pressure rises, the height of the mercury column rises as well. Similarly, when atmospheric pressure falls, the height of the column falls. The unit *millimeter of mercury* is often called a **torr**, after the Italian physicist Evangelista Torricelli (1608–1647) who invented the barometer:

$$1 \text{ mmHg} = 1 \text{ torr}$$

A second unit of pressure is the **atmosphere (atm)**, the average pressure at sea level. Since one atmosphere of pressure pushes a column of mercury to a height of 760 mm, 1 atm and 760 mmHg are equal:

$$1 \text{ atm} = 760 \text{ mmHg}$$

A fully inflated mountain bike tire has a pressure of about 6 atm, and the pressure at the top of Mount Everest is about 0.31 atm.

The SI unit of pressure is the **pascal (Pa)**, defined as 1 newton (N) per square meter:

$$1 \text{ Pa} = 1 \text{ N/m}^2$$

The pascal is a much smaller unit of pressure than the atmosphere:

$$1 \text{ atm} = 101,325 \text{ Pa}$$

Other common units of pressure include inches of mercury (in Hg) and pounds per square inch (psi):

$$1 \text{ atm} = 29.92 \text{ in Hg} \quad 1 \text{ atm} = 14.7 \text{ psi}$$

Table 5.1, on the next page, summarizes common pressure units.

## Pressure Imbalance

▲ **FIGURE 5.3 Pressure Imbalance** The discomfort you may feel in your ears upon ascending a mountain is caused by a pressure imbalance between the cavities in your ears and the outside air.

## The Mercury Barometer

▲ **FIGURE 5.4 The Mercury Barometer** Average atmospheric pressure at sea level can support a column of mercury 760 mm in height.

**TABLE 5.1** Common Units of Pressure

Unit	Abbreviation	Average Air Pressure at Sea Level
Pascal (1 N/m <sup>2</sup> )	Pa	101,325 Pa
Pounds per square inch	psi	14.7 psi
Torr (1 mmHg)	torr	760 torr (exact)
Inches of mercury	in Hg	29.92 in Hg
Atmosphere	atm	1 atm

**Example 5.1** Converting between Pressure Units

A high-performance road bicycle tire is inflated to a total pressure of 132 psi. What is this pressure in mmHg?

**SORT** The problem gives a pressure in psi and asks you to convert the units to mmHg.

**GIVEN:** 132 psi

**FIND:** mmHg

**STRATEGIZE** Since Table 5.1 does not have a direct conversion factor between psi and mmHg but does provide relationships between both of these units and atmospheres, convert to atm as an intermediate step.

**CONCEPTUAL PLAN****RELATIONSHIPS USED**

1 atm = 14.7 psi

760 mmHg = 1 atm (both from Table 5.1)

**SOLVE** Follow the conceptual plan to solve the problem. Begin with 132 psi and use the conversion factors to arrive at the pressure in mmHg.

**SOLUTION**

$$132 \text{ psi} \times \frac{1 \text{ atm}}{14.7 \text{ psi}} \times \frac{760 \text{ mmHg}}{1 \text{ atm}} = 6.82 \times 10^3 \text{ mmHg}$$

**CHECK** The units of the answer are correct. The magnitude of the answer ( $6.82 \times 10^3$  mmHg) is greater than the given pressure in psi. This is reasonable since mmHg is a much smaller unit than psi.

**FOR PRACTICE 5.1** Your local weather report announces that the barometric pressure is 30.44 in Hg. Convert this pressure to psi.

**FOR MORE PRACTICE 5.1** Convert a pressure of 23.8 in Hg to kPa.

**The Manometer****The Manometer: A Way to Measure Pressure in the Laboratory**

We can measure the pressure of a gas sample in the laboratory with a **manometer**. A manometer is a U-shaped tube containing a dense liquid, usually mercury, as shown in Figure 5.5. In this manometer, one end of the tube is open to atmospheric pressure and the other is attached to a flask containing the gas sample. If the pressure of the gas sample is exactly equal to atmospheric pressure, then the mercury levels on both sides of the tube are the same. If the pressure of the gas sample is *greater than* atmospheric pressure, the mercury level on the left side of the tube is *higher than* the level on the right. If the pressure of the sample is *less than* atmospheric pressure, the mercury level on the left side is *lower than* the level on the right. This type of manometer always measures the pressure of the gas sample relative to atmospheric pressure. The difference in height between the two levels is equal to the difference between the sample's

**▲ FIGURE 5.5 The Manometer** A manometer measures the pressure exerted by a sample of gas.

pressure and atmospheric pressure. To accurately calculate the absolute pressure of the sample, we also need a barometer to measure atmospheric pressure (which can vary from day to day).

## Chemistry AND Medicine | Blood Pressure

**B**lood pressure is the force within our arteries that drives the circulation of blood throughout the body. Blood pressure in the body is analogous to water pressure in a plumbing system. Just as water pressure pushes water through the pipes to faucets and fixtures throughout a house, blood pressure pushes blood to muscles and other tissues throughout the body. However, unlike the water pressure in a plumbing system—which is typically nearly constant—blood pressure varies with each heartbeat. When the heart muscle contracts, blood pressure increases; between contractions it decreases. Systolic blood pressure is the peak pressure during a contraction, and diastolic blood pressure is the lowest pressure between contractions. Just as excessively high water pressure in a plumbing system can damage pipes, blood pressure that is too high in a circulatory system can damage the heart and arteries, resulting in increased risk of stroke and heart attack.

Medical professionals usually measure blood pressure with an instrument called a sphygmomanometer—an inflatable cuff equipped with a pressure gauge—and a stethoscope. The cuff is wrapped around the patient's arm and inflated with air. As air is pumped into the cuff, the pressure in the cuff increases. The cuff tightens around the arm and compresses the artery, momentarily stopping blood flow. The person measuring the blood pressure listens to the artery through the stethoscope while slowly releasing the air pressure in the cuff. When the air pressure in the cuff equals the systolic blood pressure (the peak pressure), a pulse is heard through the stethoscope. The pulse is the sound of blood getting through the compressed artery during a contraction of the heart. The pressure reading at that exact moment is the systolic blood pressure. As the pressure in the cuff continues to decrease, the blood can flow through the compressed artery even between contractions, so the pulsing sound stops. The pressure reading when the pulsing sound stops is the diastolic blood pressure (the lowest pressure).

A blood pressure measurement is usually reported as two pressures, in mmHg, separated by a slash. For example, a blood pressure measurement of 122/84 indicates that the systolic blood pressure is 122 mmHg and the diastolic blood pressure is 84 mmHg. Although the value of blood pressure can vary throughout the day, healthy (or normal) values are

▲ A health care provider measures blood pressure with an inflatable cuff that compresses the main artery in the arm. A stethoscope is used to listen for blood flowing through the artery with each heartbeat.

usually considered to be below 120 mmHg for systolic and below 80 mmHg for diastolic (Table 5.2). High blood pressure, also called hypertension, entails the health risks mentioned previously.

Risk factors for hypertension include obesity, high salt (sodium) intake, high alcohol intake, lack of exercise, stress, a family history of high blood pressure, and age (blood pressure tends to increase as we get older). Mild hypertension can be managed with diet and exercise. Moderate to severe cases require doctor-prescribed medication.

**TABLE 5.2** Blood Pressure Ranges

Blood Pressure	Systolic (mmHg)	Diastolic (mmHg)
Hypotension	<100	<60
Normal	100–119	60–79
Prehypertension	120–139	80–89
Hypertension Stage 1	140–159	90–99
Hypertension Stage 2	>160	>100

## 5.3 The Simple Gas Laws: Boyle's Law, Charles's Law, and Avogadro's Law

Simple Gas Laws and Ideal Gas Law

We have learned about pressure and its characteristics in Section 5.2. We now broaden our discussion to include the four basic properties of a gas sample: pressure ( $P$ ), volume ( $V$ ), temperature ( $T$ ), and amount in moles ( $n$ ). These properties are interrelated—when one changes, it affects the others. The *simple gas laws* describe the relationships between

pairs of these properties. For example, one simple gas law describes how *volume* varies with *pressure* at constant temperature and amount of gas; another law describes how volume varies with *temperature* at constant pressure and amount of gas. These laws were deduced from observations in which two of the four basic properties were held constant in order to elucidate the relationship between the other two.

## Boyle's Law: Volume and Pressure

In the early 1660s, the pioneering English scientist Robert Boyle (1627–1691) and his assistant Robert Hooke (1635–1703) used a J-tube (Figure 5.6) to measure the volume of a sample of gas at different pressures. They trapped a sample of air in the J-tube and added mercury to increase the pressure on the gas. Boyle and Hooke observed an *inverse relationship* between volume and pressure—an increase in one causes a decrease in the other—as shown in Figure 5.7. This relationship is now known as **Boyle's law**.

Boyle's law assumes constant temperature and constant amount of gas.

$$\text{Boyle's law: } V \propto \frac{1}{P} \text{ (constant } T \text{ and } n\text{)}$$

Boyle's law follows from the idea that pressure results from the collisions of the gas particles with the walls of their container. When the volume of a gas sample decreases, the same number of gas particles is crowded into a smaller volume, resulting in more collisions with the walls and therefore an increase in pressure (Figure 5.8).

Scuba divers learn about Boyle's law during certification because it explains why a diver should not ascend toward the surface without continuous breathing. For every 10 m of depth that a diver descends in water, she experiences an additional 1 atm of pressure due to the weight of the water above her (Figure 5.9). The pressure regulator used in scuba diving delivers air into the diver's lungs at a pressure that matches the external pressure; otherwise the diver could not inhale the air (see *Chemistry in Your Day: Extra-Long Snorkels* on page 205). For example, when a diver is 20 m below the surface, the regulator delivers air at a pressure of 3 atm to match the 3 atm of pressure around the diver (1 atm due to normal atmospheric pressure and 2 additional atmospheres due to the weight of the water at 20 m). Suppose that a diver inhaled a lungful of air at a pressure of 3 atm and swam quickly to the surface (where the pressure is 1 atm) while holding her breath. What would happen to the volume of air in her lungs?

The J-Tube

**▲ FIGURE 5.6 The J-Tube** In a J-tube, a column of mercury traps a sample of gas. The pressure on the gas can be increased by increasing the height (*h*) of mercury in the column.

Boyle's Law

As pressure increases, volume decreases.

**▲ FIGURE 5.7 Volume versus Pressure** A plot of the volume of a gas sample versus pressure. The plot shows that volume and pressure are inversely related.

### Volume versus Pressure: A Molecular View

**FIGURE 5.8 Molecular Interpretation of Boyle's Law** As the volume of a gas sample decreases, gas molecules collide with surrounding surfaces more frequently, resulting in greater pressure.

Since the pressure decreases by a factor of 3, the volume of the air in her lungs would increase by a factor of 3—a dangerous situation. The volume increase in the diver's lungs would be so great that she would not be able to hold her breath all the way to the surface—the air would force itself out of her mouth but probably not before the expanded air severely damaged her lungs, possibly killing her. Consequently, the most important rule in diving is *never hold your breath*. To avoid catastrophic results, divers must ascend slowly and breathe continuously, allowing the regulator to bring the air pressure in their lungs back to 1 atm by the time they reach the surface.

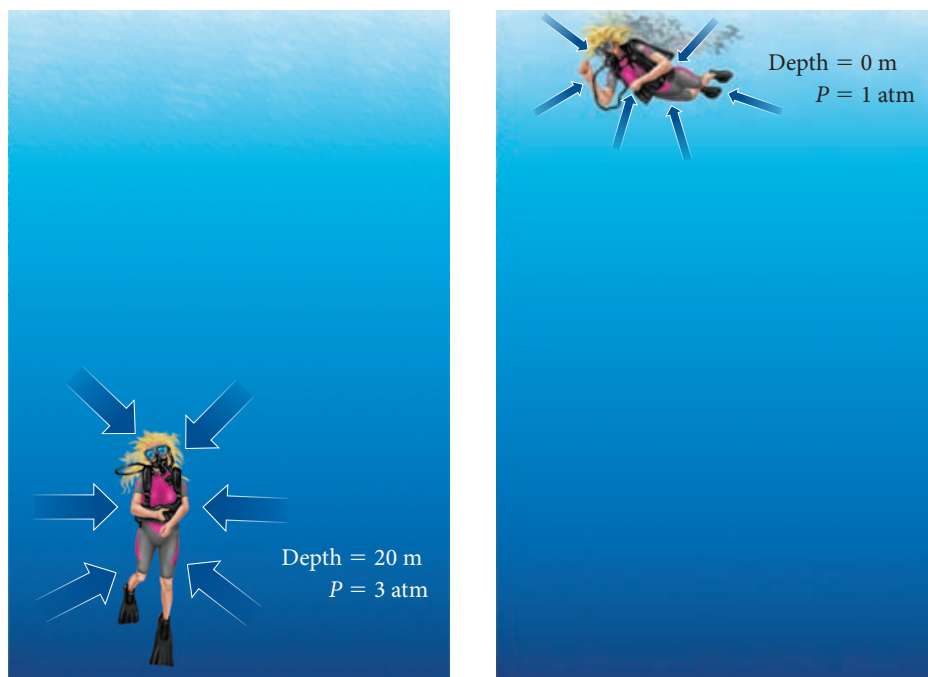

We can use Boyle's law to calculate the volume of a gas following a pressure change or the pressure of a gas following a volume change *as long as the temperature and the amount of gas remain constant*. For these types of calculations, we write Boyle's law in a slightly different way.

$$\text{Since } V \propto \frac{1}{P}, \quad \text{then } V = (\text{constant}) \times \frac{1}{P} \quad \text{or} \quad V = \frac{(\text{constant})}{P}$$

If we multiply both sides by  $P$ , we find that the product of  $P$  and  $V$  is equal to a constant:

$$PV = \text{constant}$$

If two quantities are proportional, then one is equal to the other multiplied by a constant.

**FIGURE 5.9 Increase in Pressure with Depth** For every 10 m of depth, a diver experiences approximately 1 additional atmosphere of pressure due to the weight of the surrounding water. At 20 m, for example, the diver experiences approximately 3 atm of pressure (1 atm of normal atmospheric pressure plus an additional 2 atm due to the weight of the water).

This relationship indicates that if the pressure increases, the volume decreases, but the product  $P \times V$  always equals the same constant. For two different sets of conditions, we can say that:

$$P_1 V_1 = \text{constant} = P_2 V_2$$

or:

$$P_1 V_1 = P_2 V_2 \quad [5.2]$$

where  $P_1$  and  $V_1$  are the initial pressure and volume of the gas and  $P_2$  and  $V_2$  are the final volume and pressure.

### Example 5.2 Boyle's Law

A woman has an initial lung volume of 2.75 L, which is filled with air at an atmospheric pressure of 1.02 atm. If she increases her lung volume to 3.25 L without inhaling any additional air, what is the pressure in her lungs?

To solve the problem, first solve Boyle's law (Equation 5.2) for  $P_2$  and then substitute the given quantities to calculate  $P_2$ .

#### SOLUTION

$$\begin{aligned} P_1 V_1 &= P_2 V_2 \\ P_2 &= \frac{V_1}{V_2} P_1 \\ &= \frac{2.75 \text{ L}}{3.25 \text{ L}} 1.02 \text{ atm} \\ &= 0.863 \text{ atm} \end{aligned}$$

**FOR PRACTICE 5.2** A snorkeler takes a syringe filled with 16 mL of air from the surface, where the pressure is 1.0 atm, to an unknown depth. The volume of the air in the syringe at this depth is 7.5 mL. What is the pressure at the unknown depth? If the pressure increases by 1 atm for every additional 10 m of depth, how deep is the snorkeler?

## Charles's Law: Volume and Temperature

Suppose we keep the pressure of a gas sample constant and measure its volume at a number of different temperatures. Figure 5.10 shows the results of several such measurements.

**FIGURE 5.10 Volume versus Temperature** The volume of a fixed amount of gas at a constant pressure increases linearly with increasing temperature in kelvins. (The extrapolated lines cannot be measured experimentally because all gases condense into liquids before  $-273.15^\circ\text{C}$  is reached.)

## Chemistry IN YOUR DAY Extra-Long Snorkels

Several episodes of *The Flintstones* cartoon featured Fred Flintstone and Barney Rubble snorkeling. Their snorkels, however, were not the modern kind, but long reeds that stretched from the surface of the water down to many meters of depth. Fred and Barney swam around in deep water while breathing air provided to them by these extra-long snorkels. Would this work? Why do people bother with scuba diving equipment if they could instead simply use 10-meter snorkels as Fred and Barney did?

When we breathe, we expand the volume of our chest cavity, reducing the pressure in our lungs to less than 1 atm (Boyle's law). Because of this pressure differential, air from outside our lungs flows into them. Extra-long snorkels do not work because the pressure exerted by water at depth is too great. A diver at 10 m experiences an external pressure of 2 atm. This is more than the muscles of the chest cavity can overcome. Instead, the chest cavity and lungs are compressed, resulting in an air pressure within them of more than 1 atm. If the diver had a snorkel that went to the surface—where the air pressure is 1 atm—air would flow out of the diver's lungs (from greater pressure to less pressure), not into them. It would be impossible for the diver to breathe.

### QUESTION

A diver takes a balloon with a volume of 2.5 L from the surface, where the pressure is 1.0 atm, to a depth of 20 m, where the pressure is 3.0 atm. What happens to the volume of the balloon? What if the end of the submerged balloon is on a long pipe that goes to the surface and is attached to another balloon? Which way would air flow as the diver descended?

▲ In the popular cartoon *The Flintstones*, cavemen used long reeds to breathe surface air while swimming at depth. This would not work because the increased pressure at depth would force air out of their lungs; the pressure would not allow them to inhale.

▲ If two balloons were joined by a long tube and one end was submerged in water, what would happen to the volumes of the two balloons?

From the plot we can see a relationship between volume and temperature: the volume of a gas increases with increasing temperature. Looking at the plot more closely reveals more—volume and temperature are *linearly related*. If two variables are linearly related, plotting one against the other produces a straight line.

Another interesting feature emerges if we extend or *extrapolate* each line in the plot in Figure 5.10 backward from the lowest measured temperature. The dotted extrapolated lines show that the gas should have a zero volume at  $-273.15^\circ\text{C}$ . Recall from Chapter 1 that  $-273.15^\circ\text{C}$  corresponds to 0 K (zero on the Kelvin scale), the coldest possible temperature. The extrapolated lines indicate that below  $-273.15^\circ\text{C}$ , the gas would have a negative volume, which is physically impossible. For this reason, we refer to 0 K as *absolute zero*—colder temperatures do not exist.

The first person to carefully quantify the relationship between the volume of a gas and its temperature was J. A. C. Charles (1746–1823), a French mathematician and physicist. Charles was interested in gases and was among the first people to ascend in a hydrogen-filled balloon. The direct proportionality between volume and temperature is named **Charles's law** after him.

Charles's law:  $V \propto T$  (constant  $P$  and  $n$ )

Charles's law assumes constant pressure and constant amount of gas.

When the temperature of a gas sample increases, the gas particles move faster; collisions with the walls are more frequent, and the force exerted with each collision is greater. The only way for the pressure (the force per unit area) to remain constant is for

▲ A hot-air balloon floats because the hot air within the balloon is less dense than the surrounding cold air.

▲ If we place a balloon into liquid nitrogen (77 K), it shrivels up as the air within it cools and occupies less volume at the same external pressure.

## Volume versus Temperature: A Molecular View

▲ **FIGURE 5.11 Molecular Interpretation of Charles's Law** If we move a balloon from an ice water bath to a boiling water bath, its volume expands as the gas particles within the balloon move faster (due to the increased temperature) and collectively occupy more space.

the gas to occupy a larger volume so that collisions become less frequent and occur over a larger area (Figure 5.11▲).

Charles's law explains why the second floor of a house is usually warmer than the ground floor. According to Charles's law, when air is heated, its volume increases, resulting in a lower density. The warm, less dense air tends to rise in a room filled with colder, denser air. Similarly, Charles's law explains why a hot-air balloon can take flight. The gas that fills a hot-air balloon is warmed with a burner, increasing its volume, lowering its density, and causing it to float in the colder, denser surrounding air.

You can experience Charles's law directly by holding a partially inflated balloon over a warm toaster. As the air in the balloon warms, you can feel the balloon expanding. Alternatively, you can put an inflated balloon into liquid nitrogen and watch it become smaller as it cools.

We can use Charles's law to calculate the volume of a gas following a temperature change or the temperature of a gas following a volume change *as long as the pressure and the amount of gas are constant*. For these calculations, we rearrange Charles's law as follows:

$$\text{Since } V \propto T, \text{ then } V = \text{constant} \times T$$

If we divide both sides by  $T$ , we find that  $V/T$  is equal to a constant:

$$V/T = \text{constant}$$

If the temperature increases, the volume increases in direct proportion so that the quotient,  $V/T$ , is always equal to the same constant. So, for two different measurements, we can say that:

$$V_1/T_1 = \text{constant} = V_2/T_2$$

or

$$\frac{V_1}{T_1} = \frac{V_2}{T_2} \quad [5.3]$$

where  $V_1$  and  $T_1$  are the initial volume and temperature of the gas and  $V_2$  and  $T_2$  are the final volume and temperature. *The temperatures must always be expressed in kelvins (K)* because, as shown in Figure 5.10, the volume of a gas is directly proportional to its *absolute* temperature, not its temperature in °C. For example, doubling the temperature of a gas sample from 1 °C to 2 °C does not double its volume, but doubling the temperature from 200 K to 400 K does.

**Example 5.3** Charles's Law

A sample of gas has a volume of 2.80 L at an unknown temperature. When the sample is submerged in ice water at  $T = 0.00\text{ }^{\circ}\text{C}$ , its volume decreases to 2.57 L. What was its initial temperature (in K and in  $^{\circ}\text{C}$ )?

To solve the problem, first solve Charles's law for  $T_1$ .

**SOLUTION**

$$\frac{V_1}{T_1} = \frac{V_2}{T_2}$$

$$T_1 = \frac{V_1}{V_2} T_2$$

Before you substitute the numerical values to calculate  $T_1$ , convert the temperature to kelvins (K). *Remember, gas law problems must always be worked with Kelvin temperatures.*

$$T_2(\text{K}) = 0.00 + 273.15 = 273.15\text{ K}$$

Substitute  $T_2$  and the other given quantities to calculate  $T_1$ .

$$T_1 = \frac{V_1}{V_2} T_2$$

$$= \frac{2.80\text{ L}}{2.57\text{ L}} 273.15\text{ K}$$

$$= 297.6\text{ K}$$

Calculate  $T_1$  in  $^{\circ}\text{C}$  by subtracting 273.15 from the value in kelvins.

$$T_1(^{\circ}\text{C}) = 297.6 - 273.15 = 24^{\circ}\text{C}$$

**FOR PRACTICE 5.3** A gas in a cylinder with a moveable piston has an initial volume of 88.2 mL. If we heat the gas from  $35^{\circ}\text{C}$  to  $155^{\circ}\text{C}$ , what is its final volume (in mL)?

**Boyle's Law and Charles's Law** The pressure exerted on a sample of a fixed amount of gas is doubled at constant temperature, and then the temperature of the gas in kelvins is doubled at constant pressure. What is the final volume of the gas?

- (a) The final volume is twice the initial volume.
- (b) The final volume of the gas is four times the initial volume.
- (c) The final volume of the gas is one-half the initial volume.
- (d) The final volume of the gas is one-fourth the initial volume.
- (e) The final volume of the gas is the same as the initial volume.

**CONCEPTUAL CONNECTION 5.1****Avogadro's Law: Volume and Amount (in Moles)**

So far, we have discussed the relationships between volume and pressure, and volume and temperature, but we have considered only a constant amount of a gas. What happens when the amount of gas changes? The volume of a gas sample (at constant temperature and pressure) as a function of the amount of gas (in moles) in the sample is shown in Figure 5.12. We can see that the relationship between volume and amount is linear. As we might expect, extrapolation to zero moles shows zero volume. This relationship, first stated formally by Amedeo Avogadro (1776–1856), is **Avogadro's law**.

Avogadro's law:  $V \propto n$  (constant  $T$  and  $P$ )

When the amount of gas in a sample increases at constant temperature and pressure, its volume increases in direct proportion because the greater number of gas particles fill more space.

► **FIGURE 5.12** Volume versus Number of Moles The volume of a gas sample increases linearly with the number of moles of gas in the sample.

**Avogadro's Law**  
As amount of gas increases, volume increases.

You experience Avogadro's law when you inflate a balloon. With each exhaled breath, you add more gas particles to the inside of the balloon, increasing its volume. We can use Avogadro's law to calculate the volume of a gas following a change in the amount of the gas *as long as the pressure and temperature of the gas are constant*. For these types of calculations, we express Avogadro's law as:

$$\frac{V_1}{n_1} = \frac{V_2}{n_2} \quad [5.4]$$

where  $V_1$  and  $n_1$  are the initial volume and number of moles of the gas and  $V_2$  and  $n_2$  are the final volume and number of moles. In calculations, we use Avogadro's law in a manner similar to the other gas laws, as demonstrated in Example 5.4.

Avogadro's law assumes constant temperature and constant pressure and is independent of the nature of the gas.

### Example 5.4 Avogadro's Law

A male athlete in a kinesiology research study has a lung volume of 6.15 L during a deep inhalation. At this volume, his lungs contain 0.254 mol of air. During exhalation, his lung volume decreases to 2.55 L. How many moles of gas did the athlete exhale? Assume constant temperature and pressure.

To solve the problem, first solve Avogadro's law for the number of moles of gas left in the athlete's lungs after exhalation,  $n_2$ . Then substitute the given quantities to calculate  $n_2$ .

Since the lungs initially contained 0.254 mol of air, calculate the amount of air exhaled by subtracting the result from 0.254 mol. (In Chapter 1, we introduced the practice of underlining the least [right-most] significant digit of intermediate answers but not rounding the final answer until the very end of the calculation. We continue that practice throughout the book. However, in order to avoid unnecessary notation, we will not carry additional digits in cases, such as this one, where doing so does not affect the final answer.)

#### SOLUTION

$$\begin{aligned} \frac{V_1}{n_1} &= \frac{V_2}{n_2} \\ n_2 &= \frac{V_2}{V_1} n_1 \\ &= \frac{2.55 \text{ L}}{6.15 \text{ L}} 0.254 \text{ mol} \\ &= 0.105 \text{ mol} \\ \text{moles exhaled} &= 0.254 \text{ mol} - 0.105 \text{ mol} \\ &= 0.149 \text{ mol} \end{aligned}$$

**FOR PRACTICE 5.4** A chemical reaction occurring in a cylinder equipped with a moveable piston produces 0.621 mol of a gaseous product. If the cylinder contained 0.120 mol of gas before the reaction and had an initial volume of 2.18 L, what is its volume after the reaction? (Assume constant pressure and temperature and that the initial amount of gas completely reacts.)

Simple Gas Laws and Ideal Gas Law

## 5.4 The Ideal Gas Law

The relationships that we have discussed so far can be combined into a single law that encompasses all of them. So far, we have shown that:

$$V \propto \frac{1}{P} \quad (\text{Boyle's law})$$

$$V \propto T \quad (\text{Charles's law})$$

$$V \propto n \quad (\text{Avogadro's law})$$

Combining these three expressions, we find that  $V$  is proportional to  $nT/P$ :

$$V \propto \frac{nT}{P}$$

The volume of a gas is directly proportional to the number of moles of gas and to the temperature of the gas, but is inversely proportional to the pressure of the gas.

We can replace the proportionality sign with an equals sign by incorporating  $R$ , a proportionality constant called the *ideal gas constant*:

$$V = \frac{RnT}{P}$$

Rearranging, we get the equation:

$$PV = nRT \quad [5.5]$$

This equation is the **ideal gas law**, and a hypothetical gas that exactly follows this law is an **ideal gas**. The value of  $R$ , the **ideal gas constant**, is the same for all gases and has the value:

$$R = 0.08206 \frac{\text{L} \cdot \text{atm}}{\text{mol} \cdot \text{K}}$$

The ideal gas law contains within it the simple gas laws that we have discussed. For example, recall that Boyle's law states that  $V \propto 1/P$  when the amount of gas ( $n$ ) and the temperature of the gas ( $T$ ) are kept constant. We can rearrange the ideal gas law as follows:

$$PV = nRT$$

First, divide both sides by  $P$ :

$$V = \frac{nRT}{p}$$

Then put the variables that are constant, along with  $R$ , in parentheses:

$$V = (nRT) \frac{1}{P}$$

Since  $n$  and  $T$  are constant in this case, and since  $R$  is always a constant, we can write:

$$V \propto (\text{constant}) \times \frac{1}{p}$$

which means that  $V \propto 1/P$ .

The ideal gas law also shows how other pairs of variables are related. For example, from Charles's law we know that  $V \propto T$  at constant pressure and constant number of moles. But what if we heat a sample of gas at constant *volume* and constant number of moles? This question applies to the warning labels on aerosol cans such as hair spray or deodorants. These labels warn against excessive heating or incineration of the can, even after the contents are used up. Why? An "empty" aerosol can is not really empty but contains a fixed amount of gas trapped in a fixed volume. What would happen if we were to heat the can? We can rearrange the ideal gas law to clearly see the relationship between pressure and temperature at constant volume and constant number of moles:

$$PV = nRT$$

$$P = \frac{nRT}{V} = \left( \frac{nRT}{V} \right)_T$$

Since  $n$  and  $V$  are constant and since  $R$  is always a constant:

$$P = (\text{constant}) \times T$$

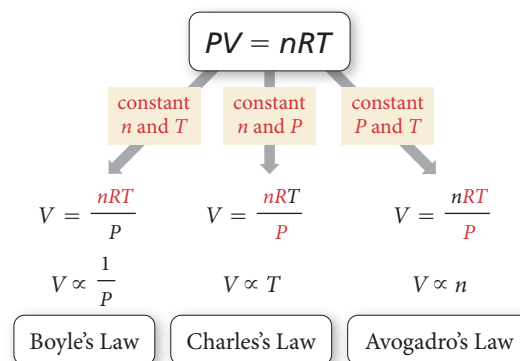

This relationship between pressure and temperature is also known as *Gay-Lussac's law*. As the temperature of a fixed amount of gas in a fixed volume increases, the pressure increases. In an aerosol can, this pressure increase can blow the can apart, which is why aerosol cans should not be heated or incinerated. They might explode.

We can use the ideal gas law to determine the value of any one of the four variables ( $P$ ,  $V$ ,  $n$ , or  $T$ ) given the other three. To do so, we must express each of the quantities in the ideal gas law in the units within  $R$ :

- pressure ( $P$ ) in atm
- volume ( $V$ ) in L
- moles ( $n$ ) in mol
- temperature ( $T$ ) in K

L = liters  
atm = atmospheres  
mol = moles  
K = kelvins

## Ideal Gas Law

▲ The ideal gas law contains the simple gas laws within it.

| Divide both sides by  $V$ .

▲ The labels on most aerosol cans warn against incineration. Since the volume of the can is constant, an increase in temperature causes an increase in pressure and possibly an explosion.

**Example 5.5** Ideal Gas Law I

Calculate the volume occupied by 0.845 mol of nitrogen gas at a pressure of 1.37 atm and a temperature of 315 K.

**SORT** The problem gives you the number of moles of nitrogen gas, the pressure, and the temperature. You are asked to find the volume.

**GIVEN:**  $n = 0.845 \text{ mol}$ ,  
 $P = 1.37 \text{ atm}$ ,  $T = 315 \text{ K}$

**FIND:**  $V$

**STRATEGIZE** You are given three of the four variables ( $P$ ,  $T$ , and  $n$ ) in the ideal gas law and asked to find the fourth ( $V$ ). The conceptual plan shows how the ideal gas law provides the relationship between the known quantities and the unknown quantity.

**CONCEPTUAL PLAN****RELATIONSHIPS USED**

$PV = nRT$  (ideal gas law)

**SOLVE** To solve the problem, first solve the ideal gas law for  $V$ .

**SOLUTION**

$$PV = nRT$$

$$V = \frac{nRT}{P}$$

$$V = \frac{0.845 \text{ mol} \times 0.08206 \frac{\text{L} \cdot \text{atm}}{\text{mol} \cdot \text{K}} \times 315 \text{ K}}{1.37 \text{ atm}} = 15.9 \text{ L}$$

Then substitute the given quantities to calculate  $V$ .

**CHECK** The units of the answer are correct. The magnitude of the answer (15.9 L) makes sense because, as you will see in the next section, one mole of an ideal gas under standard temperature and pressure (273 K and 1 atm) occupies 22.4 L. Although this is not standard temperature and pressure, the conditions are close enough for a ballpark check of the answer. Since this gas sample contains 0.845 mol, a volume of 15.9 L is reasonable.

**FOR PRACTICE 5.5** An 8.50-L tire contains 0.552 mol of gas at a temperature of 305 K. What is the pressure (in atm and psi) of the gas in the tire?

**Example 5.6** Ideal Gas Law II

Calculate the number of moles of gas in a 3.24-L basketball inflated to a *total pressure* of 24.3 psi at 25 °C. (Note: The *total pressure* is not the same as the pressure read on a pressure gauge such as the type used for checking a car or bicycle tire. That pressure, called the *gauge pressure*, is the *difference* between the total pressure and atmospheric pressure. In this case, if atmospheric pressure is 14.7 psi, the gauge pressure would be 9.6 psi. However, for calculations involving the ideal gas law, you must use the *total pressure* of 24.3 psi.)

**SORT** The problem gives you the pressure, the volume, and the temperature. You are asked to find the number of moles of gas.

**GIVEN:**  $P = 24.3 \text{ psi}$ ,  $V = 3.24 \text{ L}$ ,  $T(^{\circ}\text{C}) = 25^{\circ}\text{C}$

**FIND:**  $n$

**STRATEGIZE** The conceptual plan shows how the ideal gas law provides the relationship between the given quantities and the quantity to be found.

**CONCEPTUAL PLAN**

**RELATIONSHIPS USED**  $PV = nRT$  (ideal gas law)

**SOLVE** To solve the problem, first solve the ideal gas law for  $n$ .

Before substituting into the equation, convert  $P$  and  $T$  into the correct units.

Finally, substitute into the equation and calculate  $n$ .

**SOLUTION**

$$PV = nRT$$

$$n = \frac{PV}{RT}$$

$$P = 24.3 \text{ psi} \times \frac{1 \text{ atm}}{14.7 \text{ psi}} = 1.6531 \text{ atm}$$

(Since rounding the intermediate answer would result in a slightly different final answer, mark the least significant digit in the intermediate answer but don't round until the end.)

$$T (\text{K}) = 25 + 273 = 298 \text{ K}$$

$$n = \frac{1.6531 \text{ atm} \times 3.24 \text{ L}}{0.08206 \frac{\text{L} \cdot \text{atm}}{\text{mol} \cdot \text{K}} \times 298 \text{ K}} = 0.219 \text{ mol}$$

**CHECK** The units of the answer are correct. The magnitude of the answer (0.219 mol) makes sense because, as you will see in the next section, one mole of an ideal gas under standard temperature and pressure (273 K and 1 atm) occupies 22.4 L. At a pressure that is 65% higher than standard pressure, the volume of 1 mol of gas is proportionally lower. Since this gas sample occupies 3.24 L, the answer of 0.219 mol is reasonable.

**FOR PRACTICE 5.6** What volume does 0.556 mol of gas occupy at a pressure of 715 mmHg and a temperature of 58 °C?

**FOR MORE PRACTICE 5.6** Determine the pressure in mmHg of a 0.133-g sample of helium gas in a 648-mL container at 32 °C.

## 5.5 Applications of the Ideal Gas Law: Molar Volume, Density, and Molar Mass of a Gas

The molar volume of 22.4 L only applies at STP.

We just examined how we can use the ideal gas law to calculate one of the variables ( $P$ ,  $V$ ,  $T$ , or  $n$ ) given the other three. We now turn to three other applications of the ideal gas law: molar volume, density, and molar mass.

### Molar Volume at Standard Temperature and Pressure

The volume occupied by one mole of a substance is its **molar volume**. For gases, we often specify the molar volume under conditions known as **standard temperature** ( $T = 0^\circ\text{C}$  or 273 K) and **pressure** ( $P = 1.00 \text{ atm}$ ), abbreviated as **STP**. Applying the ideal gas law, we can determine that the molar volume of an ideal gas at STP is:

$$\begin{aligned} V &= \frac{nRT}{P} \\ &= \frac{1.00 \text{ mol} \times 0.08206 \frac{\text{L} \cdot \text{atm}}{\text{mol} \cdot \text{K}} \times 273 \text{ K}}{1.00 \text{ atm}} \\ &= 22.4 \text{ L} \end{aligned}$$

▲ One mole of any gas occupies approximately 22.4 L at standard temperature (273 K) and pressure (1.0 atm).

The molar volume of an ideal gas at STP is useful because—as we saw in the *Check* steps of Examples 5.5 and 5.6—it gives us a way to approximate the volume of an ideal gas under conditions that are close to STP.

## CONCEPTUAL CONNECTION 5.2

**Molar Volume** Assuming ideal behavior, which of these gas samples has the greatest volume at STP?

- (a) 1 g of H<sub>2</sub>
- (b) 1 g of O<sub>2</sub>
- (c) 1 g of Ar

## Density of a Gas

Since one mole of an ideal gas occupies 22.4 L under standard temperature and pressure, we can readily calculate the density of an ideal gas under these conditions. Because density is mass/volume, and because the mass of one mole of a gas is simply its molar mass, the *density of a gas* is its molar mass divided by its molar volume:

$$\text{Density} = \frac{\text{molar mass}}{\text{molar volume}}$$

We can calculate the density of a gas at STP by using 22.4 L as the molar volume. For example, the densities of helium and nitrogen gas at STP are:

$$d_{\text{He}} = \frac{4.00 \text{ g/mol}}{22.4 \text{ L/mol}} = 0.179 \text{ g/L} \quad d_{\text{N}_2} = \frac{28.02 \text{ g/mol}}{22.4 \text{ L/mol}} = 1.25 \text{ g/L}$$

Notice that *the density of a gas is directly proportional to its molar mass*. The greater the molar mass of a gas, the more dense the gas. For this reason, a gas with a molar mass lower than that of air tends to rise in air. For example, both helium and hydrogen gas (molar masses of 4.00 and 2.01 g/mol, respectively) have molar masses that are lower than the average molar mass of air (approximately 28.8 g/mol). Therefore, a balloon filled with either helium or hydrogen gas floats in air.

We can calculate the density of a gas more generally (under any conditions) by using the ideal gas law. To do so, we can arrange the ideal gas law as:

$$PV = nRT$$

$$\frac{n}{V} = \frac{P}{RT}$$

Since the left-hand side of this equation has units of moles/liter, it represents the *molar density*. We obtain the density in grams/liter from the molar density by multiplying by the molar mass ( $\mathcal{M}$ ):

$$\begin{array}{ccccc} \frac{\text{moles}}{\text{liter}} & \times & \frac{\text{grams}}{\text{mole}} & = & \frac{\text{grams}}{\text{liter}} \\ \uparrow & & \uparrow & & \uparrow \\ \text{Molar density} & & \text{Molar mass} & & \text{Density in grams/liter} \end{array}$$

Therefore,

$$d = \frac{P\mathcal{M}}{RT} \quad [5.6]$$

Notice that, as expected, density increases with increasing molar mass. Notice also that, as we discussed in Section 5.3, density decreases with increasing temperature.

The primary components of air are nitrogen (about four-fifths) and oxygen (about one-fifth). We discuss the detailed composition of air in Section 5.6.

$$\begin{array}{c} \text{Density} \\ \left\{ \begin{array}{l} \frac{n}{V} \\ \mathcal{M} \end{array} \right. = \frac{P\mathcal{M}}{RT} \\ \uparrow \quad \uparrow \\ \text{Molar density} \quad \text{Molar mass} \\ d = \frac{P\mathcal{M}}{RT} \end{array}$$

**Example 5.7** Density

Calculate the density of nitrogen gas at 125 °C and a pressure of 755 mmHg.

**SORT** The problem gives you the temperature and pressure of nitrogen gas and asks you to find its density.

**GIVEN:**  $T(^{\circ}\text{C}) = 125^{\circ}\text{C}$ ,  $P = 755 \text{ mmHg}$

**FIND:**  $d$

**STRATEGIZE** Equation 5.6 provides the relationship between the density of a gas and its temperature, pressure, and molar mass. The temperature and pressure are given. You can calculate the molar mass from the formula of the gas, which you know is  $\text{N}_2$ .

**CONCEPTUAL PLAN**

**RELATIONSHIPS USED**

$$d = \frac{PM}{RT} \text{ (density of a gas)}$$

Molar mass  $\text{N}_2 = 28.02 \text{ g/mol}$

**SOLVE** To solve the problem, gather each of the required quantities in the correct units. Convert the temperature to kelvins and the pressure to atmospheres.

**SOLUTION**

$$T(\text{K}) = 125 + 273 = 398 \text{ K}$$

$$P = 755 \text{ mmHg} \times \frac{1 \text{ atm}}{760 \text{ mmHg}} = 0.99342 \text{ atm}$$

$$\begin{aligned} d &= \frac{PM}{RT} \\ &= \frac{0.99342 \text{ atm} \left( 28.02 \frac{\text{g}}{\text{mol}} \right)}{0.08206 \frac{\text{L} \cdot \text{atm}}{\text{mol} \cdot \text{K}} (398 \text{ K})} \\ &= 0.852 \text{ g/L} \end{aligned}$$

Substitute the quantities into the equation to calculate density.

**CHECK** The units of the answer are correct. The magnitude of the answer (0.852 g/L) makes sense because earlier you calculated the density of nitrogen gas at STP as 1.25 g/L. Since the temperature is higher than standard temperature, it follows that the density is lower.

**FOR PRACTICE 5.7** Calculate the density of xenon gas at a pressure of 742 mmHg and a temperature of 45 °C.

**FOR MORE PRACTICE 5.7** The density of a gas is 1.43 g/L at a temperature of 23 °C and a pressure of 0.789 atm. Calculate the molar mass of the gas.

**Density of a Gas** Arrange the following gases in order of increasing density at STP: Ne,  $\text{Cl}_2$ ,  $\text{F}_2$ , and  $\text{O}_2$ .

CONCEPTUAL  
**CONNECTION 5.3**

## Molar Mass of a Gas

We can use the ideal gas law in combination with mass measurements to calculate the molar mass of an unknown gas. First, we measure the mass and volume of an unknown gas under conditions of known pressure and temperature. Then, we determine the amount of the gas in moles from the ideal gas law. Finally, we calculate the molar mass by dividing the mass (in grams) by the amount (in moles) as demonstrated in Example 5.8.

**Example 5.8** Molar Mass of a Gas

A sample of gas has a mass of 0.311 g. Its volume is 0.225 L at a temperature of 55 °C and a pressure of 886 mmHg. Find its molar mass.

**SORT** The problem gives you the mass of a gas sample, along with its volume, temperature, and pressure. You are asked to find the molar mass.

**STRATEGIZE** The conceptual plan has two parts. In the first part, use the ideal gas law to find the number of moles of gas.

In the second part, use the definition of molar mass to determine the molar mass.

**GIVEN:**  $m = 0.311 \text{ g}$ ,  $V = 0.225 \text{ L}$ ,  
 $T (^{\circ}\text{C}) = 55 ^{\circ}\text{C}$ ,  $P = 886 \text{ mmHg}$

**FIND:** molar mass (g/mol)

**CONCEPTUAL PLAN****RELATIONSHIPS USED**

$$PV = nRT$$

$$\text{Molar mass} = \frac{\text{mass } (m)}{\text{moles } (n)}$$

**SOLVE** To find the number of moles, first solve the ideal gas law for  $n$ .

Before substituting into the equation for  $n$ , convert the pressure to atm and the temperature to K.

Then substitute into the equation and calculate  $n$ , the number of moles.

Finally, use the number of moles ( $n$ ) and the given mass ( $m$ ) to calculate the molar mass.

**SOLUTION**

$$PV = nRT$$

$$n = \frac{PV}{RT}$$

$$P = 886 \text{ mmHg} \times \frac{1 \text{ atm}}{760 \text{ mmHg}} = 1.1658 \text{ atm}$$

$$T(\text{K}) = 55 + 273 = 328 \text{ K}$$

$$n = \frac{1.1658 \text{ atm} \times 0.225 \text{ L}}{0.08206 \frac{\text{L} \cdot \text{atm}}{\text{mol} \cdot \text{K}} \times 328 \text{ K}}$$

$$= 9.7454 \times 10^{-3} \text{ mol}$$

$$\text{molar mass} = \frac{\text{mass } (m)}{\text{moles } (n)}$$

$$= \frac{0.311 \text{ g}}{9.7454 \times 10^{-3} \text{ mol}}$$

$$= 31.9 \text{ g/mol}$$

**CHECK** The units of the answer are correct. The magnitude of the answer (31.9 g/mol) is a reasonable number for a molar mass. If you calculated a very small number (such as any number smaller than 1) or a very large number, you solved the problem incorrectly. Most gases have molar masses between one and several hundred grams per mole.

**FOR PRACTICE 5.8** The mass of a sample of gas is 827 mg. Its volume is 0.270 L at a temperature of 88 °C and a pressure of 975 mmHg. Find its molar mass.

Mixtures of Gases and  
Partial Pressures

**5.6****Mixtures of Gases and Partial Pressures**

Many gas samples are not pure, but are mixtures of gases. Dry air, for example, is a mixture containing nitrogen, oxygen, argon, carbon dioxide, and a few other gases in trace amounts (Table 5.3).

Because the molecules in an ideal gas do not interact (as we will discuss further in Section 5.8), each of the components in an ideal gas mixture acts independently of the others. For example, the nitrogen molecules in air exert a certain pressure—78% of the total pressure—that is independent of the other gases in the mixture. Likewise, the oxygen molecules in air exert a certain pressure—21% of the total pressure—that is also independent of the other gases in the mixture. The pressure due to any individual component in a gas mixture is its **partial pressure** ( $P_n$ ). We can calculate partial pressure from the ideal gas law by assuming that each gas component acts independently.

$$P_n = n_n \frac{RT}{V}$$

For a multicomponent gas mixture, we calculate the partial pressure of each component from the ideal gas law and the number of moles of that component ( $n_n$ ) as follows:

$$P_a = n_a \frac{RT}{V}; \quad P_b = n_b \frac{RT}{V}; \quad P_c = n_c \frac{RT}{V}; \quad \dots \quad [5.7]$$

The sum of the partial pressures of the components in a gas mixture equals the total pressure:

$$P_{\text{total}} = P_a + P_b + P_c + \dots \quad [5.8]$$

where  $P_{\text{total}}$  is the total pressure and  $P_a, P_b, P_c, \dots$  are the partial pressures of the components. This relationship is known as **Dalton's law of partial pressures**.

Combining Equations 5.7 and 5.8, we get:

$$\begin{aligned} P_{\text{total}} &= P_a + P_b + P_c + \dots \\ &= n_a \frac{RT}{V} + n_b \frac{RT}{V} + n_c \frac{RT}{V} + \dots \\ &= (n_a + n_b + n_c + \dots) \frac{RT}{V} \\ &= (n_{\text{total}}) \frac{RT}{V} \end{aligned} \quad [5.9]$$

The total number of moles in the mixture, when substituted into the ideal gas law, indicates the total pressure of the sample.

If we divide Equation 5.7 by Equation 5.9, we get:

$$\frac{P_a}{P_{\text{total}}} = \frac{n_a(RT/V)}{n_{\text{total}}(RT/V)} = \frac{n_a}{n_{\text{total}}} \quad [5.10]$$

The quantity  $n_a/n_{\text{total}}$ , the number of moles of a component in a mixture divided by the total number of moles in the mixture, is the **mole fraction** ( $\chi_a$ ):

$$\chi_a = \frac{n_a}{n_{\text{total}}} \quad [5.11]$$

Rearranging Equation 5.10 and substituting the definition of mole fraction gives:

$$\begin{aligned} \frac{P_a}{P_{\text{total}}} &= \frac{n_a}{n_{\text{total}}} \\ P_a &= \frac{n_a}{n_{\text{total}}} P_{\text{total}} = \chi_a P_{\text{total}} \end{aligned}$$

or simply

$$P_a = \chi_a P_{\text{total}} \quad [5.12]$$

The partial pressure of a component in a gaseous mixture is its mole fraction multiplied by the total pressure. For gases, the mole fraction of a component is equivalent to its percent by volume divided by 100%. Therefore, based on Table 5.3, we calculate the partial pressure of nitrogen ( $P_{\text{N}_2}$ ) in air at 1.00 atm as:

$$\begin{aligned} P_{\text{N}_2} &= 0.78 \times 1.00 \text{ atm} \\ &= 0.78 \text{ atm} \end{aligned}$$

**TABLE 5.3** Composition of Dry Air

Gas	Percent by Volume (%)
Nitrogen (N <sub>2</sub> )	78
Oxygen (O <sub>2</sub> )	21
Argon (Ar)	0.9
Carbon dioxide (CO <sub>2</sub> )	0.04

Likewise, the partial pressure of oxygen in air at 1.00 atm is 0.21 atm and the partial pressure of Ar in air is 0.009 atm. Applying Dalton's law of partial pressures to air at 1.00 atm, we can find the total pressure:

$$\begin{aligned}P_{\text{total}} &= P_{\text{N}_2} + P_{\text{O}_2} + P_{\text{Ar}} \\P_{\text{total}} &= 0.78 \text{ atm} + 0.21 \text{ atm} + 0.009 \text{ atm} \\&= 1.00 \text{ atm}\end{aligned}$$

For these purposes, we can ignore the contribution of the  $\text{CO}_2$  and other trace gases because they are so small.

## CONCEPTUAL CONNECTION 5.4

**Partial Pressures** A gas mixture contains an equal number of moles of He and Ne. The total pressure of the mixture is 3.0 atm. What are the partial pressures of He and Ne?

### Example 5.9 Total Pressure and Partial Pressures

A 1.00-L mixture of helium, neon, and argon has a total pressure of 662 mmHg at 298 K. If the partial pressure of helium is 341 mmHg and the partial pressure of neon is 112 mmHg, what mass of argon is present in the mixture?

**SORT** The problem gives you the partial pressures of two of the three components in a gas mixture, along with the total pressure, the volume, and the temperature, and asks you to find the mass of the third component.

**STRATEGIZE** You can find the mass of argon from the number of moles of argon, which you can calculate from the partial pressure of argon and the ideal gas law. Begin by using Dalton's law to determine the partial pressure of argon.

Then use the partial pressure of argon together with the volume of the sample and the temperature to find the number of moles of argon.

Finally, use the molar mass of argon to calculate the mass of argon from the number of moles of argon.

**GIVEN:**  $P_{\text{He}} = 341 \text{ mmHg}$ ,  
 $P_{\text{Ne}} = 112 \text{ mmHg}$ ,  
 $P_{\text{total}} = 662 \text{ mmHg}$ ,  
 $V = 1.00 \text{ L}$ ,  $T = 298 \text{ K}$

**FIND:**  $m_{\text{Ar}}$

#### CONCEPTUAL PLAN

#### RELATIONSHIPS USED

$P_{\text{total}} = P_{\text{He}} + P_{\text{Ne}} + P_{\text{Ar}}$  (Dalton's law)

$PV = nRT$  (ideal gas law)

molar mass Ar = 39.95 g/mol

**SOLVE** Follow the conceptual plan. To find the partial pressure of argon, solve the equation for  $P_{\text{Ar}}$  and substitute the values of the other partial pressures to calculate  $P_{\text{Ar}}$ .

Convert the partial pressure from mmHg to atm and use it in the ideal gas law to calculate the amount of argon in moles.

Use the molar mass of argon to convert from amount of argon in moles to mass of argon.

#### SOLUTION

$$\begin{aligned}P_{\text{total}} &= P_{\text{He}} + P_{\text{Ne}} + P_{\text{Ar}} \\P_{\text{Ar}} &= P_{\text{total}} - P_{\text{He}} - P_{\text{Ne}} \\&= 662 \text{ mmHg} - 341 \text{ mmHg} - 112 \text{ mmHg} \\&= 209 \text{ mmHg}\end{aligned}$$

$$209 \text{ mmHg} \times \frac{1 \text{ atm}}{760 \text{ mmHg}} = 0.275 \text{ atm}$$

$$n = \frac{PV}{RT} = \frac{0.275 \text{ atm}(1.00 \text{ L})}{0.08206 \frac{\text{L} \cdot \text{atm}}{\text{mol} \cdot \text{K}}(298 \text{ K})} = 1.125 \times 10^{-2} \text{ mol Ar}$$

$$1.125 \times 10^{-2} \text{ mol Ar} \times \frac{39.95 \text{ g Ar}}{1 \text{ mol Ar}} = 0.449 \text{ g Ar}$$

**CHECK** The units of the answer are correct. The magnitude of the answer makes sense because the volume is 1.0 L, which at STP would contain about 1/22 mol. Since the partial pressure of argon in the mixture is about 1/3 of the total pressure, you can roughly estimate about 1/66 of one molar mass of argon, which is fairly close to your answer.

**FOR PRACTICE 5.9** A sample of hydrogen gas is mixed with water vapor. The mixture has a total pressure of 755 torr, and the water vapor has a partial pressure of 24 torr. What amount (in moles) of hydrogen gas is contained in 1.55 L of this mixture at 298 K?

## Deep-Sea Diving and Partial Pressures

Our lungs have evolved to breathe oxygen at a partial pressure of  $P_{O_2} = 0.21$  atm. If the total pressure decreases—when we climb a mountain, for example—the partial pressure of oxygen also decreases. On top of Mount Everest, where the total pressure is 0.311 atm, the partial pressure of oxygen is only 0.065 atm. Low oxygen levels produce a physiological condition called **hypoxia** or oxygen starvation (Figure 5.13▶). Mild hypoxia causes dizziness, headache, and shortness of breath. Severe hypoxia, which occurs when  $P_{O_2}$  drops below 0.1 atm, may result in unconsciousness or even death. For this reason, climbers hoping to make the summit of Mount Everest usually carry oxygen to breathe.

Though not as dangerous as a lack of oxygen, too much oxygen can also cause physiological problems. Recall from Section 5.3 that scuba divers breathe pressurized air. At 30 m, a scuba diver breathes air at a total pressure of 4.0 atm, making  $P_{O_2}$  about 0.84 atm. This elevated partial pressure of oxygen raises the density of oxygen molecules in the lungs, resulting in a higher concentration of oxygen in body tissues. When  $P_{O_2}$  increases beyond 1.4 atm, the increased oxygen concentration in body tissues causes a condition called **oxygen toxicity**, which results in muscle twitching, tunnel vision, and convulsions. Divers who venture too deep without proper precautions have drowned because of oxygen toxicity. A second problem associated with breathing pressurized air is the increase of nitrogen in the lungs. At 30 m, a scuba diver breathes nitrogen at  $P_{N_2} = 3.12$  atm, which increases the nitrogen concentration in body tissues and fluids. When  $P_{N_2}$  increases beyond about 4 atm, a condition called **nitrogen narcosis** or *rapture of the deep* results. Divers describe this condition as feeling inebriated or drunk. A diver breathing compressed air at 60 m feels as if he has consumed too much wine.

To avoid oxygen toxicity and nitrogen narcosis, deep-sea divers—those who descend beyond 50 m—breathe specialized mixtures of gases. One common mixture is heliox, a mixture of helium and oxygen. These mixtures usually contain a smaller percentage of oxygen than would be found in air, thereby lowering the risk of oxygen toxicity. Heliox also contains helium instead of nitrogen, eliminating the risk of nitrogen narcosis.

**▲ FIGURE 5.13 Oxygen Partial Pressure Limits** The partial pressure of oxygen in air at sea level is 0.21 atm. Partial pressures of oxygen below 0.1 atm and above 1.4 atm are dangerous to humans.

**Surface**  
 $P_{\text{tot}} = 1$  atm  
 $P_{N_2} = 0.78$  atm  
 $P_{O_2} = 0.21$  atm

**30 m**  
 $P_{\text{tot}} = 4$  atm  
 $P_{N_2} = 3.12$  atm  
 $P_{O_2} = 0.84$  atm

▶ When a diver breathes compressed air, the abnormally high partial pressure of oxygen in the lungs leads to an elevated concentration of oxygen in body tissues.

**Example 5.10** Partial Pressures and Mole Fractions

A 12.5-L scuba diving tank contains a helium–oxygen (heliox) mixture made up of 24.2 g of He and 4.32 g of O<sub>2</sub> at 298 K. Calculate the mole fraction and partial pressure of each component in the mixture and the total pressure of the mixture.

**SORT** The problem gives the masses of two gases in a mixture and the volume and temperature of the mixture. You are to find the mole fraction and partial pressure of each component, as well as the total pressure.

**STRATEGIZE** The conceptual plan has several parts. To calculate the mole fraction of each component, you must first find the number of moles of each component. Therefore, in the first part of the conceptual plan, convert the masses to moles using the molar masses.

In the second part, calculate the mole fraction of each component using the mole fraction definition.

To calculate *partial pressures* calculate the *total pressure* and then use the mole fractions from the previous part to calculate the partial pressures. Calculate the total pressure from the sum of the moles of both components. (Alternatively, you can calculate the partial pressures of the components individually, using the number of moles of each component. Then you can sum them to obtain the total pressure.)

Last, use the mole fractions of each component and the total pressure to calculate the partial pressure of each component.

**SOLVE** Follow the plan to solve the problem. Begin by converting each of the masses to amounts in moles.

Calculate each of the mole fractions.

Calculate the total pressure.

Finally, calculate the partial pressure of each component.

**GIVEN:**  $m_{\text{He}} = 24.2 \text{ g}$ ,  $m_{\text{O}_2} = 4.32 \text{ g}$ ,  
 $V = 12.5 \text{ L}$ ,  $T = 298 \text{ K}$

**FIND:**  $\chi_{\text{He}}$ ,  $\chi_{\text{O}_2}$ ,  $P_{\text{He}}$ ,  $P_{\text{O}_2}$ ,  $P_{\text{total}}$

**CONCEPTUAL PLAN**

$$\chi_{\text{He}} = \frac{n_{\text{He}}}{n_{\text{He}} + n_{\text{O}_2}}; \quad \chi_{\text{O}_2} = \frac{n_{\text{O}_2}}{n_{\text{He}} + n_{\text{O}_2}}$$

$$P_{\text{total}} = \frac{(n_{\text{He}} + n_{\text{O}_2})RT}{V}$$

$$P_{\text{He}} = \chi_{\text{He}}P_{\text{total}}; \quad P_{\text{O}_2} = \chi_{\text{O}_2}P_{\text{total}}$$

**RELATIONSHIPS USED**

$\chi_a = n_a/n_{\text{total}}$  (mole fraction definition)

$$P_{\text{total}}V = n_{\text{total}}RT$$

$$P_a = \chi_a P_{\text{total}}$$

**SOLUTION**

$$24.2 \text{ g He} \times \frac{1 \text{ mol He}}{4.00 \text{ g He}} = 6.05 \text{ mol He}$$

$$4.32 \text{ g O}_2 \times \frac{1 \text{ mol O}_2}{32.00 \text{ g O}_2} = 0.135 \text{ mol O}_2$$

$$\chi_{\text{He}} = \frac{n_{\text{He}}}{n_{\text{He}} + n_{\text{O}_2}} = \frac{6.05}{6.05 + 0.135} = 0.97817$$

$$\chi_{\text{O}_2} = \frac{n_{\text{O}_2}}{n_{\text{He}} + n_{\text{O}_2}} = \frac{0.135}{6.05 + 0.135} = 0.021827$$

$$P_{\text{total}} = \frac{(n_{\text{He}} + n_{\text{O}_2})RT}{V}$$

$$= \frac{(6.05 \text{ mol} + 0.135 \text{ mol}) \left( 0.08206 \frac{\text{L} \cdot \text{atm}}{\text{mol} \cdot \text{K}} \right) (298 \text{ K})}{12.5 \text{ L}}$$

$$= 12.099 \text{ atm}$$

$$P_{\text{He}} = \chi_{\text{He}} P_{\text{total}} = 0.97817 \times 12.099 \text{ atm} = 11.8 \text{ atm}$$

$$P_{\text{O}_2} = \chi_{\text{O}_2} P_{\text{total}} = 0.021827 \times 12.099 \text{ atm}$$

$$= 0.264 \text{ atm}$$

**CHECK** The units of the answers are correct, and the magnitudes are reasonable.

**FOR PRACTICE 5.10** A diver breathes a heliox mixture with an oxygen mole fraction of 0.050. What must the total pressure be for the partial pressure of oxygen to be 0.21 atm?

## Collecting Gases over Water

When the desired product of a chemical reaction is a gas, the gas is often collected by the displacement of water. For example, suppose we use the reaction of zinc with hydrochloric acid as a source of hydrogen gas:

To collect the gas, we can set up an apparatus like the one shown in Figure 5.14 ▼. As the hydrogen gas forms, it bubbles through the water and gathers in the collection flask. The hydrogen gas collected in this way is not pure, however. It is mixed with water vapor because some water molecules evaporate and combine with the hydrogen molecules.

The partial pressure of water in the mixture, called its **vapor pressure**, depends on temperature (Table 5.4). Vapor pressure increases with increasing temperature because higher temperatures cause more water molecules to evaporate. We will discuss vapor pressure more thoroughly in Chapter 11.

Suppose we collect hydrogen gas over water at a total pressure of 758.2 mmHg and a temperature of 25 °C. What is the partial pressure of the hydrogen gas? We know that the total pressure is 758.2 mmHg and that the partial pressure of water is 23.78 mmHg (its vapor pressure at 25 °C):

$$P_{\text{total}} = P_{\text{H}_2} + P_{\text{H}_2\text{O}}$$

$$758.2 \text{ mmHg} = P_{\text{H}_2} + 23.78 \text{ mmHg}$$

Therefore,

$$\begin{aligned} P_{\text{H}_2} &= 758.2 \text{ mmHg} - 23.78 \text{ mmHg} \\ &= 734.4 \text{ mmHg} \end{aligned}$$

The partial pressure of the hydrogen in the mixture is 734.4 mmHg.

Appendix IIE includes a more complete table of the vapor pressure of water versus temperature.

**TABLE 5.4** Vapor Pressure of Water versus Temperature

Temperature (°C)	Pressure (mmHg)	Temperature (°C)	Pressure (mmHg)
0	4.58	55	118.2
5	6.54	60	149.6
10	9.21	65	187.5
15	12.79	70	233.7
20	17.55	75	289.1
25	23.78	80	355.1
30	31.86	85	433.6
35	42.23	90	525.8
40	55.40	95	633.9
45	71.97	100	760.0
50	92.6		

► **FIGURE 5.14** Collecting a Gas over Water When the gaseous product of a chemical reaction is collected over water, the product molecules (in this case  $\text{H}_2$ ) mix with water molecules. The pressure of water in the final mixture is equal to the vapor pressure of water at the temperature at which the gas is collected. The partial pressure of the product is the total pressure minus the partial pressure of water.

**Example 5.11** Collecting Gases over Water

In order to determine the rate of photosynthesis (the conversion by plants of carbon dioxide and water into glucose and oxygen), the oxygen gas emitted by an aquatic plant is collected over water at a temperature of 293 K and a total pressure of 755.2 mmHg. Over a specific time period, a total of 1.02 L of gas is collected. What mass of oxygen gas (in grams) forms?

**SORT** The problem gives the volume of gas collected over water as well as the temperature and the pressure. You are to find the mass in grams of oxygen that forms.

**STRATEGIZE** You can determine the mass of oxygen from the amount of oxygen in moles, which you can calculate from the ideal gas law if you know the partial pressure of oxygen. Since the oxygen is mixed with water vapor, you find the partial pressure of oxygen in the mixture by subtracting the partial pressure of water at 293 K (20 °C) from the total pressure.

Next, use the ideal gas law to determine the number of moles of oxygen from its partial pressure, volume, and temperature.

Finally, use the molar mass of oxygen to convert the number of moles to grams.

**GIVEN:**  $V = 1.02 \text{ L}$ ,  $P_{\text{total}} = 755.2 \text{ mmHg}$ ,  $T = 293 \text{ K}$

**FIND:** g  $\text{O}_2$

**CONCEPTUAL PLAN**

$$P_{\text{O}_2} = P_{\text{total}} - P_{\text{H}_2\text{O}} (20^\circ\text{C})$$

**RELATIONSHIPS USED**

$$P_{\text{total}} = P_a + P_b + P_c + \dots \text{ (Dalton's law)}$$

$$PV = nRT \text{ (ideal gas law)}$$

**SOLVE** Follow the conceptual plan to solve the problem. Begin by calculating the partial pressure of oxygen in the oxygen/water mixture. You can find the partial pressure of water at 20 °C in Table 5.4.

Next, solve the ideal gas law for number of moles.

Before substituting into the ideal gas law, convert the partial pressure of oxygen from mmHg to atm.

Substitute into the ideal gas law to find the number of moles of oxygen.

Finally, use the molar mass of oxygen to convert to grams of oxygen.

**SOLUTION**

$$\begin{aligned} P_{\text{O}_2} &= P_{\text{total}} - P_{\text{H}_2\text{O}} (20^\circ\text{C}) \\ &= 755.2 \text{ mmHg} - 17.55 \text{ mmHg} \\ &= 737.65 \text{ mmHg} \end{aligned}$$

$$n_{\text{O}_2} = \frac{P_{\text{O}_2}V}{RT}$$

$$737.65 \text{ mmHg} \times \frac{1 \text{ atm}}{760 \text{ mmHg}} = 0.97059 \text{ atm}$$

$$\begin{aligned} n_{\text{O}_2} &= \frac{P_{\text{O}_2}V}{RT} = \frac{0.97059 \text{ atm} (1.02 \text{ L})}{0.08206 \frac{\text{L} \cdot \text{atm}}{\text{mol} \cdot \text{K}} (293 \text{ K})} \\ &= 4.1175 \times 10^{-2} \text{ mol} \end{aligned}$$

$$4.1175 \times 10^{-2} \text{ mol O}_2 \times \frac{32.00 \text{ g O}_2}{1 \text{ mol O}_2} = 1.32 \text{ g O}_2$$

**CHECK** The answer is in the correct units. You can quickly check the magnitude of the answer by using molar volume. Under STP one liter is about  $1/22$  of one mole. Therefore the answer should be about  $1/22$  the molar mass of oxygen ( $1/22 \times 32 = 1.45$ ). The magnitude of the answer seems reasonable.

**FOR PRACTICE 5.11** A common way to make hydrogen gas in the laboratory is to place a metal such as zinc in hydrochloric acid. The hydrochloric acid reacts with the metal to produce hydrogen gas, which is then collected over water. Suppose a student carries out this reaction and collects a total of 154.4 mL of gas at a pressure of 742 mmHg and a temperature of 25 °C. What mass of hydrogen gas (in mg) does the student collect?

## 5.7 Gases in Chemical Reactions: Stoichiometry Revisited

In Chapter 4, we discussed how to use the coefficients in chemical equations as conversion factors between number of moles of reactants and number of moles of products in a chemical reaction. We can use these conversion factors to determine, for example, the mass of product obtained in a chemical reaction based on a given mass of reactant, or the mass of one reactant needed to react completely with a given mass of another reactant. The general conceptual plan for these kinds of calculations is:

where A and B are two different substances involved in the reaction and the conversion factor between amounts (in moles) of each comes from the stoichiometric coefficients in the balanced chemical equation.

In reactions involving *gaseous* reactant or products, we often specify the quantity of a gas in terms of its volume at a given temperature and pressure. As we have seen, stoichiometry involves relationships between amounts in moles. For stoichiometric calculations involving gases, we can use the ideal gas law to determine the amounts in moles from the volumes, or to determine the volumes from the amounts in moles.

$$n = \frac{PV}{RT} \quad V = \frac{nRT}{P}$$

The pressures here could also be partial pressures.

The general conceptual plan for these kinds of calculations is:

Examples 5.12 and 5.13 demonstrate this kind of calculation.

### Example 5.12 Gases in Chemical Reactions

Methanol ( $\text{CH}_3\text{OH}$ ) can be synthesized by the reaction:

What volume (in liters) of hydrogen gas, at a temperature of 355 K and a pressure of 738 mmHg, is needed to synthesize 35.7 g of methanol?

**SORT** You are given the mass of methanol, the product of the chemical reaction. You are asked to find the required volume of one of the reactants (hydrogen gas) at a specified temperature and pressure.

**GIVEN:** 35.7 g  $\text{CH}_3\text{OH}$ ,  
 $T = 355 \text{ K}$ ,  $P = 738 \text{ mmHg}$   
**FIND:**  $V_{\text{H}_2}$

—Continued on the next page

—Continued

**STRATEGIZE** You can calculate the required volume of hydrogen gas from the number of moles of hydrogen gas, which you can obtain from the number of moles of methanol via the stoichiometry of the reaction.

First, find the number of moles of methanol from its mass by using the molar mass.

Then use the stoichiometric relationship from the balanced chemical equation to find the number of moles of hydrogen you need to form that quantity of methanol.

Finally, substitute the number of moles of hydrogen together with the pressure and temperature into the ideal gas law to find the volume of hydrogen.

**CONCEPTUAL PLAN****RELATIONSHIPS USED**

$PV = nRT$  (ideal gas law)

2 mol  $\text{H}_2$  : 1 mol  $\text{CH}_3\text{OH}$  (from balanced chemical equation)

molar mass  $\text{CH}_3\text{OH} = 32.04 \text{ g/mol}$

**SOLVE** Follow the conceptual plan to solve the problem. Begin by using the mass of methanol to determine the number of moles of methanol.

Next, convert the number of moles of methanol to moles of hydrogen.

Finally, use the ideal gas law to calculate the volume of hydrogen. Before substituting into the equation, you need to convert the pressure to atmospheres.

**SOLUTION**

$$35.7 \text{ g CH}_3\text{OH} \times \frac{1 \text{ mol CH}_3\text{OH}}{32.04 \text{ g CH}_3\text{OH}} = 1.1142 \text{ mol CH}_3\text{OH}$$

$$1.1142 \text{ mol CH}_3\text{OH} \times \frac{2 \text{ mol H}_2}{1 \text{ mol CH}_3\text{OH}} = 2.2284 \text{ mol H}_2$$

$$V_{\text{H}_2} = \frac{n_{\text{H}_2}RT}{P}$$

$$P = 738 \text{ mmHg} \times \frac{1 \text{ atm}}{760 \text{ mmHg}} = 0.97105 \text{ atm}$$

$$V_{\text{H}_2} = \frac{(2.2284 \text{ mol}) \left( 0.08206 \frac{\text{L} \cdot \text{atm}}{\text{mol} \cdot \text{K}} \right) (355 \text{ K})}{0.97105 \text{ atm}} = 66.9 \text{ L}$$

**CHECK** The units of the answer are correct. The magnitude of the answer (66.9 L) seems reasonable. You are given slightly more than one molar mass of methanol, which is therefore slightly more than one mole of methanol. From the equation you can see that you need 2 mol hydrogen to make 1 mol methanol, so the answer must be slightly greater than 2 mol hydrogen. Under standard temperature and pressure, slightly more than 2 mol hydrogen occupies slightly more than  $2 \times 22.4 \text{ L} = 44.8 \text{ L}$ . At a temperature greater than standard temperature, the volume would be even greater; therefore, your answer is reasonable.

**FOR PRACTICE 5.12** In the reaction shown here, 4.58 L of  $\text{O}_2$  forms at  $P = 745 \text{ mmHg}$  and  $T = 308 \text{ K}$ . How many grams of  $\text{Ag}_2\text{O}$  decomposed?

**FOR MORE PRACTICE 5.12** In the previous reaction, what mass of  $\text{Ag}_2\text{O}(s)$  (in grams) is required to form 388 mL of oxygen gas at  $P = 734 \text{ mmHg}$  and  $25.0^\circ\text{C}$ ?

## Molar Volume and Stoichiometry

In Section 5.5 we saw that under standard temperature and pressure, 1 mol of an ideal gas occupies 22.4 L. Consequently, if a reaction occurs at or near standard temperature

and pressure, we can use  $1 \text{ mol} = 22.4 \text{ L}$  as a conversion factor in stoichiometric calculations, as demonstrated in Example 5.13.

### Example 5.13 Using Molar Volume in Gas Stoichiometric Calculations

How many grams of water form when 1.24 L of  $\text{H}_2$  gas at STP completely reacts with  $\text{O}_2$ ?

**SORT** You are given the volume of hydrogen gas (a reactant) at STP and asked to determine the mass of water that forms upon complete reaction.

**GIVEN:** 1.24 L  $\text{H}_2$

**FIND:** g  $\text{H}_2\text{O}$

**STRATEGIZE** Since the reaction occurs under standard temperature and pressure, you can convert directly from the volume (in liters) of hydrogen gas to the amount in moles. Then use the stoichiometric relationship from the balanced equation to find the number of moles of water formed. Finally, use the molar mass of water to obtain the mass of water formed.

#### CONCEPTUAL PLAN

#### RELATIONSHIPS USED

$1 \text{ mol} = 22.4 \text{ L}$  (at STP)

$2 \text{ mol H}_2 : 2 \text{ mol H}_2\text{O}$  (from balanced equation)

molar mass  $\text{H}_2\text{O} = 18.02 \text{ g/mol}$

**SOLVE** Follow the conceptual plan to solve the problem.

$$1.24 \text{ L H}_2 \times \frac{1 \text{ mol H}_2}{22.4 \text{ L H}_2} \times \frac{2 \text{ mol H}_2\text{O}}{2 \text{ mol H}_2} \times \frac{18.02 \text{ g H}_2\text{O}}{1 \text{ mol H}_2\text{O}} = 0.998 \text{ g H}_2\text{O}$$

**CHECK** The units of the answer are correct. The magnitude of the answer (0.998 g) is about  $1/18$  of the molar mass of water, roughly equivalent to the approximately  $1/22$  of a mole of hydrogen gas given, as expected for the 1:1 stoichiometric relationship between number of moles of hydrogen and number of moles of water.

**FOR PRACTICE 5.13** How many liters of oxygen (at STP) are required to form 10.5 g of  $\text{H}_2\text{O}$ ?

**Pressure and Number of Moles** Nitrogen and hydrogen react to form ammonia according to the following equation:

Consider the following representations of the initial mixture of reactants and the resulting mixture after the reaction has been allowed to react for some time:

If the volume is kept constant, and nothing is added to the reaction mixture, what happens to the total pressure during the course of the reaction?

- (a) the pressure increases
- (b) the pressure decreases
- (c) the pressure does not change

### CONCEPTUAL CONNECTION 5.5

## 5.8 Kinetic Molecular Theory: A Model for Gases

### Kinetic Molecular Theory

**▲ FIGURE 5.15 A Model for Gas Behavior** In the kinetic molecular theory of gases, a gas sample is modeled as a collection of particles in constant straight-line motion. The size of each particle is negligibly small, and the particles' collisions are elastic.

In Chapter 1, we discussed how the scientific approach proceeds from observations to laws and eventually to theories. Remember that laws summarize behavior—for example, Charles's law summarizes *how* the volume of a gas depends on temperature—whereas theories give the underlying reasons for the behavior. A theory of gas behavior explains, for example, *why* the volume of a gas increases with increasing temperature.

The simplest model for the behavior of gases is the **kinetic molecular theory**. In this theory, a gas is modeled as a collection of particles (either molecules or atoms, depending on the gas) in constant motion (Figure 5.15◀). A single particle moves in a straight line until it collides with another particle (or with the wall of the container). Kinetic molecular theory has three basic postulates (or assumptions):

- 1. The size of a particle is negligibly small.** Kinetic molecular theory assumes that the particles themselves occupy negligible volume, even though they have mass. This postulate is justified because, under normal pressures, the space between atoms or molecules in a gas is very large compared to the size of the atoms or molecules themselves. For example, in a sample of argon gas at STP, only about 0.01% of the volume is occupied by atoms, and the average distance from one argon atom to another is 3.3 nm. In comparison, the atomic radius of argon is 97 pm. If an argon atom were the size of a golf ball, its nearest neighbor would be, on average, over 4 ft (1.2 m) away at STP.
- 2. The average kinetic energy of a particle is proportional to the temperature in kelvins.** The motion of atoms or molecules in a gas is due to thermal energy, which distributes itself among the particles in the gas. At any given moment, some particles are moving faster than others—there is a distribution of velocities—but the higher the temperature, the faster the overall motion and the greater the average kinetic energy. Notice that *kinetic energy* ( $\frac{1}{2}mv^2$ )—not *velocity*—is proportional to temperature. The atoms in a sample of helium and a sample of argon at the same temperature have the same average *kinetic energy* but not the same average *velocity*. Because the helium atoms are lighter, they must move faster to have the same kinetic energy as argon atoms.
- 3. The collision of one particle with another (or with the walls of its container) is completely elastic.** When two particles collide, they may *exchange energy*, but there is no overall *loss of energy*. Any kinetic energy lost by one particle is completely gained by the other. In other words, the particles have no “stickiness,” and they are not deformed by the collision. An encounter between two particles in kinetic molecular theory is more like the collision between two billiard balls than the collision between two lumps of clay (Figure 5.16▶). Between collisions, the particles do not exert any forces on one another.

**▲ FIGURE 5.16 Elastic versus Inelastic Collisions** When two billiard balls collide, the collision is elastic—the total kinetic energy of the colliding bodies is the same before and after the collision. When two lumps of clay collide, the collision is inelastic—the kinetic energy of the colliding bodies dissipates in the form of heat during the collision.

If we start with the postulates of kinetic molecular theory, we can mathematically derive the ideal gas law (as we demonstrate later). Since the ideal gas law follows directly from kinetic molecular theory, we have confidence that the assumptions of the theory are valid, at least under conditions where the ideal gas law applies.

## How Kinetic Molecular Theory Explains Pressure and the Simple Gas Laws

Let's examine how the concept of pressure as well as each of the gas laws we have examined in this chapter follow conceptually from kinetic molecular theory.

### The Nature of Pressure

In Section 5.2, we defined pressure as force divided by area:

$$P = \frac{F}{A}$$

From Newton's second law, the force ( $F$ ) associated with an individual collision is given by  $F = ma$ , where  $m$  is the mass of the particle and  $a$  is its acceleration as it changes its direction of travel due to the collision.

According to kinetic molecular theory, a gas is a collection of particles in constant motion. The motion results in collisions between the particles and the surfaces around them. As each particle collides with a surface, it exerts a force upon that surface. The result of many particles in a gas sample exerting forces on the surfaces around them is a constant pressure.

### Boyle's Law

Boyle's law states that for a constant number of particles at constant temperature, the volume of a gas is inversely proportional to its pressure. According to kinetic molecular theory, if we decrease the volume of a gas, we force the gas particles to occupy a smaller space. As long as the temperature remains the same, the number of collisions with the surrounding surfaces (per unit surface area) must necessarily increase, resulting in a greater pressure.

### Charles's Law

Charles's law states that for a constant number of particles at constant pressure, the volume of a gas is proportional to its temperature. According to kinetic molecular theory, when we increase the temperature of a gas, the average speed, and thus the average kinetic energy, of the particles increases. Since this greater kinetic energy results in more frequent collisions and more force per collision, the pressure of the gas increases if its volume is held constant (Gay-Lussac's law). The only way for the pressure to remain constant is for the volume to increase. The greater volume spreads the collisions out over a greater surface area so that the pressure (defined as force per unit area) is unchanged.

### Avogadro's Law

Avogadro's law states that at constant temperature and pressure, the volume of a gas is proportional to the number of particles. According to kinetic molecular theory, when we increase the number of particles in a gas sample, the number of collisions with the surrounding surfaces increases. The greater number of collisions results in a greater overall force on surrounding surfaces; the only way for the pressure to remain constant is for the volume to increase so that the number of particles per unit volume (and thus the number of collisions) remains constant.

### Dalton's Law

Dalton's law states that the total pressure of a gas mixture is the sum of the partial pressures of its components. According to Dalton's law, the components in a gas mixture act identically to, and independently of, one another. According to kinetic molecular theory, the particles have negligible size and they do not interact. Consequently, the only property that distinguishes one type of particle from another is its mass.

However, even particles of different masses have the same average kinetic energy at a given temperature, so they exert the same force upon collision with a surface. Consequently, adding components to a gas mixture—even different *kinds* of gases—has the same effect as simply adding more particles. The partial pressures of all the components sum to the overall pressure.

## CONCEPTUAL CONNECTION 5.6

**Kinetic Molecular Theory I** As described by kinetic molecular theory, depict a gas sample containing equal molar amounts of argon and xenon. Use red dots to represent argon atoms and blue dots to represent xenon atoms. Give each atom a “tail” to represent its velocity relative to the others in the mixture.

## Kinetic Molecular Theory and the Ideal Gas Law

We have just seen how each of the gas laws conceptually follows from kinetic molecular theory. We can also *derive* the ideal gas law from the postulates of kinetic molecular theory. In other words, the kinetic molecular theory is a quantitative model that *implies*  $PV = nRT$ . Let's explore this derivation.

The pressure on a wall of a container (Figure 5.17▼) occupied by particles in constant motion is the total force on the wall (due to the collisions) divided by the area of the wall.

$$P = \frac{F_{\text{total}}}{A} \quad [5.13]$$

Recall that the force ( $F$ ) associated with an individual collision is given by  $F = ma$ , where  $m$  is the mass of the particle and  $a$  is its acceleration as it changes its direction of travel due to the collision. The acceleration for each collision is the change in velocity ( $\Delta v$ ) divided by the time interval ( $\Delta t$ ), so the force imparted for each collision is:

$$F_{\text{collision}} = m \frac{\Delta v}{\Delta t} \quad [5.14]$$

If a particle collides elastically with the wall, it bounces off the wall with no loss of energy. For a straight-line collision, the change in velocity is  $2v$  (the particle's velocity was  $v$  before the collision and  $-v$  after the collision; therefore, the change is  $2v$ ). The force per collision is given by:

$$F_{\text{collision}} = m \frac{2v}{\Delta t} \quad [5.15]$$

The total number of collisions in the time interval  $\Delta t$  on a wall of surface area  $A$  is proportional to the number of particles that can reach the wall in this time interval—in other words, all particles within a distance of  $v\Delta t$  of the wall. These particles occupy a

### Calculating Gas Pressure: A Molecular View

► **FIGURE 5.17** The Pressure on the Wall of a Container The pressure on the wall of a container can be calculated by determining the total force due to collisions of the particles with the wall.

volume given by  $v \Delta t \times A$ , and their total number is equal to this volume multiplied by the density of particles in the container ( $n/V$ ):

Number of collisions  $\propto$  number of particles within  $v \Delta t$

$$\propto \underbrace{v \Delta t \times A}_{\text{Volume}} \times \underbrace{\frac{n}{V}}_{\text{Density of particles}} \quad [5.16]$$

The *total force* on the wall is equal to the force per collision multiplied by the number of collisions:

$$\begin{aligned} F_{\text{total}} &= F_{\text{collision}} \times \text{number of collisions} \\ &\propto m \frac{2v}{\Delta t} \times v \Delta t \times A \times \frac{n}{V} \\ &\propto mv^2 \times A \times \frac{n}{V} \end{aligned} \quad [5.17]$$

The pressure on the wall is equal to the total force divided by the surface area of the wall:

$$\begin{aligned} P &= \frac{F_{\text{total}}}{A} \\ &\propto \frac{mv^2 \times A \times \frac{n}{V}}{A} \\ P &\propto mv^2 \times \frac{n}{V} \end{aligned} \quad [5.18]$$

Notice that Equation 5.18 contains within it Boyle's law ( $P \propto 1/V$ ) and Avogadro's law ( $V \propto n$ ). We can get the complete ideal gas law from postulate 2 of the kinetic molecular theory, which states that the average kinetic energy ( $\frac{1}{2}mv^2$ ) is proportional to the temperature in kelvins ( $T$ ):

$$mv^2 \propto T \quad [5.19]$$

By combining Equations 5.18 and 5.19, we get:

$$\begin{aligned} P &\propto \frac{T \times n}{V} \\ PV &\propto nT \end{aligned} \quad [5.20]$$

The proportionality can be replaced by an equals sign if we provide the correct constant,  $R$ :

$$PV = nRT \quad [5.21]$$

In other words, the kinetic molecular theory (a model for how gases behave) predicts behavior that is consistent with our observations and measurements of gases—the theory agrees with the experiment. Recall from Chapter 1 that a scientific theory is the most powerful kind of scientific knowledge. In the kinetic molecular theory, we have a model for what a gas is like. Although the model is not perfect—indeed, it breaks down under certain conditions, as we shall see later in this chapter—it predicts a great deal about the behavior of gases. Therefore, the model is a good approximation of what a gas is actually like. A careful examination of the conditions under which the model breaks down (see Section 5.10) gives us even more insight into the behavior of gases.

## Temperature and Molecular Velocities

According to kinetic molecular theory, particles of different masses have the same average kinetic energy at a given temperature. The kinetic energy of a particle depends on its mass and velocity according to the equation:

$$\text{KE} = \frac{1}{2}mv^2$$

The only way for particles of different masses to have the same kinetic energy is for them to have different velocities as we saw in Conceptual Connection 5.6. *In a gas mixture at a given temperature, lighter particles travel faster (on average) than heavier ones.*

In kinetic molecular theory, we define the root mean square velocity ( $u_{\text{rms}}$ ) of a particle as:

$$u_{\text{rms}} = \sqrt{\overline{u^2}} \quad [5.22]$$

where  $\overline{u^2}$  is the average of the squares of the particle velocities. Even though the root mean square velocity of a collection of particles is not identical to the average velocity, the two are close in value and conceptually similar. Root mean square velocity is a special *type* of average. The average kinetic energy of one mole of gas particles is given by the equation:

$$\text{KE}_{\text{avg}} = \frac{1}{2}N_A m \overline{u^2} \quad [5.23]$$

where  $N_A$  is Avogadro's number, and  $m$  is the mass of the particle.

Postulate 2 of the kinetic molecular theory states that the average kinetic energy is proportional to the temperature in kelvins. The constant of proportionality in this relationship is  $(3/2)R$ :

$$\text{KE}_{\text{avg}} = (3/2)RT \quad [5.24]$$

where  $R$  is the gas constant, but in different units ( $R = 8.314 \text{ J/mol} \cdot \text{K}$ ) than those we use in the ideal gas law. If we combine Equations 5.23 and 5.24, and solve for  $\overline{u^2}$ , we get:

$$(1/2)N_A m \overline{u^2} = (3/2)RT$$

$$\overline{u^2} = \frac{(3/2)RT}{(1/2)N_A m} = \frac{3RT}{N_A m}$$

Taking the square root of both sides, we get:

$$\sqrt{\overline{u^2}} = u_{\text{rms}} = \sqrt{\frac{3RT}{N_A m}} \quad [5.25]$$

In Equation 5.25,  $m$  is the mass of a particle in kg and  $N_A$  is Avogadro's number. The product  $N_A m$ , then, is the molar mass in kg/mol. If we call this quantity  $\mathcal{M}$ , then the expression for mean square velocity as a function of temperature becomes the following important result:

$$u_{\text{rms}} = \sqrt{\frac{3RT}{\mathcal{M}}} \quad [5.26]$$

The root mean square velocity of a collection of gas particles is proportional to the square root of the temperature in kelvins and inversely proportional to the square root of the molar mass of the particles (which because of the units of  $R$  must be in kilograms per mole). The root mean square velocity of nitrogen molecules at 25 °C, for example, is 515 m/s (1152 mi/hr). The root mean square velocity of hydrogen molecules at room temperature is 1920 m/s (4295 mi/hr). Notice that the lighter molecules move much faster at a given temperature.

## CONCEPTUAL CONNECTION 5.7

**Root Mean Square Velocity** How does the approximate root mean square velocity of neon compare to that of krypton at the same temperature?

- The root mean square velocity of Ne is approximately four times that of Kr.
- The root mean square velocity of Ne is approximately two times that of Kr.
- The root mean square velocity of Ne is approximately one-half that of Kr.
- The root mean square velocity of Ne is approximately one-fourth that of Kr.

The  $(3/2)R$  proportionality constant comes from a derivation that is beyond the scope of this textbook.

The joule (J) is a unit of energy that we will discuss in more detail in Section 6.2.

$$\left(1 \text{ J} = 1 \text{ kg} \frac{\text{m}^2}{\text{s}^2}\right)$$

## Variation of Velocity Distribution with Molar Mass

**▲ FIGURE 5.18** Velocity Distribution for Several Gases at 25 °C At a given temperature, there is a distribution of velocities among the particles in a sample of gas. The exact shape and peak of the distribution vary with the molar mass of the gas.

The root mean square velocity, as we have seen, is a kind of average velocity. Some particles move faster and some move more slowly than this average. The velocities of all the particles in a gas sample form distributions like those shown in Figure 5.18▲. We can see from these distributions that some particles indeed travel at the root mean square velocity. However, many particles travel faster and many travel more slowly than the root mean square velocity. For lighter particles, such as helium and hydrogen, the velocity distribution is shifted toward higher velocities and the curve becomes broader, indicating a wider range of velocities. Figure 5.19► illustrates the velocity distribution for nitrogen at different temperatures. As the temperature increases, the root mean square velocity increases and the distribution becomes broader.

## Variation of Velocity Distribution with Temperature

**▲ FIGURE 5.19** Velocity Distribution for Nitrogen at Several Temperatures As the temperature of a gas sample increases, the velocity distribution of the molecules shifts toward higher velocity and becomes less sharply peaked.

### Example 5.14 Root Mean Square Velocity

Calculate the root mean square velocity of oxygen molecules at 25 °C.

**SORT** You are given the kind of molecule and the temperature and asked to find the root mean square velocity.

**GIVEN:**  $\text{O}_2$ ,  $t = 25\text{ }^\circ\text{C}$

**FIND:**  $u_{\text{rms}}$

**STRATEGIZE** The conceptual plan for this problem shows how you can use the molar mass of oxygen and the temperature (in kelvins) with the equation that defines the root mean square velocity to calculate root mean square velocity.

**CONCEPTUAL PLAN**

$$\begin{array}{c} \boxed{\mathcal{M}, T} \longrightarrow \boxed{u_{\text{rms}}} \\ u_{\text{rms}} = \sqrt{\frac{3RT}{\mathcal{M}}} \end{array}$$

**RELATIONSHIP USED**

$$u_{\text{rms}} = \sqrt{\frac{3RT}{\mathcal{M}}} \text{ (Equation 5.26)}$$

**SOLVE** First, gather the required quantities in the correct units. Note that molar mass must be in kg/mol.

**SOLUTION**

$$T = 25 + 273 = 298\text{ K}$$

$$\mathcal{M} = \frac{32.00\text{ g O}_2}{1\text{ mol O}_2} \times \frac{1\text{ kg}}{1000\text{ g}} = \frac{32.00 \times 10^{-3}\text{ kg O}_2}{1\text{ mol O}_2}$$

—Continued on the next page

—Continued

Substitute the quantities into the equation to calculate root mean square velocity. Note that  $1 \text{ J} = 1 \text{ kg} \cdot \text{m}^2/\text{s}^2$ .

$$\begin{aligned}
 u_{\text{rms}} &= \sqrt{\frac{3RT}{\mathcal{M}}} \\
 &= \sqrt{\frac{3\left(8.314 \frac{\text{J}}{\text{mol} \cdot \text{K}}\right)(298 \text{ K})}{\frac{32.00 \times 10^{-3} \text{ kg } \text{O}_2}{1 \text{ mol } \text{O}_2}}} \\
 &= \sqrt{2.32 \times 10^5 \frac{\text{J}}{\text{kg}}} \\
 &= \sqrt{2.32 \times 10^5 \frac{\text{kg} \cdot \text{m}^2}{\text{kg} \cdot \text{s}^2}} = 482 \text{ m/s}
 \end{aligned}$$

**CHECK** The units of the answer (m/s) are correct. The magnitude of the answer seems reasonable because oxygen is slightly heavier than nitrogen and should therefore have a slightly lower root mean square velocity at the same temperature. Recall from earlier that the root mean square velocity of nitrogen is 515 m/s at 25 °C.

**FOR PRACTICE 5.14** Calculate the root mean square velocity of gaseous xenon atoms at 25 °C.

## CONCEPTUAL CONNECTION 5.8

**Kinetic Molecular Theory II** Which sample of an ideal gas has the greatest pressure? Assume that the mass of each particle is proportional to its size and that all the gas samples are at the same temperature.

## 5.9 Mean Free Path, Diffusion, and Effusion of Gases

We have just seen that the root mean square velocity of gas molecules at room temperature is in the range of hundreds of meters per second. However, suppose that your roommate just put on too much perfume in the bathroom only 6 ft (1.8 m) away. Why does it take a minute or two before you can smell the fragrance? Although most molecules in a perfume bottle have higher molar masses than nitrogen, their velocities are still hundreds of meters per second, so why the delay? The answer is that even though gaseous particles travel at tremendous speeds, they also travel in haphazard paths (Figure 5.20). To a perfume molecule, the path from the perfume bottle in the bathroom to your nose 6 ft away is much like a bargain hunter's path through a busy shopping mall during a clearance sale. The molecule travels only a short distance before it collides with another molecule and changes direction, only to collide again, and so on. In fact, at room temperature and atmospheric pressure, a molecule in the air experiences

several billion collisions per second. The average distance that a molecule travels between collisions is its **mean free path**. At room temperature and atmospheric pressure, the mean free path of a nitrogen molecule with a molecular diameter of 300 pm (four times the covalent radius) is 93 nm, or about 310 molecular diameters. If the nitrogen molecule were the size of a golf ball, it would travel about 40 ft between collisions. Mean free path increases with *decreasing* pressure. Under conditions of ultrahigh vacuum ( $10^{-10}$  torr), the mean free path of a nitrogen molecule is hundreds of kilometers.

The process by which gas molecules spread out in response to a concentration gradient is **diffusion**, and even though the particles undergo many collisions, the root mean square velocity still influences the rate of diffusion. Heavier molecules diffuse more slowly than lighter ones, so the first molecules you smell from a perfume mixture (in a room with no air currents) are the lighter ones.

A process related to diffusion is **effusion**, the process by which a gas escapes from a container into a vacuum through a small hole (Figure 5.21 ▽). The rate of effusion is also related to root mean square velocity—heavier molecules effuse more slowly than lighter ones. The rate of effusion—the amount of gas that effuses in a given time—is inversely proportional to the square root of the molar mass of the gas as follows:

$$\text{rate} \propto \frac{1}{\sqrt{\mathcal{M}}}$$

The ratio of effusion rates of two different gases is given by **Graham's law of effusion**, named after Thomas Graham (1805–1869):

$$\frac{\text{rate}_A}{\text{rate}_B} = \sqrt{\frac{\mathcal{M}_B}{\mathcal{M}_A}} \quad [5.27]$$

In this expression,  $\text{rate}_A$  and  $\text{rate}_B$  are the effusion rates of gases A and B, and  $\mathcal{M}_A$  and  $\mathcal{M}_B$  are their molar masses.

Graham's law explains, in part, why helium balloons only float for a day or so. Because helium has such a low molar mass, it escapes from the balloon quite quickly. A balloon filled with air, by contrast, remains inflated longer.

### Typical Gas Molecule Path

The average distance between collisions is the mean free path.

▲ **FIGURE 5.20 Mean Free Path** A molecule in a volume of gas follows a haphazard path, involving many collisions with other molecules.

In a ventilated room, air currents also enhance the transport of gas molecules.

### Effusion

Gas escapes from container into a vacuum through a small hole.

◀ **FIGURE 5.21 Effusion**

Effusion is the escape of a gas from a container into a vacuum through a small hole.

**Example 5.15** Graham's Law of Effusion

An unknown gas effuses at a rate that is 0.462 times that of nitrogen gas (at the same temperature). Calculate the molar mass of the unknown gas in g/mol.

**SORT** You are given the ratio of effusion rates for the unknown gas and nitrogen and asked to find the molar mass of the unknown gas.

**GIVEN:**  $\frac{\text{rate}_{\text{unk}}}{\text{rate}_{\text{N}_2}} = 0.462$

**FIND:**  $\mathcal{M}_{\text{unk}}$

**STRATEGIZE** The conceptual plan uses Graham's law of effusion. You are given the ratio of rates and you know the molar mass of the nitrogen. You can use Graham's law to determine the molar mass of the unknown gas.

**CONCEPTUAL PLAN****RELATIONSHIPS USED**

$$\frac{\text{rate}_A}{\text{rate}_B} = \sqrt{\frac{\mathcal{M}_B}{\mathcal{M}_A}} \quad (\text{Graham's law})$$

**SOLVE** Solve the equation for  $\mathcal{M}_{\text{unk}}$  and substitute the correct values and calculate.

**SOLUTION**

$$\begin{aligned} \frac{\text{rate}_{\text{unk}}}{\text{rate}_{\text{N}_2}} &= \sqrt{\frac{\mathcal{M}_{\text{N}_2}}{\mathcal{M}_{\text{unk}}}} \\ \mathcal{M}_{\text{unk}} &= \frac{\mathcal{M}_{\text{N}_2}}{\left(\frac{\text{rate}_{\text{unk}}}{\text{rate}_{\text{N}_2}}\right)^2} \\ &= \frac{28.02 \text{ g/mol}}{(0.462)^2} \\ &= 131 \text{ g/mol} \end{aligned}$$

**CHECK** The units of the answer are correct. The magnitude of the answer seems reasonable for the molar mass of a gas. From the answer you can even conclude that the gas is probably xenon, which has a molar mass of 131.29 g/mol.

**FOR PRACTICE 5.15** Find the ratio of effusion rates of hydrogen gas and krypton gas.

## 5.10 Real Gases: The Effects of Size and Intermolecular Forces

One mole of an ideal gas has a volume of 22.41 L at STP. Figure 5.22 shows the molar volume of several real gases at STP. Note that most of these gases have a volume that is

**FIGURE 5.22 Molar Volumes of Real Gases** The molar volumes of several gases at STP are all close to 22.414 L, indicating that their departures from ideal behavior are small.

very close to 22.41 L, meaning that they act very nearly as ideal gases. Gases behave ideally when both of the following are true: (a) the volume of the gas particles is small compared to the space between them, and (b) the forces between the gas particles are not significant. At STP, these assumptions are valid for most common gases. However, these assumptions break down at higher pressures or lower temperatures.

## The Effect of the Finite Volume of Gas Particles

The finite volume of gas particles—that is, their actual *sizes*—becomes important at high pressure because the volume of the particles themselves occupies a significant portion of the total gas volume (Figure 5.23▶). We can see the effect of particle volume by comparing the molar volume of argon to the molar volume of an ideal gas as a function of pressure at 500 K as shown in Figure 5.24▼. At low pressures, the molar volume of argon is nearly identical to that of an ideal gas. But as the pressure increases, the molar volume of argon becomes *greater than* that of an ideal gas. At the higher pressures, the argon atoms themselves occupy a significant portion of the gas volume, making the actual volume greater than that predicted by the ideal gas law.

▲ **FIGURE 5.23 Particle Volume and Ideal Behavior** As a gas is compressed, the gas particles themselves begin to occupy a significant portion of the total gas volume, leading to deviations from ideal behavior.

### Nonideal Behavior: The effect of particle volume

### ◀ **FIGURE 5.24 The Effect of Particle Volume**

At high pressures, 1 mol of argon occupies a larger volume than 1 mol of an ideal gas because of the volume of the argon atoms themselves. (This example was chosen to minimize the effects of intermolecular forces, which are very small in argon at 500 K, thereby isolating the effect of particle volume.)

In 1873, Johannes van der Waals (1837–1923) modified the ideal gas equation to fit the behavior of real gases. From the graph for argon in Figure 5.24 we can see that the ideal gas law predicts a volume that is too small. Van der Waals suggested a small correction factor that accounts for the volume of the gas particles themselves:

$$\text{Ideal behavior} \quad V = \frac{nRT}{P}$$

$$\text{Corrected for volume of gas particles} \quad V = \frac{nRT}{P} + nb \quad [5.28]$$

The correction adds the quantity  $nb$  to the volume, where  $n$  is the number of moles and  $b$  is a constant that depends on the gas (see Table 5.5). We can rearrange the corrected equation as follows:

$$(V - nb) = \frac{nRT}{P} \quad [5.29]$$

**TABLE 5.5 Van der Waals Constants for Common Gases**

Gas	$a$ ( $\text{L}^2 \cdot \text{atm}/\text{mol}^2$ )	$b$ (L/mol)
He	0.0342	0.02370
Ne	0.211	0.0171
Ar	1.35	0.0322
Kr	2.32	0.0398
Xe	4.19	0.0511

CCl <sub>4</sub>	20.4	0.1383

## The Effect of Intermolecular Forces

Intermolecular forces, which we will discuss in more detail in Chapter 11, are attractions between the atoms or molecules that compose any substance. These attractions are typically small in gases and therefore do not matter much at low pressure because the molecules are too far apart to “feel” the attractions. They also do not matter much at high temperatures because the molecules have a lot of kinetic energy. Therefore a weak attraction between them does not affect the collision much. At lower temperatures, however, the collisions occur with less kinetic energy, and weak attractions can affect the collisions. We can understand this difference with an analogy to billiard balls. Imagine two billiard balls coated with a substance that makes them slightly sticky. If they collide when moving at high velocities, the stickiness will not have much of an effect—the balls bounce off one another as if the sticky substance was not even there. However, if the two billiard balls collide when moving very slowly (say barely rolling), the sticky substance would have an effect. The billiard balls might even stick together and not bounce off one another.

The effect of these weak attractions between particles is a decrease in the number of collisions with the surfaces of the container and a corresponding decrease in the pressure compared to that of an ideal gas. We can see the effect of intermolecular forces when we compare the pressure of 1.0 mol of xenon gas to the pressure of 1.0 mol of an ideal gas as a function of temperature and at a fixed volume of 1.0 L, as shown in Figure 5.25. At high temperature, the pressure of the xenon gas is nearly identical to that of an ideal gas. But at lower temperatures, the pressure of xenon is *less than* that of an ideal gas. At the lower temperatures, the xenon atoms spend more time interacting with each other and less time colliding with the walls, making the actual pressure less than that predicted by the ideal gas law.

From the graph for xenon shown in Figure 5.25 we can see that the ideal gas law predicts a pressure that is too large at low temperatures. Van der Waals suggested a small correction factor that accounts for the intermolecular forces between gas particles:

$$\text{Ideal behavior} \quad P = \frac{nRT}{V}$$

$$\text{Corrected for intermolecular forces} \quad P = \frac{nRT}{V} - a\left(\frac{n}{V}\right)^2 \quad [5.30]$$

The correction subtracts the quantity  $a(n/V)^2$  from the pressure, where  $n$  is the number of moles,  $V$  is the volume, and  $a$  is a constant that depends on the gas (see Table 5.5). Notice that the correction factor increases as  $n/V$  (the number of moles of particles per

**▲ FIGURE 5.25 The Effect of Intermolecular Forces** At low temperatures, the pressure of xenon is less than an ideal gas exerts because interactions among xenon molecules reduce the number of collisions with the walls of the container.

unit volume) increases because a greater concentration of particles makes it more likely that the particles will interact with one another. We can rearrange the corrected equation as:

$$P + a\left(\frac{n}{V}\right)^2 = \frac{nRT}{V} \quad [5.31]$$

## Van der Waals Equation

We can combine the effects of particle volume (Equation 5.29) and particle intermolecular forces (Equation 5.31) into one equation that describes nonideal gas behavior:

$$\left[P + a\left(\frac{n}{V}\right)^2\right] \times [V - nb] = nRT$$

Correction for intermolecular forces
Correction for particle volume

This equation is the **van der Waals equation** and we can use it to calculate the properties of a gas under nonideal conditions.

## Real Gases

We can see the combined effects of particle volume and intermolecular forces by examining a plot of  $PV/RT$  versus  $P$  for 1 mol of a number of real gases (Figure 5.26▼). For an ideal gas,  $PV/RT = n$ , the number of moles of gas. Therefore, for 1 mol of an ideal gas,  $PV/RT$  is equal to 1, as shown in the plot. For real gases,  $PV/RT$  deviates from 1, but the deviations are not uniform. For example, water displays a large negative deviation from  $PV/RT$  because, for water, the effect of intermolecular forces on lowering the pressure (relative to an ideal gas) is far greater than the effect of particle size on increasing the volume. Notice from Table 5.5 that water has a high value of  $a$ , the constant that corrects for intermolecular forces, but a moderate value of  $b$ , the constant that corrects for particle size. Therefore,  $PV/RT$  for water is lower than predicted from the ideal gas law.

By contrast, consider the behavior of helium, which displays a positive deviation from the ideal behavior. This is because helium has very weak intermolecular forces and the effect of these forces on lowering the pressure (relative to ideal gas) is small compared to the effect of particle size on increasing the volume. Therefore  $PV/RT$  for helium is greater than predicted from the ideal gas law.

◀ **FIGURE 5.26 Real versus Ideal Behavior** For 1 mol of an ideal gas,  $PV/RT$  is equal to 1. The combined effects of the volume of gas particles and the interactions among them cause each real gas to deviate from ideal behavior in a slightly different way. These curves were calculated at a temperature of 500 K.

## CONCEPTUAL CONNECTION 5.9

**Real Gases** The graph shows  $PV/RT$  for carbon dioxide at three different temperatures. Rank the curves in order of increasing temperature.

## Self-Assessment Quiz

- Q1.** A gas sample has an initial pressure of 547 mmHg and an initial volume of 0.500 L. What is the pressure (in atm) when the volume of the sample is decreased to 225 mL? (Assume constant temperature and constant number of moles of gas.)
- $1.60 \times 10^{-3}$  atm
  - 1.60 atm
  - 0.324 atm
  - 1.22 atm
- Q2.** A gas sample has a volume of 178 mL at 0.00 °C. The temperature is raised (at constant pressure) until the volume is 211 mL. What is the temperature of the gas sample in °C at this volume?
- 0.00 °C
  - 324 °C
  - 43 °C
  - 51 °C
- Q3.** What is the pressure of 1.78 g of nitrogen gas confined to a volume of 0.118 L at 25 °C?
- 13.2 atm
  - 369 atm
  - 1.10 atm
  - 26.3 atm
- Q4.** What is the density of a sample of argon gas at 55 °C and 765 mmHg?
- 2.99 g/L
  - $1.13 \times 10^3$  g/L
  - 1.49 g/L
  - 8.91 g/L
- Q5.** Which gas sample has the greatest volume at STP?
- 10.0 g Ar
  - 10.0 g Kr
  - 10.0 g Xe
  - None of the above (They all have the same volume.)
- Q6.** A 1.25-g gas sample occupies 663 mL at 25 °C and 1.00 atm. What is the molar mass of the gas?
- 0.258 g/mol
  - 0.0461 g/mol
  - 3.87 g/mol
  - 46.1 g/mol
- Q7.** A 255-mL gas sample contains argon and nitrogen at a temperature of 65 °C. The total pressure of the sample is 725 mmHg, and the partial pressure of argon is 231 mmHg. What mass of nitrogen is present in the sample?
- 0.324 g nitrogen
  - 0.167 g nitrogen
  - 0.0837 g nitrogen
  - 0.870 g nitrogen
- Q8.** A gas mixture in a 1.55-L container at 298 K contains 10.0 g of Ne and 10.0 g of Ar. Calculate the partial pressure (in atm) of Ne and Ar in the container.
- $P_{\text{Ne}} = 10.5$  atm,  $P_{\text{Ar}} = 5.29$  atm
  - $P_{\text{Ne}} = 5.83$  atm,  $P_{\text{Ar}} = 2.95$  atm
  - $P_{\text{Ne}} = 5.88$  atm,  $P_{\text{Ar}} = 5.88$  atm
  - $P_{\text{Ne}} = 7.82$  atm,  $P_{\text{Ar}} = 3.95$  atm
- Q9.** A gas sample at STP contains 1.15 g oxygen and 1.55 g nitrogen. What is the volume of the gas sample?
- 1.26 L
  - 2.04 L
  - 4.08 L
  - 61.0 L
- Q10.** Aluminum reacts with chlorine gas to form aluminum chloride.
- $$2 \text{Al}(s) + 3 \text{Cl}_2(g) \longrightarrow 2 \text{AlCl}_3(s)$$
- What minimum volume of chlorine gas (at 298 K and 225 mmHg) is required to completely react with 7.85 g of aluminum?
- 36.0 L
  - 24.0 L
  - 0.0474 L
  - 16.0 L
- Q11.** Calculate the root mean square velocity of  $\text{I}_2(g)$  at 373 K.
- 19.0 m/s
  - 191 m/s
  - 6.05 m/s
  - 99.1 m/s
- Q12.** Which gas has the greatest kinetic energy at STP?
- He
  - Ne
  - Ar
  - None of the above (All have the same kinetic energy.)
- Q13.** A sample of Xe takes 75 seconds to effuse out of a container. An unknown gas takes 37 seconds to effuse out of the identical container under identical conditions. What is the most likely identity of the unknown gas?
- He
  - $\text{O}_2$
  - $\text{Br}_2$
  - Kr

**Q14.** Consider the generic reaction:  $2 A(g) + B(g) \longrightarrow 2 C(g)$ . If a flask initially contains 1.0 atm of A and 1.0 atm of B, what will be the pressure in the flask if the reaction proceeds to completion? (Assume constant volume and temperature.)

- a) 1.0 atm    b) 1.5 atm    c) 2.0 atm    d) 3.0 atm

**Q15.** Rank the gases Ar, N<sub>2</sub>, CH<sub>4</sub>, and C<sub>2</sub>H<sub>6</sub> in order of increasing density at STP.

- a) CH<sub>4</sub> < C<sub>2</sub>H<sub>6</sub> < N<sub>2</sub> < Ar  
 b) CH<sub>4</sub> < N<sub>2</sub> < Ar < C<sub>2</sub>H<sub>6</sub>  
 c) Ar < C<sub>2</sub>H<sub>6</sub> < N<sub>2</sub> < CH<sub>4</sub>  
 d) CH<sub>4</sub> < N<sub>2</sub> < C<sub>2</sub>H<sub>6</sub> < Ar

Answers: 1. (b) 2. (d) 3. (a) 4. (c) 5. (a) 6. (d) 7. (c) 8. (d) 9. (b) 10. (a) 11. (b) 12. (d) 13. (b) 14. (b) 15. (d)

## Chapter 5 IN REVIEW

### Key Terms

#### Section 5.1

pressure (198)

#### Section 5.2

millimeter of mercury (mmHg) (199)

barometer (199)

torr (199)

atmosphere (atm) (199)

pascal (Pa) (199)

manometer (200)

#### Section 5.3

Boyle's law (202)

Charles's law (205)

Avogadro's law (207)

#### Section 5.4

ideal gas law (209)

ideal gas (209)

ideal gas constant (209)

#### Section 5.5

molar volume (211)

standard temperature and

pressure (STP) (211)

#### Section 5.6

partial pressure (215)

Dalton's law of partial pressures (215)

mole fraction ( $\chi_a$ ) (215)

hypoxia (217)

oxygen toxicity (217)

nitrogen narcosis (217)

vapor pressure (219)

#### Section 5.8

kinetic molecular theory (224)

#### Section 5.9

mean free path (231)

diffusion (231)

effusion (231)

Graham's law of effusion (231)

#### Section 5.10

van der Waals equation (235)

### Key Concepts

#### Pressure (5.1, 5.2)

- ▶ Gas pressure is the force per unit area that results from gas particles colliding with the surfaces around them. We use various units to measure pressure including mmHg, torr, Pa, psi, in Hg, and atm.

#### The Simple Gas Laws (5.3)

- ▶ The simple gas laws express relationships between pairs of variables when other variables are constant.
- ▶ Boyle's law states that the volume of a gas is inversely proportional to its pressure.
- ▶ Charles's law states that the volume of a gas is directly proportional to its temperature.
- ▶ Avogadro's law states that the volume of a gas is directly proportional to the amount (in moles).

#### The Ideal Gas Law and Its Applications (5.4, 5.5)

- ▶ The ideal gas law,  $PV = nRT$ , describes the relationship among all four gas variables and contains the simple gas laws within it.
- ▶ We can use the ideal gas law to find one of the four variables given the other three. We can use it to calculate the molar volume of an

ideal gas, which is 22.4 L at STP, and to calculate the density and molar mass of a gas.

#### Mixtures of Gases and Partial Pressures (5.6)

- ▶ In a mixture of gases, each gas acts independently of the others so that any overall property of the mixture is the sum of the properties of the individual components.
- ▶ The pressure of any individual component is its partial pressure.

#### Gas Stoichiometry (5.7)

- ▶ In reactions involving gaseous reactants and products, we often report quantities in volumes at specified pressures and temperatures. We can convert these quantities to amounts (in moles) using the ideal gas law. Then we can use the stoichiometric coefficients from the balanced equation to determine the stoichiometric amounts of other reactants or products.
- ▶ The general form for these types of calculations is: volume A  $\rightarrow$  amount A (in moles)  $\rightarrow$  amount B (in moles)  $\rightarrow$  quantity of B (in desired units).
- ▶ In cases where the reaction is carried out at STP, we can use the molar volume at STP (22.4 L = 1 mol) to convert between volume in liters and amount in moles.

## Kinetic Molecular Theory and Its Applications (5.8, 5.9)

- Kinetic molecular theory is a quantitative model for gases. The theory has three main assumptions: (1) gas particles are negligibly small, (2) the average kinetic energy of a gas particle is proportional to the temperature in kelvins, and (3) the collision of one gas particle with another is completely elastic (the particles do not stick together). The gas laws all follow from the kinetic molecular theory.
- We can use kinetic molecular theory to derive the expression for the root mean square velocity of gas particles. This velocity is inversely proportional to the molar mass of the gas, and therefore—at a given temperature—smaller gas particles are (on average) moving more quickly than larger ones.
- The kinetic molecular theory also allows us to predict the mean free path of a gas particle (the distance it travels between collisions) and relative rates of diffusion or effusion.

## Real Gases (5.10)

- Real gases differ from ideal gases to the extent that they do not always fit the assumptions of kinetic molecular theory.
- These assumptions tend to break down at high pressures where the volume is higher than predicted for an ideal gas because the particles are no longer negligibly small compared to the space between them.
- The assumptions also break down at low temperatures where the pressure is lower than predicted because the attraction between molecules combined with low kinetic energies causes partially inelastic collisions.
- The van der Waals equation predicts gas properties under nonideal conditions.

## Key Equations and Relationships

Relationship between Pressure ( $P$ ), Force ( $F$ ), and Area ( $A$ ) (5.2)

$$P = \frac{F}{A}$$

Boyle's Law: Relationship between Pressure ( $P$ ) and Volume ( $V$ ) (5.3)

$$V \propto \frac{1}{P}$$

$$P_1V_1 = P_2V_2$$

Charles's Law: Relationship between Volume ( $V$ ) and Temperature ( $T$ ) (5.3)

$$V \propto T \text{ (in K)}$$

$$\frac{V_1}{T_1} = \frac{V_2}{T_2}$$

Avogadro's Law: Relationship between Volume ( $V$ ) and Amount in Moles ( $n$ ) (5.3)

$$V \propto n$$

$$\frac{V_1}{n_1} = \frac{V_2}{n_2}$$

Ideal Gas Law: Relationship between Volume ( $V$ ), Pressure ( $P$ ), Temperature ( $T$ ), and Amount ( $n$ ) (5.4)

$$PV = nRT$$

Dalton's Law: Relationship between Partial Pressures  $P_n$  in Mixture of Gases and Total Pressure ( $P_{\text{total}}$ ) (5.6)

$$P_{\text{total}} = P_a + P_b + P_c + \dots$$

$$P_a = \frac{n_aRT}{V} \quad P_b = \frac{n_bRT}{V} \quad P_c = \frac{n_cRT}{V}$$

Mole Fraction ( $\chi_a$ ) (5.6)

$$\chi_a = \frac{n_a}{n_{\text{total}}}$$

$$P_a = \chi_a P_{\text{total}}$$

Average Kinetic Energy ( $\text{KE}_{\text{avg}}$ ) (5.8)

$$\text{KE}_{\text{avg}} = \frac{3}{2}RT$$

Relationship between Root Mean Square Velocity ( $u_{\text{rms}}$ ) and Temperature ( $T$ ) (5.8)

$$u_{\text{rms}} = \sqrt{\frac{3RT}{M}}$$

Relationship of Effusion Rates of Two Different Gases (5.9)

$$\frac{\text{rate A}}{\text{rate B}} = \sqrt{\frac{M_B}{M_A}}$$

Van der Waals Equation: The Effects of Volume and Intermolecular Forces on Nonideal Gas Behavior (5.10)

$$\left[ P + a \left( \frac{n}{V} \right)^2 \right] \times (V - nb) = nRT$$

## Key Learning Outcomes

### CHAPTER OBJECTIVES

Converting between Pressure Units (5.2)

Relating Volume and Pressure:  
Boyle's Law (5.3)

### ASSESSMENT

Example 5.1 For Practice 5.1 For More Practice 5.1  
Exercises 25–28

Example 5.2 For Practice 5.2 Exercises 31, 32

Relating Volume and Temperature: Charles's Law (5.3)	Example 5.3 For Practice 5.3 Exercises 33, 34
Relating Volume and Moles: Avogadro's Law (5.3)	Example 5.4 For Practice 5.4 Exercises 35, 36
Determining $P$ , $V$ , $n$ , or $T$ Using the Ideal Gas Law (5.4)	Examples 5.5, 5.6 For Practice 5.5, 5.6 For More Practice 5.6 Exercises 37–46, 51, 52
Relating the Density of a Gas to Its Molar Mass (5.5)	Example 5.7 For Practice 5.7 For More Practice 5.7 Exercises 55, 56
Calculating the Molar Mass of a Gas with the Ideal Gas Law (5.5)	Example 5.8 For Practice 5.8 Exercises 57–60
Calculating Total Pressure, Partial Pressures, and Mole Fractions of Gases in a Mixture (5.6)	Examples 5.9, 5.10, 5.11 For Practice 5.9, 5.10, 5.11 Exercises 61, 62, 65, 67, 68, 70
Relating the Amounts of Reactants and Products in Gaseous Reactions: Stoichiometry (5.7)	Examples 5.12, 5.13 For Practice 5.12, 5.13 For More Practice 5.12 Exercises 71–77
Calculating the Root Mean Square Velocity of a Gas (5.8)	Example 5.14 For Practice 5.14 Exercises 83, 84
Calculating the Effusion Rate or the Ratio of Effusion Rates of Two Gases (5.9)	Example 5.15 For Practice 5.15 Exercises 85–88

## EXERCISES

### Review Questions

- What is pressure? What causes pressure?
- Explain what happens when a person inhales. What forces air into the lungs?
- Explain what happens when a person exhales. What forces air out of the lungs?
- What are the common units of pressure? List them in order of smallest to largest unit.
- What is a manometer? How does it measure the pressure of a sample of gas?
- Summarize each of the simple gas laws (Boyle's law, Charles's law, and Avogadro's law). For each, explain the relationship between the two variables and also state which variables must be kept constant.
- Explain why people may experience ear pain after a rapid change in altitude.
- Explain why scuba divers should never hold their breath when they ascend to the surface.
- Why is it impossible to breathe air through an extra-long snorkel (longer than a couple of meters) while swimming under water?
- Explain why hot-air balloons float above the ground and why the second story of a two-story home is often warmer than the ground story.
- What is the ideal gas law? Why is it useful?
- Explain how the ideal gas law contains within it the simple gas laws (show an example).
- Define molar volume and list its value for a gas at STP.
- How does the density of a gas depend on temperature? Pressure? How does it depend on the molar mass of the gas?
- What is partial pressure? What is the relationship between the partial pressures of each gas in a sample and the total pressure of gas in the sample?
- Why do deep-sea divers breathe a mixture of helium and oxygen?
- When a gas is collected over water, is the gas pure? Why or why not? How can the partial pressure of the collected gas be determined?
- If a reaction occurs in the gas phase at STP, we can determine the mass of a product from the volumes of reactants. Explain.
- What are the basic postulates of kinetic molecular theory? How does the concept of pressure follow from kinetic molecular theory?
- Explain how Boyle's law, Charles's law, Avogadro's law, and Dalton's law all follow from kinetic molecular theory.
- How is the kinetic energy of a gas related to temperature? How is the root mean square velocity of a gas related to its molar mass?
- Describe how the molecules in a perfume bottle travel from the bottle to your nose. What is mean free path?

23. Explain the difference between diffusion and effusion. How is the effusion rate of a gas related to its molar mass?

24. Deviations from the ideal gas law are observed at high pressure and low temperature. Explain this in light of kinetic molecular theory.

## Problems by Topic

### Converting between Pressure Units

25. The pressure in Denver, Colorado (elevation 5280 ft), averages about 24.9 in Hg. Convert this pressure to each indicated unit.  
a. atm      b. mmHg      c. psi      d. Pa
26. The pressure on top of Mount Everest (29,029 ft) averages about 235 mmHg. Convert this pressure to each indicated unit.  
a. torr      b. psi      c. in Hg      d. atm
27. The North American record for highest recorded barometric pressure is 31.85 in Hg, set in 1989 in Northway, Alaska. Convert this pressure to each indicated unit.  
a. mmHg      b. atm      c. torr      d. kPa (kilopascals)
28. The world record for lowest pressure (at sea level) was 652.5 mmHg recorded inside Typhoon Tip on October 12, 1979, in the western Pacific Ocean. Convert this pressure to each indicated unit.  
a. torr      b. atm      c. in Hg      d. psi
29. Given a barometric pressure of 762.4 mmHg, calculate the pressure of each gas sample as indicated by the manometer.

30. Given a barometric pressure of 751.5 mmHg, calculate the pressure of each gas sample as indicated by the manometer.

### Simple Gas Laws

31. A sample of gas has an initial volume of 5.6 L at a pressure of 735 mmHg. If the volume of the gas is increased to 9.4 L, what is its pressure?

32. A sample of gas has an initial volume of 13.9 L at a pressure of 1.22 atm. If the sample is compressed to a volume of 10.3 L, what is its pressure?
33. A 48.3-mL sample of gas in a cylinder is warmed from 22 °C to 87 °C. What is its volume at the final temperature?
34. A syringe containing 1.55 mL of oxygen gas is cooled from 95.3 °C to 0.0 °C. What is the final volume of oxygen gas?
35. A balloon contains 0.158 mol of gas and has a volume of 2.46 L. If an additional 0.113 mol of gas is added to the balloon (at the same temperature and pressure), what is its final volume?
36. A cylinder with a moveable piston contains 0.553 mol of gas and has a volume of 253 mL. What is its volume if an additional 0.365 mol of gas is added to the cylinder? (Assume constant temperature and pressure.)

### Ideal Gas Law

37. What volume is occupied by 0.118 mol of helium gas at a pressure of 0.97 atm and a temperature of 305 K? Would the volume be different if the gas was argon (under the same conditions)?
38. What volume is occupied by 12.5 g of argon gas at a pressure of 1.05 atm and a temperature of 322 K? Would the volume be different if the sample were 12.5 g of helium (under identical conditions)?
39. What is the pressure in a 10.0-L cylinder filled with 0.448 mol of nitrogen gas at a temperature of 315 K?
40. What is the pressure in a 15.0-L cylinder filled with 32.7 g of oxygen gas at a temperature of 302 K?
41. A cylinder contains 28.5 L of oxygen gas at a pressure of 1.8 atm and a temperature of 298 K. How much gas (in moles) is in the cylinder?
42. What is the temperature of 0.52 mol of gas at a pressure of 1.3 atm and a volume of 11.8 L?
43. An automobile tire has a maximum rating of 38.0 psi (gauge pressure). The tire is inflated (while cold) to a volume of 11.8 L and a gauge pressure of 36.0 psi at a temperature of 12.0 °C. On a hot day, the tire warms to 65.0 °C, and its volume expands to 12.2 L. Does the pressure in the tire exceed its maximum rating? (Note: The *gauge pressure* is the *difference* between the total pressure and atmospheric pressure. In this case, assume that atmospheric pressure is 14.7 psi.)
44. A weather balloon is inflated to a volume of 28.5 L at a pressure of 748 mmHg and a temperature of 28.0 °C. The balloon rises in the atmosphere to an altitude of approximately 25,000 ft, where the pressure is 385 mmHg and the temperature is -15.0 °C. Assuming the balloon can freely expand, calculate the volume of the balloon at this altitude.
45. A piece of dry ice (solid carbon dioxide) with a mass of 28.8 g sublimates (converts from solid to gas) into a large balloon. Assuming that all of the carbon dioxide ends up in the balloon, what is the volume of the balloon at 22 °C and a pressure of 742 mmHg?
46. A 1.0-L container of liquid nitrogen is kept in a closet measuring 1.0 m by 1.0 m by 2.0 m. Assuming that the container is completely full, that the temperature is 25.0 °C, and that the atmospheric pressure is 1.0 atm, calculate the percent (by volume) of air that is displaced if all of the liquid nitrogen evaporates. (Liquid nitrogen has a density of 0.807 g/mL.)

47. A wine-dispensing system uses argon canisters to pressurize and preserve wine in the bottle. An argon canister for the system has a volume of 55.0 mL and contains 26.0 g of argon. Assuming ideal gas behavior, what is the pressure in the canister at 295 K? When the argon is released from the canister, it expands to fill the wine bottle. How many 750.0-mL wine bottles can be purged with the argon in the canister at a pressure of 1.20 atm and a temperature of 295 K?
48. Cyclists sometimes use pressurized carbon dioxide inflators to inflate a bicycle tire in the event of a flat. These inflators use metal cartridges that contain 16.0 g of carbon dioxide. At 298 K, to what pressure (in psi) can the carbon dioxide in the cartridge inflate a 3.45-L mountain bike tire? (Note: The *gauge pressure* is the *difference* between the total pressure and atmospheric pressure. In this case, assume that atmospheric pressure is 14.7 psi.)
49. Which gas sample has the greatest pressure? Assume that all the samples are at the same temperature. Explain.

50. This picture represents a sample of gas at a pressure of 1 atm, a volume of 1 L, and a temperature of 25 °C. Draw a similar picture showing what would happen to the sample if the volume were reduced to 0.5 L and the temperature were increased to 250 °C. What would happen to the pressure?
51. Aerosol cans carry clear warnings against incineration because of the high pressures that can develop upon heating. Suppose that a can contains a residual amount of gas at a pressure of 755 mmHg and a temperature of 25 °C. What would the pressure be if the can were heated to 1155 °C?
52. A sample of nitrogen gas in a 1.75-L container exerts a pressure of 1.35 atm at 25 °C. What is the pressure if the volume of the container is maintained constant and the temperature is raised to 355 °C?

54. Use the molar volume of a gas at STP to calculate the density (in g/L) of nitrogen gas at STP.
55. What is the density (in g/L) of hydrogen gas at 20.0 °C and a pressure of 1655 psi?
56. A sample of N<sub>2</sub>O gas has a density of 2.85 g/L at 298 K. What is the pressure of the gas (in mmHg)?
57. A 248-mL gas sample has a mass of 0.433 g at a pressure of 745 mmHg and a temperature of 28 °C. What is the molar mass of the gas?
58. A 113-mL gas sample has a mass of 0.171 g at a pressure of 721 mmHg and a temperature of 32 °C. What is the molar mass of the gas?
59. A sample of gas has a mass of 38.8 mg. Its volume is 224 mL at a temperature of 55 °C and a pressure of 886 torr. Find the molar mass of the gas.
60. A sample of gas has a mass of 0.555 g. Its volume is 117 mL at a temperature of 85 °C and a pressure of 753 mmHg. Find the molar mass of the gas.

### Partial Pressure

61. A gas mixture contains each of the following gases at the indicated partial pressures: N<sub>2</sub>, 215 torr; O<sub>2</sub>, 102 torr; and He, 117 torr. What is the total pressure of the mixture? What mass of each gas is present in a 1.35-L sample of this mixture at 25.0 °C?
62. A gas mixture with a total pressure of 745 mmHg contains each of the following gases at the indicated partial pressures: CO<sub>2</sub>, 125 mmHg; Ar, 214 mmHg; and O<sub>2</sub>, 187 mmHg. The mixture also contains helium gas. What is the partial pressure of the helium gas? What mass of helium gas is present in a 12.0-L sample of this mixture at 273 K?
63. A 1.20-g sample of dry ice is added to a 755 mL flask containing nitrogen gas at a temperature of 25.0 °C and a pressure of 725 mmHg. The dry ice sublimates (converts from solid to gas), and the mixture returns to 25.0 °C. What is the total pressure in the flask?
64. A 275-mL flask contains pure helium at a pressure of 752 torr. A second flask with a volume of 475 mL contains pure argon at a pressure of 722 torr. If we connect the two flasks through a stopcock and we open the stopcock, what is the partial pressure of each gas and the total pressure?
65. A gas mixture contains 1.25 g N<sub>2</sub> and 0.85 g O<sub>2</sub> in a 1.55 L container at 18 °C. Calculate the mole fraction and partial pressure of each component in the gas mixture.
66. What is the mole fraction of oxygen gas in air (see Table 5.3)? What volume of air contains 10.0 g of oxygen gas at 273 K and 1.00 atm?
67. The hydrogen gas formed in a chemical reaction is collected over water at 30.0 °C at a total pressure of 732 mmHg. What is the partial pressure of the hydrogen gas collected in this way? If the total volume of gas collected is 722 mL, what mass of hydrogen gas is collected?
68. The air in a bicycle tire is bubbled through water and collected at 25 °C. If the total volume of gas collected is 5.45 L at a temperature of 25 °C and a pressure of 745 torr, how many moles of gas were in the bicycle tire?
69. The zinc in a copper-plated penny will dissolve in hydrochloric acid if the copper coating is filed down in several spots (so that the hydrochloric acid can get to the zinc). The reaction between the acid and the zinc is  $2\text{H}^+(\text{aq}) + \text{Zn}(\text{s}) \longrightarrow \text{H}_2(\text{g}) + \text{Zn}^{2+}(\text{aq})$ . When the zinc in a certain penny dissolves, the total volume of gas collected over water at 25 °C is 0.951 L at a total pressure of 748 mmHg. What mass of hydrogen gas is collected?

### Molar Volume, Density, and Molar Mass of a Gas

53. Use the molar volume of a gas at STP to determine the volume (in L) occupied by 33.6 g of neon at STP.

70. A heliox deep-sea diving mixture contains 2.0 g of oxygen to every 98.0 g of helium. What is the partial pressure of oxygen when this mixture is delivered at a total pressure of 8.5 atm?

### Reaction Stoichiometry Involving Gases

71. Consider the chemical reaction:

How many liters of hydrogen gas are formed from the complete reaction of 15.7 g C? Assume that the hydrogen gas is collected at a pressure of 1.0 atm and a temperature of 355 K.

72. Consider the chemical reaction:

What mass of  $\text{H}_2\text{O}$  is required to form 1.4 L of  $\text{O}_2$  at a temperature of 315 K and a pressure of 0.957 atm?

73.  $\text{CH}_3\text{OH}$  can be synthesized by the reaction:

What volume of  $\text{H}_2$  gas (in L), at 748 mmHg and 86 °C, is required to synthesize 25.8 g  $\text{CH}_3\text{OH}$ ? How many liters of CO gas, measured under the same conditions, are required?

74. Oxygen gas reacts with powdered aluminum according to the reaction:

What volume of  $\text{O}_2$  gas (in L), measured at 782 mmHg and 25 °C, completely reacts with 53.2 g Al?

75. Automobile air bags inflate following a serious impact. The impact triggers the chemical reaction:

If an automobile air bag has a volume of 11.8 L, what mass of  $\text{NaN}_3$  (in g) is required to fully inflate the air bag upon impact? Assume STP conditions.

76. Lithium reacts with nitrogen gas according to the reaction:

What mass of lithium (in g) reacts completely with 58.5 mL of  $\text{N}_2$  gas at STP?

77. Hydrogen gas (a potential future fuel) can be formed by the reaction of methane with water according to the equation:

In a particular reaction, 25.5 L of methane gas (measured at a pressure of 732 torr and a temperature of 25 °C) mixes with 22.8 L of water vapor (measured at a pressure of 702 torr and a temperature of 125 °C). The reaction produces 26.2 L of hydrogen gas at STP. What is the percent yield of the reaction?

78. Ozone is depleted in the stratosphere by chlorine from  $\text{CF}_3\text{Cl}$  according to this set of equations:

What total volume of ozone at a pressure of 25.0 mmHg and a temperature of 225 K is destroyed when all of the chlorine from 15.0 g of  $\text{CF}_3\text{Cl}$  goes through 10 cycles of the given reactions?

79. Chlorine gas reacts with fluorine gas to form chlorine trifluoride.

A 2.00-L reaction vessel, initially at 298 K, contains chlorine gas at a partial pressure of 337 mmHg and fluorine gas at a partial pressure of 729 mmHg. Identify the limiting reactant and determine the theoretical yield of  $\text{ClF}_3$  in grams.

80. Carbon monoxide gas reacts with hydrogen gas to form methanol.

A 1.50-L reaction vessel, initially at 305 K, contains carbon monoxide gas at a partial pressure of 232 mmHg and hydrogen gas at a partial pressure of 397 mmHg. Identify the limiting reactant and determine the theoretical yield of methanol in grams.

### Kinetic Molecular Theory

81. Consider a 1.0-L sample of helium gas and a 1.0-L sample of argon gas, both at room temperature and atmospheric pressure.

- Do the atoms in the helium sample have the same *average kinetic energy* as the atoms in the argon sample?
- Do the atoms in the helium sample have the same *average velocity* as the atoms in the argon sample?
- Do the argon atoms, because they are more massive, exert a greater pressure on the walls of the container? Explain.
- Which gas sample has the faster rate of effusion?

82. A flask at room temperature contains exactly equal amounts (in moles) of nitrogen and xenon.

- Which of the two gases exerts the greater partial pressure?
- The molecules or atoms of which gas have the greater average velocity?
- The molecules of which gas have the greater average kinetic energy?
- If a small hole were opened in the flask, which gas effuses more quickly?

83. Calculate the root mean square velocity and kinetic energy of  $\text{F}_2$ ,  $\text{Cl}_2$ , and  $\text{Br}_2$  at 298 K. Rank these three halogens with respect to their rate of effusion.

84. Calculate the root mean square velocity and kinetic energy of CO,  $\text{CO}_2$ , and  $\text{SO}_3$  at 298 K. Which gas has the greatest velocity? The greatest kinetic energy? The greatest effusion rate?

85. We separate U-235 from U-238 by fluorinating a sample of uranium to form  $\text{UF}_6$  (which is a gas) and then taking advantage of the different rates of effusion and diffusion for compounds containing the two isotopes. Calculate the ratio of effusion rates for  $^{238}\text{UF}_6$  and  $^{235}\text{UF}_6$ . The atomic mass of U-235 is 235.054 amu and that of U-238 is 238.051 amu.

86. Calculate the ratio of effusion rates for Ar and Kr.

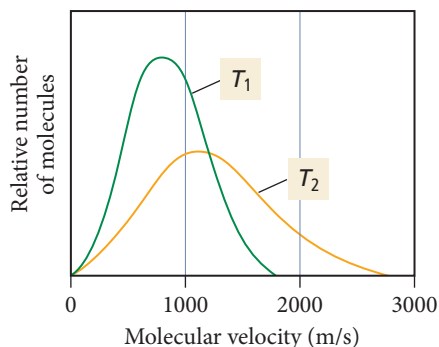

87. A sample of neon effuses from a container in 76 seconds. The same amount of an unknown noble gas requires 155 seconds. Identify the second gas.

88. A sample of  $\text{N}_2\text{O}$  effuses from a container in 42 seconds. How long will it take the same amount of gaseous  $\text{I}_2$  to effuse from the same container under identical conditions?

89. The graph shows the distribution of molecular velocities for two different molecules (A and B) at the same temperature. Which molecule has the higher molar mass? Which molecule has the higher rate of effusion?

90. The graph shows the distribution of molecular velocities for the same molecule at two different temperatures ( $T_1$  and  $T_2$ ). Which temperature is greater? Explain.

## Cumulative Problems

95. Modern pennies are composed of zinc coated with copper. A student determines the mass of a penny to be 2.482 g and then makes several scratches in the copper coating (to expose the underlying zinc). The student puts the scratched penny in hydrochloric acid, where the following reaction occurs between the zinc and the HCl (the copper remains undissolved):

The student collects the hydrogen produced over water at 25 °C. The collected gas occupies a volume of 0.899 L at a total pressure of 791 mmHg. Calculate the percent zinc (by mass) in the penny. (Assume that all the Zn in the penny dissolves.)

96. A 2.85-g sample of an unknown chlorofluorocarbon decomposes and produces 564 mL of chlorine gas at a pressure of 752 mmHg and a temperature of 298 K. What is the percent chlorine (by mass) in the unknown chlorofluorocarbon?
97. The mass of an evacuated 255 mL flask is 143.187 g. The mass of the flask filled with 267 torr of an unknown gas at 25 °C is 143.289 g. Calculate the molar mass of the unknown gas.
98. A 118-mL flask is evacuated and found to have a mass of 97.129 g. When the flask is filled with 768 torr of helium gas at 35 °C, it has a mass of 97.171 g. Was the helium gas pure?
99. A gaseous hydrogen- and carbon-containing compound is decomposed and found to contain 82.66% carbon and 17.34% hydrogen by mass. The mass of 158 mL of the gas, measured at 556 mmHg and 25 °C, was 0.275 g. What is the molecular formula of the compound?
100. A gaseous hydrogen- and carbon-containing compound is decomposed and found to contain 85.63% C and 14.37% H by mass. The mass of 258 mL of the gas, measured at STP, was 0.646 g. What is the molecular formula of the compound?
101. Consider the reaction:

If  $\text{O}_2$  is collected over water at 40.0 °C and a total pressure of 745 mmHg, what volume of gas is collected for the complete reaction of 24.78 g of NiO?

## Real Gases

91. Which postulate of the kinetic molecular theory breaks down under conditions of high pressure? Explain.
92. Which postulate of the kinetic molecular theory breaks down under conditions of low temperature? Explain.
93. Use the van der Waals equation and the ideal gas equation to calculate the volume of 1.000 mol of neon at a pressure of 500.0 atm and a temperature of 355.0 K. Explain why the two values are different. (Hint: One way to solve the van der Waals equation for  $V$  is to use successive approximations. Use the ideal gas law to get a preliminary estimate for  $V$ .)
94. Use the van der Waals equation and the ideal gas equation to calculate the pressure exerted by 1.000 mol of  $\text{Cl}_2$  in a volume of 5.000 L at a temperature of 273.0 K. Explain why the two values are different.

102. Consider the reaction:

If this reaction produces 15.8 g of Ag(s), what total volume of gas can be collected over water at a temperature of 25 °C and a total pressure of 752 mmHg?

103. When hydrochloric acid is poured over potassium sulfide, 42.9 mL of hydrogen sulfide gas is produced at a pressure of 752 torr and 25.8 °C. Write an equation for the gas-evolution reaction and determine how much potassium sulfide (in grams) reacted.
104. Consider the reaction:
- $$2\text{SO}_2\text{(g)} + \text{O}_2\text{(g)} \longrightarrow 2\text{SO}_3\text{(g)}$$
- If 285.5 mL of  $\text{SO}_2$  reacts with 158.9 mL of  $\text{O}_2$  (both measured at 315 K and 50.0 mmHg), what is the limiting reactant and the theoretical yield of  $\text{SO}_3$ ?
  - If 187.2 mL of  $\text{SO}_3$  is collected (measured at 315 K and 50.0 mmHg), what is the percent yield for the reaction?
105. Ammonium carbonate decomposes upon heating according to the balanced equation:

Calculate the total volume of gas produced at 22 °C and 1.02 atm by the complete decomposition of 11.83 g of ammonium carbonate.

106. Ammonium nitrate decomposes explosively upon heating according to the balanced equation:

Calculate the total volume of gas (at 125 °C and 748 mmHg) produced by the complete decomposition of 1.55 kg of ammonium nitrate.

107. Olympic cyclists fill their tires with helium to make them lighter. Calculate the mass of air in an air-filled tire and the mass of helium in a helium-filled tire. What is the mass difference between the two? Assume that the volume of the tire is 855 mL, that it is filled to a total pressure of 125 psi, and that the temperature is 25 °C. Also, assume an average molar mass for air of 28.8 g/mol.

- 108.** In a common classroom demonstration, a balloon is filled with air and submerged in liquid nitrogen. The balloon contracts as the gases within the balloon cool. Suppose a balloon initially contains 2.95 L of air at a temperature of 25.0 °C and a pressure of 0.998 atm. Calculate the expected volume of the balloon upon cooling to -196 °C (the boiling point of liquid nitrogen). When the demonstration is carried out, the actual volume of the balloon decreases to 0.61 L. How does the observed volume of the balloon compare to your calculated value? Explain the difference.

- 109.** Gaseous ammonia is injected into the exhaust stream of a coal-burning power plant to reduce the pollutant NO to N<sub>2</sub> according to the reaction:

Suppose that the exhaust stream of a power plant has a flow rate of 335 L/s at a temperature of 955 K, and that the exhaust contains a partial pressure of NO of 22.4 torr. What should be the flow rate of ammonia delivered at 755 torr and 298 K into the stream to react completely with the NO if the ammonia is 65.2% pure (by volume)?

- 110.** The emission of NO<sub>2</sub> by fossil fuel combustion can be prevented by injecting gaseous urea into the combustion mixture. The urea reduces NO (which oxidizes in air to form NO<sub>2</sub>) according to the reaction:

Suppose that the exhaust stream of an automobile has a flow rate of 2.55 L/s at 655 K and contains a partial pressure of NO of 12.4 torr. What total mass of urea is necessary to react completely with the NO formed during 8.0 hours of driving?

- 111.** An ordinary gasoline can measuring 30.0 cm by 20.0 cm by 15.0 cm is evacuated with a vacuum pump. Assuming that virtually all of the air can be removed from inside the can and that atmospheric pressure is 14.7 psi, what is the total force (in pounds) on the surface of the can? Do you think that the can could withstand the force?
- 112.** Twenty-five milliliters of liquid nitrogen (density = 0.807 g/mL) is poured into a cylindrical container with a radius of 10.0 cm and a length of 20.0 cm. The container initially contains only air at a pressure of 760.0 mmHg (atmospheric pressure) and a temperature of 298 K. If the liquid nitrogen completely vaporizes, what is the total force (in lb) on the interior of the container at 298 K?
- 113.** A 160.0-L helium tank contains pure helium at a pressure of 1855 psi and a temperature of 298 K. How many 3.5-L helium balloons will the helium in the tank fill? (Assume an atmospheric pressure of 1.0 atm and a temperature of 298 K.)
- 114.** An 11.5-mL sample of liquid butane (density = 0.573 g/mL) is evaporated in an otherwise empty container at a temperature of 28.5 °C. The pressure in the container following evaporation is 892 torr. What is the volume of the container?
- 115.** A scuba diver creates a spherical bubble with a radius of 2.5 cm at a depth of 30.0 m where the total pressure (including

atmospheric pressure) is 4.00 atm. What is the radius of the bubble when it reaches the surface of the water? (Assume that the atmospheric pressure is 1.00 atm and the temperature is 298 K.)

- 116.** A particular balloon can be stretched to a maximum surface area of 1257 cm<sup>2</sup>. The balloon is filled with 3.0 L of helium gas at a pressure of 755 torr and a temperature of 298 K. The balloon is then allowed to rise in the atmosphere. If the atmospheric temperature is 273 K, at what pressure will the balloon burst? (Assume the balloon is the shape of a sphere.)
- 117.** A catalytic converter in an automobile uses a palladium or platinum catalyst (a substance that increases the rate of a reaction without being consumed by the reaction) to convert carbon monoxide gas to carbon dioxide according to the reaction:

A chemist researching the effectiveness of a new catalyst combines a 2.0:1.0 mole ratio mixture of carbon monoxide and oxygen gas (respectively) over the catalyst in a 2.45-L flask at a total pressure of 745 torr and a temperature of 552 °C. When the reaction is complete, the pressure in the flask has dropped to 552 torr. What percentage of the carbon monoxide was converted to carbon dioxide?

- 118.** A quantity of N<sub>2</sub> occupies a volume of 1.0 L at 300 K and 1.0 atm. The gas expands to a volume of 3.0 L as the result of a change in both temperature and pressure. Find the density of the gas at these new conditions.
- 119.** A mixture of CO(g) and O<sub>2</sub>(g) in a 1.0-L container at 1.0 × 10<sup>3</sup> K has a total pressure of 2.2 atm. After some time, the total pressure falls to 1.9 atm as the result of the formation of CO<sub>2</sub>. Determine the mass (in grams) of CO<sub>2</sub> that forms.
- 120.** The radius of a xenon atom is 1.3 × 10<sup>-8</sup> cm. A 100-mL flask is filled with Xe at a pressure of 1.0 atm and a temperature of 273 K. Calculate the fraction of the volume that is occupied by Xe atoms. (Hint: The atoms are spheres.)
- 121.** A natural gas storage tank is a cylinder with a moveable top. Its volume can change only as its height changes, and its radius remains fixed. The height of the cylinder is 22.6 m on a day when the temperature is 22 °C. The next day the height of the cylinder increases to 23.8 m when the gas expands because of a heat wave. Determine the temperature on the second day, assuming that the pressure and amount of gas in the storage tank have not changed.
- 122.** A mixture of 8.0 g CH<sub>4</sub> and 8.0 g Xe is placed in a container and the total pressure is found to be 0.44 atm. Determine the partial pressure of CH<sub>4</sub>.
- 123.** A steel container of volume 0.35 L can withstand pressures up to 88 atm before exploding. What mass of helium can be stored in this container at 299 K?
- 124.** Binary compounds of alkali metals and hydrogen react with water to liberate H<sub>2</sub>(g). The H<sub>2</sub> from the reaction of a sample of NaH with an excess of water fills a volume of 0.490 L above the water. The temperature of the gas is 35 °C and the total pressure is 758 mmHg. Determine the mass of H<sub>2</sub> liberated and the mass of NaH that reacted.
- 125.** In a given diffusion apparatus, 15.0 mL of HBr gas diffuses in 1.0 min. In the same apparatus and under the same conditions, 20.3 mL of an unknown gas diffuses in 1.0 min. The unknown gas is a hydrocarbon. Find its molecular formula.
- 126.** A sample of N<sub>2</sub>O<sub>3</sub>(g) has a pressure of 0.017 atm. The temperature (in K) is doubled and the N<sub>2</sub>O<sub>3</sub> undergoes complete decomposition to NO<sub>2</sub>(g) and NO(g). Find the total pressure of the mixture of gases assuming constant volume and no additional temperature change.

- 127.** When 0.583 g of neon is added to an 800-cm<sup>3</sup> bulb containing a sample of argon, the total pressure of the gases is 1.17 atm at a temperature of 295 K. Find the mass of the argon in the bulb.
- 128.** A gas mixture composed of helium and argon has a density of 0.670 g/L at a 755 mmHg and 298 K. What is the composition of the mixture by volume?

- 129.** A gas mixture contains 75.2% nitrogen and 24.8% krypton by mass. What is the partial pressure of krypton in the mixture if the total pressure is 745 mmHg?

## Challenge Problems

- 130.** A 10-L container is filled with 0.10 mol of H<sub>2</sub>(g) and heated to 3000 K, causing some of the H<sub>2</sub>(g) to decompose into H(g). The pressure is found to be 3.0 atm. Find the partial pressure of the H(g) that forms from H<sub>2</sub> at this temperature. (Assume two significant figures for the temperature.)
- 131.** A mixture of NH<sub>3</sub>(g) and N<sub>2</sub>H<sub>4</sub>(g) is placed in a sealed container at 300 K. The total pressure is 0.50 atm. The container is heated to 1200 K at which time both substances decompose completely according to the equations  $2\text{NH}_3(\text{g}) \longrightarrow \text{N}_2(\text{g}) + 3\text{H}_2(\text{g})$ ;  $\text{N}_2\text{H}_4(\text{g}) \longrightarrow \text{N}_2(\text{g}) + 2\text{H}_2(\text{g})$ . After decomposition is complete, the total pressure at 1200 K is found to be 4.5 atm. Find the percent of N<sub>2</sub>H<sub>4</sub>(g) in the original mixture. (Assume two significant figures for the temperature.)
- 132.** A quantity of CO gas occupies a volume of 0.48 L at 1.0 atm and 275 K. The pressure of the gas is lowered, and its temperature is raised until its volume is 1.3 L. Determine the density of the CO under the new conditions.
- 133.** When CO<sub>2</sub>(g) is put in a sealed container at 701 K and a pressure of 10.0 atm and is heated to 1401 K, the pressure rises to 22.5 atm. Some of the CO<sub>2</sub> decomposes to CO and O<sub>2</sub>. Calculate the mole percent of CO<sub>2</sub> that decomposes.
- 134.** The world burns approximately  $3.7 \times 10^{12}$  kg of fossil fuel per year. Use the combustion of octane as the representative reaction and determine the mass of carbon dioxide (the most significant greenhouse gas) formed per year. The current concentration of carbon dioxide in the atmosphere is approximately 399 ppm (by volume). By what percentage does the concentration increase each year due to fossil fuel combustion? Approximate the average properties of the entire atmosphere by assuming that the atmosphere extends from sea level to 15 km and that it has an average pressure of 381 torr and average temperature of 275 K. Assume Earth is a perfect sphere with a radius of 6371 km.

- 135.** The atmosphere slowly oxidizes hydrocarbons in a number of steps that eventually convert the hydrocarbon into carbon dioxide and water. The overall reaction of a number of such steps for methane gas is

Suppose that an atmospheric chemist combines 155 mL of methane at STP, 885 mL of oxygen at STP, and 55.5 mL of NO at STP in a 2.0 L flask. The flask is allowed to stand for several weeks at 275 K. If the reaction reaches 90.0% of completion (90.0% of the limiting reactant is consumed), what is the partial pressure of each of the reactants and products in the flask at 275 K? What is the total pressure in the flask?

- 136.** Two identical balloons are filled to the same volume, one with air and one with helium. The next day, the volume of the air-filled balloon has decreased by 5.0%. By what percent has the volume of the helium-filled balloon decreased? (Assume that the air is four-fifths nitrogen and one-fifth oxygen and that the temperature did not change.)
- 137.** A mixture of CH<sub>4</sub>(g) and C<sub>2</sub>H<sub>6</sub>(g) has a total pressure of 0.53 atm. Just enough O<sub>2</sub>(g) is added to the mixture to bring about its complete combustion to CO<sub>2</sub>(g) and H<sub>2</sub>O(g). The total pressure of the two product gases is 2.2 atm. Assuming constant volume and temperature, find the mole fraction of CH<sub>4</sub> in the mixture.
- 138.** A sample of C<sub>2</sub>H<sub>2</sub>(g) has a pressure of 7.8 kPa. After some time a portion of it reacts to form C<sub>6</sub>H<sub>6</sub>(g). The total pressure of the mixture of gases is then 3.9 kPa. Assume the volume and the temperature do not change. What fraction of C<sub>2</sub>H<sub>2</sub>(g) has undergone reaction?

## Conceptual Problems

- 139.** When the driver of an automobile applies the brakes, the passengers are pushed toward the front of the car, but a helium balloon is pushed toward the back of the car. Upon forward acceleration, the passengers are pushed toward the back of the car, but the helium balloon is pushed toward the front of the car. Why?
- 140.** Suppose that a liquid is 10 times denser than water. If you were to sip this liquid at sea level using a straw, what is the maximum length your straw would be?
- 141.** This reaction occurs in a closed container:

A reaction mixture initially contains 1.5 L of A and 2.0 L of B. Assuming that the volume and temperature of the reaction mixture remain constant, what is the percent change in pressure if the reaction goes to completion?

- 142.** One mole of nitrogen and one mole of neon are combined in a closed container at STP. How big is the container?
- 143.** Exactly equal amounts (in moles) of gas A and gas B are combined in a 1-L container at room temperature. Gas B has a molar mass that is twice that of gas A. Which statement is true for the mixture of gases and why?
- The molecules of gas B have greater kinetic energy than those of gas A.
  - Gas B has a greater partial pressure than gas A.
  - The molecules of gas B have a greater average velocity than those of gas A.
  - Gas B makes a greater contribution to the average density of the mixture than gas A.
- 144.** Which gas would you expect to deviate most from ideal behavior under conditions of low temperature: F<sub>2</sub>, Cl<sub>2</sub>, or Br<sub>2</sub>? Explain.

- 145.** The volume of a sample of a fixed amount of gas is decreased from 2.0 L to 1.0 L. The temperature of the gas in kelvins is then doubled. What is the final pressure of the gas in terms of the initial pressure?
- 146.** Which gas sample has the greatest volume at STP?
- a. 10.0 g Kr    b. 10.0 g Xe    c. 10.0 g He

- 147.** Draw a depiction of a gas sample, as described by kinetic molecular theory, containing equal molar amounts of helium, neon, and krypton. Use different color dots to represent each element. Give each atom a “tail” to represent its velocity relative to the others in the mixture.

## Active Classroom Learning

## Questions for Group Work

Discuss these questions with the group and record your consensus answer.

- 148.** Assign one of the three simple gas laws to each member of your group. For the assigned gas law, have each member write two equations, draw a graph, and describe it in a complete sentence. Have each group member present his or her law to the group.
- 149.** Review the ideal gas law. Without referring back to the text, use algebra to write the ideal gas law and solve for each of the individual variables it contains. Have each group member solve for a different variable and present answers to the group.
- 150.** Hydrogen peroxide ( $\text{H}_2\text{O}_2$ ) decomposes in the presence of a catalyst to form water and oxygen. The catalyst is added to 5.00 mL of a hydrogen peroxide solution at 25.0 °C, and 49.5 mL of gas is collected over water at a total pressure of 763.8 mmHg.
- Write and balance the chemical reaction (note: catalysts do not appear in balanced chemical equations).
  - Look up the vapor pressure of water under these conditions.
  - What is the partial pressure of oxygen collected over the water?
  - How many moles of oxygen are collected?

- How many grams of hydrogen peroxide were in the original sample?
  - What is the concentration (in mol/L) of the hydrogen peroxide solution?
  - Which part of this process is conceptually most difficult for your group?
- 151.** A box contains equal amounts of helium, argon, and krypton (all gases) at 25 °C. Using complete sentences, describe the temperatures, masses, average velocities, and average kinetic energy of the three kinds of gas in the mixture. What do they have in common? What are the differences? How are these properties related?
- 152.** Calculate the pressure exerted by 1 mol of an ideal gas in a box that is 0.500 L and 298 K. Have each group member calculate the pressure of 1 mol of the following gases in the same box at the same temperature: He, Ne,  $\text{H}_2$ ,  $\text{CH}_4$ , and  $\text{CO}_2$ . Compare group members' answers as well as all answers with the pressure of an ideal gas. Assuming that the van der Waals equation predictions are accurate, account for why the pressure of each gas is higher or lower than that predicted for an ideal gas.

## Data Interpretation and Analysis

## Nitrogen Oxide from Automobiles

- 153.** Air contains about 78.08% nitrogen gas, 20.95% oxygen gas, and 0.97% other gases by volume. When air is combusted in automobile engines, nitrogen oxide gases form. One of these gases, nitric oxide (NO), rapidly oxidizes in air to form nitrogen dioxide ( $\text{NO}_2$ ).

Scientists are concerned about the level of  $\text{NO}_x$  gas ( $\text{NO}_x$  is the term used to refer collectively to nitrogen oxide gases) being emitted by automobile exhaust. People breathing air with elevated levels of  $\text{NO}_2$  gas are susceptible to increased incidence of asthma attacks, respiratory infection, and inflammation of the breathing airways, which leads to coughing and wheezing. As a result, government and state regulations require new cars to emit less nitrogen oxide gas than new cars did in the past and older cars to have yearly inspections to check the efficiency of their engines. One purpose of a three-way catalytic converter is to convert the  $\text{NO}_x$  gases produced as a by-product of the combustion of gasoline with air to  $\text{N}_2$  and  $\text{O}_2$ .

The EPA mandates that the overall average concentration of nitrogen dioxide in the air not exceed 0.053 ppmv and not exceed a one-hour average of 0.100 ppmv. Monitoring gas pollutants in cities allows engineers and scientists to caution the public about possible health risks. Figure a charts the average concentration of nitrogen dioxide ( $\text{NO}_2$ ) and ozone ( $\text{O}_3$ ), gases over seven days from nine gas detection stations located equal distances from each other in a city. The particular gas detection system employed in this city can measure the concentration of  $\text{NO}_2$ ,  $\text{O}_3$ , and CO gases but does not measure the concentration of NO.

**▲ FIGURE a** Average Concentration of Nitrogen Dioxide,  $\text{NO}_2$ , and Ozone,  $\text{O}_3$ , over Seven Days

Source: <http://www.cas.manchester.ac.uk/resprojects/holmemoss/results/fig2/>

Parts-per-billion-volume (ppbv) or parts-per-million-volume (ppmv) units are used in gas measurements. This unit is based on volume-to-volume ratio and is not the same as parts-per-billion (or parts-per-million) used in aqueous measurements, which is based on a mass-per-mass ratio. The following formula converts ppmv (parts-per-million-volume) to  $\text{mg}/\text{m}^3$  for a gas at a pressure of 1 atm:

$$\text{mg}/\text{m}^3 = \text{ppmv} \cdot \frac{\mathcal{M}}{(0.08206 \cdot T)}$$

where  $\mathcal{M}$  is the molar mass of a gas in units of grams per mole,  $T$  is the temperature in Kelvin, and 0.08206 is the ideal gas constant in units of  $\text{L} \cdot \text{atm}/\text{mol} \cdot \text{K}$ .

Use the information provided in the figure to answer the following questions:

- What type of relationship exists between nitrogen dioxide and ozone between March 14 and March 16?
- What number of moles of  $\text{NO}_2$  in  $1.00 \text{ m}^3$  of air was produced on March 14? Assume an average temperature of  $25.0^\circ\text{C}$  and a pressure of  $1.00 \text{ atm}$ . Note that the moles of  $\text{NO}_2$  produced is the difference between the existing amount at the start of the day and the peak amount.
- Calculate the number of moles of  $\text{O}_3$  in  $1.00 \text{ m}^3$  consumed on March 14. Note that the moles of  $\text{O}_3$  consumed is the difference between the existing amount at the start of the day and the minimum amount.
- Determine the mole-to-mole ratio of  $\text{O}_3$  consumed to  $\text{NO}_2$  produced.
- The following chemical equations model the interactions of nitrogen dioxide gas and ozone gas. Which set of equations best accounts for the trends observed in the graph? Explain your answer.
  - $\text{N}_2 + \text{O}_2 \longrightarrow 2 \text{NO}$   
 $\text{NO} + \text{O}_3 \longrightarrow \text{NO}_2 + \text{O}_2 + \text{light}$
  - $4 \text{NH}_3 + 5 \text{O}_2 \longrightarrow 4 \text{NO} + 6 \text{H}_2\text{O}$   
 $2 \text{NO} + \text{O}_2 \longrightarrow 2 \text{NO}_2$   
 $\text{NO}_2 + \text{O}_3 \longrightarrow \text{NO}_3 + \text{O}_2$

- What were inhabitants doing in the city between 9 am and 9 pm on March 14 and 15 that might account for the rise and fall of the concentration of both nitrogen dioxide and ozone? Most likely, what day of the week was March 18?
- Assume you have a  $1.00\text{-m}^3$  sample of air collected in the city during the peak production of  $\text{NO}_2$  on March 15. The gas sample has a total pressure of  $1.00 \text{ atm}$  and a temperature of  $25.00^\circ\text{C}$ . Calculate the partial pressures of  $\text{NO}_2$  and  $\text{O}_3$  in this sample of gas in units of atmospheres.
- On average, what was the highest  $\text{NO}_2$  gas concentration produced in one day in this city during the time period illustrated in Figure a?
- Did the concentration of  $\text{NO}_2$  gas exceed either the  $0.053\text{-ppmv}$  level standard or the  $100.0\text{-ppb}$  average over the period shown in Figure a?
- Assume the nine gas detection stations cover a volume of  $2.0 \text{ mile} \times 2.0 \text{ mile} \times 0.15 \text{ mile}$ . If the  $\text{NO}_2$  gas concentration is uniform throughout this volume at the highest concentration, how many grams of  $\text{NO}_2$  gas are in the air?

## Answers to Conceptual Connections

### Boyle's Law and Charles's Law

- 5.1 (e)** The final volume of the gas is the same as the initial volume because doubling the pressure *decreases* the volume by a factor of two, but doubling the temperature *increases* the volume by a factor of two. The two changes in volume are equal in magnitude but opposite in sign, resulting in a final volume that is equal to the initial volume.

### Molar Volume

- 5.2 (a)** Since one gram of  $\text{H}_2$  contains the greatest number of moles (due to  $\text{H}_2$  having the lowest molar mass of the listed gases), and since one mole of *any* ideal gas occupies the same volume, the  $\text{H}_2$  occupies the greatest volume.

### Density of a Gas

- 5.3**  $\text{Ne} < \text{O}_2 < \text{F}_2 < \text{Cl}_2$

### Partial Pressures

- 5.4**  $P_{\text{He}} = 1.5 \text{ atm}$ ;  $P_{\text{Ne}} = 1.5 \text{ atm}$ . Since the number of moles of each gas is equal, the mole fraction of each gas is  $0.50$  and the partial pressure of each gas is  $0.50 \times P_{\text{tot}}$ .

### Pressure and Number of Moles

- 5.5 (b)** Since the total number of gas molecules decreases, the total pressure—the sum of all the partial pressures—must also decrease.

### Kinetic Molecular Theory I

- 5.6** Although the velocity “tails” have different lengths, the average length of the tails on the argon atoms in your drawing should be longer than the average length of the tails on the xenon atoms. Because the argon atoms are

lighter, they must on average move faster than the xenon atoms to have the same kinetic energy.

### Root Mean Square Velocity

- 5.7 (b)** The molar mass of neon ( $20.18 \text{ g/mol}$ ) is approximately one-quarter the molar mass of krypton ( $83.80 \text{ g/mol}$ ), so the root mean square velocity of neon is  $\sqrt{\frac{1}{4}}$  times that of krypton.

### Kinetic Molecular Theory II

- 5.8 (c)** Since the temperature and the volume are both constant, the ideal gas law tells us that the pressure depends solely on the number of particles. Sample (c) has the greatest number of particles per unit volume and therefore has the greatest pressure. The pressures of samples (a) and (b) at a given temperature are identical. Even though the particles in (b) are more massive than those in (a), they have the same average kinetic energy at a given temperature. The particles in (b) move more slowly than those in (a), and so exert the same pressure as the particles in (a).

### Real Gases

- 5.9**  $A < B < C$ . Curve A is the lowest temperature curve because it deviates the most from ideality. The tendency for the intermolecular forces in carbon dioxide to lower the pressure (relative to that of an ideal gas) is greatest at low temperature (because the molecules are moving more slowly and are therefore less able to overcome the intermolecular forces). As a result, the curve that dips the lowest must correspond to the lowest temperature.

# Thermochemistry

There is a fact, or if you wish, a law, governing all natural phenomena that are known to date. There is no known exception to this law—it is exact as far as we know. The law is called the conservation of energy. It states that there is a certain quantity, which we call energy, that does not change in the manifold changes which nature undergoes.

**KEY LEARNING OUTCOMES 287**

**W**e have spent the first few chapters of this book examining one of the two major components of our universe—matter. We now turn our attention to the other major component—energy. As far as we know, matter and energy—which can be interchanged but not destroyed—make up the physical universe. Unlike matter, energy is not something we can touch or hold in our hand, but we experience it in many ways. The warmth of sunlight, the feel of wind on our faces, and the force that presses us back when a car accelerates are all manifestations of energy and its interconversions. And of course energy is critical to society and to the world. The standard of living around the globe is strongly correlated with the access to and use of energy resources. Most of those resources, as we shall see, are chemical ones, and we can understand their advantages as well as their drawbacks in terms of chemistry.

▲ A chemical hand warmer contains substances that react to emit heat.

## 6.1 Chemical Hand Warmers

My family loves to snowboard. However, my wife hates being cold (with a passion), especially in her hands and toes. Her solution is the chemical hand warmer, a small pouch that comes sealed in a plastic package. She opens the package and places the pouch in her glove or boot. The pouch slowly warms up and keeps her hand (or foot) warm all day long.

Warming your hands with chemical hand warmers involves many of the principles of **thermochemistry**, the study of the relationships between chemistry and energy. When you open the package that contains the hand warmer, the contents are exposed

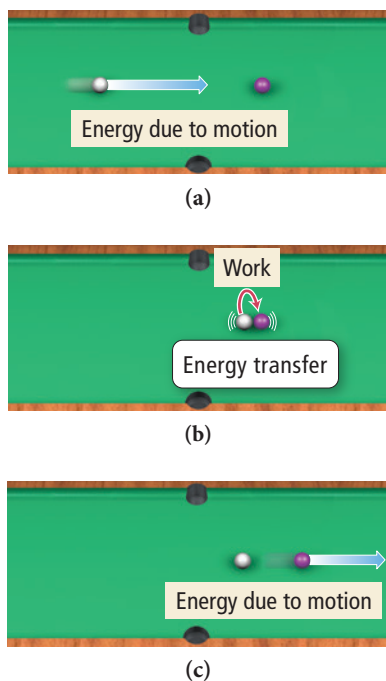

to air, and an *exothermic reaction* occurs. Most hand warmers use the oxidation of iron as the exothermic reaction:

The useful product of this reaction is not a substance—it is *heat*. We'll define heat more carefully later, but heat is what you feel when you touch something that is warmer than your hand (in this case, the hand warmer). Although some of the heat is lost through the minute openings in your gloves (which is why my wife prefers mittens, which have fewer openings), most of it is transferred to your hands and to the pocket of air surrounding your hands, resulting in a temperature increase. The magnitude of the temperature increase depends on the size of the hand warmer and the size of your glove (as well as some other details). But in general, the size of the temperature increase is proportional to the amount of heat released by the reaction.

In this chapter, we examine the relationship between chemical reactions and energy. Specifically, we look at how chemical reactions can *exchange* energy with their surroundings and how we can quantify the magnitude of those exchanges. These kinds of calculations are important, not only for chemical hand warmers, but also for many other important processes such as the production of energy.

▲ (a) A rolling billiard ball has energy due to its motion. (b) When the ball collides with a second ball it does work, transferring energy to the second ball. (c) The second ball has energy as it rolls away from the collision.

Breaking chemical bonds always takes energy. The chemical reactions that produce energy involve breaking weak bonds (which absorbs small amounts of energy) and forming stronger bonds (which releases large amounts of energy).

## 6.2 The Nature of Energy: Key Definitions

Recall that we briefly examined energy in Section 1.5. We defined **energy** as the capacity to do work and defined **work** as the result of a force acting through a distance. When you push a box across the floor, you have done work. Consider another example of work: a billiard ball rolling across a billiard table and colliding straight on with a second, stationary billiard ball. The rolling ball has *energy* due to its motion. When it collides with another ball it does *work*, resulting in the *transfer* of energy from one ball to the other. The second billiard ball absorbs the energy and begins to roll across the table.

As we just saw with chemical hand warmers, energy can also be transferred through **heat**, the flow of energy caused by a temperature difference. For example, if you hold a cup of coffee in your hand, energy is transferred, in the form of heat, from the hot coffee to your cooler hand. Think of *energy* as something that an object or set of objects possesses. Think of *heat* and *work* as ways that objects or sets of objects *exchange* energy.

### Types of Energy

The energy contained in a rolling billiard ball is an example of **kinetic energy**, the energy associated with the *motion* of an object. The energy contained in a hot cup of coffee is **thermal energy**, the energy associated with the *temperature* of an object. Thermal energy is actually a type of kinetic energy because it arises from the motions of atoms or molecules within a substance. If you raise a billiard ball off the table, you increase its **potential energy**, the energy associated with the *position* or *composition* of an object. The potential energy of the billiard ball, for example, is a result of its position in Earth's gravitational field. Raising the ball off the table, against Earth's gravitational pull, gives the ball more potential energy. Another example of potential energy is the energy contained in a compressed spring. When you compress a spring, you push against the forces that tend to maintain the spring's uncompressed shape, storing energy as potential energy. **Chemical energy**, the energy associated with the relative positions of electrons and nuclei in atoms and molecules, is also a form of potential energy. Some chemical compounds, such as the methane in natural gas or the iron in a chemical hand warmer, are like compressed springs—they contain potential energy, and a chemical reaction can release that potential energy. Figure 6.1 summarizes these different kinds of energy.

▲ FIGURE 6.1 The Different Manifestations of Energy

## Energy Transformation I

▲ **FIGURE 6.2** Energy Transformation: Potential and Kinetic Energy I (a) A billiard ball held above the ground has gravitational potential energy. (b) When the ball is released, the potential energy is transformed into kinetic energy, the energy of motion.

## Energy Conservation and Energy Transfer

The **law of conservation of energy** states that *energy can be neither created nor destroyed*. However, energy can be transferred from one object to another, and it can assume different forms. For example, if you drop a raised billiard ball, some of its potential energy becomes kinetic energy as the ball falls toward the table, as shown in Figure 6.2▲. If you release a compressed spring, the potential energy becomes kinetic energy as the spring expands outward, as shown in Figure 6.3▼. When iron reacts with oxygen within a chemical hand warmer, the chemical energy of the iron and oxygen becomes thermal energy that increases the temperature of your hand and glove.

A good way to understand and track energy changes is to define the **system** under investigation. For example, the system may be the chemicals in a beaker, or it may be the iron reacting in a hand warmer. The system's **surroundings** are everything with which the system can exchange energy. If we define the chemicals in a beaker as the system, the surroundings may include the water in which the chemicals are dissolved (for aqueous solutions), the beaker itself, the lab bench on which the beaker sits, the air in the room, and so on. For the iron in the hand warmer, the surroundings include your hand, your glove, the air in the glove, and even the air outside of the glove.

In an energy exchange, energy transfers between the system and the surroundings, as shown in Figure 6.4► on the next page. If the system loses energy, the surroundings gain the same exact amount of energy, and vice versa. When the iron within the chemical hand warmer reacts, the system loses energy to the surroundings, producing the desired temperature increase within your gloves.

## Units of Energy

We can deduce the units of energy from the definition of kinetic energy. An object of mass  $m$ , moving at velocity  $v$ , has a kinetic energy KE given by the equation:

$$\text{KE} = \frac{1}{2}mv^2$$

kg
m/s

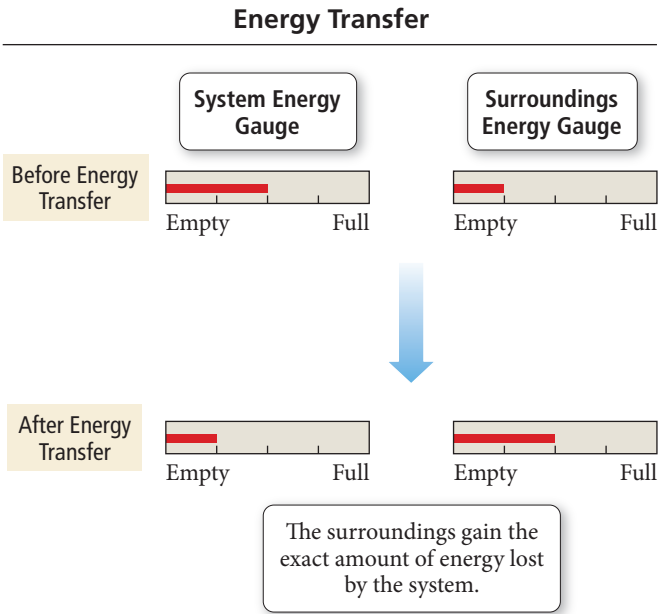

Einstein showed that it is mass–energy that is conserved; one can be converted into the other. This equivalence becomes important in nuclear reactions, discussed in Chapter 20. In ordinary chemical reactions, however, the interconversion of mass and energy is not a significant factor, and we can regard mass and energy as independently conserved.

## Energy Transformation II

[6.1] ▲ **FIGURE 6.3** Energy Transformation: Potential and Kinetic Energy II (a) A compressed spring has potential energy. (b) When the spring is released, the potential energy is transformed into kinetic energy.

► **FIGURE 6.4 Energy Transfer** If a system and surroundings had energy gauges (which measure energy content in the way a fuel gauge measures fuel content), an energy transfer in which the system transfers energy to the surroundings would result in a decrease in the energy content of the system and an increase in the energy content of the surroundings. The total amount of energy, however, must be conserved.

$3.6 \times 10^5$  J or 0.10 kWh  
used in 1 hour

▲ A watt (W) is 1 J/s, so a 100 W lightbulb uses 100 J every second or  $3.6 \times 10^5$  J every hour.

The “calorie” referred to on all nutritional labels (regardless of the capitalization) is always the capital C Calorie.

The SI unit of mass is the kg and the unit of velocity is m/s. The SI unit of energy is therefore  $\text{kg} \cdot \text{m}^2/\text{s}^2$ , defined as the **joule (J)**, named after the English scientist James Joule (1818–1889).

$$1 \text{ kg} \frac{\text{m}^2}{\text{s}^2} = 1 \text{ J}$$

One joule is a relatively small amount of energy—for example, a 100-watt lightbulb uses  $3.6 \times 10^5$  J in 1 hour. Therefore, we often use the kilojoule (kJ) in our energy discussions and calculations (1 kJ = 1000 J). A second commonly used unit of energy is the **calorie (cal)**, originally defined as the amount of energy required to raise the temperature of 1 g of water by 1 °C. The current definition is 1 cal = 4.184 J (exact); a calorie is a larger unit than a joule. A related energy unit is the nutritional, or uppercase “C” **Calorie (Cal)**, equivalent to 1000 lowercase “c” calories. The Calorie is the same as a kilocalorie (kcal): 1 Cal = 1 kcal = 1000 cal. Electricity bills typically are based on another, even larger, energy unit, the **kilowatt-hour (kWh)**: 1 kWh =  $3.60 \times 10^6$  J. Electricity costs \$0.08–\$0.15 per kWh. Table 6.1 lists various energy units and their conversion factors. Table 6.2 shows the amount of energy required for various processes.

**TABLE 6.1** Energy Conversion Factors\*

1 calorie (cal)	= 4.184 joules (J)
1 Calorie (Cal) or kilocalorie (kcal)	= 1000 cal = 4184 J
1 kilowatt-hour (kWh)	= $3.60 \times 10^6$ J

\*All conversion factors in this table are exact.

**TABLE 6.2** Energy Uses in Various Units

Unit	Amount Required to Raise Temperature of 1 g of Water by 1 °C	Amount Required to Light 100 W Bulb for 1 Hour	Amount Used by Human Body in Running 1 Mile (Approximate)	Amount Used by Average U.S. Citizen in 1 Day
joule (J)	4.18	$3.60 \times 10^5$	$4.2 \times 10^5$	$9.0 \times 10^8$
calorie (cal)	1.00	$8.60 \times 10^4$	$1.0 \times 10^5$	$2.2 \times 10^8$
Calorie (Cal)	0.00100	86.0	100	$2.2 \times 10^5$
kilowatt-hour (kWh)	$1.16 \times 10^{-6}$	0.100	0.12	$2.5 \times 10^2$

## 6.3 The First Law of Thermodynamics: There Is No Free Lunch

The First Law of Thermodynamics

**Thermodynamics** is the general study of energy and its interconversions. The laws of thermodynamics are among the most fundamental in all of science, governing virtually every process that involves change. The **first law of thermodynamics** is the law of energy conservation, which we state as follows:

**The total energy of the universe is constant.**

In other words, since energy is neither created nor destroyed, and since the universe does not exchange energy with anything else, its energy content does not change.

The first law has many implications: the most important one is that with energy, you cannot get something for nothing. The best you can do with energy is break even—there is no free lunch. According to the first law, a device that would continually produce energy with no energy input, sometimes known as a *perpetual motion machine*, cannot exist. Occasionally, the media report or speculate on the discovery of a machine that can produce energy without the need for energy input. For example, you may have heard someone propose an electric car that recharges itself while driving, or a new motor that can create additional usable electricity as well as the electricity to power itself. Although some hybrid (electric and gasoline powered) vehicles can capture energy from braking and use that energy to recharge their batteries, they could never run indefinitely without additional fuel. As for the motor that powers an external load as well as itself—no such thing exists. Our society has a continual need for energy, and as our current energy resources dwindle, new energy sources will be required. But those sources, whatever they may be, must follow the first law of thermodynamics—energy is always conserved.

### Internal Energy

The **internal energy ( $E$ )** of a system is *the sum of the kinetic and potential energies of all of the particles that compose the system*. Internal energy is a **state function**, which means that its value depends *only on the state of the system*, not on how the system arrived at that state.

## Chemistry IN YOUR DAY

### Redheffer's Perpetual Motion Machine

In 1812, a man named Charles Redheffer appeared in Philadelphia with a machine that he claimed could run forever without any energy input—a perpetual motion machine. He set up the machine on the edge of town and charged admission to view it. He also appealed to the city for money to build a larger version of the machine. When city commissioners came out to inspect the machine, Redheffer did his best to keep them from viewing it too closely. Nonetheless, one of the commissioners noticed something suspicious: the gears that supposedly ran to an external driveshaft were cut in the wrong direction. The driveshaft that the machine was allegedly powering was instead powering the machine. The city commissioners hired a local engineer and clockmaker named Isaiah Lukens to make a similar machine to expose Redheffer's deception. Lukens's machine was even more ingenious than Redheffer's, and Redheffer left Philadelphia exposed as a fraud.

Redheffer was persistent, however, and took his machine to New York. In 1813, during a public display of the machine, the famous mechanical engineer Robert Fulton (1765–1815)—who had demonstrated the first successful steamboat six years earlier—noticed a rhythm to the machine's motion. It seemed to speed up and slow down at regular intervals. Fulton knew that such rhythmic motion is indicative of motion generated by a manual crank. He knocked away some boards in a wall next to the machine and discovered a long belt that led to an enclosed room where, indeed, an old man sat turning a crank. Redheffer's machine—like many other perpetual motion machines throughout history—was again exposed as a hoax.

#### QUESTION

Can you think of any recent claims of perpetual motion or limitless free energy?

► **FIGURE 6.5 Altitude as a State Function** The change in altitude during a climb depends only on the difference between the final and initial altitudes, not on the route traveled.

The state of a chemical system is specified by parameters such as temperature, pressure, concentration, and physical state (solid, liquid, or gas). Consider the mountain-climbing analogy depicted in Figure 6.5▲. The elevation at any point during a mountain climb is analogous to a state function. For example, when we reach 10,000 ft, our elevation is 10,000 ft, no matter how we got there. The distance we traveled to get there, by contrast, is not a state function; we could have climbed the mountain by any number of routes, each requiring us to cover a different distance.

Since state functions depend only on the state of the system, the value of a *change* in a state function is always the difference between its final and initial values. If we start climbing a mountain at an elevation of 3000 ft and reach the summit at 10,000 ft, then our elevation change is 7000 ft (10,000 ft – 3000 ft), regardless of what path we traveled.

Like an altitude change, an internal energy change ( $\Delta E$ ) is determined by the difference in internal energy between the final and initial states:

$$\Delta E = E_{\text{final}} - E_{\text{initial}}$$

In a chemical system, the reactants constitute the initial state and the products constitute the final state. So  $\Delta E$  is the difference in internal energy between the products and the reactants:

$$\Delta E = E_{\text{products}} - E_{\text{reactants}} \quad [6.2]$$

For example, consider the reaction between carbon and oxygen to form carbon dioxide:

Just as we can portray the changes that occur when climbing a mountain with an *altitude* diagram that depicts the *altitude* before and after the climb (see Figure 6.5), we can portray the energy changes that occur during a reaction with an *energy* diagram, which compares the *internal energy* of the reactants and the products:

The vertical axis of the diagram is *internal energy*, which increases as we move up on the diagram. For this reaction, the reactants are *higher* on the diagram than the products because they have higher internal energy. As the reaction occurs, the reactants become products, which have lower internal energy. Therefore, energy is given off by the reaction and  $\Delta E$  (that is,  $E_{\text{products}} - E_{\text{reactants}}$ ) is *negative*.

Where does the energy lost by the reactants (as they transform to products) go? If we define the thermodynamic *system* as the reactants and products of the reaction, then energy flows *out of the system* and *into the surroundings*.

According to the first law, energy must be conserved. Therefore, the amount of energy lost by the system must exactly equal the amount gained by the surroundings:

$$\Delta E_{\text{sys}} = -\Delta E_{\text{surr}} \quad [6.3]$$

Now, suppose the reaction is reversed:

The energy-level diagram is nearly identical, with one important difference:  $\text{CO}_2(\text{g})$  is now the reactant and  $\text{C}(\text{s})$  and  $\text{O}_2(\text{g})$  are the products. Instead of decreasing in energy as the reaction occurs, the system increases in energy as shown at right. In this reversed reaction  $\Delta E$  is *positive* and energy flows *into the system* and *out of the surroundings*:

#### Summarizing Energy Flow:

- ▶ If the reactants have a higher internal energy than the products,  $\Delta E_{\text{sys}}$  is negative and energy flows out of the system into the surroundings.
- ▶ If the reactants have a lower internal energy than the products,  $\Delta E_{\text{sys}}$  is positive and energy flows into the system from the surroundings.

We can think of the internal energy of the system in the same way we think about the balance in a checking account. Energy flowing *out of* the system is like a withdrawal and therefore carries a negative sign. Energy flowing *into* the system is like a deposit and carries a positive sign.

**System and Surroundings** Consider these fictitious internal energy gauges for a chemical system and its surroundings:

Which diagram best represents the energy gauges for the same system and surroundings following an energy exchange in which  $\Delta E_{\text{sys}}$  is negative?

#### CONCEPTUAL CONNECTION 6.1

## Heat and Work

As we discussed in Section 6.2, a system can exchange energy with its surroundings through *heat* and *work*:

According to the first law of thermodynamics, the change in the internal energy of the system ( $\Delta E$ ) is the sum of the heat transferred ( $q$ ) and the work done ( $w$ ):

$$\Delta E = q + w \quad [6.4]$$

In Equation 6.4, and from this point forward, we follow the standard convention that  $\Delta E$  (with no subscript) refers to the internal energy change of the *system*. As shown in Table 6.3, energy entering the system through heat or work carries a positive sign, and energy leaving the system through heat or work carries a negative sign. Recall our checking account analogy. The system is like the checking account—withdrawals are negative and deposits are positive.

**TABLE 6.3** Sign Conventions for  $q$ ,  $w$ , and  $\Delta E$

$q$ (heat)	+ system <i>gains</i> thermal energy	– system <i>loses</i> thermal energy
$w$ (work)	+ work done <i>on</i> the system	– work done <i>by</i> the system
$\Delta E$ (change in internal energy)	+ energy flows <i>into</i> the system	– energy flows <i>out of</i> the system

We can define our system as the previously discussed billiard ball rolling across a pool table. The rolling ball has a certain initial amount of kinetic energy. When it reaches the other end of the table, the rolling ball collides head-on with a second ball. Assume that the first ball loses all of its kinetic energy so that it remains completely still (it has no kinetic energy) at the point of collision. The total change in internal energy ( $\Delta E$ ) for the first ball is the difference between its initial kinetic energy and its final kinetic energy (which is zero); the first billiard ball lost all of its energy. What happened to that energy? According to the first law, it must have been transferred to the surroundings. In fact, the energy lost by the system must *exactly equal* the amount gained by the surroundings:

$$\Delta E_{\text{sys}} = -\Delta E_{\text{surr}}$$

The surroundings include both the pool table and the second ball. The pool table absorbs some of the ball's kinetic energy as the ball rolls down the table. Minute bumps on the table surface cause friction, which slows the ball down by converting kinetic energy to heat ( $q$ ). The second ball absorbs some of the ball's kinetic energy in the form of work ( $w$ ) upon collision.

Although it is always the case that  $\Delta E_{\text{sys}} = -\Delta E_{\text{surr}}$ , the exact amount of *work* done on the second ball depends on the quality of the billiard table. On a smooth, high-quality billiard table, the amount of energy lost to friction is relatively small, as illustrated in Figure 6.6(a)▶. The speed of the first ball is not reduced by much as it travels across the table, and a great deal of its original kinetic energy is available to perform work when it collides with the second ball. In contrast, on a rough, poor-quality table, the ball loses much of its initial kinetic energy as heat, leaving only a relatively small amount available for work, as illustrated in Figure 6.6(b)▶.

Notice that the respective amounts of energy converted to heat and work depend on the details of the pool table and the path taken, while the change in internal energy of the rolling ball does not. Because internal energy is a state function, the value of  $\Delta E$  for the process in which the ball moves across the table and collides with another ball depends

**▲ FIGURE 6.6 Energy, Work, and Heat** (a) On a smooth table, most of the first billiard ball's initial kinetic energy is transferred to the second ball as work. Only a small amount is lost to heat. (b) On a rough table, most of the first billiard ball's initial kinetic energy is lost to heat. Only a small amount is left to do work on the second billiard ball.

only on the ball's initial and final kinetic energy. Work and heat, however, are *not* state functions; therefore, the values of  $q$  and  $w$  depend on the details of the ball's journey across the table. On the smooth table,  $w$  is greater in magnitude than  $q$ ; on the rough table,  $q$  is greater in magnitude than  $w$ . However,  $\Delta E$  (the sum of  $q$  and  $w$ ) is constant.

**Heat and Work** Identify each energy exchange as heat or work and determine whether the sign of heat or work (relative to the system) is positive or negative.

- An ice cube melts and cools the surrounding beverage. (The ice cube is the system.)
- A metal cylinder is rolled up a ramp. (The metal cylinder is the system.)
- Steam condenses on skin, causing a burn. (The condensing steam is the system.)

CONCEPTUAL  
**CONNECTION 6.2**

**Example 6.1** Internal Energy, Heat, and Work

A potato cannon provides a good example of the heat and work associated with a chemical reaction. In a potato cannon, a potato is stuffed into a long cylinder that is capped on one end and open at the other. Some kind of fuel is introduced under the potato at the capped end—usually through a small hole—and ignited. The potato shoots out of the cannon, sometimes flying hundreds of feet, and the cannon emits heat to the surroundings. If the burning of the fuel performs 855 J of work on the potato and produces 1422 J of heat, what is  $\Delta E$  for the burning of the fuel? (Note: A potato cannon can be dangerous and should not be constructed without proper training and experience.)

**SOLUTION** To solve the problem, substitute the values of  $q$  and  $w$  into the equation for  $\Delta E$ . Since work is done by the system on the surroundings,  $w$  is negative. Similarly, because heat is released by the system to the surroundings,  $q$  is also negative.

$$\begin{aligned}\Delta E &= q + w \\ &= -1422 \text{ J} - 855 \text{ J} \\ &= -2277 \text{ J}\end{aligned}$$

**FOR PRACTICE 6.1** A cylinder and piston assembly (defined as the system) is warmed by an external flame. The contents of the cylinder expand, doing work on the surroundings by pushing the piston outward against the external pressure. If the system absorbs 559 J of heat and does 488 J of work during the expansion, what is the value of  $\Delta E$ ?

**6.4** Quantifying Heat and Work

In the previous section, we calculated  $\Delta E$  based on *given values of  $q$  and  $w$* . We now turn to *calculating  $q$  (heat) and  $w$  (work)* based on changes in temperature and volume.

**Heat**

Recall from Section 6.2 that *heat* is the exchange of thermal energy between a system and its surroundings caused by a temperature difference. Notice the distinction between heat and temperature. Temperature is a *measure* of the thermal energy within a sample of matter. Heat is the *transfer* of thermal energy. Thermal energy always flows from matter at higher temperatures to matter at lower temperatures. For example, a hot cup of coffee transfers thermal energy—as heat—to the lower-temperature surroundings as it cools down. Imagine a world where the cooler surroundings actually got colder as they transferred thermal energy to the hot coffee, which got hotter. Such a world exists only in our imaginations (or in the minds of science fiction writers), because the spontaneous transfer of heat from a hotter object to a colder one is a fundamental principle of our universe—no exception has ever been observed. The thermal energy in the molecules that compose the hot coffee distributes itself to the molecules in the surroundings. The heat transfer from the coffee to the surroundings stops when the two reach the same temperature, a condition called **thermal equilibrium**. At thermal equilibrium, there is no additional net transfer of heat.

The reason for this one-way transfer is related to the second law of thermodynamics, which we discuss in Chapter 18.

**Temperature Changes and Heat Capacity**

When a system absorbs heat ( $q$ ), its temperature changes by  $\Delta T$ :

Experiments show that the heat absorbed by a system and its corresponding temperature change are directly proportional:  $q \propto \Delta T$ . The constant of proportionality

between  $q$  and  $\Delta T$  is the system's *heat capacity* ( $C$ ), a measure of the system's ability to absorb thermal energy without undergoing a large change in temperature.

$$q = C \times \Delta T \quad [6.5]$$

Heat capacity

Notice that the higher the heat capacity of a system, the smaller the change in temperature for a given amount of absorbed heat. We define the **heat capacity** ( $C$ ) of a system as the quantity of heat required to change its temperature by  $1^\circ\text{C}$ . As we can see by solving Equation 6.5 for heat capacity, the units of heat capacity are those of heat (typically J) divided by those of temperature (typically  $^\circ\text{C}$ ):

$$C = \frac{q}{\Delta T} = \frac{\text{J}}{^\circ\text{C}}$$

In order to understand two important concepts related to heat capacity, imagine putting a steel saucepan on a kitchen flame. The saucepan's temperature rises rapidly as it absorbs heat from the flame. However, if you add some water to the saucepan, the temperature rises more slowly. Why? The first reason is that when you add the water, the same amount of heat must now warm more matter, so the temperature rises more slowly. In other words, heat capacity is an extensive property—it *depends on the amount of matter being heated* (see Section 1.6). The second (and more fundamental) reason is that *water is more resistant to temperature change than steel*—water has an intrinsically higher capacity to absorb heat without undergoing a large temperature change. The measure of the *intrinsic capacity* of a substance to absorb heat is its **specific heat capacity** ( $C_s$ ), the amount of heat required to raise the temperature of *1 gram* of the substance by  $1^\circ\text{C}$ . The units of specific heat capacity (also called *specific heat*) are  $\text{J/g} \cdot ^\circ\text{C}$ . Table 6.4 lists the values of the specific heat capacity for several substances. Heat capacity is sometimes reported as **molar heat capacity**, the amount of heat required to raise the temperature of *1 mole* of a substance by  $1^\circ\text{C}$ . The units of molar heat capacity are  $\text{J/mol} \cdot ^\circ\text{C}$ . We can see from these definitions that *specific* heat capacity and *molar* heat capacity are intensive properties—they depend on the *kind* of substance being heated, not on the amount.

Notice that water has the highest specific heat capacity of all the substances in Table 6.4—changing the temperature of water requires a lot of heat. If you have ever experienced the drop in temperature that occurs when traveling from an inland region to the coast during the summer, you have experienced the effects of water's high specific heat capacity. On a summer's day in California, for example, the temperature difference between Sacramento (an inland city) and San Francisco (a coastal city) may be as large as  $18^\circ\text{C}$  ( $30^\circ\text{F}$ )—San Francisco enjoys a cool  $20^\circ\text{C}$  ( $68^\circ\text{F}$ ), while Sacramento bakes at nearly  $38^\circ\text{C}$  ( $100^\circ\text{F}$ ). Yet the intensity of sunlight falling on these two cities is the same. Why the large temperature difference? San Francisco sits on a peninsula, surrounded by the water of the Pacific Ocean. Water, with its high heat capacity, absorbs much of the sun's heat without undergoing a large increase in temperature, keeping San Francisco cool. Sacramento, by contrast, is about 160 km (100 mi) inland. The land surrounding Sacramento, with its low heat capacity, undergoes a large increase in temperature as it absorbs a similar amount of heat.

Similarly, only two U.S. states have never recorded a temperature above  $100^\circ\text{F}$ . One of them is obvious: Alaska. It is too far north to get that hot. The other one, however, may come as a surprise. It is Hawaii. The high heat capacity of the water that surrounds the only island state moderates the temperature, preventing Hawaii from ever getting too hot.

We can use the specific heat capacity of a substance to quantify the relationship between the amount of heat added to a given amount of the substance and the corresponding temperature increase. The following equation relates these quantities:

$$\text{Heat (J)} \rightarrow q = m \times C_s \times \Delta T \quad [6.6]$$

Mass (g)      Specific heat capacity  $\text{J/g} \cdot ^\circ\text{C}$       Temperature change ( $^\circ\text{C}$ )

**TABLE 6.4** Specific Heat Capacities of Some Common Substances

Substance	Specific Heat Capacity, $C_s(\text{J/g} \cdot ^\circ\text{C})^*$
<b>Elements</b>	
Lead	0.128
Gold	0.128
Silver	0.235
Copper	0.385
Iron	0.449
Aluminum	0.903
<b>Compounds</b>	
Ethanol	2.42
Water	4.18
<b>Materials</b>	
Glass (Pyrex)	0.75
Granite	0.79
Sand	0.84

\*At  $298\text{ K}$ .

▲ The high heat capacity of the water surrounding San Francisco results in relatively cool summer temperatures.

$\Delta T$  in  $^{\circ}\text{C}$  is equal to  $\Delta T$  in K, but not equal to  $\Delta T$  in  $^{\circ}\text{F}$  (Section 1.6).

where  $q$  is the amount of heat in J,  $m$  is the mass of the substance in g,  $C_s$  is the specific heat capacity in  $\text{J/g}\cdot^{\circ}\text{C}$ , and  $\Delta T$  is the temperature change in  $^{\circ}\text{C}$ . Example 6.2 demonstrates the use of this equation.

### Example 6.2 Temperature Changes and Heat Capacity

Suppose you find a penny (minted before 1982, when pennies were almost entirely copper) in the snow. How much heat is absorbed by the penny as it warms from the temperature of the snow, which is  $-8.0^{\circ}\text{C}$ , to the temperature of your body,  $37.0^{\circ}\text{C}$ ? Assume the penny is pure copper and has a mass of 3.10 g.

**SORT** You are given the mass of copper as well as its initial and final temperature. You are asked to find the heat required for the given temperature change.

**GIVEN:**  $m = 3.10$  g copper

$$T_i = -8.0^{\circ}\text{C}$$

$$T_f = 37.0^{\circ}\text{C}$$

**FIND:**  $q$

**STRATEGIZE** The equation  $q = m \times C_s \times \Delta T$  gives the relationship between the amount of heat ( $q$ ) and the temperature change ( $\Delta T$ ).

**CONCEPTUAL PLAN**

**RELATIONSHIPS USED**

$$q = m \times C_s \times \Delta T \text{ (Equation 6.6)}$$

$$C_s = 0.385 \text{ J/g}\cdot^{\circ}\text{C} \text{ (Table 6.4)}$$

**SOLVE** Gather the necessary quantities for the equation in the correct units and substitute into the equation to calculate  $q$ .

**SOLUTION**

$$\Delta T = T_f - T_i = 37.0^{\circ}\text{C} - (-8.0^{\circ}\text{C}) = 45.0^{\circ}\text{C}$$

$$q = m \times C_s \times \Delta T$$

$$= 3.10 \text{ g} \times 0.385 \frac{\text{J}}{\text{g}\cdot^{\circ}\text{C}} \times 45.0^{\circ}\text{C} = 53.7 \text{ J}$$

**CHECK** The units (J) are correct for heat. The sign of  $q$  is *positive*, as it should be because the penny *absorbed* heat from the surroundings.

**FOR PRACTICE 6.2** To determine whether a shiny gold-colored rock is actually gold, a chemistry student decides to measure its heat capacity. She first weighs the rock and finds it has a mass of 4.7 g. She then finds that upon absorption of 57.2 J of heat, the temperature of the rock rises from  $25^{\circ}\text{C}$  to  $57^{\circ}\text{C}$ . Find the specific heat capacity of the substance composing the rock and determine whether the value is consistent with the rock being pure gold.

**FOR MORE PRACTICE 6.2** A 55.0-g aluminum block initially at  $27.5^{\circ}\text{C}$  absorbs 725 J of heat. What is the final temperature of the aluminum?

### CONCEPTUAL CONNECTION 6.3

**The Heat Capacity of Water** Suppose you are cold-weather camping and decide to heat some objects to bring into your sleeping bag for added warmth. You place a large water jug and a rock of equal mass near the fire. Over time, both the rock and the water jug warm to about  $38^{\circ}\text{C}$  ( $100^{\circ}\text{F}$ ). If you could bring only one into your sleeping bag, which one should you choose to keep you the warmer? Why?

## Thermal Energy Transfer

As we noted earlier, when two substances of different temperature are combined, thermal energy flows as heat from the hotter substance to the cooler one. If we assume that the two substances are thermally isolated from everything else, then the heat lost by one substance exactly equals the heat gained by the other (according to the law of energy conservation). If we define one substance as the system and the other as the surroundings, we can quantify the heat exchange as:

$$q_{\text{sys}} = -q_{\text{surr}}$$

Suppose a block of metal initially at 55 °C is submerged into water initially at 25 °C. Thermal energy transfers as heat from the metal to the water:

The metal becomes colder and the water becomes warmer until the two substances reach the same temperature (thermal equilibrium). The exact temperature change that occurs depends on the masses of the metal and the water and on their specific heat capacities. Since  $q = m \times C_s \times \Delta T$ , we can arrive at the following relationship:

$$q_{\text{metal}} = -q_{\text{water}}$$

$$m_{\text{metal}} \times C_{s, \text{metal}} \times \Delta T_{\text{metal}} = -m_{\text{water}} \times C_{s, \text{water}} \times \Delta T_{\text{water}}$$

Example 6.3 shows how to work with thermal energy transfer.

### Example 6.3 Thermal Energy Transfer

A 32.5 g cube of aluminum initially at 45.8 °C is submerged into 105.3 g of water at 15.4 °C. What is the final temperature of both substances at thermal equilibrium? (Assume that the aluminum and the water are thermally isolated from everything else.)

**SORT** You are given the masses of aluminum and water and their initial temperatures. You are asked to find the final temperature.

**STRATEGIZE** The heat lost by the aluminum ( $q_{\text{Al}}$ ) equals the heat gained by the water ( $q_{\text{H}_2\text{O}}$ ).

Use the relationship between  $q$  and  $\Delta T$  and the given variables to find a relationship between  $\Delta T_{\text{Al}}$  and  $\Delta T_{\text{H}_2\text{O}}$ .

Use the relationship between  $\Delta T_{\text{Al}}$  and  $\Delta T_{\text{H}_2\text{O}}$  (that you just found) along with the initial temperatures of the aluminum and the water to determine the final temperature. Note that at thermal equilibrium, the final temperature of the aluminum and the water is the same, that is,  $T_{\text{f, Al}} = T_{\text{f, H}_2\text{O}} = T_{\text{f}}$ .

**GIVEN:**  $m_{\text{Al}} = 32.5 \text{ g}$   $m_{\text{H}_2\text{O}} = 105.3 \text{ g}$   
 $T_{\text{i, Al}} = 45.8 \text{ °C}$ ;  $T_{\text{i, H}_2\text{O}} = 15.4 \text{ °C}$

**FIND:**  $T_{\text{f}}$

**CONCEPTUAL PLAN**  $q_{\text{Al}} = -q_{\text{H}_2\text{O}}$

$$m_{\text{Al}} C_{s, \text{Al}} \Delta T_{\text{Al}} = -m_{\text{H}_2\text{O}} C_{s, \text{H}_2\text{O}} \Delta T_{\text{H}_2\text{O}}$$

$$\Delta T_{\text{Al}} = \text{constant} \times \Delta T_{\text{H}_2\text{O}}$$

$$T_{\text{i, Al}}; T_{\text{i, H}_2\text{O}} \rightarrow T_{\text{f}}$$

$$\Delta T_{\text{Al}} = \text{constant} \times \Delta T_{\text{H}_2\text{O}}$$

**RELATIONSHIPS USED**

$C_{s, \text{H}_2\text{O}} = 4.18 \text{ J/g} \cdot \text{°C}$ ;  $C_{s, \text{Al}} = 0.903 \text{ J/g} \cdot \text{°C}$  (Table 6.4)

$q = m \times C_s \times \Delta T$  (Equation 6.6)

—Continued on the next page

—Continued

**SOLVE**

Write the equation for the relationship between the heat lost by the aluminum ( $q_{\text{Al}}$ ) and the heat gained by the water  $q_{\text{Al}} = -q_{\text{H}_2\text{O}}$  and substitute  $q = m \times C_s \times \Delta T$  for each substance.

Substitute the values of  $m$  (given) and  $C_s$  (from Table 6.4) for each substance and solve the equation for  $\Delta T_{\text{Al}}$ . (Alternatively, you can solve the equation for  $\Delta T_{\text{H}_2\text{O}}$ .)

Substitute the initial temperatures of aluminum and water into the relationship from the previous step and solve the expression for the final temperature ( $T_f$ ). Remember that the final temperature for both substances will be the same.

**SOLUTION**

$$q_{\text{Al}} = -q_{\text{H}_2\text{O}}$$

$$m_{\text{Al}} \times C_{s,\text{Al}} \times \Delta T_{\text{Al}} = -m_{\text{H}_2\text{O}} \times C_{s,\text{H}_2\text{O}} \times \Delta T_{\text{H}_2\text{O}}$$

$$32.5 \text{ g} \times \frac{0.903 \text{ J}}{\text{g} \cdot ^\circ\text{C}} \cdot \Delta T_{\text{Al}} = -105.3 \text{ g} \times \frac{4.18 \text{ J}}{\text{g} \cdot ^\circ\text{C}} \cdot \Delta T_{\text{H}_2\text{O}}$$

$$29.348 \cdot \Delta T_{\text{Al}} = -440.15 \cdot \Delta T_{\text{H}_2\text{O}}$$

$$\Delta T_{\text{Al}} = -14.998 \cdot \Delta T_{\text{H}_2\text{O}}$$

$$T_f - T_{i,\text{Al}} = -14.998(T_f - T_{i,\text{H}_2\text{O}})$$

$$T_f = -14.998 \cdot T_f + 14.998 \cdot T_{i,\text{H}_2\text{O}} + T_{i,\text{Al}}$$

$$T_f + 14.998 \cdot T_f = 14.998 \cdot T_{i,\text{H}_2\text{O}} + T_{i,\text{Al}}$$

$$15.998 \cdot T_f = 14.998 \cdot T_{i,\text{H}_2\text{O}} + T_{i,\text{Al}}$$

$$T_f = \frac{14.998 \cdot T_{i,\text{H}_2\text{O}} + T_{i,\text{Al}}}{15.998} = \frac{14.998 \cdot 15.4^\circ\text{C} + 45.8^\circ\text{C}}{15.998}$$

$$= 17.3^\circ\text{C}$$

**CHECK** The units  $^\circ\text{C}$  are correct. The final temperature of the mixture is closer to the initial temperature of the *water* than the *aluminum*. This makes sense for two reasons: (1) water has a higher specific heat capacity than aluminum, and (2) there is more water than aluminum. Because the aluminum loses the same amount of heat that is gained by the water, the greater mass and specific heat capacity of the water make the temperature change in the water *less than* the temperature change in the aluminum.

**FOR PRACTICE 6.3** A block of copper of unknown mass has an initial temperature of  $65.4^\circ\text{C}$ . The copper is immersed in a beaker containing  $95.7 \text{ g}$  of water at  $22.7^\circ\text{C}$ . When the two substances reach thermal equilibrium, the final temperature is  $24.2^\circ\text{C}$ . What is the mass of the copper block?

## CONCEPTUAL CONNECTION 6.4

**Thermal Energy Transfer** Substances A and B, initially at different temperatures, come in contact with each other and reach thermal equilibrium. The mass of substance A is twice the mass of substance B. The specific heat capacity of substance B is twice the specific heat capacity of substance A. Which statement is true about the final temperature of the two substances once thermal equilibrium is reached?

- (a) The final temperature is closer to the initial temperature of substance A than it is to the initial temperature of substance B.
- (b) The final temperature is closer to the initial temperature of substance B than it is to the initial temperature of substance A.
- (c) The final temperature is exactly midway between the initial temperatures of substances A and B.

## Work: Pressure–Volume Work

We have seen that energy transfer between a system and its surroundings can occur via heat ( $q$ ) or work ( $w$ ). We just calculated the *heat* associated with an observed *temperature* change. We now turn to calculating the *work* associated with an observed *volume* change. Although a chemical reaction can do several different types of work, for now we limit our discussion to **pressure–volume work**. We have already defined work as a force acting through a distance. Pressure–volume work occurs when the force is caused by a volume change against an external pressure. For example, pressure–volume work occurs in the cylinder of an automobile engine. The combustion of gasoline causes gases

within the cylinders to expand, pushing the piston outward and ultimately moving the wheels of the car.

We can derive an equation for the value of pressure–volume work from the definition of work as a force ( $F$ ) acting through a distance ( $D$ ):

$$w = F \times D \quad [6.7]$$

When the volume of a cylinder increases (Figure 6.7▼), it pushes against an external force. That external force is the external pressure ( $P_{\text{ext}}$ ), which is defined as force ( $F$ ) divided by area ( $A$ ):

$$P_{\text{ext}} = \frac{F}{A} \quad \text{or} \quad F = P_{\text{ext}} \times A$$

If we substitute this expression for force into the definition of work given in Equation 6.7, we arrive at the expression:

$$\begin{aligned} w &= F \times D \\ &= P_{\text{ext}} \times A \times D \end{aligned}$$

The distance through which the force acts is the change in the height of the piston as it moves during the expansion ( $\Delta h$ ). Substituting  $\Delta h$  for  $D$ , we get:

$$w = P_{\text{ext}} \times A \times \Delta h$$

The volume of a cylinder is the area of its base times its height, so  $A \times \Delta h$  is actually the change in volume ( $\Delta V$ ) that occurs during the expansion. Thus, the expression for work becomes the product of the pressure times the change in volume:

$$w = P_{\text{ext}} \Delta V$$

Still missing from the equation is the *sign* of the work done by the expanding gases. As the volume of the cylinder increases, work is done *on* the surroundings *by* the system, so  $w$  should be negative. However, upon expansion,  $V_2$  (the final volume) is greater than  $V_1$  (the initial volume) so  $\Delta V$  is positive. In order for  $w$  to be negative for a positive expansion, we need to add a negative sign to our equation. In other words,  $w$  and  $\Delta V$  must be opposite in sign:

$$w = -P_{\text{ext}} \Delta V \quad [6.8]$$

So the work caused by an expansion of volume is the negative of the pressure that the volume expands against multiplied by the change in volume that occurs during the expansion. The units of the work obtained by using this equation are those of pressure (usually atm) multiplied by those of volume (usually L). To convert between  $\text{L} \cdot \text{atm}$  and J, we use the conversion factor  $101.3 \text{ J} = 1 \text{ L} \cdot \text{atm}$ .

▲ The combustion of gasoline within an engine's cylinders does pressure–volume work that ultimately results in the motion of the car.

The force in this equation must be a constant force.

▲ FIGURE 6.7 Piston Moving within a Cylinder against an External Pressure

**Example 6.4** Pressure–Volume Work

To inflate a balloon you must do pressure–volume work on the surroundings. If you inflate a balloon from a volume of 0.100 L to 1.85 L against an external pressure of 1.00 atm, how much work is done (in joules)?

**SORT** You know the initial and final volumes of the balloon and the pressure against which it expands. The balloon and its contents are the system.

**GIVEN:**  $V_1 = 0.100 \text{ L}$   
 $V_2 = 1.85 \text{ L}$   
 $P = 1.00 \text{ atm}$

**FIND:**  $w$

**STRATEGIZE** The equation  $w = -P_{\text{ext}} \Delta V$  specifies the amount of work done during a volume change against an external pressure.

**CONCEPTUAL PLAN**

**SOLVE** To solve the problem, calculate the value of  $\Delta V$  and substitute it, together with  $P_{\text{ext}}$ , into the equation.

**SOLUTION**

$$\begin{aligned}\Delta V &= V_2 - V_1 \\ &= 1.85 \text{ L} - 0.100 \text{ L} \\ &= 1.75 \text{ L} \\ w &= -P_{\text{ext}} \Delta V \\ &= -1.00 \text{ atm} \times 1.75 \text{ L} \\ &= -1.75 \text{ L} \cdot \text{atm}\end{aligned}$$

Convert the units of the answer ( $\text{L} \cdot \text{atm}$ ) to joules using  $101.3 \text{ J} = 1 \text{ L} \cdot \text{atm}$ .

$$-1.75 \text{ L} \cdot \text{atm} \times \frac{101.3 \text{ J}}{1 \text{ L} \cdot \text{atm}} = -177 \text{ J}$$

**CHECK** The units (J) are correct for work. The sign of the work is negative, as it should be for an expansion: work is done on the surroundings by the expanding balloon.

**FOR PRACTICE 6.4** A cylinder equipped with a piston expands against an external pressure of 1.58 atm. If the initial volume is 0.485 L and the final volume is 1.245 L, how much work (in J) is done?

**FOR MORE PRACTICE 6.4** When fuel is burned in a cylinder equipped with a piston, the volume expands from 0.255 L to 1.45 L against an external pressure of 1.02 atm. In addition, 875 J is emitted as heat. What is  $\Delta E$  for the burning of the fuel?

## 6.5 Measuring $\Delta E$ for Chemical Reactions: Constant-Volume Calorimetry

We now have a complete picture of how a system exchanges energy with its surroundings via heat and pressure–volume work:

Recall from Section 6.3 that the change in internal energy that occurs during a chemical reaction ( $\Delta E$ ) is a measure of *all of the energy* (heat and work) exchanged with the surroundings ( $\Delta E = q + w$ ). Therefore, we can measure the changes in temperature (to

calculate heat) and the changes in volume (to calculate work) that occur during a chemical reaction, and then sum them together to calculate  $\Delta E$ . However, an easier way to obtain the value of  $\Delta E$  for a chemical reaction is to force all of the energy change associated with a reaction to manifest itself as heat rather than work. We can then measure the temperature change caused by the heat flow.

Recall that  $\Delta E = q + w$  and that  $w = -P_{\text{ext}} \Delta V$ . If a reaction is carried out at constant volume, then  $\Delta V = 0$  and  $w = 0$ . The heat evolved (or given off), called the *heat at constant volume* ( $q_v$ ), is then equal to  $\Delta E_{\text{rxn}}$ :

$$\Delta E_{\text{rxn}} = q_v + w \quad \begin{array}{l} \text{Equals zero} \\ \text{at constant volume} \end{array}$$

$$\Delta E_{\text{rxn}} = q_v \quad [6.9]$$

We can measure the heat evolved in a chemical reaction using *calorimetry*. In **calorimetry**, we measure the thermal energy exchanged between the reaction (defined as the system) and the surroundings by observing the change in temperature of the surroundings:

The magnitude of the temperature change in the surroundings depends on the magnitude of  $\Delta E$  for the reaction and on the heat capacity of the surroundings.

Figure 6.8 shows a **bomb calorimeter**, a piece of equipment that measures  $\Delta E$  for combustion reactions. In a bomb calorimeter, the reaction occurs in a sealed container called a *bomb*, which ensures that the reaction occurs at constant volume. To use a bomb calorimeter, we put the sample to be burned (of known mass) into a cup equipped with an ignition wire. We then seal the cup into the bomb, which is filled with oxygen gas, and place the bomb in a water-filled, insulated container. The container is equipped with a stirrer and a thermometer. Finally, we ignite the sample with a wire coil and monitor the temperature with the thermometer. The temperature change ( $\Delta T$ ) is related to the heat absorbed by the entire calorimeter assembly ( $q_{\text{cal}}$ ) by the equation:

$$q_{\text{cal}} = C_{\text{cal}} \times \Delta T \quad [6.10]$$

where  $C_{\text{cal}}$  is the heat capacity of the entire calorimeter assembly (which is usually determined in a separate measurement involving the burning of a substance that gives off a known amount of heat). If no heat escapes from the calorimeter, the amount of heat *gained* by the calorimeter exactly equals that *released* by the reaction (the two are equal in magnitude but opposite in sign):

$$q_{\text{cal}} = -q_{\text{rxn}} \quad [6.11]$$

Since the reaction occurs under conditions of constant volume,  $q_{\text{rxn}} = q_v = \Delta E_{\text{rxn}}$ . This measured quantity is the change in the internal energy of the reaction for the specific amount of reactant burned. To get  $\Delta E_{\text{rxn}}$  per mole of a particular reactant—a more general quantity—we divide by the number of moles that actually reacted, as demonstrated in Example 6.5.

**FIGURE 6.8 The Bomb Calorimeter** A bomb calorimeter measures changes in internal energy for combustion reactions.

The heat capacity of the calorimeter,  $C_{\text{cal}}$ , has units of energy over temperature; its value accounts for all of the heat absorbed by all of the components within the calorimeter (including the water).

**Example 6.5** Measuring  $\Delta E_{\text{rxn}}$  in a Bomb Calorimeter

When 1.010 g of sucrose ( $\text{C}_{12}\text{H}_{22}\text{O}_{11}$ ) undergoes combustion in a bomb calorimeter, the temperature rises from 24.92 °C to 28.33 °C. Find  $\Delta E_{\text{rxn}}$  for the combustion of sucrose in kJ/mol sucrose. The heat capacity of the bomb calorimeter, determined in a separate experiment, is 4.90 kJ/°C. (You can ignore the heat capacity of the small sample of sucrose because it is negligible compared to the heat capacity of the calorimeter.)

**SORT** You are given the mass of sucrose, the heat capacity of the calorimeter, and the initial and final temperatures. You are asked to find the change in internal energy for the reaction.

**GIVEN:** 1.010 g  $\text{C}_{12}\text{H}_{22}\text{O}_{11}$   
 $T_i = 24.92\text{ }^{\circ}\text{C}$   
 $T_f = 28.33\text{ }^{\circ}\text{C}$   
 $C_{\text{cal}} = 4.90\text{ kJ}/^{\circ}\text{C}$

**FIND:**  $\Delta E_{\text{rxn}}$

**STRATEGIZE** The conceptual plan has three parts. In the first part, use the temperature change and the heat capacity of the calorimeter to find  $q_{\text{cal}}$ .

In the second part, use  $q_{\text{cal}}$  to get  $q_{\text{rxn}}$  (which just involves changing the sign). Since the bomb calorimeter ensures constant volume,  $q_{\text{rxn}}$  is equivalent to  $\Delta E_{\text{rxn}}$  for the amount of sucrose burned.

In the third part, divide  $q_{\text{rxn}}$  by the number of moles of sucrose to determine  $\Delta E_{\text{rxn}}$  per mole of sucrose.

**CONCEPTUAL PLAN**

$$\Delta E_{\text{rxn}} = \frac{q_{\text{rxn}}}{\text{mol C}_{12}\text{H}_{22}\text{O}_{11}}$$

**RELATIONSHIPS USED**

$$q_{\text{cal}} = C_{\text{cal}} \times \Delta T = -q_{\text{rxn}}$$

$$\text{molar mass C}_{12}\text{H}_{22}\text{O}_{11} = 342.3\text{ g/mol}$$

**SOLVE** Gather the necessary quantities in the correct units and substitute these into the equation to calculate  $q_{\text{cal}}$ .

Find  $q_{\text{rxn}}$  by taking the negative of  $q_{\text{cal}}$ .

Find  $\Delta E_{\text{rxn}}$  per mole of sucrose by dividing  $q_{\text{rxn}}$  by the number of moles of sucrose (calculated from the given mass of sucrose and its molar mass).

**SOLUTION**

$$\begin{aligned}\Delta T &= T_f - T_i \\ &= 28.33\text{ }^{\circ}\text{C} - 24.92\text{ }^{\circ}\text{C} = 3.41\text{ }^{\circ}\text{C}\end{aligned}$$

$$q_{\text{cal}} = C_{\text{cal}} \times \Delta T$$

$$q_{\text{cal}} = 4.90 \frac{\text{kJ}}{^{\circ}\text{C}} \times 3.41\text{ }^{\circ}\text{C} = 16.7\text{ kJ}$$

$$q_{\text{rxn}} = -q_{\text{cal}} = -16.7\text{ kJ}$$

$$\begin{aligned}\Delta E_{\text{rxn}} &= \frac{q_{\text{rxn}}}{\text{mol C}_{12}\text{H}_{22}\text{O}_{11}} \\ &= \frac{-16.7\text{ kJ}}{1.010\text{ g C}_{12}\text{H}_{22}\text{O}_{11} \times \frac{1\text{ mol C}_{12}\text{H}_{22}\text{O}_{11}}{342.3\text{ g C}_{12}\text{H}_{22}\text{O}_{11}}} \\ &= -5.66 \times 10^3\text{ kJ/mol C}_{12}\text{H}_{22}\text{O}_{11}\end{aligned}$$

**CHECK** The units of the answer (kJ) are correct for a change in internal energy. The sign of  $\Delta E_{\text{rxn}}$  is negative, as it should be for a combustion reaction that gives off energy.

**FOR PRACTICE 6.5** When 1.550 g of liquid hexane ( $\text{C}_6\text{H}_{14}$ ) undergoes combustion in a bomb calorimeter, the temperature rises from 25.87 °C to 38.13 °C. Find  $\Delta E_{\text{rxn}}$  for the reaction in kJ/mol hexane. The heat capacity of the bomb calorimeter, determined in a separate experiment, is 5.73 kJ/°C.

**FOR MORE PRACTICE 6.5** The combustion of toluene has a  $\Delta E_{\text{rxn}}$  of  $-3.91 \times 10^3\text{ kJ/mol}$ . When 1.55 g of toluene ( $\text{C}_7\text{H}_8$ ) undergoes combustion in a bomb calorimeter, the temperature rises from 23.12 °C to 37.57 °C. Find the heat capacity of the bomb calorimeter.

## 6.6 Enthalpy: The Heat Evolved in a Chemical Reaction at Constant Pressure

The Change in Enthalpy for a Chemical Reaction

We have just seen that when a chemical reaction occurs in a sealed container under conditions of constant volume, the energy evolves only as heat. However, when a chemical reaction occurs open to the atmosphere under conditions of constant pressure—such as a reaction occurring in an open beaker or the burning of natural gas on a stove—the energy can evolve as both heat and work. As we have also seen,  $\Delta E_{\text{rxn}}$  is a measure of the *total energy change* (both heat and work) that occurs during the reaction. However, in many cases, we are interested only in the heat exchanged, not the work done. For example, when we burn natural gas on a stove to cook food, we do not really care how much work the combustion reaction does on the atmosphere by expanding against it—we just want to know how much heat is given off to cook the food. Under conditions of constant pressure, a thermodynamic quantity called *enthalpy* represents exactly this.

We define the **enthalpy ( $H$ )** of a system as the sum of its internal energy and the product of its pressure and volume:

$$H = E + PV \quad [6.12]$$

Since internal energy, pressure, and volume are all state functions, enthalpy is also a state function. The *change in enthalpy* ( $\Delta H$ ) for any process occurring under constant pressure is given by the expression:

$$\Delta H = \Delta E + P \Delta V \quad [6.13]$$

To better understand this expression, we can interpret the two terms on the right with the help of relationships already familiar to us. We saw previously that  $\Delta E = q + w$ . If we represent the heat at constant pressure as  $q_p$ , then the change in internal energy at constant pressure is  $\Delta E = q_p + w$ . In addition, from our definition of pressure-volume work, we know that  $P_{\text{ext}} \Delta V = -w$ . Substituting these expressions into the expression for  $\Delta H$  gives us the following expression:

$$\begin{aligned} \Delta H &= \Delta E + P \Delta V \\ &= (q_p + w) + P \Delta V \\ &= q_p + w - w \\ \Delta H &= q_p \end{aligned} \quad [6.14]$$

We can see that  $\Delta H$  is equal to  $q_p$ , the heat at constant pressure.

Conceptually (and often numerically),  $\Delta H$  and  $\Delta E$  are similar: they both represent changes in a state function for the system. However,  $\Delta E$  is a measure of *all of the energy* (heat and work) exchanged with the surroundings, while  $\Delta H$  is a measure of only the heat exchanged under conditions of constant pressure. For chemical reactions that do not exchange much work with the surroundings—that is, those that do not cause a large change in reaction volume as they occur— $\Delta H$  and  $\Delta E$  are nearly identical in value. For chemical reactions that produce or consume large amounts of gas, and therefore result in large volume changes,  $\Delta H$  and  $\Delta E$  may differ slightly in value.

**The Difference between  $\Delta H$  and  $\Delta E$**  Lighters are usually fueled by butane ( $\text{C}_4\text{H}_{10}$ ). When 1 mol of butane burns at constant pressure, it produces 2658 kJ of heat and does 3 kJ of work. What are the values of  $\Delta H$  and  $\Delta E$  for the combustion of one mole of butane?

CONCEPTUAL  
CONNECTION 6.5

The signs of  $\Delta H$  and  $\Delta E$  follow the same conventions. A positive  $\Delta H$  indicates that heat flows into the system as the reaction occurs. A chemical reaction with a positive  $\Delta H$ , called an **endothermic reaction**, absorbs heat from its surroundings.

► The reaction that occurs in a chemical cold pack is endothermic—it absorbs energy from the surroundings. The combustion of natural gas is an exothermic reaction—it releases energy to the surroundings.

The reaction that occurs in a chemical cold pack, often used to ice athletic injuries, is a good example of an endothermic reaction. When you break the barrier separating the reactants in a chemical cold pack, the substances mix, react, and absorb heat from the surroundings. The surroundings—including, say, your bruised wrist—get *colder* because they *lose* energy as the cold pack absorbs it.

A chemical reaction with a negative  $\Delta H$ , called an **exothermic reaction**, gives off heat to its surroundings. The reaction that occurs in the chemical hand warmer discussed in Section 6.1 is a good example of an exothermic reaction. When the reaction takes place, heat is given off into the surroundings (including your hand and glove), making them warmer. The burning of natural gas is another exothermic reaction. As the gas burns, it gives off energy, raising the temperature of its surroundings.

#### Summarizing Enthalpy:

- The value of  $\Delta H$  for a chemical reaction is the amount of heat absorbed or evolved in the reaction under conditions of constant pressure.
- An endothermic reaction has a *positive*  $\Delta H$  and absorbs heat from the surroundings. An endothermic reaction feels cold to the touch.
- An exothermic reaction has a *negative*  $\Delta H$  and gives off heat to the surroundings. An exothermic reaction feels warm to the touch.

### Example 6.6 Exothermic and Endothermic Processes

Identify each process as endothermic or exothermic and indicate the sign of  $\Delta H$ .

- (a) sweat evaporating from skin
- (b) water freezing in a freezer
- (c) wood burning in a fire

#### SOLUTION

- (a) Sweat evaporating from skin cools the skin and is therefore endothermic, with a positive  $\Delta H$ . The skin must supply heat to the perspiration in order for it to continue to evaporate.
- (b) Water freezing in a freezer releases heat and is therefore exothermic, with a negative  $\Delta H$ . The refrigeration system in the freezer must remove this heat for the water to continue to freeze.
- (c) Wood burning in a fire releases heat and is therefore exothermic, with a negative  $\Delta H$ .

**FOR PRACTICE 6.6** Identify each process as endothermic or exothermic and indicate the sign of  $\Delta H$ .

- (a) an ice cube melting
- (b) nail polish remover quickly evaporating after it is accidentally spilled on the skin
- (c) gasoline burning within the cylinder of an automobile engine

## Exothermic and Endothermic Processes: A Molecular View

When a chemical system undergoes a change in enthalpy, where does the energy come from or go to? For example, we just saw that an exothermic chemical reaction gives off *thermal energy*—what is the source of that energy?

First, we know that the emitted thermal energy *does not* come from the original thermal energy of the system. Recall from Section 6.2 that the thermal energy of a system is the total kinetic energy of the atoms and molecules that compose the system. This kinetic energy *cannot* be the source of the energy given off in an exothermic reaction because if the atoms and molecules that compose the system were to lose kinetic energy, their temperature would necessarily fall—the system would get colder. Yet we know that in exothermic reactions, the temperature of the system and the surroundings rises. So there must be some other source of energy.

Recall also from Section 6.2 that the internal energy of a chemical system is the sum of its kinetic energy and its *potential energy*. This potential energy is the source in an exothermic chemical reaction. Under normal circumstances, chemical potential energy (or simply chemical energy) arises primarily from the electrostatic forces between the protons and electrons that compose the atoms and molecules within the system. In an exothermic reaction, some bonds break and new ones form, and the nuclei and electrons reorganize into an arrangement with lower potential energy. As the molecules rearrange, their potential energy converts into thermal energy, the heat emitted in the reaction. Note that breaking bonds always *absorbs* energy. In an exothermic reaction, weak bonds break and stronger bonds form. It only takes a small amount of energy to break the weak bonds and a greater amount is given off when the stronger bonds form, resulting in net energy production. In an endothermic reaction, the opposite happens: strong bonds break and weak ones form. The nuclei and electrons reorganize into an arrangement with higher potential energy, absorbing thermal energy in the process.

**Exothermic and Endothermic Reactions** If an endothermic reaction absorbs heat, then why does it feel cold to the touch?

CONCEPTUAL  
CONNECTION 6.6

## Stoichiometry Involving $\Delta H$ : Thermochemical Equations

The enthalpy change for a chemical reaction, abbreviated  $\Delta H_{\text{rxn}}$ , is also called the **enthalpy of reaction** or **heat of reaction** and depends on the amount of material undergoing the reaction. In other words, the amount of heat generated or absorbed when a chemical reaction occurs depends on the *amounts* of reactants that actually react. We usually specify  $\Delta H_{\text{rxn}}$  in combination with the balanced chemical equation for the reaction. *The magnitude of  $\Delta H_{\text{rxn}}$  reflects the stoichiometric amounts of reactants and products for the reaction as written.* For example, consider the balanced equation and  $\Delta H_{\text{rxn}}$  for the combustion of propane, the main component of LP gas:

The equation tells us that when 1 mol of  $\text{C}_3\text{H}_8$  reacts with 5 mol of  $\text{O}_2$  to form 3 mol of  $\text{CO}_2$  and 4 mol of  $\text{H}_2\text{O}$ , 2044 kJ of heat is emitted. We can write these relationships in the same way that we expressed stoichiometric relationships in Chapter 4, as ratios between two quantities. For example, for the reactants, we write the following ratios:

$$1 \text{ mol C}_3\text{H}_8 : -2044 \text{ kJ} \quad \text{or} \quad 5 \text{ mol O}_2 : -2044 \text{ kJ}$$

The ratios indicate that 2044 kJ of heat evolves when 1 mol of  $\text{C}_3\text{H}_8$  and 5 mol of  $\text{O}_2$  completely react. We can use these ratios to construct conversion factors between amounts of reactants or products and the quantity of heat emitted (for exothermic reactions) or

absorbed (for endothermic reactions). To find out how much heat is emitted upon the combustion of a certain mass in grams of  $\text{C}_3\text{H}_8$ , we work with the following conceptual plan:

We use the molar mass to convert between grams and moles, and the stoichiometric relationship between moles of  $\text{C}_3\text{H}_8$  and the heat of reaction to convert between moles and kilojoules, as demonstrated in Example 6.7.

### Example 6.7 Stoichiometry Involving $\Delta H$

An LP gas tank in a home barbeque contains 13.2 kg of propane,  $\text{C}_3\text{H}_8$ . Calculate the heat (in kJ) associated with the complete combustion of all of the propane in the tank.

**SORT** You are given the mass of propane and asked to find the heat evolved in its combustion.

**GIVEN:** 13.2 kg  $\text{C}_3\text{H}_8$

**FIND:**  $q$

**STRATEGIZE** Starting with kg  $\text{C}_3\text{H}_8$ , convert to g  $\text{C}_3\text{H}_8$  and then use the molar mass of  $\text{C}_3\text{H}_8$  to find the number of moles. Next, use the stoichiometric relationship between mol  $\text{C}_3\text{H}_8$  and kJ to determine the heat evolved.

#### CONCEPTUAL PLAN

#### RELATIONSHIPS USED

1000 g = 1 kg

molar mass  $\text{C}_3\text{H}_8 = 44.09 \text{ g/mol}$

1 mol  $\text{C}_3\text{H}_8$  : -2044 kJ (from balanced equation)

**SOLVE** Follow the conceptual plan to solve the problem. Begin with 13.2 kg  $\text{C}_3\text{H}_8$  and multiply by the appropriate conversion factors to arrive at kJ.

#### SOLUTION

$$13.2 \text{ kg C}_3\text{H}_8 \times \frac{1000 \text{ g}}{1 \text{ kg}} \times \frac{1 \text{ mol C}_3\text{H}_8}{44.09 \text{ g C}_3\text{H}_8} \times \frac{-2044 \text{ kJ}}{1 \text{ mol C}_3\text{H}_8} = -6.12 \times 10^5 \text{ kJ}$$

**CHECK** The units of the answer (kJ) are correct for energy. The answer is negative, as it should be for heat evolved by the reaction.

**FOR PRACTICE 6.7** Ammonia reacts with oxygen according to the equation:

Calculate the heat (in kJ) associated with the complete reaction of 155 g of  $\text{NH}_3$ .

**FOR MORE PRACTICE 6.7** What mass of butane in grams is necessary to produce  $1.5 \times 10^3 \text{ kJ}$  of heat? What mass of  $\text{CO}_2$  is produced?

## 6.7 Constant-Pressure Calorimetry: Measuring $\Delta H_{\text{rxn}}$

For many aqueous reactions, we can measure  $\Delta H_{\text{rxn}}$  fairly simply using a **coffee-cup calorimeter** shown in Figure 6.9. The calorimeter consists of two Styrofoam coffee cups, one inserted into the other, to provide insulation from the laboratory environment.

The calorimeter is equipped with a thermometer and a stirrer. The reaction occurs in a specifically measured quantity of solution within the calorimeter, so that the mass of the solution is known. During the reaction, the heat evolved (or absorbed) causes a temperature change in the solution, which the thermometer measures. If we know the specific heat capacity of the solution, normally assumed to be that of water, we can calculate  $q_{\text{soln}}$ , the heat absorbed by or lost from the solution (which is acting as the surroundings) using the equation:

$$q_{\text{soln}} = m_{\text{soln}} \times C_{\text{s, soln}} \times \Delta T$$

The insulated calorimeter prevents heat from escaping, so we assume that the heat gained by the solution equals that lost by the reaction (or vice versa):

$$q_{\text{rxn}} = -q_{\text{soln}}$$

Because the reaction happens under conditions of constant pressure (open to the atmosphere),  $q_{\text{rxn}} = q_p = \Delta H_{\text{rxn}}$ . This measured quantity is the heat of reaction for the specific amount (which is measured ahead of time) of reactants that react. To find  $\Delta H_{\text{rxn}}$  per mole of a particular reactant—a more general quantity—we divide by the number of moles that actually reacted, as demonstrated in Example 6.8.

#### Summarizing Calorimetry:

- ▶ Bomb calorimetry occurs at constant *volume* and measures  $\Delta E$  for a reaction.
- ▶ Coffee-cup calorimetry occurs at constant *pressure* and measures  $\Delta H$  for a reaction.

### The Coffee-Cup Calorimeter

**FIGURE 6.9 The Coffee-Cup Calorimeter** A coffee-cup calorimeter measures enthalpy changes for chemical reactions in solution.

The equation,  $q_{\text{rxn}} = -q_{\text{soln}}$ , assumes that no heat is lost to the calorimeter itself. If heat absorbed by the calorimeter is accounted for, the equation becomes  $q_{\text{rxn}} = -(q_{\text{soln}} + q_{\text{cal}})$ .

### Example 6.8 Measuring $\Delta H_{\text{rxn}}$ in a Coffee-Cup Calorimeter

Magnesium metal reacts with hydrochloric acid according to the balanced equation:

In an experiment to determine the enthalpy change for this reaction, 0.158 g of Mg metal is combined with enough HCl to make 100.0 mL of solution in a coffee-cup calorimeter. The HCl is sufficiently concentrated so that the Mg completely reacts. The temperature of the solution rises from 25.6 °C to 32.8 °C as a result of the reaction. Find  $\Delta H_{\text{rxn}}$  for the reaction as written. Use 1.00 g/mL as the density of the solution and  $C_{\text{s, soln}} = 4.18 \text{ J/g} \cdot ^\circ\text{C}$  as the specific heat capacity of the solution.

**SORT** You are given the mass of magnesium, the volume of solution, the initial and final temperatures, the density of the solution, and the heat capacity of the solution. You are asked to find the change in enthalpy for the reaction.

**GIVEN:** 0.158 g Mg  
100.0 mL soln  
 $T_i = 25.6^\circ\text{C}$   
 $d = 1.00 \text{ g/mL}$   
 $T_f = 32.8^\circ\text{C}$   
 $C_{\text{s, soln}} = 4.18 \text{ J/g} \cdot ^\circ\text{C}$

**FIND:**  $\Delta H_{\text{rxn}}$

**STRATEGIZE** The conceptual plan has three parts. In the first part, use the temperature change and the other given quantities, together with the equation  $q = m \times C_s \times \Delta T$ , to find  $q_{\text{soln}}$ .

#### CONCEPTUAL PLAN

$$\Delta H_{\text{rxn}} = \frac{q_{\text{rxn}}}{\text{mol Mg}}$$

#### RELATIONSHIPS USED

$$q = m \times C_s \times \Delta T$$

$$q_{\text{rxn}} = -q_{\text{soln}}$$

In the second part, use  $q_{\text{soln}}$  to get  $q_{\text{rxn}}$  (which simply involves changing the sign). Because the pressure is constant,  $q_{\text{rxn}}$  is equivalent to  $\Delta H_{\text{rxn}}$  for the amount of magnesium that reacts.

In the third part, divide  $q_{\text{rxn}}$  by the number of moles of magnesium to determine  $\Delta H_{\text{rxn}}$  per mole of magnesium.

—Continued on the next page

—Continued

**SOLVE** Gather the necessary quantities in the correct units for the equation  $q = m \times C_s \times \Delta T$  and substitute these into the equation to calculate  $q_{\text{soln}}$ . Notice that the sign of  $q_{\text{soln}}$  is positive, indicating that the solution absorbed heat from the reaction.

Find  $q_{\text{rxn}}$  by taking the negative of  $q_{\text{soln}}$ . Notice that  $q_{\text{rxn}}$  is negative, as you expect for an exothermic reaction.

Finally, find  $\Delta H_{\text{rxn}}$  per mole of magnesium by dividing  $q_{\text{rxn}}$  by the number of moles of magnesium that reacts. Find the number of moles of magnesium from the given mass of magnesium and its molar mass.

Since the stoichiometric coefficient for magnesium in the balanced chemical equation is 1, the calculated value represents  $\Delta H_{\text{rxn}}$  for the reaction as written.

**SOLUTION**

$$C_{s, \text{soln}} = 4.18 \text{ J/g} \cdot ^\circ\text{C}$$

$$m_{\text{soln}} = 100.0 \text{ mL soln} \times \frac{1.00 \text{ g}}{1 \text{ mL soln}} = 1.00 \times 10^2 \text{ g}$$

$$\begin{aligned}\Delta T &= T_f - T_i \\ &= 32.8^\circ\text{C} - 25.6^\circ\text{C} = 7.2^\circ\text{C}\end{aligned}$$

$$\begin{aligned}q_{\text{soln}} &= m_{\text{soln}} \times C_{s, \text{soln}} \times \Delta T \\ &= 1.00 \times 10^2 \text{ g} \times 4.18 \frac{\text{J}}{\text{g} \cdot ^\circ\text{C}} \times 7.2^\circ\text{C} = 3.0 \times 10^3 \text{ J}\end{aligned}$$

$$q_{\text{rxn}} = -q_{\text{soln}} = -3.0 \times 10^3 \text{ J}$$

$$\begin{aligned}\Delta H_{\text{rxn}} &= \frac{q_{\text{rxn}}}{\text{mol Mg}} \\ &= \frac{-3.0 \times 10^3 \text{ J}}{0.158 \text{ g Mg} \times \frac{1 \text{ mol Mg}}{24.31 \text{ g Mg}}} \\ &= -4.6 \times 10^5 \text{ J/mol Mg}\end{aligned}$$

**CHECK** The units of the answer (J) are correct for the change in enthalpy of a reaction. The sign is negative, as you expect for an exothermic reaction.

**FOR PRACTICE 6.8** The addition of hydrochloric acid to a silver nitrate solution precipitates silver chloride according to the reaction:

When 50.0 mL of 0.100 M  $\text{AgNO}_3$  is combined with 50.0 mL of 0.100 M  $\text{HCl}$  in a coffee-cup calorimeter, the temperature changes from  $23.40^\circ\text{C}$  to  $24.21^\circ\text{C}$ . Calculate  $\Delta H_{\text{rxn}}$  for the reaction as written. Use  $1.00 \text{ g/mL}$  as the density of the solution and  $C = 4.18 \text{ J/g} \cdot ^\circ\text{C}$  as the specific heat capacity.

## CONCEPTUAL CONNECTION 6.7

**Constant-Pressure versus Constant-Volume Calorimetry** The same reaction, with exactly the same amount of reactant, is conducted in a bomb calorimeter and in a coffee-cup calorimeter. In one of the calorimeters,  $q_{\text{rxn}} = -12.5 \text{ kJ}$  and in the other  $q_{\text{rxn}} = -11.8 \text{ kJ}$ . Which value was obtained in the bomb calorimeter? (Assume that the reaction has a positive  $\Delta V$  in the coffee-cup calorimeter.)

## 6.8 Relationships Involving $\Delta H_{\text{rxn}}$

The change in enthalpy for a reaction is always associated with a *particular* reaction. If we change the reaction in well-defined ways, then  $\Delta H_{\text{rxn}}$  also changes in well-defined ways. We now turn our attention to three quantitative relationships between a chemical equation and  $\Delta H_{\text{rxn}}$ .

**1. If a chemical equation is multiplied by some factor, then  $\Delta H_{\text{rxn}}$  is also multiplied by the same factor.**

Recall from Section 6.6 that  $\Delta H_{\text{rxn}}$  is an extensive property; it depends on the quantity of reactants undergoing reaction. Recall also that  $\Delta H_{\text{rxn}}$  is usually reported for a reaction involving stoichiometric amounts of reactants. For example, for a reaction  $A + 2 B \longrightarrow C$ ,  $\Delta H_{\text{rxn}}$  is typically reported as the amount of heat emitted or absorbed when 1 mol A reacts with 2 mol B to form 1 mol C. Therefore, if a chemical equation is multiplied by a factor, then  $\Delta H_{\text{rxn}}$  is also multiplied by the same factor. For example,

**2. If a chemical equation is reversed, then  $\Delta H_{\text{rxn}}$  changes sign.**

Recall from Section 6.6 that  $\Delta H_{\text{rxn}}$  is a state function, which means that its value depends only on the initial and final states of the system.

$$\Delta H = H_{\text{final}} - H_{\text{initial}}$$

When a reaction is reversed, the final state becomes the initial state and vice versa. Consequently,  $\Delta H_{\text{rxn}}$  changes sign:

**3. If a chemical equation can be expressed as the sum of a series of steps, then  $\Delta H_{\text{rxn}}$  for the overall equation is the sum of the heats of reaction for each step.**

This last relationship, known as **Hess's law**, also follows from the enthalpy of reaction being a state function. Since  $\Delta H_{\text{rxn}}$  is dependent only on the initial and final states, and not on the pathway the reaction follows,  $\Delta H$  obtained from summing the individual steps that lead to an overall reaction must be the same as  $\Delta H$  for that overall reaction. For example,

We illustrate Hess's law with the energy-level diagram in Figure 6.10.

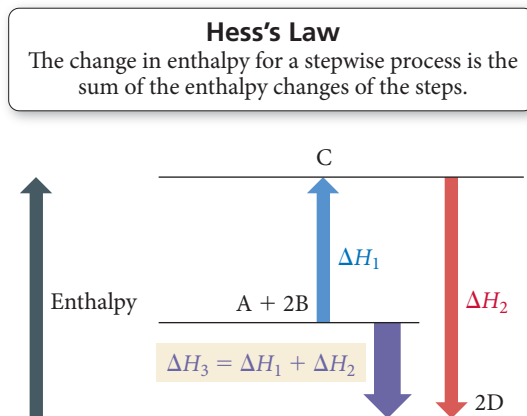

These three quantitative relationships make it possible to determine  $\Delta H$  for a reaction without directly measuring it in the laboratory. (For some reactions, direct measurement can be difficult.) If we can find related reactions (with known  $\Delta H$ 's) that sum to the reaction of interest, we can find  $\Delta H$  for the reaction of interest. For example, the following reaction between C(s) and  $\text{H}_2\text{O}(g)$  is an industrially important method of generating hydrogen gas:

We can find  $\Delta H_{\text{rxn}}$  from the following reactions that have known  $\Delta H$ 's:

We just have to determine how to sum these reactions to get the overall reaction of interest. We do this by manipulating the reactions with known  $\Delta H$ 's in such a way as to get the reactants of interest on the left, the products of interest on the right, and other species to cancel.

**▲ FIGURE 6.10 Hess's Law** The change in enthalpy for a stepwise process is the sum of the enthalpy changes of the steps.

Since the first reaction has C(s) as a reactant, and the reaction of interest also has C(s) as a reactant, we write the first reaction unchanged.

The second reaction has 2 mol of CO(g) as a reactant. However, the reaction of interest has 1 mol of CO(g) as a product. Therefore, we reverse the second reaction, change the sign of  $\Delta H$ , and multiply the reaction and  $\Delta H$  by  $\frac{1}{2}$ .

In the third reaction H<sub>2</sub>(g) is a reactant. In the reaction of interest, however, H<sub>2</sub>(g) is a product. Therefore, we reverse the equation and change the sign of  $\Delta H$ . In addition, to obtain coefficients that match the reaction of interest, and to cancel O<sub>2</sub>, we must multiply the reaction and  $\Delta H$  by  $\frac{1}{2}$ .

Lastly, we rewrite the three reactions after multiplying through by the indicated factors and show how they sum to the reaction of interest.  $\Delta H$  for the reaction of interest is the sum of the  $\Delta H$ 's for the steps.

### Example 6.9 Hess's Law

Find  $\Delta H_{\text{rxn}}$  for the reaction:

Use these reactions with known  $\Delta H$ 's:

#### SOLUTION

To work this and other Hess's law problems, manipulate the reactions with known  $\Delta H$ 's in such a way as to get the reactants of interest on the left, the products of interest on the right, and other species to cancel.

The first reaction has C<sub>3</sub>H<sub>8</sub> as a reactant, and the reaction of interest has C<sub>3</sub>H<sub>8</sub> as a product, so reverse the first reaction and change the sign of  $\Delta H$ .

The second reaction has C as a reactant and CO<sub>2</sub> as a product, just as required in the reaction of interest. However, the coefficient for C is 1, and in the reaction of interest, the coefficient for C is 3. You need to multiply this equation and its  $\Delta H$  by 3.

The third reaction has H<sub>2</sub>(g) as a reactant, as required. However, the coefficient for H<sub>2</sub> is 2, and in the reaction of interest, the coefficient for H<sub>2</sub> is 4. Multiply this reaction and its  $\Delta H$  by 2.

Rewrite the three reactions after multiplying through by the indicated factors and show how they sum to the reaction of interest.  $\Delta H$  for the reaction of interest is the sum of the  $\Delta H$ 's for the steps.

**FOR PRACTICE 6.9** Find  $\Delta H_{\text{rxn}}$  for the reaction:

Use these reactions with known  $\Delta H$ 's:

**FOR MORE PRACTICE 6.9** Find  $\Delta H_{\text{rxn}}$  for the reaction:

Use these reactions with known  $\Delta H$ 's:

## 6.9 Determining Enthalpies of Reaction from Standard Enthalpies of Formation

We have examined two ways to determine  $\Delta H$  for a chemical reaction: experimentally through calorimetry and inferentially through Hess's law. We now turn to a third and more convenient way to determine  $\Delta H$  for a large number of chemical reactions: from tabulated *standard enthalpies of formation*.

### Standard States and Standard Enthalpy Changes

Recall that  $\Delta H$  is the *change* in enthalpy for a chemical reaction—the difference in enthalpy between the products and the reactants. Because we are interested in changes in enthalpy (and not in absolute values of enthalpy itself), we are free to define the *zero* of enthalpy as conveniently as possible. Returning to our mountain-climbing analogy, a change in altitude (like a change in enthalpy) is an absolute quantity. Altitude itself (like enthalpy), however, is a relative quantity, defined relative to some standard (such as sea level in the case of altitude). We define a similar, albeit slightly more complex, standard for enthalpy. This standard has three parts: the **standard state**, the **standard enthalpy change** ( $\Delta H^\circ$ ), and the **standard enthalpy of formation** ( $\Delta H_f^\circ$ ).

#### 1. Standard State

- *For a Gas:* The standard state for a gas is the pure gas at a pressure of exactly 1 atm.
- *For a Liquid or Solid:* The standard state for a liquid or solid is the pure substance in its most stable form at a pressure of 1 atm and at the temperature of interest (often taken to be 25 °C).
- *For a Substance in Solution:* The standard state for a substance in solution is a concentration of exactly 1 M.

The standard state was changed in 1997 to a pressure of 1 bar, which is very close to 1 atm (1 atm = 1.013 bar). Both standards are now in common use.

#### 2. Standard Enthalpy Change ( $\Delta H^\circ$ )

- The change in enthalpy for a process when all reactants and products are in their standard states. The degree sign indicates standard states.

#### 3. Standard Enthalpy of Formation ( $\Delta H_f^\circ$ )

- *For a Pure Compound:* The change in enthalpy when 1 mol of the compound forms from its constituent elements in their standard states.
- *For a Pure Element in Its Standard State:*  $\Delta H_f^\circ = 0$ .

The standard enthalpy of formation is also called the **standard heat of formation**.

Assigning the value of zero to the standard enthalpy of formation for an element in its standard state is the equivalent of assigning an altitude of zero to sea level. Once we assume sea level is zero, we can then measure all subsequent changes in altitude relative to sea level. Similarly, we can measure all changes in enthalpy relative to those of pure elements in their standard states. For example, consider the standard enthalpy of formation of methane gas at 25 °C:

For methane, as with most compounds,  $\Delta H_f^\circ$  is negative. Continuing our analogy, if we think of pure elements in their standard states as being at *sea level*, then most compounds lie *below sea level*. The chemical equation for the enthalpy of formation of a compound is always written to form 1 mol of the compound, so  $\Delta H_f^\circ$  has the units of kJ/mol. Table 6.5 lists  $\Delta H_f^\circ$  values for some selected compounds. A more complete list is in Appendix IIB.

The carbon in this equation must be graphite (the most stable form of carbon at 1 atm and 25 °C).

**Example 6.10** Standard Enthalpies of Formation

Write equations for the formation of (a)  $\text{MgCO}_3(s)$  and (b)  $\text{C}_6\text{H}_{12}\text{O}_6(s)$  from their respective elements in their standard states. Include the value of  $\Delta H_f^\circ$  for each equation.

**SOLUTION****a.**  $\text{MgCO}_3(s)$ 

Write the equation with the elements in  $\text{MgCO}_3$  in their standard states as the reactants and 1 mol of  $\text{MgCO}_3$  as the product.

Balance the equation and look up  $\Delta H_f^\circ$  in Appendix IIB. (Use fractional coefficients so that the product of the reaction is 1 mol of  $\text{MgCO}_3$ .)

**b.**  $\text{C}_6\text{H}_{12}\text{O}_6(s)$ 

Write the equation with the elements in  $\text{C}_6\text{H}_{12}\text{O}_6$  in their standard states as the reactants and 1 mol of  $\text{C}_6\text{H}_{12}\text{O}_6$  as the product.

Balance the equation and look up  $\Delta H_f^\circ$  in Appendix IIB.

**FOR PRACTICE 6.10** Write equations for the formation of (a)  $\text{NaCl}(s)$  and (b)  $\text{Pb}(\text{NO}_3)_2(s)$  from their respective elements in their standard states. Include the value of  $\Delta H_f^\circ$  for each equation.

## Calculating the Standard Enthalpy Change for a Reaction

We have just seen that the standard enthalpy of formation corresponds to the *formation* of a compound from its constituent elements in their standard states:

Therefore, the *negative* of the standard enthalpy of formation corresponds to the *decomposition* of a compound into its constituent elements in their standard states:

We can use these two concepts—the decomposition of a compound into its elements and the formation of a compound from its elements—to calculate the enthalpy change of any reaction by mentally taking the reactants through two steps. In the first step we *decompose the reactants* into their constituent elements in their standard states; in the second step we *form the products* from the constituent elements in their standard states:

In these equations,  $\Sigma$  means “the sum of” so that  $\Delta H_1$  is the sum of the negatives of the heats of formation of the reactants and  $\Delta H_2$  is the sum of the heats of formation of the products.

We can demonstrate this procedure by calculating the standard enthalpy change ( $\Delta H_{\text{rxn}}^\circ$ ) for the combustion of methane:

The energy changes associated with the decomposition of the reactants and the formation of the products are shown in Figure 6.11. The first step (1) is the decomposition of 1 mol of methane into its constituent elements in their standard states. We can obtain the change in enthalpy for this step by reversing the enthalpy of formation equation for methane and changing the sign of  $\Delta H_f^\circ$ :

The second step, the formation of the products from their constituent elements, has two parts: (a) the formation of 1 mol  $\text{CO}_2$  and (b) the formation of 2 mol  $\text{H}_2\text{O}$ . Because part (b) forms 2 mol  $\text{H}_2\text{O}$ , we multiply the  $\Delta H_f^\circ$  for that step by 2:

◀ **FIGURE 6.11** Calculating the Enthalpy Change for the Combustion of Methane

As we know from Hess's law, the enthalpy of reaction for the overall reaction is the sum of the enthalpies of reaction of the individual steps:

We can streamline and generalize this process as follows:

**To calculate  $\Delta H_{\text{rxn}}^\circ$ , subtract the enthalpies of formation of the reactants multiplied by their stoichiometric coefficients from the enthalpies of formation of the products multiplied by their stoichiometric coefficients.**

In the form of an equation:

$$\Delta H_{\text{rxn}}^\circ = \sum n_p \Delta H_f^\circ (\text{products}) - \sum n_r \Delta H_f^\circ (\text{reactants}) \quad [6.15]$$

In this equation,  $n_p$  represents the stoichiometric coefficients of the products,  $n_r$  represents the stoichiometric coefficients of the reactants, and  $\Delta H_f^\circ$  represents the standard enthalpies of formation. Keep in mind when using this equation that elements in their standard states have  $\Delta H_f^\circ = 0$ . Examples 6.11 and 6.12 demonstrate this process.

### Example 6.11 $\Delta H_{\text{rxn}}^\circ$ and Standard Enthalpies of Formation

Use the standard enthalpies of formation to determine  $\Delta H_{\text{rxn}}^\circ$  for the reaction:

**SORT** You are given the balanced equation and asked to find the enthalpy of reaction.

**GIVEN:**  $4\text{NH}_3(\text{g}) + 5\text{O}_2(\text{g}) \longrightarrow 4\text{NO}(\text{g}) + 6\text{H}_2\text{O}(\text{g})$

**FIND:**  $\Delta H_{\text{rxn}}^\circ$

**STRATEGIZE** To calculate  $\Delta H_{\text{rxn}}^\circ$  from standard enthalpies of formation, subtract the heats of formation of the reactants multiplied by their stoichiometric coefficients from the heats of formation of the products multiplied by their stoichiometric coefficients.

**CONCEPTUAL PLAN**

$$\Delta H_{\text{rxn}}^\circ = \sum n_p \Delta H_f^\circ (\text{products}) - \sum n_r \Delta H_f^\circ (\text{reactants})$$

**SOLVE** Begin by looking up (in Appendix IIB) the standard enthalpy of formation for each reactant and product. Remember that the standard enthalpy of formation of pure elements in their standard state is zero. Calculate  $\Delta H_{\text{rxn}}^\circ$  by substituting into the equation.

**SOLUTION**

Reactant or product	$\Delta H_f^\circ$ (kJ/mol, from Appendix IIB)
$\text{NH}_3(\text{g})$	-45.9
$\text{O}_2(\text{g})$	0.0
$\text{NO}(\text{g})$	+91.3
$\text{H}_2\text{O}(\text{g})$	-241.8

$$\begin{aligned}
 \Delta H_{\text{rxn}}^\circ &= \sum n_p \Delta H_f^\circ (\text{products}) - \sum n_r \Delta H_f^\circ (\text{reactants}) \\
 &= [4(\Delta H_f^\circ \text{NO}(\text{g})) + 6(\Delta H_f^\circ \text{H}_2\text{O}(\text{g}))] - [4(\Delta H_f^\circ \text{NH}_3(\text{g})) + 5(\Delta H_f^\circ \text{O}_2(\text{g}))] \\
 &= [4(+91.3 \text{ kJ}) + 6(-241.8 \text{ kJ})] - [4(-45.9 \text{ kJ}) + 5(0.0 \text{ kJ})] \\
 &= -1085.6 \text{ kJ} - (-183.6 \text{ kJ}) \\
 &= -902.0 \text{ kJ}
 \end{aligned}$$

**CHECK** The units of the answer (kJ) are correct. The answer is negative, which means that the reaction is exothermic.

**FOR PRACTICE 6.11** The thermite reaction, in which powdered aluminum reacts with iron oxide, is highly exothermic.

Use standard enthalpies of formation to determine  $\Delta H_{\text{rxn}}^\circ$  for the thermite reaction.

► The reaction of powdered aluminum with iron oxide, known as the thermite reaction, releases a large amount of heat.

### Example 6.12 $\Delta H_{\text{rxn}}^\circ$ and Standard Enthalpies of Formation

A city of 100,000 people uses approximately  $1.0 \times 10^{11}$  kJ of energy per day. Suppose all of that energy comes from the combustion of liquid octane ( $\text{C}_8\text{H}_{18}$ ) to form gaseous water and gaseous carbon dioxide. Use standard enthalpies of formation to calculate  $\Delta H_{\text{rxn}}^\circ$  for the combustion of octane and then determine the number of kilograms of octane necessary to provide this amount of energy.

**SORT** You are given the amount of energy used and asked to find the mass of octane required to produce the energy.

**GIVEN:**  $1.0 \times 10^{11}$  kJ

**FIND:** kg  $\text{C}_8\text{H}_{18}$

**STRATEGIZE** The conceptual plan has three parts. In the first part, write a balanced equation for the combustion of octane.

In the second part, calculate  $\Delta H_{\text{rxn}}^\circ$  from the  $\Delta H_f^\circ$ 's of the reactants and products.

In the third part, convert from kilojoules of energy to moles of octane using the conversion factor found in step 2, and then convert from moles of octane to mass of octane using the molar mass.

#### CONCEPTUAL PLAN

(1) Write the balanced equation.

#### RELATIONSHIPS USED

molar mass  $\text{C}_8\text{H}_{18} = 114.22 \text{ g/mol}$

1 kg = 1000 g

**SOLVE** Begin by writing the balanced equation for the combustion of octane. For convenience, do not clear the 25/2 fraction in order to keep the coefficient on octane as 1.

#### SOLUTION STEP 1

#### SOLUTION STEP 2

Reactant or product	$\Delta H_f^\circ$ (kJ/mol, from Appendix IIB)
$\text{C}_8\text{H}_{18}(l)$	-250.1
$\text{O}_2(g)$	0.0
$\text{CO}_2(g)$	-393.5
$\text{H}_2\text{O}(g)$	-241.8

Look up (in Appendix IIB) the standard enthalpy of formation for each reactant and product and then calculate  $\Delta H_{\text{rxn}}^\circ$ .

—Continued on the next page

—Continued

	$\Delta H_{\text{rxn}}^{\circ} = \sum n_p \Delta H_f^{\circ} (\text{products}) - \sum n_r \Delta H_f^{\circ} (\text{reactants})$ $= [8(\Delta H_{f, \text{CO}_2(g)}^{\circ}) + 9(\Delta H_{f, \text{H}_2\text{O}(g)}^{\circ})] - \left[ 1(\Delta H_{f, \text{C}_8\text{H}_{18}(l)}^{\circ}) + \frac{25}{2}(\Delta H_{f, \text{O}_2(g)}^{\circ}) \right]$ $= [8(-393.5 \text{ kJ}) + 9(-241.8 \text{ kJ})] - \left[ 1(-250.1 \text{ kJ}) + \frac{25}{2}(0.0 \text{ kJ}) \right]$ $= -5324.2 \text{ kJ} - (-250.1 \text{ kJ})$ $= -5074.1 \text{ kJ}$
<p>From steps 1 and 2 build a conversion factor between mol C<sub>8</sub>H<sub>18</sub> and kJ.</p> <p>Follow step 3 of the conceptual plan. Begin with <math>-1.0 \times 10^{11}</math> kJ (since the city uses this much energy, the reaction must emit it, and therefore the sign is negative) and follow the steps to determine kilograms of octane.</p>	<p><b>SOLUTION STEP 3</b></p> <p>1 mol C<sub>8</sub>H<sub>18</sub> : -5074.1 kJ</p> $-1.0 \times 10^{11} \text{ kJ} \times \frac{1 \text{ mol C}_8\text{H}_{18}}{-5074.1 \text{ kJ}} \times \frac{114.22 \text{ g C}_8\text{H}_{18}}{1 \text{ mol C}_8\text{H}_{18}} \times \frac{1 \text{ kg}}{1000 \text{ g}}$ $= 2.3 \times 10^6 \text{ kg C}_8\text{H}_{18}$
<p><b>CHECK</b> The units of the answer (kg C<sub>8</sub>H<sub>18</sub>) are correct. The answer is positive, as it should be for mass. The magnitude is fairly large, as you would expect since this amount of octane is supposed to provide the energy for an entire city.</p>	
<p><b>FOR PRACTICE 6.12</b> The chemical hand warmers described in Section 6.1 produce heat when they are removed from their airtight plastic wrappers. Recall that they utilize the oxidation of iron to form iron oxide according to the reaction <math>4 \text{ Fe}(s) + 3 \text{ O}_2(g) \longrightarrow 2 \text{ Fe}_2\text{O}_3(s)</math>. Calculate <math>\Delta H_{\text{rxn}}^{\circ}</math> for this reaction and calculate how much heat is produced from a hand warmer containing 15.0 g of iron powder.</p>	

## 6.10 Energy Use and the Environment

In this chapter, we explored the relationship between chemical reactions and energy changes. As noted earlier, our society derives the majority of its energy from the energy changes associated with burning fossil fuels. Fossil fuels have traditionally been regarded as convenient sources of energy due to their abundance and portability and because they undergo combustion reactions that have large negative enthalpies of reaction (the reactions are highly exothermic). However, the burning of fossil fuels also has some serious environmental impacts.

### Energy Consumption

According to the U.S. Department of Energy, the United States currently consumes close to 100 quads (1 quad = 1 quadrillion British thermal units =  $1.06 \times 10^{18}$  J) of energy per year in the categories shown in this chart.

Source: U.S. Energy Information Administration. *Monthly Energy Review*, February, 2015.

- Residential: 21.0%
- Commercial: 18.2%
- Industrial: 33.4%
- Transportation: 27.4%

This corresponds to over 100,000 kWh of energy use per person per year. If we used physical laborers to do the equivalent amount of work, each person would need about 120 people. In other words, the average American employs the work output of 120 people, day and night, all year long! For this reason, Americans enjoy one of the highest standards of living in the world. However, our consumption of energy has significant environmental consequences.

Most U.S. energy comes from the combustion of fossil fuels, as shown in Figure 6.12. Fossil fuels include petroleum, natural gas, and coal, all of which have been considered convenient fuels because they are relatively abundant in Earth's crust (and therefore relatively inexpensive), they are easily transportable, and their combustion is highly exothermic.

**FIGURE 6.12** Energy Consumption by Source

Source: U.S. Energy Information Administration. *Monthly Energy Review*, February, 2015.

The reactions for the combustion of the main or representative components of several fossil fuels, and the associated enthalpies of reaction, are:

## Environmental Problems Associated with Fossil Fuel Use

One of the main problems associated with the burning of fossil fuels is that even though they are abundant in Earth's crust, fossil fuels are also finite. Fossil fuels originate from ancient plant and animal life and are a nonrenewable energy source—once they are all burned, they cannot be replenished. At current rates of consumption, oil and natural gas supplies will be depleted in 50 to 100 years. Although there is enough coal to last much longer, it is a dirtier fuel (it produces more pollution) and, because it is a solid, is less convenient (more difficult to transport and use) than petroleum and natural gas.

The other major problems associated with fossil fuel use stem from the products of combustion. The chemical equations we show in this section of the chapter for fossil fuel combustion all produce carbon dioxide and water. However, these equations represent the reactions under ideal conditions and do not account for impurities in the fuel, side reactions, and incomplete combustion. When these are taken into account, we can identify three major environmental problems associated with the emissions of fossil fuel combustion: air pollution, acid rain, and global climate change. We discussed acid rain in Chapter 3 (see *Chemistry in the Environment: Acid Rain* in Section 3.6). Here we address air pollution and global climate change, which we first touched on in Section 4.1.

## Air Pollution

The air in all major cities in the world is polluted. Pollution comes from a number of sources, including electricity generation, motor vehicle emissions, and industrial waste. There are many different kinds of air pollutants.

Sulfur Oxides (SO<sub>x</sub>)

Sulfur oxides include SO<sub>2</sub> and SO<sub>3</sub>, produced primarily during coal-fired electricity generation and industrial metal refining. The sulfur oxides are lung and eye irritants that affect the respiratory system and are the main precursors of acid rain (see Section 3.6).

Carbon Monoxide (CO)

Carbon monoxide forms during the incomplete combustion of fossil fuels (petroleum, natural gas, and coal). It is emitted mainly by motor vehicles. In humans and other animals, carbon monoxide displaces oxygen in the blood, forcing the heart and lungs to work harder. At high levels, CO can cause sensory impairment, decreased thinking ability, unconsciousness, and even death.

Nitrogen Oxides (NO<sub>x</sub>)

The nitrogen oxides include NO and NO<sub>2</sub>, emitted by motor vehicles, fossil fuel-based electricity generation plants, and any high-temperature combustion process occurring in air. Nitrogen dioxide is an orange-brown gas that causes the dark haze over polluted cities. Nitrogen oxides are eye and lung irritants and precursors of acid rain.

Ozone (O<sub>3</sub>)

Ozone is produced when some of the products of fossil fuel combustion, especially nitrogen oxides and unburned volatile organic compounds (VOCs), react in the presence of sunlight. The products of this reaction, which include ozone, are called *photochemical smog*. Ozone produced in this way—sometimes called ground-level ozone—should not be confused with upper atmospheric or *stratospheric* ozone. Although ozone is always the same molecule (O<sub>3</sub>), stratospheric ozone is a natural part of our environment that protects Earth from harmful ultraviolet light. Stratospheric ozone does not harm humans because we are not directly exposed to it. Ground-level ozone, on the other hand, is a pollutant to which we are directly exposed; it is an eye and lung irritant, and prolonged exposure can cause permanent lung damage.

In the United States, the U.S. Environmental Protection Agency (EPA) has established limits on these pollutants. Beginning in the 1970s, the U.S. Congress passed the Clean Air Act and its amendments, requiring U.S. cities to reduce their pollution and maintain levels below the standards set by the EPA. As a result of this legislation, pollutant levels in U.S. cities have decreased over the last 30 years, even as the number of vehicles has increased. According to the EPA, the levels of the major pollutants in the air of U.S. cities decreased significantly during the period 1980–2013, as shown in Table 6.6.

TABLE 6.6 Changes in National Average Pollutant Levels, 1980–2013

Pollutant	Change (%) in Average Level
SO <sub>2</sub>	−81
CO	−84
NO <sub>2</sub>	−60
O <sub>3</sub>	−33

\*Source: EPA's National Air Trends

**FIGURE 6.13 The Rise in Atmospheric Carbon Dioxide** Atmospheric carbon dioxide levels have been steadily increasing as a result of fossil fuel combustion. Source: Dr. Pieter Tans, NOAA/ESRL ([www.esrl.noaa.gov/gmd/ccgg/trends/](http://www.esrl.noaa.gov/gmd/ccgg/trends/)) and Dr. Ralph Keeling, Scripps Institution of Oceanography ([www.scrippsco2.ucsd.edu/](http://www.scrippsco2.ucsd.edu/))

Although the levels of pollutants (especially ozone) in some cities are still above what the EPA considers safe, real progress has been made. These trends demonstrate that legislation can improve our environment.

Global Climate Change

One of the main products of fossil fuel combustion is carbon dioxide. Carbon dioxide is a greenhouse gas; it allows visible light from the sun to enter Earth’s atmosphere but prevents heat (in the form of infrared light) from escaping. In doing so, carbon dioxide acts as a blanket, keeping Earth warm, which, in moderation, is a very good thing and allows life as we know it to exist on our planet. However, because of fossil fuel combustion, carbon dioxide levels in the atmosphere have been steadily increasing, as shown in Figure 6.13. This increase is expected to change the global climate and further raise Earth’s average temperature. Current observations suggest that Earth has already warmed by about 0.7 °C in the last century due to an approximately 38% increase in atmospheric carbon

dioxide. Computer models suggest that the warming could worsen if carbon dioxide emissions are not curbed. The possible effects of this warming include heightened storm severity, increasing numbers of floods and droughts, major shifts in agricultural zones, rising sea levels and coastal flooding, and profound changes in habitats that could result in the extinction of some plant and animal species.

### Example 6.13 Fossil Fuels and Climate Change

One way to evaluate fuels with respect to global warming is to determine how much heat they release during combustion relative to how much CO<sub>2</sub> they produce. The greater the heat relative to the amount of CO<sub>2</sub>, the better the fuel. Use the combustion reactions of carbon, natural gas, and octane, in combination with the enthalpy of combustion for each reaction (all given earlier), to calculate the heat (in kJ) released by each fuel per 1.00 kg of CO<sub>2</sub> produced.

**SORT** You are given the mass of CO<sub>2</sub> emitted and asked to find the energy output for three different fuels.

**STRATEGIZE** First write the thermochemical equations for the combustion of each fuel given in Section 6.10.

The conceptual plan has two parts. In the first part, use the molar mass of CO<sub>2</sub> to convert from mass of CO<sub>2</sub> to moles of CO<sub>2</sub>. This step is the same for each fuel.

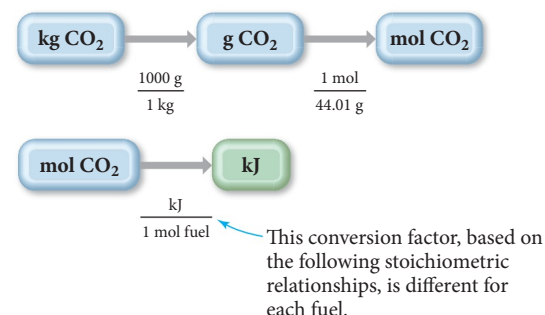

In the second part, use the stoichiometric relationship between moles of CO<sub>2</sub> produced and kilojoules of energy released to calculate the energy output. Repeat the second part for each fuel using the appropriate stoichiometric relationship from the balanced equations.

**GIVEN:** 1.00 kg CO<sub>2</sub>

**FIND:** kJ

#### CONCEPTUAL PLAN

#### STOICHIOMETRIC RELATIONSHIPS

For C: 1 mol CO<sub>2</sub> : -393.5 kJ  
 For CH<sub>4</sub>: 1 mol CO<sub>2</sub> : -802.3 kJ  
 For C<sub>8</sub>H<sub>18</sub>: 8 mol CO<sub>2</sub> : -5074.1 kJ

#### OTHER RELATIONSHIPS USED

1 kg = 1000 g  
 molar mass CO<sub>2</sub> = 44.01 g/mol

**SOLVE** Begin by converting kg CO<sub>2</sub> to mol CO<sub>2</sub>.

Then, for each fuel, convert mol CO<sub>2</sub> to kJ.

As you can see from the heat released in the production of 1 kg CO<sub>2</sub>, natural gas, CH<sub>4</sub>, provides the most energy per kg CO<sub>2</sub>; therefore, it is the best fuel with respect to climate change.

#### SOLUTION

$$1.00 \text{ kg CO}_2 \times \frac{1000 \text{ g}}{1 \text{ kg}} \times \frac{1 \text{ mol CO}_2}{44.01 \text{ g CO}_2} = 22.72 \text{ mol CO}_2$$

For C:

$$22.72 \text{ mol CO}_2 \times \frac{-393.5 \text{ kJ}}{1 \text{ mol CO}_2} = -8.94 \times 10^3 \text{ kJ}$$

For CH<sub>4</sub>:

$$22.72 \text{ mol CO}_2 \times \frac{-802.3 \text{ kJ}}{1 \text{ mol CO}_2} = -1.82 \times 10^4 \text{ kJ}$$

For C<sub>8</sub>H<sub>18</sub>:

$$22.72 \text{ mol CO}_2 \times \frac{-5074.1 \text{ kJ}}{8 \text{ mol CO}_2} = -1.44 \times 10^4 \text{ kJ}$$

—Continued on the next page

—Continued

**CHECK** Each answer is in kJ, as it should be for heat produced. Each answer is negative, as expected for exothermic combustion reactions.

**FOR PRACTICE 6.13** What mass of  $\text{CO}_2$  (in kilograms) does the combustion of a 15-gallon tank of gasoline release into the atmosphere? Assume the gasoline is pure octane ( $\text{C}_8\text{H}_{18}$ ) and that it has a density of 0.70 g/mL.

## Chemistry IN THE Environment Renewable Energy

**B**ecause of their finite supply and environmental impacts, fossil fuels will not be our major source of energy in the future. What will replace them? Although the answer is not clear, several alternative energy technologies are beginning to emerge. Unlike fossil fuels, these technologies are renewable, and we can use them indefinitely.

Our planet's greatest source of renewable energy is the sun. If we could capture and harness just a small fraction of the total sunlight falling on Earth, we could meet our energy needs several times over. The main problem with solar energy, however, is diffuseness—the sun's energy falls over an enormous area. How do we concentrate and store it? In California, some of the state's electricity is generated by parabolic troughs, solar power towers, and dish engines.

These devices use reflective surfaces to focus the sun's energy and produce enough heat to generate electricity. Although the direct cost of generating electricity this way is higher than using fossil fuels, the benefits to the environment are obvious. In addition, with time, the costs are expected to fall.

Another way to capture the sun's energy is in chemical bonds. For example, solar energy could be used to drive the decomposition of water:

The hydrogen gas produced could be stored until needed to provide energy by re-forming water in the reverse reaction:

This reaction can be carried out in an electrochemical device called a fuel cell. In a fuel cell, hydrogen and oxygen gases combine to form water and produce electricity. In 2015, Toyota introduced the Mirai (which means *future* in Japanese), the first mass-produced fuel cell vehicle. The Mirai has a 300-mile range and produces 153 horsepower. Unlike most electric vehicles (such as the Tesla Model S), a fuel cell vehicle can be refueled instead of recharged.

The refueling process only takes a few minutes (compared to recharging, which can take several hours). California has earmarked \$200 million to build a “hydrogen highway,” a series of 100 hydrogen refueling stations to be operational by 2020.

Other renewable energy sources are hydroelectric power and wind power. Hydroelectric power plants—which generate approximately 7% of U.S. electricity—harness the gravitational potential energy of water held behind a dam. Water is released at a controlled rate. As the released water falls, it acquires kinetic energy that is used to spin turbines, generating electricity. Wind power plants—which produce nearly 5% of U.S. electricity—consist of hundreds of turbines that are spun by the wind to generate electricity. Both of these technologies are cost competitive with fossil fuels, have no emissions, and are completely renewable.

Our energy future will probably involve a combination of these technologies and some new ones, combined with a focus on greater efficiency and conservation. One thing, however, is clear—the future of fossil fuels is limited.

▲ The Toyota Mirai, a fuel cell vehicle that runs on hydrogen gas and produces only water as exhaust.

▲ Wind turbines such as these generate nearly 5% of U.S. electricity.

Parabolic troughs

Solar power tower

Dish/engine

▲ The sun's energy, concentrated by reflective surfaces in various arrangements, can produce enough heat to generate electricity.

## Self-Assessment Quiz

- Q1.** A chemical system produces 155 kJ of heat and does 22 kJ of work. What is  $\Delta E$  for the *surroundings*?  
a) 177 kJ    b) -177 kJ    c) 133 kJ    d) -133 kJ
- Q2.** Which sample is most likely to undergo the smallest change in temperature upon the absorption of 100 kJ of heat?  
a) 15 g water    b) 15 g lead  
c) 50 g water    d) 50 g lead
- Q3.** How much heat must be absorbed by a 15.0-g sample of water to raise its temperature from 25.0 °C to 55.0 °C? (For water,  $C_s = 4.18 \text{ J/g}^\circ\text{C}$ .)  
a) 1.57 kJ    b) 1.88 kJ    c) 3.45 kJ    d) 107 J
- Q4.** A 12.5-g sample of granite initially at 82.0 °C is immersed into 25.0 g of water initially at 22.0 °C. What is the final temperature of both substances when they reach thermal equilibrium? (For water,  $C_s = 4.18 \text{ J/g}^\circ\text{C}$  and for granite,  $C_s = 0.790 \text{ J/g}^\circ\text{C}$ .)  
a) 52.0 °C    b)  $1.55 \times 10^3$  °C  
c) 15.7 °C    d) 27.2 °C
- Q5.** A cylinder with a moving piston expands from an initial volume of 0.250 L against an external pressure of 2.00 atm. The expansion does 288 J of work on the surroundings. What is the final volume of the cylinder?  
a) 1.42 L    b) 1.17 L    c) 144 L    d) 1.67 L
- Q6.** When a 3.80-g sample of liquid octane ( $\text{C}_8\text{H}_{18}$ ) is burned in a bomb calorimeter, the temperature of the calorimeter rises by 27.3 °C. The heat capacity of the calorimeter, measured in a separate experiment, is 6.18 kJ/°C. Determine the  $\Delta E$  for octane combustion in units of kJ/mol octane.  
a)  $-5.07 \times 10^3$  kJ/mol  
b)  $5.07 \times 10^3$  kJ/mol  
c)  $-44.4 \times 10^3$  kJ/mol  
d)  $-16.7 \times 10^3$  kJ/mol
- Q7.** Hydrogen gas reacts with oxygen to form water:  
 $2 \text{H}_2(\text{g}) + \text{O}_2(\text{g}) \longrightarrow 2 \text{H}_2\text{O}(\text{g}) \quad \Delta H = -483.5 \text{ kJ}$   
Determine the minimum mass of hydrogen gas required to produce 226 kJ of heat.  
a) 8.63 g    b) 1.88 g    c) 0.942 g    d) 0.935 g
- Q8.** Manganese reacts with hydrochloric acid to produce manganese(II) chloride and hydrogen gas:  
 $\text{Mn}(\text{s}) + 2 \text{HCl}(\text{aq}) \longrightarrow \text{MnCl}_2(\text{aq}) + \text{H}_2(\text{g})$   
When 0.625 g Mn is combined with enough hydrochloric acid to make 100.0 mL of solution in a coffee-cup calorimeter, all of the Mn reacts, raising the temperature of the solution from 23.5 °C to 28.8 °C. Find  $\Delta H_{\text{rxn}}$  for the reaction as written. (Assume that the specific heat capacity of the solution is 4.18 J/g °C and the density is 1.00 g/mL.)  
a) -195 kJ    b) -3.54 kJ  
c) -1.22 kJ    d) -2.21 kJ

- Q9.** Consider the reactions:

What is  $\Delta H$  for the reaction  $2 \text{B} \longrightarrow 3 \text{C}$ ?

- a)  $\Delta H_1 + \Delta H_2$     b)  $\Delta H_1 - \Delta H_2$   
c)  $\Delta H_2 - \Delta H_1$     d)  $2 \times (\Delta H_1 + \Delta H_2)$
- Q10.** Use standard enthalpies of formation to determine  $\Delta H_{\text{rxn}}^\circ$  for the reaction:  
 $\text{Fe}_2\text{O}_3(\text{s}) + 3 \text{CO}(\text{g}) \longrightarrow 2 \text{Fe}(\text{s}) + 3 \text{CO}_2(\text{g})$   
a) -541.2 kJ    b) -2336 kJ  
c) 541.2 kJ    d) -24.8 kJ
- Q11.** Two substances, A and B, of equal mass but at different temperatures come into thermal contact. The specific heat capacity of substance A is twice the specific heat capacity of substance B. Which statement is true of the temperature of the two substances when they reach thermal equilibrium? (Assume no heat loss other than the thermal transfer between the substances.)  
a) The final temperature of both substances is closer to the initial temperature of substance A than the initial temperature of substance B.  
b) The final temperature of both substances is closer to the initial temperature of substance B than the initial temperature of substance A.  
c) The final temperature of both substances is exactly midway between the initial temperatures of substance A and substance B.  
d) The final temperature of substance B is greater than the final temperature of substance A.
- Q12.** Which process is endothermic?  
a) the evaporation of water from the skin  
b) the burning of candle wax  
c) the oxidation of iron in a chemical hand warmer  
d) the combustion of natural gas in a stove
- Q13.** Which fuel is not a fossil fuel?  
a) coal    b) hydrogen  
c) natural gas    d) petroleum
- Q14.** The standard enthalpy of formation for glucose [ $\text{C}_6\text{H}_{12}\text{O}_6(\text{s})$ ] is -1273.3 kJ/mol. What is the correct formation equation corresponding to this  $\Delta H_f^\circ$ ?  
a)  $6 \text{C}(\text{s, graphite}) + 6 \text{H}_2\text{O}(\text{g}) \longrightarrow \text{C}_6\text{H}_{12}\text{O}_6(\text{s, glucose})$   
b)  $6 \text{C}(\text{s, graphite}) + 6 \text{H}_2\text{O}(\text{l}) \longrightarrow \text{C}_6\text{H}_{12}\text{O}_6(\text{s, glucose})$   
c)  $6 \text{C}(\text{s, graphite}) + 6 \text{H}_2(\text{l}) + 3 \text{O}_2(\text{l}) \longrightarrow \text{C}_6\text{H}_{12}\text{O}_6(\text{s, glucose})$   
d)  $6 \text{C}(\text{s, graphite}) + 6 \text{H}_2(\text{g}) + 3 \text{O}_2(\text{g}) \longrightarrow \text{C}_6\text{H}_{12}\text{O}_6(\text{s, glucose})$
- Q15.** Natural gas burns in air to form carbon dioxide and water, releasing heat.  
 $\text{CH}_4(\text{g}) + \text{O}_2(\text{g}) \longrightarrow \text{CO}_2(\text{g}) + \text{H}_2\text{O}(\text{g})$   
 $\Delta H_{\text{rxn}}^\circ = -802.3 \text{ kJ}$   
What minimum mass of  $\text{CH}_4$  is required to heat 55 g of water by 25 °C? (Assume 100% heating efficiency.)  
a) 0.115 g    b)  $2.25 \times 10^3$  g  
c) 115 g    d) 8.70 g

Answers: 1. (a) 15. (d) 14. (b) 13. (a) 12. (a) 11. (a) 10. (d) 9. (c) 8. (a) 7. (b) 6. (a) 5. (d) 4. (d) 3. (b) 2. (c) 1. (a)

# Chapter 6 IN REVIEW

## Key Terms

### Section 6.1

thermochemistry (249)

### Section 6.2

energy (250)  
work (250)  
heat (250)  
kinetic energy (250)  
thermal energy (250)  
potential energy (250)  
chemical energy (250)  
law of conservation of energy (251)  
system (251)  
surroundings (251)  
joule (J) (252)  
calorie (cal) (252)  
Calorie (Cal) (252)  
kilowatt-hour (kWh) (252)

### Section 6.3

thermodynamics (253)  
first law of thermodynamics (253)  
internal energy ( $E$ ) (253)  
state function (253)

### Section 6.4

thermal equilibrium (258)  
heat capacity ( $C$ ) (259)  
specific heat capacity ( $C_s$ ) (259)  
molar heat capacity (259)  
pressure-volume work (262)

### Section 6.5

calorimetry (265)  
bomb calorimeter (265)

### Section 6.6

enthalpy ( $H$ ) (267)

endothermic reaction (267)  
exothermic reaction (268)  
enthalpy (heat) of reaction ( $\Delta H_{\text{rxn}}$ ) (269)

### Section 6.7

coffee-cup calorimeter (270)

### Section 6.8

Hess's law (273)

### Section 6.9

standard state (275)  
standard enthalpy change ( $\Delta H^\circ$ ) (275)  
standard enthalpy of formation ( $\Delta H_f^\circ$ ) (275)  
standard heat of formation (275)

## Key Concepts

### The Nature of Energy and Thermodynamics (6.2, 6.3)

- ▶ Energy, which is measured in the SI unit of joules (J), is the capacity to do work.
- ▶ Work is the result of a force acting through a distance.
- ▶ Many different kinds of energy exist, including kinetic energy, thermal energy, potential energy, and chemical energy, a type of potential energy associated with the relative positions of electrons and nuclei in atoms and molecules.
- ▶ The first law of thermodynamics states that energy can be converted from one form to another, but the total amount of energy is always conserved.
- ▶ The internal energy ( $E$ ) of a system is the sum of all of its kinetic and potential energy. Internal energy is a state function, which means that it depends only on the state of the system and not on the pathway by which it got to that state.
- ▶ A chemical system exchanges energy with its surroundings through heat (the transfer of thermal energy caused by a temperature difference) or work. The total change in internal energy is the sum of these two quantities.

### Heat and Work (6.4)

- ▶ We quantify heat with the equation  $q = m \times C_s \times \Delta T$ . In this expression,  $C_s$  is the specific heat capacity, the amount of heat required to change the temperature of 1 g of the substance by 1 °C. Compared to most substances, water has a very high heat capacity—it takes a lot of heat to change its temperature.
- ▶ The type of work most characteristic of chemical reactions is pressure-volume work, which occurs when a gas expands against an external pressure. Pressure-volume work can be quantified with the equation  $w = -P_{\text{ext}}\Delta V$ .

- ▶ The change in internal energy ( $\Delta E$ ) that occurs during a chemical reaction is the sum of the heat ( $q$ ) exchanged and the work ( $w$ ) done:  $\Delta E = q + w$ .

### Enthalpy (6.6)

- ▶ The heat evolved in a chemical reaction occurring at constant pressure is the change in enthalpy ( $\Delta H$ ) for the reaction. Like internal energy, enthalpy is a state function.
- ▶ An endothermic reaction has a positive enthalpy of reaction; an exothermic reaction has a negative enthalpy of reaction.
- ▶ We can use the enthalpy of reaction to stoichiometrically determine the heat evolved when a specific amount of reactant reacts.

### Calorimetry (6.5, 6.7)

- ▶ Calorimetry is a method of measuring  $\Delta E$  or  $\Delta H$  for a reaction.
- ▶ In bomb calorimetry, the reaction is carried out under conditions of constant volume, so  $\Delta E = q_v$ . We can therefore use the temperature change of the calorimeter to calculate  $\Delta E$  for the reaction.
- ▶ When a reaction takes place at constant pressure, energy may be released both as heat and as work.
- ▶ In coffee-cup calorimetry, a reaction is carried out under atmospheric pressure in a solution, so  $q = \Delta H$ . We use the temperature change of the solution to calculate  $\Delta H$  for the reaction.

### Calculating $\Delta H_{\text{rxn}}$ (6.8, 6.9)

- ▶ We can calculate the enthalpy of reaction ( $\Delta H_{\text{rxn}}$ ) from known thermochemical data using the following relationships: (a) when a reaction is multiplied by a factor,  $\Delta H_{\text{rxn}}$  is multiplied by the same factor; (b) when a reaction is reversed,  $\Delta H_{\text{rxn}}$  changes sign; and (c) if a chemical reaction can be expressed as a sum of two or more steps,

$\Delta H_{\text{rxn}}$  is the sum of the  $\Delta H^\circ$ 's for the individual steps (Hess's law). We can use these relationships to determine the enthalpy change of an unknown reaction from reactions with known enthalpy changes.

- ▶ A second method to calculate  $\Delta H_{\text{rxn}}$  from known thermochemical data involves using tabulated standard enthalpies of formation for the reactants and products of the reaction. These are usually tabulated for substances in their standard states, and the enthalpy of reaction is called the standard enthalpy of reaction ( $\Delta H_{\text{rxn}}^\circ$ ). For any reaction, we obtain  $\Delta H_{\text{rxn}}^\circ$  by subtracting the sum of the enthalpies of formation of the reactants multiplied by their stoichiometric coefficients from the sum of the enthalpies of formation of the products multiplied by their stoichiometric coefficients.

## Environmental Problems Associated with Fossil Fuel Use (6.10)

- ▶ Fossil fuels are nonrenewable fuels; once humans consume them, they cannot be replaced.
- ▶ At current rates of consumption, natural gas and petroleum reserves will be depleted in 50–100 years.
- ▶ In addition to their limited supply, the products of the combustion of fossil fuels—directly or indirectly formed—contribute to environmental problems including air pollution, acid rain, and global climate change, which involves an increase in Earth's average temperature caused by  $\text{CO}_2$  emission.

## Key Equations and Relationships

Kinetic Energy (6.2)

$$\text{KE} = \frac{1}{2}mv^2$$

Change in Internal Energy ( $\Delta E$ ) of a Chemical System (6.3)

$$\Delta E = E_{\text{products}} - E_{\text{reactants}}$$

Energy Flow between System and Surroundings (6.3)

$$\Delta E_{\text{system}} = -\Delta E_{\text{surroundings}}$$

Relationship between Internal Energy ( $\Delta E$ ), Heat ( $q$ ), and Work ( $w$ ) (6.3)

$$\Delta E = q + w$$

Relationship between Heat ( $q$ ), Temperature ( $T$ ), and Heat Capacity ( $C$ ) (6.4)

$$q = C \times \Delta T$$

Relationship between Heat ( $q$ ), Mass ( $m$ ), Temperature ( $T$ ), and Specific Heat Capacity of a Substance ( $C_s$ ) (6.4)

$$q = m \times C_s \times \Delta T$$

Relationship between Work ( $w$ ), Force ( $F$ ), and Distance ( $D$ ) (6.4)

$$w = F \times D$$

Relationship between Work ( $w$ ), Pressure ( $P$ ), and Change in Volume ( $\Delta V$ ) (6.4)

$$w = -P_{\text{ext}} \Delta V$$

Change in Internal Energy ( $\Delta E$ ) of System at Constant Volume (6.5)

$$\Delta E = q_v$$

Heat of a Bomb Calorimeter ( $q_{\text{cal}}$ ) (6.5)

$$q_{\text{cal}} = C_{\text{cal}} \times \Delta T$$

Heat Exchange between a Calorimeter and a Reaction (6.5)

$$q_{\text{cal}} = -q_{\text{rxn}}$$

Relationship between Enthalpy ( $\Delta H$ ), Internal Energy ( $\Delta E$ ), Pressure ( $P$ ), and Volume ( $V$ ) (6.6)

$$\Delta H = \Delta E + P\Delta V$$

$$\Delta H = q_p$$

Relationship between Enthalpy of a Reaction ( $\Delta H_{\text{rxn}}^\circ$ ) and the Heats of Formation ( $\Delta H_f^\circ$ ) (6.9)

$$\Delta H_{\text{rxn}}^\circ = \sum n_p \Delta H_f^\circ (\text{products}) - \sum n_r \Delta H_f^\circ (\text{reactants})$$

## Key Learning Outcomes

### CHAPTER OBJECTIVES

Calculating Internal Energy from Heat and Work (6.3)

Finding Heat from Temperature Changes (6.4)

Determining Quantities in Thermal Energy Transfer (6.4)

Finding Work from Volume Changes (6.4)

### ASSESSMENT

Example 6.1 For Practice 6.1 Exercises 41–44

Example 6.2 For Practice 6.2 For More Practice 6.2 Exercises 47–50

Example 6.3 For Practice 6.3 Exercises 65–70

Example 6.4 For Practice 6.4 For More Practice 6.4 Exercises 51, 52

Using Bomb Calorimetry to Calculate $\Delta E_{\text{rxn}}$ (6.5)	Example 6.5 For Practice 6.5 For More Practice 6.5 Exercises 53, 54
Predicting Endothermic and Exothermic Processes (6.6)	Example 6.6 For Practice 6.6 Exercises 57, 58
Determining Heat from $\Delta H$ and Stoichiometry (6.6)	Examples 6.7, 6.13 For Practice 6.7, 6.13 For More Practice 6.7 Exercises 59–64
Finding $\Delta H_{\text{rxn}}$ Using Calorimetry (6.7)	Example 6.8 For Practice 6.8 Exercises 75, 76
Finding $\Delta H_{\text{rxn}}$ Using Hess's Law (6.8)	Example 6.9 For Practice 6.9 For More Practice 6.9 Exercises 79–82
Finding $\Delta H_{\text{rxn}}^\circ$ Using Standard Enthalpies of Formation (6.9)	Examples 6.10, 6.11, 6.12 For Practice 6.10, 6.11, 6.12 Exercises 83–92

## EXERCISES

### Review Questions

- What is thermochemistry? Why is it important?
- What is energy? What is work? List some examples of each.
- What is kinetic energy? What is potential energy? List some examples of each.
- State the law of conservation of energy. How does it relate to energy exchanges between a thermodynamic system and its surroundings?
- What is the SI unit of energy? List some other common units of energy.
- State the first law of thermodynamics. What are its implications?
- A friend claims to have constructed a machine that creates electricity but requires no energy input. Explain why you should be suspicious of your friend's claim.
- What is a state function? List some examples of state functions.
- What is internal energy? Is internal energy a state function?
- If energy flows out of a chemical system and into the surroundings, what is the sign of  $\Delta E_{\text{system}}$ ?
- If the internal energy of the products of a reaction is higher than the internal energy of the reactants, what is the sign of  $\Delta E$  for the reaction? In which direction does energy flow?
- What is heat? Explain the difference between heat and temperature.
- How is the change in internal energy of a system related to heat and work?
- Explain how the sum of heat and work can be a state function, even though heat and work are themselves not state functions.
- What is heat capacity? Explain the difference between heat capacity and specific heat capacity.
- Explain how the high specific heat capacity of water can affect the weather in coastal regions.
- If two objects, A and B, of different temperature come into direct contact, what is the relationship between the heat lost by one object and the heat gained by the other? What is the relationship between the temperature changes of the two objects? (Assume that the two objects do not lose any heat to anything else.)
- What is pressure–volume work? How is it calculated?
- What is calorimetry? Explain the difference between a coffee-cup calorimeter and a bomb calorimeter. What is each designed to measure?
- What is the change in enthalpy ( $\Delta H$ ) for a chemical reaction? How is  $\Delta H$  different from  $\Delta E$ ?
- Explain the difference between an exothermic and an endothermic reaction. Give the sign of  $\Delta H$  for each type of reaction.
- From a molecular viewpoint, where does the energy emitted in an exothermic chemical reaction come from? Why does the reaction mixture undergo an increase in temperature even though energy is emitted?
- From a molecular viewpoint, where does the energy absorbed in an endothermic chemical reaction go? Why does the reaction mixture undergo a decrease in temperature even though energy is absorbed?
- Is the change in enthalpy for a reaction an extensive property? Explain the relationship between  $\Delta H$  for a reaction and the amounts of reactants and products that undergo reaction.
- Explain how the value of  $\Delta H$  for a reaction changes upon each operation.
  - multiplying the reaction by a factor
  - reversing the reaction
 Why do these relationships hold?
- What is Hess's law? Why is it useful?
- What is a standard state? What is the standard enthalpy change for a reaction?
- What is the standard enthalpy of formation for a compound? For a pure element in its standard state?
- How do you calculate  $\Delta H_{\text{rxn}}^\circ$  from tabulated standard enthalpies of formation?
- What are the main sources of the energy consumed in the United States?
- What are the main environmental problems associated with fossil fuel use?
- Explain global climate change. What causes global warming? What is the evidence that global warming is occurring?

## Problems by Topic

### Energy Units

33. Convert between energy units.  
a. 534 kWh to J                      b. 215 kJ to Cal  
c. 567 Cal to J                      d.  $2.85 \times 10^3$  J to cal
34. Convert between energy units.  
a. 231 cal to kJ                      b.  $132 \times 10^4$  kJ to kcal  
c.  $4.99 \times 10^3$  kJ to kWh              d.  $2.88 \times 10^4$  J to Cal
35. Suppose that a person eats 2387 Calories per day. Convert this amount of energy into each unit.  
a. J                      b. kJ                      c. kWh
36. A particular frost-free refrigerator uses about 745 kWh of electrical energy per year. Express this amount of energy in each unit.  
a. J                      b. kJ                      c. Cal

### Internal Energy, Heat, and Work

37. Which statement is true of the internal energy of a system and its surroundings during an energy exchange with a negative  $\Delta E_{\text{sys}}$ ?  
a. The internal energy of the system increases and the internal energy of the surroundings decreases.  
b. The internal energy of both the system and the surroundings increases.  
c. The internal energy of both the system and the surroundings decreases.  
d. The internal energy of the system decreases and the internal energy of the surroundings increases.
38. During an energy exchange, a chemical system absorbs energy from its surroundings. What is the sign of  $\Delta E_{\text{sys}}$  for this process? Explain.
39. Identify each energy exchange as primarily heat or work and determine whether the sign of  $\Delta E$  is positive or negative for the system.  
a. Sweat evaporates from skin, cooling the skin. (The evaporating sweat is the system.)  
b. A balloon expands against an external pressure. (The contents of the balloon is the system.)  
c. An aqueous chemical reaction mixture is warmed with an external flame. (The reaction mixture is the system.)
40. Identify each energy exchange as primarily heat or work and determine whether the sign of  $\Delta E$  is positive or negative for the system.  
a. A rolling billiard ball collides with another billiard ball. The first billiard ball (defined as the system) stops rolling after the collision.  
b. A book falls to the floor. (The book is the system).  
c. A father pushes his daughter on a swing. (The daughter and the swing are the system).
41. A system releases 622 kJ of heat and does 105 kJ of work on the surroundings. What is the change in internal energy of the system?
42. A system absorbs 196 kJ of heat and the surroundings do 117 kJ of work on the system. What is the change in internal energy of the system?
43. The gas in a piston (defined as the system) warms and absorbs 655 J of heat. The expansion performs 344 J of work on the surroundings. What is the change in internal energy for the system?
44. The air in an inflated balloon (defined as the system) warms over a toaster and absorbs 115 J of heat. As it expands, it does 77 kJ of work. What is the change in internal energy for the system?
45. We pack two identical coolers for a picnic, placing 24 12-ounce soft drinks and five pounds of ice in each. However, the drinks that we put into cooler A were refrigerated for several hours before they were packed in the cooler, while the drinks that we put into cooler B were at room temperature. When we open the two coolers three hours later, most of the ice in cooler A is still present, while nearly all of the ice in cooler B has melted. Explain this difference.
46. A kilogram of aluminum metal and a kilogram of water are each warmed to  $75^\circ\text{C}$  and placed in two identical insulated containers. One hour later, the two containers are opened and the temperature of each substance is measured. The aluminum has cooled to  $35^\circ\text{C}$ , while the water has cooled only to  $66^\circ\text{C}$ . Explain this difference.
47. How much heat is required to warm 1.50 L of water from  $25.0^\circ\text{C}$  to  $100.0^\circ\text{C}$ ? (Assume a density of  $1.0\text{ g/mL}$  for the water.)
48. How much heat is required to warm 1.50 kg of sand from  $25.0^\circ\text{C}$  to  $100.0^\circ\text{C}$ ?
49. Suppose that 25 g of each substance is initially at  $27.0^\circ\text{C}$ . What is the final temperature of each substance upon absorbing 2.35 kJ of heat?  
a. gold                      b. silver                      c. aluminum                      d. water
50. An unknown mass of each substance, initially at  $23.0^\circ\text{C}$ , absorbs  $1.95 \times 10^3$  J of heat. The final temperature is recorded. Find the mass of each substance.  
a. Pyrex glass ( $T_f = 55.4^\circ\text{C}$ )                      b. sand ( $T_f = 62.1^\circ\text{C}$ )  
c. ethanol ( $T_f = 44.2^\circ\text{C}$ )                      d. water ( $T_f = 32.4^\circ\text{C}$ )
51. How much work (in J) is required to expand the volume of a pump from 0.0 L to 2.5 L against an external pressure of 1.1 atm?
52. The average human lung expands by about 0.50 L during each breath. If this expansion occurs against an external pressure of 1.0 atm, how much work (in J) is done during the expansion?
53. The air within a piston equipped with a cylinder absorbs 565 J of heat and expands from an initial volume of 0.10 L to a final volume of 0.85 L against an external pressure of 1.0 atm. What is the change in internal energy of the air within the piston?
54. A gas is compressed from an initial volume of 5.55 L to a final volume of 1.22 L by an external pressure of 1.00 atm. During the compression the gas releases 124 J of heat. What is the change in internal energy of the gas?

### Heat, Heat Capacity, and Work

### Enthalpy and Thermochemical Stoichiometry

55. When 1 mol of a fuel burns at constant pressure, it produces 3452 kJ of heat and does 11 kJ of work. What are  $\Delta E$  and  $\Delta H$  for the combustion of the fuel?
56. The change in internal energy for the combustion of 1.0 mol of octane at a pressure of 1.0 atm is 5084.3 kJ. If the change in enthalpy is 5074.1 kJ, how much work is done during the combustion?
57. Determine whether each process is exothermic or endothermic and indicate the sign of  $\Delta H$ .  
a. natural gas burning on a stove  
b. isopropyl alcohol evaporating from skin  
c. water condensing from steam
58. Determine whether each process is exothermic or endothermic and indicate the sign of  $\Delta H$ .  
a. dry ice evaporating                      b. a sparkler burning  
c. the reaction that occurs in a chemical cold pack used to ice athletic injuries

59. Consider the thermochemical equation for the combustion of acetone ( $\text{C}_3\text{H}_6\text{O}$ ), the main ingredient in nail polish remover:

If a bottle of nail polish remover contains 177 mL of acetone, how much heat is released by its complete combustion? The density of acetone is 0.788 g/mL.

60. What mass of natural gas ( $\text{CH}_4$ ) must burn to emit 267 kJ of heat?

61. Nitromethane ( $\text{CH}_3\text{NO}_2$ ) burns in air to produce significant amounts of heat.

How much heat is produced by the complete reaction of 5.56 kg of nitromethane?

62. Titanium reacts with iodine to form titanium(III) iodide, emitting heat.

Determine the masses of titanium and iodine that react if  $1.55 \times 10^3$  kJ of heat is emitted by the reaction.

63. The propane fuel ( $\text{C}_3\text{H}_8$ ) used in gas barbecues burns according to the thermochemical equation:

If a pork roast must absorb  $1.6 \times 10^3$  kJ to fully cook, and if only 10% of the heat produced by the barbecue is actually absorbed by the roast, what mass of  $\text{CO}_2$  is emitted into the atmosphere during the grilling of the pork roast?

64. Charcoal is primarily carbon. Determine the mass of  $\text{CO}_2$  produced by burning enough carbon (in the form of charcoal) to produce  $5.00 \times 10^2$  kJ of heat.

### Thermal Energy Transfer

65. A silver block, initially at  $58.5^\circ\text{C}$ , is submerged into 100.0 g of water at  $24.8^\circ\text{C}$ , in an insulated container. The final temperature of the mixture upon reaching thermal equilibrium is  $26.2^\circ\text{C}$ . What is the mass of the silver block?
66. A 32.5-g iron rod, initially at  $22.7^\circ\text{C}$ , is submerged into an unknown mass of water at  $63.2^\circ\text{C}$ , in an insulated container. The final temperature of the mixture upon reaching thermal equilibrium is  $59.5^\circ\text{C}$ . What is the mass of the water?
67. A 31.1-g wafer of pure gold, initially at  $69.3^\circ\text{C}$ , is submerged into 64.2 g of water at  $27.8^\circ\text{C}$  in an insulated container. What is the final temperature of both substances at thermal equilibrium?
68. A 2.85-g lead weight, initially at  $10.3^\circ\text{C}$ , is submerged in 7.55 g of water at  $52.3^\circ\text{C}$  in an insulated container. What is the final temperature of both substances at thermal equilibrium?
69. Two substances, A and B, initially at different temperatures, come into contact and reach thermal equilibrium. The mass of substance A is 6.15 g and its initial temperature is  $20.5^\circ\text{C}$ . The mass of substance B is 25.2 g and its initial temperature is  $52.7^\circ\text{C}$ . The final temperature of both substances at thermal equilibrium is  $46.7^\circ\text{C}$ . If the specific heat capacity of substance B is  $1.17 \text{ J/g}\cdot^\circ\text{C}$ , what is the specific heat capacity of substance A?
70. A 2.74-g sample of a substance suspected of being pure gold is warmed to  $72.1^\circ\text{C}$  and submerged into 15.2 g of water initially at  $24.7^\circ\text{C}$ . The final temperature of the mixture is  $26.3^\circ\text{C}$ . What is the heat capacity of the unknown substance? Could the substance be pure gold?

### Calorimetry

71. Exactly 1.5 g of a fuel burns under conditions of constant pressure and then again under conditions of constant volume. In measurement A the reaction produces 25.9 kJ of heat, and in measurement B the reaction produces 23.3 kJ of heat. Which measurement (A or B) corresponds to conditions of constant pressure? Which one corresponds to conditions of constant volume? Explain.
72. In order to obtain the largest possible amount of heat from a chemical reaction in which there is a large increase in the number of moles of gas, should you carry out the reaction under conditions of constant volume or constant pressure? Explain.
73. When 0.514 g of biphenyl ( $\text{C}_{12}\text{H}_{10}$ ) undergoes combustion in a bomb calorimeter, the temperature rises from  $25.8^\circ\text{C}$  to  $29.4^\circ\text{C}$ . Find  $\Delta E_{\text{rxn}}$  for the combustion of biphenyl in kJ/mol biphenyl. The heat capacity of the bomb calorimeter, determined in a separate experiment, is  $5.86 \text{ kJ}/^\circ\text{C}$ .
74. Mothballs are composed primarily of the hydrocarbon naphthalene ( $\text{C}_{10}\text{H}_8$ ). When 1.025 g of naphthalene burns in a bomb calorimeter, the temperature rises from  $24.25^\circ\text{C}$  to  $32.33^\circ\text{C}$ . Find  $\Delta E_{\text{rxn}}$  for the combustion of naphthalene. The heat capacity of the bomb calorimeter, determined in a separate experiment, is  $5.11 \text{ kJ}/^\circ\text{C}$ .
75. Zinc metal reacts with hydrochloric acid according to the balanced equation:

When 0.103 g of  $\text{Zn}(s)$  is combined with enough  $\text{HCl}$  to make 50.0 mL of solution in a coffee-cup calorimeter, all of the zinc reacts, raising the temperature of the solution from  $22.5^\circ\text{C}$  to  $23.7^\circ\text{C}$ . Find  $\Delta H_{\text{rxn}}$  for this reaction as written. (Use  $1.0 \text{ g/mL}$  for the density of the solution and  $4.18 \text{ J/g}\cdot^\circ\text{C}$  as the specific heat capacity.)

76. Instant cold packs used to ice athletic injuries on the field contain ammonium nitrate and water separated by a thin plastic divider. When the divider is broken, the ammonium nitrate dissolves according to the endothermic reaction:

In order to measure the enthalpy change for this reaction, 1.25 g of  $\text{NH}_4\text{NO}_3$  is dissolved in enough water to make 25.0 mL of solution. The initial temperature is  $25.8^\circ\text{C}$  and the final temperature (after the solid dissolves) is  $21.9^\circ\text{C}$ . Calculate the change in enthalpy for the reaction in kJ. (Use  $1.0 \text{ g/mL}$  as the density of the solution and  $4.18 \text{ J/g}\cdot^\circ\text{C}$  as the specific heat capacity.)

### Quantitative Relationships Involving $\Delta H$ and Hess's Law

77. For each generic reaction, determine the value of  $\Delta H_2$  in terms of  $\Delta H_1$ .
- |  |                  |
|--|------------------|
| a. $\text{A} + \text{B} \longrightarrow 2 \text{C}$                    | $\Delta H_1$     |
| $2 \text{C} \longrightarrow \text{A} + \text{B}$                       | $\Delta H_2 = ?$ |
| b. $\text{A} + \frac{1}{2} \text{B} \longrightarrow \text{C}$          | $\Delta H_1$     |
| $2 \text{A} + \text{B} \longrightarrow 2 \text{C}$                     | $\Delta H_2 = ?$ |
| c. $\text{A} \longrightarrow \text{B} + 2 \text{C}$                    | $\Delta H_1$     |
| $\frac{1}{2} \text{B} + \text{C} \longrightarrow \frac{1}{2} \text{A}$ | $\Delta H_2 = ?$ |
78. Consider the generic reaction:
- $$\text{A} + 2 \text{B} \longrightarrow \text{C} + 3 \text{D} \quad \Delta H = 155 \text{ kJ}$$
- Determine the value of  $\Delta H$  for each related reaction.
- $3 \text{A} + 6 \text{B} \longrightarrow 3 \text{C} + 9 \text{D}$
  - $\text{C} + 3 \text{D} \longrightarrow \text{A} + 2 \text{B}$
  - $\frac{1}{2} \text{C} + \frac{3}{2} \text{D} \longrightarrow \frac{1}{2} \text{A} + \text{B}$
79. Calculate  $\Delta H_{\text{rxn}}$  for the reaction:
- $$\text{Fe}_2\text{O}_3(s) + 3 \text{CO}(g) \longrightarrow 2 \text{Fe}(s) + 3 \text{CO}_2(g)$$

Use the following reactions and given  $\Delta H^\circ_f$ 's:

80. Calculate  $\Delta H_{\text{rxn}}$  for the reaction:

Use the following reactions and given  $\Delta H^\circ_f$ 's:

81. Calculate  $\Delta H_{\text{rxn}}$  for the reaction:

Use the following reactions and given  $\Delta H^\circ_f$ 's:

$$\Delta H = -3244.8 \text{ kJ}$$

82. Calculate  $\Delta H_{\text{rxn}}$  for the reaction:

Use the following reactions and given  $\Delta H^\circ_f$ 's:

### Enthalpies of Formation and $\Delta H$

83. Write an equation for the formation of each compound from its elements in their standard states, and find  $\Delta H^\circ_f$  for each in Appendix IIB.

84. Write an equation for the formation of each compound from its elements in their standard states, and find  $\Delta H^\circ_{\text{rxn}}$  for each in Appendix IIB.

85. Hydrazine ( $\text{N}_2\text{H}_4$ ) is a fuel used by some spacecraft. It is normally oxidized by  $\text{N}_2\text{O}_4$  according to the equation:

Calculate  $\Delta H^\circ_{\text{rxn}}$  for this reaction using standard enthalpies of formation.

86. Pentane ( $\text{C}_5\text{H}_{12}$ ) is a component of gasoline that burns according to the following balanced equation:

Calculate  $\Delta H^\circ_{\text{rxn}}$  for this reaction using standard enthalpies of formation. (The standard enthalpy of formation of liquid pentane is  $-146.8 \text{ kJ/mol}$ .)

87. Use standard enthalpies of formation to calculate  $\Delta H^\circ_{\text{rxn}}$  for each reaction.

88. Use standard enthalpies of formation to calculate  $\Delta H^\circ_{\text{rxn}}$  for each reaction.

89. During photosynthesis, plants use energy from sunlight to form glucose ( $\text{C}_6\text{H}_{12}\text{O}_6$ ) and oxygen from carbon dioxide and water. Write a balanced equation for photosynthesis and calculate  $\Delta H^\circ_{\text{rxn}}$ .

90. Ethanol ( $\text{C}_2\text{H}_5\text{OH}$ ) can be made from the fermentation of crops and has been used as a fuel additive to gasoline. Write a balanced equation for the combustion of ethanol and calculate  $\Delta H^\circ_{\text{rxn}}$ .

91. Top fuel dragsters and funny cars burn nitromethane as fuel according to the balanced combustion equation:

$$\Delta H^\circ_{\text{rxn}} = -1418 \text{ kJ}$$

The enthalpy of combustion for nitromethane is  $-709.2 \text{ kJ/mol}$ . Calculate the standard enthalpy of formation ( $\Delta H^\circ_f$ ) for nitromethane.

92. The explosive nitroglycerin ( $\text{C}_3\text{H}_5\text{N}_3\text{O}_9$ ) decomposes rapidly upon ignition or sudden impact according to the balanced equation:

$$\Delta H^\circ_{\text{rxn}} = -5678 \text{ kJ}$$

Calculate the standard enthalpy of formation ( $\Delta H^\circ_f$ ) for nitroglycerin.

### Energy Use and the Environment

93. Determine the mass of  $\text{CO}_2$  produced by burning enough of each fuel to produce  $1.00 \times 10^2 \text{ kJ}$  of heat. Which fuel contributes least to global warming per kJ of heat produced?

$$\Delta H^\circ_{\text{rxn}} = -802.3 \text{ kJ}$$

$$\Delta H^\circ_{\text{rxn}} = -2043 \text{ kJ}$$

$$\Delta H^\circ_{\text{rxn}} = -5074.1 \text{ kJ}$$

94. Methanol ( $\text{CH}_3\text{OH}$ ) has been suggested as a fuel to replace gasoline. Write a balanced equation for the combustion of methanol, find  $\Delta H^\circ_{\text{rxn}}$ , and determine the mass of carbon dioxide emitted per kJ of heat produced. Use the information from the previous exercise to calculate the same quantity for octane,  $\text{C}_8\text{H}_{18}$ . How does methanol compare to octane with respect to global warming?

95. The citizens of the world burn the fossil fuel equivalent of  $7 \times 10^{12} \text{ kg}$  of petroleum per year. Assume that all of this petroleum is in the form of octane ( $\text{C}_8\text{H}_{18}$ ) and calculate how much  $\text{CO}_2$  (in kg) the world produces from fossil fuel combustion per year. (Hint: Begin by writing a balanced equation for the combustion of octane.) If the atmosphere currently contains approximately  $3 \times 10^{15} \text{ kg}$  of  $\text{CO}_2$ , how long will it take for the world's fossil fuel combustion to double the amount of atmospheric carbon dioxide?

96. In a sunny location, sunlight has a power density of about  $1 \text{ kW/m}^2$ . Photovoltaic solar cells can convert this power into electricity with 15% efficiency. If a typical home uses 385 kWh of electricity per month, how many square meters of solar cells are required to meet its energy requirements? Assume that electricity can be generated from the sunlight for 8 hours per day.

▲ What area of solar cells do you need to power a home?

## Cumulative Problems

97. The kinetic energy of a rolling billiard ball is given by  $KE = \frac{1}{2}mv^2$ . Suppose a 0.17-kg billiard ball is rolling down a pool table with an initial speed of 4.5 m/s. As it travels, it loses some of its energy as heat. The ball slows down to 3.8 m/s and then collides head-on with a second billiard ball of equal mass. The first billiard ball completely stops and the second one rolls away with a velocity of 3.8 m/s. Assume the first billiard ball is the system. Calculate  $w$ ,  $q$ , and  $\Delta E$  for the process.
98. A 100-W lightbulb is placed in a cylinder equipped with a moveable piston. The lightbulb is turned on for 0.015 hour, and the assembly expands from an initial volume of 0.85 L to a final volume of 5.88 L against an external pressure of 1.0 atm. Use the wattage of the lightbulb and the time it is on to calculate  $\Delta E$  in joules (assume that the cylinder and lightbulb assembly is the system and assume two significant figures). Calculate  $w$  and  $q$ .
99. Evaporating sweat cools the body because evaporation is an endothermic process:
- $$\text{H}_2\text{O}(l) \longrightarrow \text{H}_2\text{O}(g) \quad \Delta H_{\text{rxn}}^\circ = +44.01 \text{ kJ}$$
- Estimate the mass of water that must evaporate from the skin to cool the body by 0.50 °C. Assume a body mass of 95 kg and assume that the specific heat capacity of the body is 4.0 J/g · °C.
100. LP gas burns according to the exothermic reaction:
- $$\text{C}_3\text{H}_8(g) + 5 \text{O}_2(g) \longrightarrow 3 \text{CO}_2(g) + 4 \text{H}_2\text{O}(g) \quad \Delta H_{\text{rxn}}^\circ = -2044 \text{ kJ}$$
- What mass of LP gas is necessary to heat 1.5 L of water from room temperature (25.0 °C) to boiling (100.0 °C)? Assume that during heating, 15% of the heat emitted by the LP gas combustion goes to heat the water. The rest is lost as heat to the surroundings.
101. Use standard enthalpies of formation to calculate the standard change in enthalpy for the melting of ice. (The  $\Delta H_f^\circ$  for  $\text{H}_2\text{O}(s)$  is  $-291.8 \text{ kJ/mol}$ .) Use this value to calculate the mass of ice required to cool 355 mL of a beverage from room temperature (25.0 °C) to 0.0 °C. Assume that the specific heat capacity and density of the beverage are the same as those of water.
102. Dry ice is solid carbon dioxide. Instead of melting, solid carbon dioxide sublimates according to the equation:

◀ When carbon dioxide sublimates, the gaseous  $\text{CO}_2$  is cold enough to cause water vapor in the air to condense, forming fog.

When dry ice is added to warm water, heat from the water causes the dry ice to sublime more quickly. The evaporating carbon dioxide produces a dense fog often used to create special effects. In a simple dry ice fog machine, dry ice is added to warm water in a Styrofoam cooler. The dry ice produces fog until it evaporates away, or until the water gets too cold to sublime the dry ice quickly enough. Suppose that a small Styrofoam cooler holds 15.0 L of water heated to 85 °C. Use standard enthalpies of formation to calculate the change in enthalpy for dry ice sublimation, and calculate the mass of dry ice that should be added to the water so that the dry ice completely sublimates away when the water reaches 25 °C. Assume no heat loss to the surroundings. (The  $\Delta H_f^\circ$  for  $\text{CO}_2(s)$  is  $-427.4 \text{ kJ/mol}$ .)

103. A 25.5-g aluminum block is warmed to 65.4 °C and plunged into an insulated beaker containing 55.2 g water initially at 22.2 °C. The aluminum and the water are allowed to come to thermal equilibrium. Assuming that no heat is lost, what is the final temperature of the water and aluminum?
104. If 50.0 mL of ethanol (density = 0.789 g/mL) initially at 7.0 °C is mixed with 50.0 mL of water (density = 1.0 g/mL) initially at 28.4 °C in an insulated beaker, and assuming that no heat is lost, what is the final temperature of the mixture?
105. Palmitic acid ( $\text{C}_{16}\text{H}_{32}\text{O}_2$ ) is a dietary fat found in beef and butter. The caloric content of palmitic acid is typical of fats in general. Write a balanced equation for the complete combustion of palmitic acid and calculate the standard enthalpy of combustion. What is the caloric content of palmitic acid in Cal/g? Do the same calculation for table sugar (sucrose,  $\text{C}_{12}\text{H}_{22}\text{O}_{11}$ ). Which dietary substance (sugar or fat) contains more Calories per gram? The standard enthalpy of formation of palmitic acid is  $-208 \text{ kJ/mol}$  and that of sucrose is  $-2226.1 \text{ kJ/mol}$ . [Use  $\text{H}_2\text{O}(l)$  in the balanced chemical equations because the metabolism of these compounds produces liquid water.]
106. Hydrogen and methanol have both been proposed as alternatives to hydrocarbon fuels. Write balanced reactions for the complete combustion of hydrogen and methanol and use standard enthalpies of formation to calculate the amount of heat released per kilogram of the fuel. Which fuel contains the most energy in the least mass? How does the energy of these fuels compare to that of octane ( $\text{C}_8\text{H}_{18}$ )?
107. Derive a relationship between  $\Delta H$  and  $\Delta E$  for a process in which the temperature of a fixed amount of an ideal gas changes.
108. Under certain nonstandard conditions, oxidation by  $\text{O}_2(g)$  of 1 mol of  $\text{SO}_2(g)$  to  $\text{SO}_3(g)$  absorbs 89.5 kJ. The enthalpy of formation of  $\text{SO}_3(g)$  is  $-204.2 \text{ kJ}$  under these conditions. Find the enthalpy of formation of  $\text{SO}_2(g)$ .
109. One tablespoon of peanut butter has a mass of 16 g. It is combusted in a calorimeter whose heat capacity is 120.0 kJ/°C. The temperature of the calorimeter rises from 22.2 °C to 25.4 °C. Find the food caloric content of peanut butter.
110. A mixture of 2.0 mol of  $\text{H}_2(g)$  and 1.0 mol of  $\text{O}_2(g)$  is placed in a sealed evacuated container made of a perfect insulating material at 25 °C. The mixture is ignited with a spark and reacts to form liquid water. Determine the temperature of the water.
111. A 20.0-L volume of an ideal gas in a cylinder with a piston is at a pressure of 3.0 atm. Enough weight is suddenly removed from the piston to lower the external pressure to 1.5 atm. The gas then expands at constant temperature until its pressure is 1.5 atm. Find  $\Delta E$ ,  $\Delta H$ ,  $q$ , and  $w$  for this change in state.
112. When 10.00 g of phosphorus is burned in  $\text{O}_2(g)$  to form  $\text{P}_4\text{O}_{10}(s)$ , enough heat is generated to raise the temperature of 2950 g of water from 18.0 °C to 38.0 °C. Calculate the enthalpy of formation of  $\text{P}_4\text{O}_{10}(s)$  under these conditions.
113. The  $\Delta H$  for the oxidation of sulfur in the gas phase to  $\text{SO}_3$  is  $-204 \text{ kJ/mol}$  and for the oxidation of  $\text{SO}_2$  to  $\text{SO}_3$  is  $89.5 \text{ kJ/mol}$ . Find the enthalpy of formation of  $\text{SO}_2$  under these conditions.
114. The  $\Delta H_f^\circ$  of  $\text{TiI}_3(s)$  is  $-328 \text{ kJ/mol}$  and the  $\Delta H^\circ$  for the reaction  $2 \text{Ti}(s) + 3 \text{I}_2(g) \longrightarrow 2 \text{TiI}_3(s)$  is  $-839 \text{ kJ}$ . Calculate the  $\Delta H$  of sublimation of  $\text{I}_2(s)$ , which is a solid at 25 °C.
115. A gaseous fuel mixture contains 25.3% methane ( $\text{CH}_4$ ), 38.2% ethane ( $\text{C}_2\text{H}_6$ ), and the rest propane ( $\text{C}_3\text{H}_8$ ) by volume. When the fuel mixture contained in a 1.55 L tank, stored at 755 mmHg and 298 K, undergoes complete combustion, how much heat is

emitted? (Assume that the water produced by the combustion is in the gaseous state.)

- 116.** A gaseous fuel mixture stored at 745 mmHg and 298 K contains only methane ( $\text{CH}_4$ ) and propane ( $\text{C}_3\text{H}_8$ ). When 11.7 L of this fuel mixture is burned, it produces 769 kJ of heat. What is the mole fraction of methane in the mixture? (Assume that the water produced by the combustion is in the gaseous state.)
- 117.** A copper cube with an edge measuring 1.55 cm and an aluminum cube with an edge measuring 1.62 cm are both heated to

55.0 °C and submerged in 100.0 mL of water at 22.2 °C. What is the final temperature of the water when equilibrium is reached? (Assume a density of 0.998 g/mL for water.)

- 118.** A pure gold ring and a pure silver ring have a total mass of 14.9 g. The two rings are heated to 62.0 °C and dropped into 15.0 mL of water at 23.5 °C. When equilibrium is reached, the temperature of the water is 25.0 °C. What is the mass of each ring? (Assume a density of 0.998 g/mL for water.)

## Challenge Problems

- 119.** A typical frostless refrigerator uses 655 kWh of energy per year in the form of electricity. Suppose that all of this electricity is generated at a power plant that burns coal containing 3.2% sulfur by mass and that all of the sulfur is emitted as  $\text{SO}_2$  when the coal is burned. If all of the  $\text{SO}_2$  goes on to react with rainwater to form  $\text{H}_2\text{SO}_4$ , what mass of  $\text{H}_2\text{SO}_4$  does the annual operation of the refrigerator produce? (Hint: Assume that the remaining percentage of the coal is carbon and begin by calculating  $\Delta H^\circ_{\text{rxn}}$  for the combustion of carbon.)
- 120.** A large sport utility vehicle has a mass of  $2.5 \times 10^3$  kg. Calculate the mass of  $\text{CO}_2$  emitted into the atmosphere upon accelerating the SUV from 0.0 mph to 65.0 mph. Assume that the required energy comes from the combustion of octane with 30% efficiency. (Hint: Use  $\text{KE} = \frac{1}{2}mv^2$  to calculate the kinetic energy required for the acceleration.)
- 121.** Combustion of natural gas (primarily methane) occurs in most household heaters. The heat given off in this reaction is used to raise the temperature of the air in the house. Assuming that all the energy given off in the reaction goes to heating up only the air in the house, determine the mass of methane required to heat the air in a house by 10.0 °C. Assume that the house dimensions are 30.0 m  $\times$  30.0 m  $\times$  3.0 m, specific heat capacity of air is 30 J/K  $\cdot$  mol, and 1.00 mol of air occupies 22.4 L for all temperatures concerned.
- 122.** When backpacking in the wilderness, hikers often boil water to sterilize it for drinking. Suppose that you are planning a backpacking trip and will need to boil 35 L of water for your group. What volume of fuel should you bring? Assume that the fuel has an average formula of  $\text{C}_7\text{H}_{16}$ , 15% of the heat generated from combustion goes to heat the water (the rest is lost to the surroundings), the density of the fuel is 0.78 g/mL, the initial temperature of the water is 25.0 °C, and the standard enthalpy of formation of  $\text{C}_7\text{H}_{16}$  is  $-224.4$  kJ/mol.
- 123.** An ice cube of mass 9.0 g is added to a cup of coffee. The coffee's initial temperature is 90.0 °C and the cup contains 120.0 g of liquid. Assume the specific heat capacity of the coffee is the same as that of water. The heat of fusion of ice (the heat associated with ice melting) is 6.0 kJ/mol. Find the temperature of the coffee after the ice melts.
- 124.** Find  $\Delta H$ ,  $\Delta E$ ,  $q$ , and  $w$  for the freezing of water at  $-10.0$  °C. The specific heat capacity of ice is 2.04 J/g  $\cdot$  °C and its heat of fusion (the quantity of heat associated with melting) is  $-332$  J/g.
- 125.** Starting from the relationship between temperature and kinetic energy for an ideal gas, find the value of the molar heat capacity of an ideal gas when its temperature is changed at constant volume. Find its molar heat capacity when its temperature is changed at constant pressure.
- 126.** An amount of an ideal gas expands from 12.0 L to 24.0 L at a constant pressure of 1.0 atm. Then the gas is cooled at a constant volume of 24.0 L back to its original temperature. Then it contracts back to its original volume. Find the total heat flow for the entire process.
- 127.** The heat of vaporization of water at 373 K is 40.7 kJ/mol. Find  $q$ ,  $w$ ,  $\Delta E$ , and  $\Delta H$  for the evaporation of 454 g of water at this temperature at 1 atm.
- 128.** Find  $\Delta E$ ,  $\Delta H$ ,  $q$ , and  $w$  for the change in state of 1.0 mol  $\text{H}_2\text{O}(l)$  at 80 °C to  $\text{H}_2\text{O}(g)$  at 110 °C. The heat capacity of  $\text{H}_2\text{O}(l)$  at  $=75.3$  J/mol K, heat capacity of  $\text{H}_2\text{O}(g) = 25.0$  J/mol K, and the heat of vaporization of  $\text{H}_2\text{O}$  is  $40.7 \times 10^3$  J/mol at 100 °C.
- 129.** The heat of combustion of liquid octane ( $\text{C}_8\text{H}_{18}$ ) to carbon dioxide and liquid water at 298 K is  $-1303$  kJ/mol. Find  $\Delta E$  for this reaction.
- 130.** Find  $\Delta H$  for the combustion of ethanol ( $\text{C}_2\text{H}_6\text{O}$ ) to carbon dioxide and liquid water from the following data. The heat capacity of the bomb calorimeter is 34.65 kJ/K and the combustion of 1.765 g of ethanol raises the temperature of the calorimeter from 294.33 K to 295.84 K.

## Conceptual Problems

- 131.** Which statement is true of the internal energy of the system and its surroundings following a process in which  $\Delta E_{\text{sys}} = +65$  kJ? Explain.
- The system and the surroundings both lose 65 kJ of energy.
  - The system and the surroundings both gain 65 kJ of energy.
  - The system loses 65 kJ of energy and the surroundings gain 65 kJ of energy.
  - The system gains 65 kJ of energy and the surroundings lose 65 kJ of energy.
- 132.** The internal energy of an ideal gas depends only on its temperature. Which statement is true of an isothermal (constant-temperature) expansion of an ideal gas against a constant external pressure? Explain.
- $\Delta E$  is positive
  - $w$  is positive
  - $q$  is positive
  - $\Delta E$  is negative
- 133.** Which expression describes the heat evolved in a chemical reaction when the reaction is carried out at constant pressure? Explain.
- $\Delta E - w$
  - $\Delta E$
  - $\Delta E - q$
- 134.** Two identical new refrigerators are plugged in for the first time. Refrigerator A is empty (except for air) and refrigerator B is filled with jugs of water. The compressors of both refrigerators

immediately turn on and begin cooling the interiors of the refrigerators. After two hours, the compressor of refrigerator A turns off while the compressor of refrigerator B continues to run. The next day, the compressor of refrigerator A can be heard turning on and off every few minutes, while the compressor of refrigerator B turns off and on every hour or so (and stays on longer each time). Explain these observations.

- 135.** A 1-kg cylinder of aluminum and 1-kg jug of water, both at room temperature, are put into a refrigerator. After 1 hour, the temperature of each object is measured. One of the objects is much cooler than the other. Which one is cooler and why?
- 136.** Two substances A and B, initially at different temperatures, are thermally isolated from their surroundings and allowed to come into thermal contact. The mass of substance A is twice the

mass of substance B, but the specific heat capacity of substance B is four times the specific heat capacity of substance A. Which substance will undergo a larger change in temperature?

- 137.** When 1 mol of a gas burns at constant pressure, it produces 2418 J of heat and does 5 J of work. Determine  $\Delta E$ ,  $\Delta H$ ,  $q$ , and  $w$  for the process.
- 138.** In an exothermic reaction, the reactants lose energy and the reaction feels hot to the touch. Explain why the reaction feels hot even though the reactants are losing energy. Where does the energy come from?
- 139.** Which statement is true of a reaction in which  $\Delta V$  is positive? Explain.  
 a.  $\Delta H = \Delta E$     b.  $\Delta H > \Delta E$     c.  $\Delta H < \Delta E$

### Active Classroom Learning

## Questions for Group Work

Discuss these questions with the group and record your consensus answer.

- 140.** Have each group member write a problem involving the transfer of heat from one material in Table 6.4 to another material in the table. Working as a group, solve each problem. The group member who wrote each problem may act as the group facilitator when the group is working on his or her problem. What do all of your problems have in common? How do they differ?
- 141.** Classify each process as endothermic or exothermic. What is the sign of  $\Delta H$  for each process? Explain your answers.
- gasoline burning in an engine
  - steam condensing on a mirror
  - water boiling in a pot

Provide at least two additional examples of exothermic processes and two additional examples of endothermic processes. Have each member of your group provide an example.

- 142.** A propane tank on a home barbeque contains  $10.4 \times 10^3$  g of propane.
- Write the balanced chemical reaction for the combustion of gaseous propane ( $\text{C}_3\text{H}_8$ ) to form water vapor and gaseous carbon dioxide.

- Use the value for  $\Delta H_{\text{rxn}}$  provided in the text to calculate the total amount of heat produced when the entire contents of the tank of propane is burned.
  - What mass of water could be warmed from  $25^\circ\text{C}$  to  $100^\circ\text{C}$  with this much heat?
- 143.** Consider the decomposition of liquid hydrogen peroxide ( $\text{H}_2\text{O}_2$ ) to form water and oxygen.
- What is the heat of formation for hydrogen peroxide?
  - What is the heat of formation for liquid water?
  - What is the heat of formation for gaseous oxygen? Why?
  - Write the balanced chemical equations that correspond to the  $\Delta H$  values you looked up for parts a, b, and c.
  - Write the balanced chemical equation for the decomposition of hydrogen peroxide to form water and oxygen. (Write the equation such that the coefficient on oxygen is 1.)
  - What is the heat of reaction for the process in part e?
  - Draw a scale diagram of this reaction (1 cm = 100 kJ) that shows the relative energies of reactants (on the left), products (on the right), and the elements in their most stable states (in the middle). Label all the energies you know.

## Data Interpretation and Analysis

### Heat Content of Fuels

- 144.** To compare the energy content of fuels, we can use the quantities known as *higher heating value (HHV)* and *lower heating value (LHV)*. The HHV assumes that the reaction product water is formed in the liquid state. The HHV is the same as the change in enthalpy of combustion,  $\Delta H_{\text{comb}}$ . The LHV assumes that water is formed in the gas state. The LHV is therefore the sum of the HHV (which is negative) and the heat of vaporization of water (which is positive).

The structures shown here represent molecules of  $\text{C}_1$ ,  $\text{C}_2$ , and  $\text{C}_3$  straight-chain alkanes and straight-chain alcohols.

Figure a ▼ lists the changes in enthalpy when straight-chain alkanes and straight-chain alcohols undergo combustion to form gaseous carbon dioxide and liquid water.

Alkane	$\Delta H_{\text{comb}}(\text{kJ/mol})$	Alcohol	$\Delta H_{\text{comb}}(\text{kJ/mol})$
$\text{CH}_4(\text{g})$	-890	$\text{CH}_3\text{OH}(\text{l})$	-726
$\text{C}_2\text{H}_6(\text{g})$	-1560	$\text{CH}_3\text{CH}_2\text{OH}(\text{l})$	-1367
$\text{C}_3\text{H}_8(\text{g})$	-2219	$\text{CH}_3(\text{CH}_2)_2\text{OH}(\text{l})$	-2021
$\text{C}_4\text{H}_{10}(\text{g})$	-2877	$\text{CH}_3(\text{CH}_2)_3\text{OH}(\text{l})$	-2676
$\text{C}_5\text{H}_{12}(\text{l})$	-3509	$\text{CH}_3(\text{CH}_2)_4\text{OH}(\text{l})$	-3329
$\text{C}_6\text{H}_{14}(\text{l})$	-4163	$\text{CH}_3(\text{CH}_2)_5\text{OH}(\text{l})$	-3984
$\text{C}_7\text{H}_{16}(\text{l})$	-4817	$\text{CH}_3(\text{CH}_2)_6\text{OH}(\text{l})$	-4638
$\text{C}_8\text{H}_{18}(\text{l})$	-5470	$\text{CH}_3(\text{CH}_2)_7\text{OH}(\text{l})$	-5294

▲ **FIGURE a** Change in Enthalpy Values for Combustion of Straight-Chain Alkanes and Straight-Chain Alcohols

Figure b ▼ plots  $\Delta H_{\text{comb}}$  versus the number of carbon atoms for alkanes and alcohols. Note that there is an almost linear relationship between  $\Delta H_{\text{comb}}$  and the number of carbon atoms.

◀ **FIGURE b** Enthalpies of Combustion of Linear Alkanes and Alcohols

Source: <http://www.docbrown.info/page07/delta1Hd.htm>

Use the information provided in the figures to answer the following questions:

- Complete and balance the combustion equations using whole-number coefficients for carbon dioxide and  $\text{H}_2\text{O}$ , assuming liquid water forms:
  - $\text{CH}_3\text{CH}_2\text{CH}_3(\text{g}) + \text{O}_2(\text{g}) \longrightarrow \text{ } + \text{ }$
  - $\text{CH}_3\text{CH}_2\text{CH}_2\text{OH}(\text{l}) + \text{O}_2(\text{g}) \longrightarrow \text{ } + \text{ }$
- Given  $\Delta H_{\text{vap}}(\text{H}_2\text{O})$  is +44 kJ/mol, if the reactions in part a were written to produce  $\text{H}_2\text{O}(\text{g})$  instead of  $\text{H}_2\text{O}(\text{l})$ , would you expect the magnitude (or absolute value) of  $\Delta H_{\text{comb}}$  to increase, decrease, or stay the same? Explain.
- Calculate  $\Delta H$  for the combustion of propane gas,  $\text{C}_3\text{H}_8$ , assuming  $\text{H}_2\text{O}(\text{g})$  is produced instead of  $\text{H}_2\text{O}(\text{l})$ . Compare your value to the value of  $\Delta H$  for propane in Figure a.
- When one mole of propane gas (used to cook food on a outdoor grill) undergoes complete combustion at constant pressure, is the amount of heat released the HHV or the LHV? Explain.
- For each  $-\text{CH}_2-$  unit added to the alkanes, what is the change in enthalpy of combustion,  $\Delta H_{\text{comb}}$ ?
- Given  $\Delta H_{\text{vap}}$  for pentane ( $\text{C}_5\text{H}_{12}$ ) is +36 kJ/mol, explain why the change in enthalpy of combustion,  $\Delta H_{\text{comb}}$  between gaseous methane and gaseous ethane is larger than the change in enthalpy of combustion,  $\Delta H_{\text{comb}}$  between gaseous butane,  $\text{C}_4\text{H}_{10}$ , and liquid pentane.

## Answers to Conceptual Connections

### System and Surroundings

- 6.1** The correct answer is (a). When  $\Delta E_{\text{sys}}$  is negative, energy flows out of the system and into the surroundings. The energy increase in the surroundings must exactly match the decrease in the system.

### Heat and Work

- 6.2** (a) heat, sign is positive (b) work, sign is positive (c) heat, sign is negative

### The Heat Capacity of Water

- 6.3** Bring the water into your sleeping bag; it has the higher heat capacity and will therefore release more heat as it cools.

### Thermal Energy Transfer

- 6.4** (c) The specific heat capacity of substance B is twice that of A, but since the mass of B is half that of A, the quantity  $m \times C_s$  is identical for both substances so that the final temperature is exactly midway between the two initial temperatures.

### The Difference between $\Delta H$ and $\Delta E$

- 6.5**  $\Delta H$  represents only the heat exchanged; therefore,  $\Delta H = -2658 \text{ kJ}$ .  $\Delta E$  represents the heat and work exchanged;

therefore,  $\Delta E = -2661 \text{ kJ}$ . The signs of both  $\Delta H$  and  $\Delta E$  are negative because heat and work are flowing out of the system and into the surroundings. Notice that the values of  $\Delta H$  and  $\Delta E$  are similar in magnitude, as is the case in many chemical reactions.

### Exothermic and Endothermic Reactions

- 6.6** An endothermic reaction feels cold to the touch because the reaction (acting here as the system) absorbs heat from the surroundings. When you touch the vessel in which the reaction occurs, you, being part of the surroundings, lose heat to the system (the reaction), which makes you feel cold. The heat absorbed by the reaction (from your body, in this case) does not increase its temperature, but rather becomes potential energy stored in chemical bonds.

### Constant-Pressure versus Constant-Volume Calorimetry

- 6.7** The value of  $q_{\text{rxn}}$  with the greater magnitude ( $-12.5 \text{ kJ}$ ) must have come from the bomb calorimeter. Recall that  $\Delta E_{\text{rxn}} = q_{\text{rxn}} + w_{\text{rxn}}$ . In a bomb calorimeter, the energy change that occurs in the course of the reaction all takes the form of heat ( $q$ ). In a coffee-cup calorimeter, the amount of energy released as heat may be smaller because some of the energy may be used to do work ( $w$ ).

# The Quantum-Mechanical Model of the Atom

**Anyone who is not shocked by quantum mechanics has not understood it.**

—NIELS BOHR (1885–1962)

- 7.1** Schrödinger's Cat 298
- 7.2** The Nature of Light 298
- 7.3** Atomic Spectroscopy and the Bohr Model 308
- 7.4** The Wave Nature of Matter: The de Broglie Wavelength, the Uncertainty Principle, and Indeterminacy 311

- 7.5** Quantum Mechanics and the Atom 317
- 7.6** The Shapes of Atomic Orbitals 323

**KEY LEARNING OUTCOMES 330**

The early part of the twentieth century brought changes that revolutionized how we think about physical reality, especially in the atomic realm. Before then, all descriptions of the behavior of matter had been deterministic—the present conditions completely determining the future. The new theory of quantum mechanics suggested that for subatomic particles—electrons, neutrons, and protons—the present does NOT completely determine the future. For example, if you shoot one electron down a path and measure where it lands, a second electron shot down the same path under the same conditions will most likely land in a different place! Several unusually gifted scientists, including Albert Einstein, Niels Bohr, Louis de Broglie, Max Planck, Werner Heisenberg, P. A. M. Dirac, and Erwin Schrödinger, developed quantum-mechanical theory. These scientists did not necessarily feel comfortable with their own theory. Bohr said, “Anyone who is not shocked by quantum mechanics has not understood it.” Schrödinger wrote, “I don’t like it, and I’m sorry I ever had anything to do with it.” Albert Einstein disbelieved the very theory he helped develop, stating, “God does not play dice with the universe.” In fact, Einstein attempted to disprove quantum mechanics—without success—until he died. Today, quantum mechanics forms the foundation of chemistry—explaining the periodic table and the behavior of the elements in chemical bonding—as well as providing the practical basis for lasers, computers, and countless other applications.

▲ The thought experiment known as Schrödinger’s cat is intended to show that the strangeness of the quantum world does not transfer to the macroscopic world.

## 7.1 Schrödinger’s Cat

Atoms and the particles that compose them are unimaginably small. Electrons have a mass of less than a trillionth of a trillionth of a gram, a size so small that it is

immeasurable. A single speck of dust contains more electrons than the number of people who have existed on Earth over all the centuries of time. Electrons are *small* in the absolute sense of the word—they are among the smallest particles that make up matter. And yet, as we have seen in the preceding chapters, an atom's electrons determine many of its chemical and physical properties. If we are to understand these properties, we must try to understand electrons.

In the early twentieth century, scientists discovered that the *absolutely small* (or *quantum*) world of the electron behaves differently than the *large* (or *macroscopic*) world that we are used to observing. Chief among these differences is the idea that, when unobserved, *absolutely small particles like electrons can be in two different states at the same time*. For example, through a process called radioactive decay (see Chapter 20) an atom can emit small (that is, *absolutely small*) energetic particles from its nucleus. In the macroscopic world, something either emits an energetic particle or it doesn't. In the quantum world, however, the unobserved atom can be in a state in which it is doing both—emitting the particle and not emitting the particle—simultaneously. At first, this seems absurd. The absurdity resolves itself, however, upon observation. When we set out to measure the emitted particle, the act of measurement actually forces the atom into one state or the other.

Early twentieth-century physicists struggled with this idea. Austrian physicist Erwin Schrödinger (1887–1961), in an attempt to demonstrate that this quantum strangeness could never transfer itself to the macroscopic world, published a paper in 1935 that contained a thought experiment about a cat, now known as Schrödinger's cat. In the thought experiment, the imaginary cat is put into a steel chamber that contains radioactive atoms such as the atom described in the previous paragraph. The chamber is equipped with a mechanism that, upon the emission of an energetic particle by one of the radioactive atoms, causes a hammer to break a flask of hydrocyanic acid, a poison. If the flask breaks, the poison is released and the cat dies.

Now here comes the absurdity: if the steel chamber is closed, the whole system remains unobserved, and the radioactive atom is in a state in which it has both emitted the particle and not emitted the particle (with equal probability). Therefore, the cat is both dead and undead. Schrödinger put it this way: “[the steel chamber would have] *in it the living and dead cat (pardon the expression) mixed or smeared out in equal parts.*” When the chamber is opened, the act of observation forces the entire system into one state or the other: the cat is either dead or alive, not both. However, while unobserved, the cat is both dead and alive. The absurdity of the both dead and undead cat in Schrödinger's thought experiment was meant to demonstrate how quantum strangeness does not transfer to the macroscopic world.

In this chapter, we examine the **quantum-mechanical model** of the atom, a model that explains the strange behavior of electrons. In particular, we focus on how the model describes electrons as they exist within atoms, and how those electrons determine the chemical and physical properties of elements. You have already learned much about those properties. You know, for example, that some elements are metals and that others are nonmetals. You know that the noble gases are chemically inert and that the alkali metals are chemically reactive. You know that sodium tends to form  $1+$  ions and that fluorine tends to form  $1-$  ions. But we have not explored *why*. The quantum-mechanical model explains why. In doing so, it explains the modern periodic table and provides the basis for our understanding of chemical bonding.

## The Nature of Light

### 7.2 The Nature of Light

Before we explore electrons and their behavior within the atom, we must understand some of the properties of light. As quantum mechanics developed, light was (surprisingly) found to have many characteristics in common with electrons. Chief among these is the *wave-particle duality* of light. Certain properties of light are best described by thinking of it as a wave, while other properties are best described by

thinking of it as a particle. In this section, we first explore the wave behavior of light and its particle behavior. We then turn to electrons to see how they display the same wave-particle duality.

## The Wave Nature of Light

Light is **electromagnetic radiation**, a type of energy embodied in oscillating electric and magnetic fields. A *magnetic field* is a region of space where a magnetic particle experiences a force (think of the space around a magnet). An *electric field* is a region of space where an electrically charged particle experiences a force. A proton, for example, has an electric field around it. If you bring another charged particle into that field, that particle will experience a force.

We can describe electromagnetic radiation as a wave composed of oscillating, mutually perpendicular electric and magnetic fields propagating through space, as shown in Figure 7.1. In a vacuum, these waves move at a constant speed of  $3.00 \times 10^8$  m/s (186,000 mi/s)—fast enough to circle Earth in one-seventh of a second. This great speed is the reason for the delay between the moment when you see a firework in the sky and the moment when you hear the sound of its explosion. The light from the exploding firework reaches your eye almost instantaneously. The sound, traveling much more slowly (340 m/s), takes longer. The same thing happens in a thunderstorm—you see the flash of lightning immediately, but the sound of thunder takes a few seconds to reach you. (The sound of thunder is delayed by five seconds for each mile between you and its origin.)

◀ Because light travels nearly a million times faster than sound, the flash of lightning reaches your eyes before the roll of thunder reaches your ears.

### Electromagnetic Radiation

◀ **FIGURE 7.1 Electromagnetic Radiation** We describe electromagnetic radiation as a wave composed of oscillating electric and magnetic fields. The fields oscillate in perpendicular planes.

► **FIGURE 7.2 Wavelength and Amplitude** Wavelength and amplitude are independent properties. The wavelength of light determines its color. The amplitude, or intensity, determines its brightness.

The symbol  $\lambda$  is the Greek letter lambda, pronounced “lamb-duh.”

We characterize a wave by its *amplitude* and its *wavelength*. In the graphical representation shown here, the **amplitude** of the wave is the vertical height of a crest (or depth of a trough). The amplitude of the electric and magnetic field waves in light determines the light’s *intensity* or brightness—the greater the amplitude, the greater the intensity. The **wavelength** ( $\lambda$ ) of the wave is the distance between adjacent crests (or any two analogous points) and is measured in units such as meters, micrometers, or nanometers. Amplitude and wavelength can vary independently of one another, as shown in Figure 7.2▲.

The symbol  $\nu$  is the Greek letter nu, pronounced “noo.”

Like all waves, light is also characterized by its **frequency** ( $\nu$ ), the number of cycles (or wave crests) that pass through a stationary point in a given period of time. The units of frequency are cycles per second (cycle/s) or simply  $s^{-1}$ . An equivalent unit of frequency is the hertz (Hz), defined as 1 cycle/s. The frequency of a wave is directly proportional to the speed at which the wave is traveling—the faster the wave, the greater the number of crests that pass a fixed location per unit time. Frequency is also *inversely* proportional to the wavelength ( $\lambda$ )—the farther apart the crests, the lower the number of crests that pass a fixed location per unit time. For light, therefore, we can write the equation:

$$\nu = \frac{c}{\lambda} \quad [7.1]$$

where the speed of light,  $c$ , and the wavelength,  $\lambda$ , are both expressed in the same unit of distance. Wavelength and frequency represent different ways of specifying the same information—if we know one, we can readily calculate the other.

For *visible light*—light that can be seen by the human eye—wavelength (or, alternatively, frequency) determines color. White light, produced by the sun or by a lightbulb, contains a spectrum of wavelengths and therefore a spectrum of colors. We see these colors—red, orange, yellow, green, blue, indigo, and violet—in a rainbow or when white light passes through a prism (Figure 7.3►). Red light, with a wavelength of about 750 nanometers (nm), has the longest wavelength of visible light; violet light, with a wavelength of about 400 nm, has the shortest. The presence of a variety of wavelengths in white light is responsible for the way we perceive colors in objects. When a substance

1 nano =  $10^{-9}$

▲ **FIGURE 7.3 Components of White**

**Light** We can pass white light through a prism and decompose it into its constituent colors, each with a different wavelength. The array of colors makes up the spectrum of visible light.

▲ **FIGURE 7.4 The Color of an**

**Object** A red shirt is red because it reflects predominantly red light while absorbing most other colors.

absorbs some colors while reflecting others, it appears colored. For example, a red shirt appears red because it reflects predominantly red light while absorbing most other colors (Figure 7.4▲). Our eyes see only the reflected light, making the shirt appear red.

### Example 7.1 Wavelength and Frequency

Calculate the wavelength (in nm) of the red light emitted by a barcode scanner that has a frequency of  $4.62 \times 10^{14} \text{ s}^{-1}$ .

#### SOLUTION

You are given the frequency of the light and asked to find its wavelength. Use Equation 7.1, which relates frequency to wavelength. You can convert the wavelength from meters to nanometers by using the conversion factor between the two ( $1 \text{ nm} = 10^{-9} \text{ m}$ ).

$$\begin{aligned} \nu &= \frac{c}{\lambda} \\ \lambda &= \frac{c}{\nu} = \frac{3.00 \times 10^8 \text{ m/s}}{4.62 \times 10^{14} / \text{s}} \\ &= 6.49 \times 10^{-7} \text{ m} \\ &= 6.49 \times 10^{-7} \text{ m} \times \frac{1 \text{ nm}}{10^{-9} \text{ m}} = 649 \text{ nm} \end{aligned}$$

**FOR PRACTICE 7.1** A laser dazzles the audience in a rock concert by emitting green light with a wavelength of 515 nm. Calculate the frequency of the light.

## The Electromagnetic Spectrum

Visible light makes up only a tiny portion of the entire **electromagnetic spectrum**, which includes all wavelengths of electromagnetic radiation. Figure 7.5▶ on the next page shows the main regions of the electromagnetic spectrum, ranging in wavelength from  $10^{-15} \text{ m}$  (gamma rays) to  $10^5 \text{ m}$  (radio waves). In Figure 7.5, short-wavelength, high-frequency radiation is on the right and long-wavelength, low-frequency radiation is on the left.

We will see later in this section that short-wavelength light inherently has greater energy than long-wavelength light (because of the particle nature of light). The most energetic forms of electromagnetic radiation have the shortest wavelengths. The form of electromagnetic radiation with the shortest wavelength is the **gamma ( $\gamma$ ) ray**. Gamma rays are produced by the sun, other stars, and certain unstable atomic nuclei on Earth. Excessive exposure to gamma rays is dangerous to humans because the high energy of gamma rays can damage biological molecules.

Next on the electromagnetic spectrum, with longer wavelengths than gamma rays, are **X-rays**, familiar to us from their medical use. X-rays pass through many substances

We will discuss gamma rays in more detail in Chapter 20.

**▲ FIGURE 7.5 The Electromagnetic Spectrum** The right side of the spectrum consists of high-energy, high-frequency, short-wavelength radiation. The left side consists of low-energy, low-frequency, long-wavelength radiation. Visible light constitutes a small segment in the middle.

▲ To produce a medical X-ray, short-wavelength electromagnetic radiation passes through the skin and creates an image of bones and internal organs.

▲ Warm objects emit infrared light, which is invisible to the eye but can be captured on film or by detectors to produce an infrared photograph.

that block visible light and are therefore used to image bones and internal organs. Like gamma rays, X-rays are sufficiently energetic to damage biological molecules. Although several annual medical X-rays are relatively harmless, too much exposure to X-rays increases cancer risk.

Sandwiched between X-rays and visible light in the electromagnetic spectrum is **ultraviolet (UV) radiation**, most familiar to us as the component of sunlight that produces a sunburn or suntan. Though not as energetic as gamma rays or X-rays, ultraviolet light still carries enough energy to damage biological molecules. Excessive exposure to ultraviolet light increases the risk of skin cancer and cataracts and causes premature wrinkling of the skin.

Next on the spectrum is **visible light**, ranging from violet (shorter wavelength, higher energy) to red (longer wavelength, lower energy). Visible light—at low to moderate intensity—does not carry enough energy to damage biological molecules. It does, however, cause certain molecules in our eyes to change their shape, sending a signal to our brains that results in our ability to see.

Beyond visible light lies **infrared (IR) radiation**. The heat you feel when you place your hand near a hot object is infrared radiation. All warm objects, including human bodies, emit infrared light. Although infrared light is invisible to our eyes, infrared sensors can detect it and are often employed in night vision technology to help people “see” in the dark.

Beyond infrared light, at longer wavelengths still, are **microwaves**, used for radar and in microwave ovens. Although microwave radiation has longer wavelengths and therefore lower energies than visible or infrared light, it is efficiently absorbed by water and can therefore heat substances that contain water. The longest wavelengths on the electromagnetic spectrum are those of **radio waves**, which are used to transmit the signals responsible for AM and FM radio, cellular telephone, television, and other forms of communication.

## CONCEPTUAL CONNECTION 7.1

**Frequency of Light** Which group of types of light is listed in order of increasing frequency?

- (a) visible, ultraviolet, infrared
- (b) infrared, visible, ultraviolet
- (c) ultraviolet, visible, infrared
- (d) infrared, ultraviolet, visible

## Chemistry AND Medicine

## Radiation Treatment for Cancer

**X**-rays and gamma rays are sometimes called ionizing radiation because their short wavelengths correspond to high energies that can ionize atoms and molecules. When ionizing radiation interacts with biological molecules, it can permanently change or even destroy them. Consequently, we normally try to limit our exposure to ionizing radiation. However, doctors use ionizing radiation to destroy molecules within unwanted cells such as cancer cells.

In radiation therapy (also called radiotherapy) doctors aim X-ray or gamma-ray beams at cancerous tumors (groups of cells that divide uncontrollably and invade surrounding healthy tissue). The ionizing radiation damages the molecules within the tumor's cells that carry genetic information—information necessary for the cell to grow and divide. Consequently, the cell dies or stops dividing. Ionizing radiation also damages molecules in healthy cells, but cancerous cells divide more quickly than normal cells, making them more susceptible to genetic damage. Nonetheless, harm to healthy tissues during radiation therapy treatments can result in side effects such as fatigue, skin lesions, hair loss, and organ damage. Medical workers try to reduce such effects by appropriate shielding (of healthy tissue) and by targeting the tumor from multiple directions, minimizing the exposure of healthy cells while maximizing the exposure of cancerous cells.

Another side effect of exposing healthy cells to radiation is that the healthy cells may become cancerous. If a treatment for cancer may cause cancer, why do we continue to use it? In radiation therapy, as in most other disease therapies, there is an associated risk. We take risks all the time, many of them for lesser reasons. For example, every time we fly in an airplane or drive in a car, we risk injury or even death. Why? Because we perceive the benefit—the convenience of being able to travel a significant distance in a short time—to be worth the relatively small risk. The situation is similar in cancer therapy, or any other medical therapy for that matter. The benefit of cancer therapy (possibly curing a cancer that might otherwise kill you) is worth the risk (a slight increase in the chance of developing a future cancer).

## QUESTION

Why is visible light (by itself) not used to destroy cancerous tumors?

▲ During radiation therapy, a tumor is targeted from multiple directions in order to minimize the exposure of healthy cells while maximizing the exposure of cancerous cells.

▲ In radiation therapy, highly energetic gamma rays are aimed at cancerous tumors.

## Interference and Diffraction

Waves, including electromagnetic waves, interact with each other in a characteristic way called **interference**: they cancel each other out or build each other up, depending on their alignment upon interaction. For example, if two waves of equal amplitude are *in phase* when they interact—that is, they align with overlapping crests—a wave with twice the amplitude results. This is called **constructive interference**.

On the other hand, if two waves are completely *out of phase* when they interact—that is, they align so that the crest from one source overlaps with the trough from the other source—the waves cancel by **destructive interference**.

▲ When a reflected wave meets an incoming wave near the shore, the two waves interfere constructively for an instant, producing a large-amplitude spike.

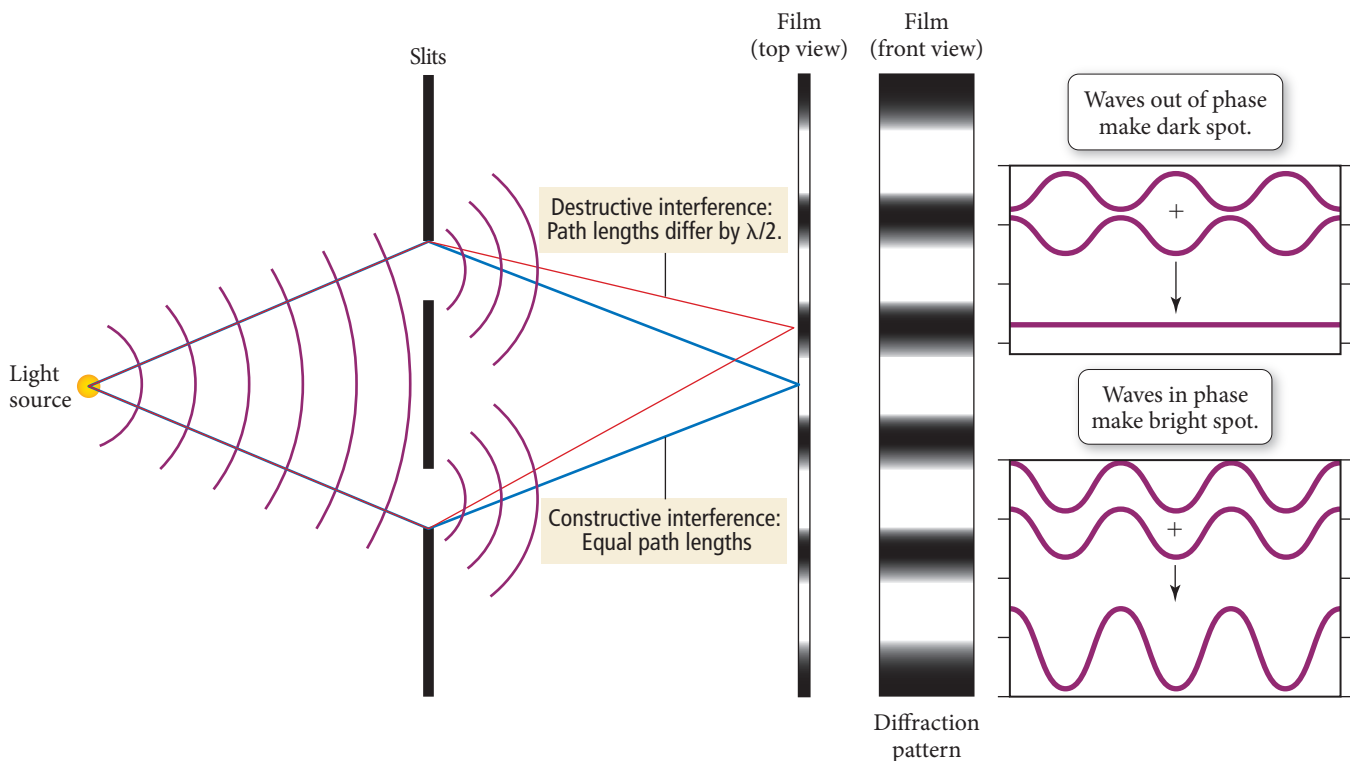

► **FIGURE 7.6 Diffraction** In this view from above, we can see how a wave bends, or diffracts, when it encounters an obstacle or slit with a size comparable to its wavelength. When a wave passes through a small opening, it spreads out. Particles, by contrast, do not diffract; they simply pass through the opening.

Waves also exhibit a characteristic behavior called **diffraction** (Figure 7.6▲). When a wave encounters an obstacle or a slit that is comparable in size to its wavelength, it bends (or *diffracts*) around it. The diffraction of light through two slits separated by a distance comparable to the wavelength of the light, coupled with interference, results in an *interference pattern*, illustrated in Figure 7.7▼. Each slit acts

### Interference from Two Slits

▲ **FIGURE 7.7 Interference from Two Slits** When a beam of light passes through two small slits, the two resulting waves interfere with each other. Whether the interference is constructive or destructive at any given point depends on the difference in the path lengths traveled by the waves. The resulting interference pattern appears as a series of bright and dark lines on a screen.

as a new wave source, and the two new waves interfere with each other. The resulting pattern is a series of bright and dark lines that can be viewed on a screen (or recorded on a film) placed a short distance behind the slits. At the center of the screen, the two waves travel equal distances and interfere constructively to produce a bright line. A small distance away from the center in either direction, the two waves travel slightly different distances, so they are out of phase. At the point where the difference in distance is one-half of one wavelength, the interference is destructive and a dark line appears on the screen. A bit further away from the center we see constructive interference again because the difference between the paths is one whole wavelength. The end result is the interference pattern shown by the light and dark bars in Figure 7.7. Notice that interference results from the ability of a wave to diffract through two slits—an inherent property of waves.

## The Particle Nature of Light

Prior to the early 1900s, and especially after the discovery of the diffraction of light, light was thought to be purely a wave phenomenon. Its behavior was described adequately by classical electromagnetic theory, which treated the electric and magnetic fields that constitute light as waves propagating through space. However, a number of discoveries brought the classical view into question. Chief among these discoveries was the *photoelectric effect*.

The **photoelectric effect** is the observation that many metals emit electrons when light shines upon them, as shown in Figure 7.8. Classical electromagnetic theory attributed this effect to the transfer of energy from the light to an electron in the metal, which resulted in the dislodgment of the electron. According to this explanation, only the amplitude (intensity) of the light affects the emission of electrons, not the wavelength. In other words, according to the classical description, the rate at which electrons leave the metal due to the photoelectric effect increases with increasing intensity of the light. A dim light was expected to result in a *lag time* between the initial shining of the light and the subsequent emission of an electron. The lag time would be the

The term *classical*, as in classical electromagnetic theory or classical mechanics, refers to descriptions of matter and energy before the advent of quantum mechanics.

### The Photoelectric Effect

▲ **FIGURE 7.8 The Photoelectric Effect** (a) When sufficiently energetic light shines on a metal surface, the surface emits electrons. (b) The emitted electrons can be measured as an electrical current.

**FIGURE 7.9 The Photoelectric Effect** A plot of the electron ejection rate versus frequency of light for the photoelectric effect.

Einstein was not the first to suggest that energy was quantized. Max Planck (1858–1947) used the idea in 1900 to account for certain characteristics of radiation from hot bodies.

The energy of a photon is directly proportional to its frequency and inversely proportional to its wavelength.

minimum amount of time required for the dim light to transfer sufficient energy to the electron to dislodge it.

The experimental results, however, did not support the classical prediction. Scientists found that a high-frequency, low-intensity light produces electrons *without* the predicted lag time. Furthermore, the light used to dislodge electrons in the photoelectric effect exhibits a *threshold frequency*, below which no electrons are emitted from the metal, no matter how long the light shines on the metal. Figure 7.9 is a graph of the rate of electron ejection from the metal versus the frequency of light used. Notice that increasing the intensity of the light does not change the threshold frequency. In other words, low-frequency (long-wavelength) light *does not* eject electrons from a metal regardless of its intensity or its duration. But high-frequency (short-wavelength) light *does* eject electrons, even if its intensity is low. What could explain this odd behavior?

In 1905, Albert Einstein (1879–1955) proposed a bold explanation for the photoelectric effect: *light energy must come in packets*. According to Einstein, the amount of energy ( $E$ ) in a light packet depends on its frequency ( $\nu$ ) according to the following equation:

$$E = h\nu \quad [7.2]$$

where  $h$ , called *Planck's constant*, has the value  $h = 6.626 \times 10^{-34} \text{ J} \cdot \text{s}$ . A *packet* of light is called a **photon** or a **quantum** of light. Since  $\nu = c/\lambda$ , the energy of a photon can also be expressed in terms of wavelength as follows:

$$E = \frac{hc}{\lambda} \quad [7.3]$$

Unlike classical electromagnetic theory, in which light was viewed purely as a wave whose intensity was *continuously variable*, Einstein suggested that light was *lumpy*. From this perspective, a beam of light is *not* a wave propagating through space, but a shower of particles (photons), each with energy  $h\nu$ .

## Example 7.2 Photon Energy

A nitrogen gas laser pulse with a wavelength of 337 nm contains 3.83 mJ of energy. How many photons does it contain?

**SORT** You are given the wavelength and total energy of a light pulse and asked to find the number of photons it contains.

**STRATEGIZE** In the first part of the conceptual plan, calculate the energy of an individual photon from its wavelength.

In the second part, divide the total energy of the pulse by the energy of a photon to determine the number of photons in the pulse.

**SOLVE** To execute the first part of the conceptual plan, convert the wavelength to meters and substitute it into the equation to calculate the energy of a 337-nm photon.

**GIVEN:**  $E_{\text{pulse}} = 3.83 \text{ mJ}$   
 $\lambda = 337 \text{ nm}$

**FIND:** number of photons

**CONCEPTUAL PLAN**

$$\frac{E_{\text{pulse}}}{E_{\text{photon}}} = \text{number of photons}$$

**RELATIONSHIPS USED**  $E = hc/\lambda$  (Equation 7.3)

**SOLUTION**

$$\begin{aligned} \lambda &= 337 \text{ nm} \times \frac{10^{-9} \text{ m}}{1 \text{ nm}} = 3.37 \times 10^{-7} \text{ m} \\ E_{\text{photon}} &= \frac{hc}{\lambda} = \frac{(6.626 \times 10^{-34} \text{ J} \cdot \text{s}) \left(3.00 \times 10^8 \frac{\text{m}}{\text{s}}\right)}{3.37 \times 10^{-7} \text{ m}} \\ &= 5.8985 \times 10^{-19} \text{ J} \end{aligned}$$

To execute the second part of the conceptual plan, convert the energy of the pulse from mJ to J. Then divide the energy of the pulse by the energy of a photon to obtain the number of photons.

$$3.83 \text{ mJ} \times \frac{10^{-3} \text{ J}}{1 \text{ mJ}} = 3.83 \times 10^{-3} \text{ J}$$

$$\begin{aligned} \text{number of photons} &= \frac{E_{\text{pulse}}}{E_{\text{photon}}} = \frac{3.83 \times 10^{-3} \text{ J}}{5.8985 \times 10^{-19} \text{ J}} \\ &= 6.49 \times 10^{15} \text{ photons} \end{aligned}$$

**CHECK** The units of the answer, photons, are correct. The magnitude of the answer ( $10^{15}$ ) is reasonable. Photons are small particles, and any macroscopic collection must contain a large number of them.

**FOR PRACTICE 7.2** A 100-watt lightbulb radiates energy at a rate of 100 J/s. (The watt, a unit of power, or energy over time, is defined as 1 J/s.) If all of the light emitted has a wavelength of 525 nm, how many photons are emitted per second? (Assume three significant figures in this calculation.)

**FOR MORE PRACTICE 7.2** The energy required to dislodge electrons from sodium metal via the photoelectric effect is 275 kJ/mol. What wavelength in nm of light has sufficient energy per photon to dislodge an electron from the surface of sodium?

### Example 7.3 Wavelength, Energy, and Frequency

Arrange these three types of electromagnetic radiation—visible light, X-rays, and microwaves—in order of increasing  
(a) wavelength.      (b) frequency.      (c) energy per photon.

#### SOLUTION

Examine Figure 7.5 and note that X-rays have the shortest wavelength, followed by visible light and then microwaves.

(a) wavelength  
X-rays < visible < microwaves

Since frequency and wavelength are inversely proportional—the longer the wavelength, the shorter the frequency—the ordering with respect to frequency is the reverse of the ordering with respect to wavelength.

(b) frequency  
microwaves < visible < X-rays

Energy per photon decreases with increasing wavelength but increases with increasing frequency; therefore, the ordering with respect to energy per photon is the same as for frequency.

(c) energy per photon  
microwaves < visible < X-rays

**FOR PRACTICE 7.3** Arrange these three colors of visible light—green, red, and blue—in order of increasing  
(a) wavelength.      (b) frequency.      (c) energy per photon.

Einstein's idea that light is quantized elegantly explains the photoelectric effect. The emission of electrons from the metal depends on whether or not a single photon has sufficient energy (as given by  $h\nu$ ) to dislodge a single electron. For an electron bound to the metal with binding energy  $\phi$ , the threshold frequency is reached when the energy of the photon is equal to  $\phi$ .

The symbol  $\phi$  is the Greek letter phi, pronounced "fi."

#### Threshold frequency condition

$$h\nu = \phi$$

Energy of photon
Binding energy of emitted electron

Low-frequency light does not eject electrons because no single photon has the minimum energy necessary to dislodge the electron. We can draw an analogy between a photon ejecting an electron from a metal surface and a ball breaking a glass window. In this analogy, low-frequency photons are like ping-pong balls—a ping-pong ball thrown at a glass window does not break it (just as a low-frequency photon does not eject an electron). Increasing the *intensity* of low-frequency light is like increasing the number of ping-pong

balls thrown at the window—doing so simply increases the number of low-energy photons but does not produce any single photon with sufficient energy. In contrast, increasing the *frequency* of the light, even at low intensity, *increases the energy of each photon*. In our analogy, a high-frequency photon is like a baseball—a baseball thrown at a glass window breaks it (just as a high-frequency photon dislodges an electron with no lag time).

As the frequency of the light increases past the threshold frequency, the excess energy of the photon (beyond what is needed to dislodge the electron) transfers to the electron in the form of kinetic energy. The kinetic energy (KE) of the ejected electron, therefore, is the difference between the energy of the photon ( $h\nu$ ), and the binding energy of the electron, as given by the equation:

$$\text{KE} = h\nu - \phi$$

Although the quantization of light explained the photoelectric effect, the wave explanation of light continued to have explanatory power as well, depending on the circumstances of the particular observation. So the principle that slowly emerged (albeit with some measure of resistance) is what we now call the *wave-particle duality of light*. Sometimes light appears to behave like a wave, at other times like a particle. Which behavior we observe depends on the particular experiment.

## CONCEPTUAL CONNECTION 7.2

**The Photoelectric Effect** We shine light of three different wavelengths—325 nm, 455 nm, and 632 nm—on a metal surface. We record the following observations for each wavelength, labeled A, B, and C:

Observation A: No photoelectrons were observed.

Observation B: Photoelectrons with a kinetic energy of 155 kJ/mol were observed.

Observation C: Photoelectrons with a kinetic energy of 51 kJ/mol were observed.

Which observation corresponds to which wavelength of light?

## 7.3 Atomic Spectroscopy and the Bohr Model

The discovery of the particle nature of light began to break down the division that existed in nineteenth-century physics between electromagnetic radiation, which was thought of as a wave phenomenon, and the small particles (protons, neutrons, and electrons) that compose atoms, which were thought to follow Newton's laws of motion. Just as the photoelectric effect suggested the particle nature of light, so certain observations about atoms began to suggest a wave nature for particles. The most important of these observations came from *atomic spectroscopy*, the study of the electromagnetic radiation absorbed and emitted by atoms.

When an atom absorbs energy—in the form of heat, light, or electricity—it often reemits that energy as light. For example, a neon sign is composed of one or more glass tubes filled with neon gas. When an electric current is passed through the tube, the neon atoms absorb some of the electrical energy and reemit it as the familiar red light of a neon sign. If the atoms in the tube are different (that is, not neon), they emit light of a different color. In other words, atoms of each element emit light of a characteristic color. Mercury atoms, for example, emit light that appears blue, helium atoms emit light that appears violet, and hydrogen atoms emit light that appears reddish (Figure 7.10▶).

Remember that the color of visible light is determined by its wavelength. Closer inspection of the light emitted by various atoms reveals that it contains several distinct wavelengths. We can separate the light emitted by a single element in a glass tube into its constituent wavelengths by passing it through a prism (just like we separate the white

▲ The familiar red light from a neon sign is emitted by neon atoms that have absorbed electrical energy, which the atoms reemit as visible radiation.

light from a lightbulb), as shown in Figure 7.11▼. The result is a series of bright lines called an **emission spectrum**. The emission spectrum of a particular element is always the same—it consists of the same bright lines at the same characteristic wavelengths. We can use the emission spectrum to identify the element. For example, light arriving from a distant star contains the emission spectra of the elements that compose the star. Analysis of the light allows us to identify the elements present in the star.

Notice the differences between a white light spectrum and the emission spectra of hydrogen, helium, and barium (shown in Figure 7.11). The white light spectrum is *continuous*, meaning that there are no sudden interruptions in the intensity of the light as a function of wavelength—the spectrum consists of light of all wavelengths. The emission spectra of hydrogen, helium, and barium, however, are not continuous—they consist of bright lines at specific wavelengths, with complete darkness in between. That is, only certain discrete wavelengths of light are present. Classical physics could not explain why these spectra consisted of discrete lines. In fact, according to classical physics, an atom composed of an electron orbiting a nucleus should emit a continuous white light spectrum. Even more problematic, the electron should lose energy as it emits the light and spirals into the nucleus. According to classical physics, an atom should not even be stable.

Johannes Rydberg (1854–1919), a Swedish mathematician, analyzed many atomic spectra and developed an equation that predicts the wavelengths of the hydrogen emission spectrum. However, his equation (shown in the margin) gives little insight into *why* atomic spectra are discrete, *why* atoms are stable, or *why* his equation works.

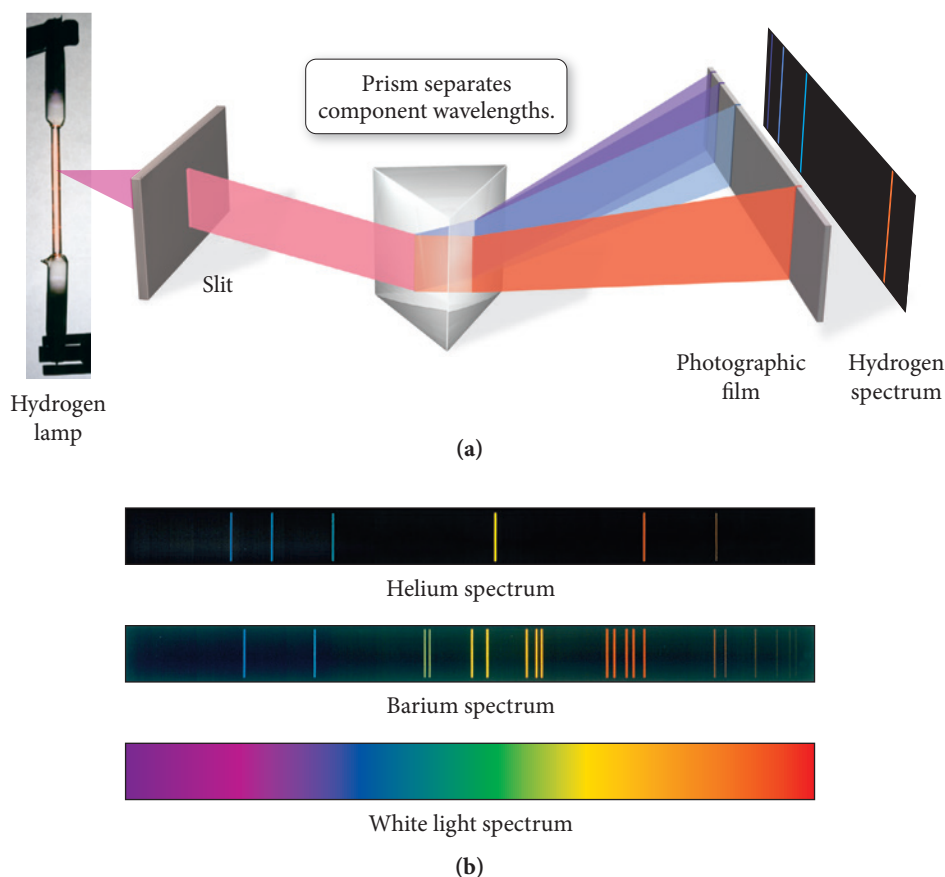

The Danish physicist Niels Bohr (1885–1962) attempted to develop a model for the atom that explained atomic spectra. In his model, electrons travel around the nucleus in

▲ **FIGURE 7.10** Mercury, Helium, and Hydrogen Each element emits a characteristic color.

The Rydberg equation is  $1/\lambda = R(1/m^2 - 1/n^2)$ , where  $R$  is the Rydberg constant ( $1.097 \times 10^7 \text{ m}^{-1}$ ) and  $m$  and  $n$  are integers.

### Emission Spectra

▲ **FIGURE 7.11** Emission Spectra (a) The light emitted from a hydrogen, helium, or barium lamp consists of specific wavelengths that can be separated by passing the light through a prism. (b) The resulting bright lines constitute an emission spectrum characteristic of the element that produced it.

## The Bohr Model and Emission Spectra

▲ **FIGURE 7.12 The Bohr Model and Emission Spectra** According to the Bohr model, each spectral line is produced when an electron falls from one stable orbit, or stationary state, to another of lower energy.

circular orbits (analogous to those of the planets around the sun). However, in contrast to planetary orbits—which theoretically can exist at any distance from the sun—Bohr's orbits exist only at specific, fixed distances from the nucleus. The energy of each Bohr orbit is also fixed, or *quantized*. Bohr called these orbits *stationary states* and suggested that, although they obey the laws of classical mechanics, they also possess “a peculiar, mechanically unexplainable, stability.” Scientists now know that the stationary states were really manifestations of the wave nature of the electron, which we will expand upon shortly. Bohr further proposed that, in contradiction to classical electromagnetic theory, an electron orbiting the nucleus in a stationary state emits no radiation. It is only when an electron jumps, or makes a *transition*, from one stationary state to another that radiation is emitted or absorbed (Figure 7.12◀).

## Chemistry IN YOUR DAY Atomic Spectroscopy, a Bar Code for Atoms

When you check out of the grocery store, a laser scanner reads the bar code on the items that you buy. Each item has a unique code that identifies the item and its price. Similarly, each element in the periodic table has a spectrum unlike that of any other element. For example, Figure 7.13▶ shows the emission spectra of oxygen and neon. (In Figure 7.11, we saw the emission spectra of hydrogen, helium, and barium.) Notice that each spectrum is unique and, as such, can be used to identify the substance.

The presence of intense lines in the spectra of a number of metals is the basis for *flame tests*, simple tests used to identify elements in ionic compounds in the absence of a precise analysis of a compound's spectrum. For example, the emission spectrum of sodium features two closely spaced, bright yellow lines. When a crystal of a sodium salt (or a drop of a solution containing a sodium salt) is put into a flame, the flame glows bright yellow (Figure 7.14▶). As Figure 7.14 shows, other metals exhibit similarly characteristic colors in flame tests. Each color represents an especially bright spectral emission line (or a combination of two or more such lines). Similar emissions form the basis of the colors seen in fireworks.

Although the *emission* of light from elements is easier to detect, the *absorption* of light by elements is even more commonly used for purposes of identification. Whereas emission spectra consist of bright lines on a dark background, absorption spectra consist of dark lines on a bright background (Figure 7.15▶). An absorption spectrum is measured by passing white light through a sample and observing what wavelengths are *missing* due to absorption by the sample. Notice that, in the spectrum of mercury shown in Figure 7.15, the absorption lines are at the same wavelengths as the emission lines. This is because the processes that produce them are mirror images. In emission, an electron makes a transition from a higher-energy level to a lower-energy one. In absorption, the transition is between the same two energy levels, but from the lower level to the higher one.

▲ Fireworks typically contain the salts of such metals as sodium, calcium, strontium, barium, and copper. Emissions from these elements produce the brilliant colors of pyrotechnic displays.

▲ **FIGURE 7.13 Emission Spectra of Oxygen and Neon** The emission spectrum of each element is unique, and we can use it to identify the element.

◀ **FIGURE 7.14** Flame Tests (from left to right) for Sodium, Potassium, Lithium, and Barium We can identify elements by the characteristic color of the light they produce when heated. The colors derive from especially bright lines in their emission spectra.

Absorption spectrometers, found in most chemistry laboratories, typically plot the intensity of absorption as a function of wavelength. Such plots are useful both for identifying substances (qualitative analysis) and for determining the concentration of substances (quantitative analysis). Quantitative analysis is possible because the amount of light absorbed by a sample depends on the concentration of the absorbing substance within the sample. For example, we can determine the concentration of  $\text{Ca}^{2+}$  in a hard water sample by measuring the quantity of light absorbed by the calcium ion at its characteristic wavelength.

In spite of its initial success in explaining the line spectrum of hydrogen, the Bohr model left many unanswered questions. It did, however, serve as an intermediate model between a classical view of the electron and a fully quantum-mechanical view, and therefore has great historical and conceptual importance. Nonetheless, it was ultimately replaced by a more complete quantum-mechanical theory that fully incorporated the wave nature of the electron.

◀ **FIGURE 7.15** Emission and Absorption Spectrum of Mercury Elements absorb light of the same wavelengths that they radiate when heated. When these wavelengths are subtracted from a beam of white light, the result is a pattern of dark lines corresponding to an absorption spectrum.

The transitions between stationary states in a hydrogen atom are quite unlike transitions in the macroscopic world. The electron is *never* observed *between* states; it is observed only in one state or another. The emission spectrum of an atom consists of discrete lines because the stationary states exist only at specific, fixed energies. The energy of the photon emitted when an electron makes a transition from one stationary state to another is the energy difference between the two stationary states. Transitions between stationary states that are closer together, therefore, produce light of lower energy (longer wavelength) than transitions between stationary states that are farther apart.

## 7.4 The Wave Nature of Matter: The de Broglie Wavelength, the Uncertainty Principle, and Indeterminacy

The heart of quantum-mechanical theory is the wave nature of the electron, first proposed by Louis de Broglie (1892–1987) in 1924 and confirmed by experiments in 1927. It seemed incredible at the time, but electrons—which were then thought of only as particles and known to have mass—also have a wave nature. The wave nature of

The Wave Nature of Matter

The Davisson–Germer experiment of 1927 provided the first evidence of electron wave properties. In this experiment, electrons were observed to undergo diffraction by a metal crystal.

For interference to occur, the spacing of the slits has to be on the order of atomic dimensions.

the electron is seen most clearly in its diffraction. If an electron beam is aimed at two closely spaced slits, and a series (or array) of detectors is arranged to detect the electrons after they pass through the slits, an interference pattern similar to that observed for light (see Figure 7.6) is recorded behind the slits (Figure 7.16(a)▼). The detectors at the center of the array (midway between the two slits) detect a large number of electrons—exactly the opposite of what you would expect for particles (Figure 7.16(b)▼). Moving outward from this center spot, the detectors alternately detect small numbers of electrons and then large numbers again and so on, forming an interference pattern characteristic of waves.

Counter to what might be our initial intuition about electron interference, the interference pattern is *not caused by pairs of electrons interfering with each other, but rather by single electrons interfering with themselves*. If the electron source is turned down to a very low level, so that electrons come out only one at a time, *the interference pattern remains*. In other words, we can design an experiment in which electrons come out of the source singly. We can then record where each electron strikes the detector after it has

**▲ FIGURE 7.16 Electron Diffraction** When a beam of electrons goes through two closely spaced slits **(a)**, they create an interference pattern, as if the electrons were waves. By contrast, a beam of particles passing through two slits **(b)** produces two smaller beams of particles. Notice that particle beams produce two bright stripes with darkness in between but waves produce the brightest strip directly in the center of the screen.

passed through the slits. If we record the positions of thousands of electrons over a long period of time, we find the same interference pattern shown in Figure 7.16(a).

This observation leads us to an important conclusion: *the wave nature of the electron is an inherent property of individual electrons*. Recall from Section 7.1 that unobserved electrons can simultaneously occupy two different states. In this case, the unobserved electron goes through both slits—it exists in two states simultaneously, just like Schrödinger’s cat—and interferes with itself. This wave nature explains the existence of stationary states (in the Bohr model) and prevents the electrons in an atom from crashing into the nucleus as predicted by classical physics. We now turn to three important manifestations of the electron’s wave nature: the de Broglie wavelength, the uncertainty principle, and indeterminacy.

## The de Broglie Wavelength

As we have seen, a single electron traveling through space has a wave nature; its wavelength is related to its kinetic energy (the energy associated with its motion). The faster the electron is moving, the higher its kinetic energy and the shorter its wavelength. The wavelength ( $\lambda$ ) of an electron of mass  $m$  moving at velocity  $v$  is given by the **de Broglie relation**:

$$\lambda = \frac{h}{mv} \quad \text{de Broglie relation} \quad [7.4]$$

where  $h$  is Planck’s constant. Notice that the velocity of a moving electron is related to its wavelength—knowing one is equivalent to knowing the other.

The mass of an object ( $m$ ) times its velocity ( $v$ ) is its momentum. Therefore, the wavelength of an electron is inversely proportional to its momentum.

### Example 7.4 De Broglie Wavelength

Calculate the wavelength of an electron traveling with a speed of  $2.65 \times 10^6$  m/s.

**SORT** You are given the speed of an electron and asked to calculate its wavelength.

**GIVEN:**  $v = 2.65 \times 10^6$  m/s

**FIND:**  $\lambda$

**STRATEGIZE** The conceptual plan shows how the de Broglie relation relates the wavelength of an electron to its mass and velocity.

**CONCEPTUAL PLAN**

**RELATIONSHIPS USED**

$\lambda = h/mv$  (de Broglie relation, Equation 7.4)

**SOLVE** Substitute the velocity, Planck’s constant, and the mass of an electron into Equation 7.4 to calculate the electron’s wavelength. To correctly cancel the units, break down the J in Planck’s constant into its SI base units ( $1 \text{ J} = 1 \text{ kg} \cdot \text{m}^2/\text{s}^2$ ).

**SOLUTION**

$$\begin{aligned} \lambda &= \frac{h}{mv} = \frac{6.626 \times 10^{-34} \frac{\text{kg} \cdot \text{m}^2}{\text{s}^2} \cancel{\text{s}}}{(9.11 \times 10^{-31} \cancel{\text{kg}}) \left( 2.65 \times 10^6 \frac{\text{m}}{\text{s}} \right)} \\ &= 2.74 \times 10^{-10} \text{ m} \end{aligned}$$

**CHECK** The units of the answer (m) are correct. The magnitude of the answer is very small, as expected for the wavelength of an electron.

**FOR PRACTICE 7.4** What is the velocity of an electron that has a de Broglie wavelength approximately the length of a chemical bond? Assume the length of a chemical bond is  $1.2 \times 10^{-10}$  m.

## CONCEPTUAL CONNECTION 7.3

**The de Broglie Wavelength of Macroscopic Objects** Since quantum-mechanical theory is universal, it applies to all objects, regardless of size. Therefore, according to the de Broglie relation, a thrown baseball should also exhibit wave properties. Why don't we observe such properties at the ballpark?

## The Uncertainty Principle

The wave nature of the electron is difficult to reconcile with its particle nature. How can a single entity behave as both a wave and a particle? We can begin to address this question by returning to the single-electron diffraction experiment. How does a single electron aimed at a double slit produce an interference pattern? We saw previously that the electron travels through both slits and interferes with itself. This idea is testable. We simply have to observe the single electron as it travels through both of the slits. If it travels through both slits simultaneously, our hypothesis is correct. But here is where nature gets tricky.

Any experiment designed to observe the electron as it travels through the slits results in the detection of an electron “particle” traveling through a single slit and no interference pattern. Recall from Section 7.1 that an *unobserved* electron can occupy two different states; however, the act of observation forces it into one state or the other. Similarly, the act of observing the electron as it travels through both slits forces it to go through only one slit. The electron diffraction experiment illustrated here is designed to observe which slit the electron travels through by using a laser beam placed directly behind the slits:

An electron that crosses the laser beam produces a tiny “flash” when a single photon is scattered at the point of crossing. If a flash shows up behind a particular slit, that indicates an electron is passing through that slit. When the experiment is performed, the flash always originates either from one slit *or* the other, but *never* from both at once. Furthermore, the interference pattern, which was present without the laser, is absent when the electrons are observed going through the slits. With the laser on, the electrons hit positions directly behind each slit, as if they were ordinary particles; their wavelike behavior is no longer manifested.

As it turns out, no matter how hard we try or whatever method we set up, *we can never both see the interference pattern and simultaneously determine which hole the electron goes through*. It has never been done, and most scientists agree that it never will. In the words of theoretical physicist P. A. M. Dirac (1902–1984),

There is a limit to the fineness of our powers of observation and the smallness of the accompanying disturbance—a limit which is inherent in the nature of things and can never be surpassed by improved technique or increased skill on the part of the observer.

The single electron diffraction experiment demonstrates that we cannot simultaneously observe both the wave nature and the particle nature of the electron. When we try to observe which hole the electron goes through (associated with the particle nature of the electron), we lose the interference pattern (associated with the wave nature of the electron). When we try to observe the interference pattern, we cannot determine which hole the electron goes through. The wave nature and particle nature of the electron are said to be **complementary properties**. Complementary properties exclude one another—the more we know about one, the less we know about the other. Which of two complementary properties we observe depends on the experiment we perform—in quantum mechanics, the observation of an event affects its outcome.

As we just saw in the de Broglie relation, the *velocity* of an electron is related to its *wave nature*. The *position* of an electron, however, is related to its *particle nature*. (Particles have well-defined position, but waves do not.) Consequently, our inability to observe the electron simultaneously as both a particle and a wave means that *we cannot simultaneously measure its position and its velocity*. Werner Heisenberg (1901–1976) formalized this idea with the equation:

$$\Delta x \times m\Delta v \geq \frac{h}{4\pi} \text{ Heisenberg's uncertainty principle} \quad [7.5]$$

where  $\Delta x$  is the uncertainty in the position,  $\Delta v$  is the uncertainty in the velocity,  $m$  is the mass of the particle, and  $h$  is Planck's constant. **Heisenberg's uncertainty principle** states that the product of  $\Delta x$  and  $m\Delta v$  must be greater than or equal to a finite number ( $h/4\pi$ ). In other words, the more accurately we know the position of an electron (the smaller  $\Delta x$ ), the less accurately we can know its velocity (the bigger  $\Delta v$ ) and vice versa. The complementarity of the wave nature and particle nature of the electron results in the complementarity of velocity and position.

Although Heisenberg's uncertainty principle may seem puzzling, it actually solves a great puzzle. Without the uncertainty principle, we are left with a paradox: how can something be *both* a particle and a wave? Saying that an object is both a particle and a wave is like saying that an object is both a circle and a square, a contradiction. Heisenberg solved the contradiction by introducing complementarity—an electron is observed as *either* a particle or a wave, but never both at once. This idea was captured by Schrödinger's thought experiment about the cat, which we discussed in Section 7.1: when observed, the cat is either dead or alive, not both.

## Indeterminacy and Probability Distribution Maps

According to classical physics, and in particular Newton's laws of motion, particles move in a *trajectory* (or path) that is determined by the particle's velocity (the speed and direction of travel), its position, and the forces acting on it. Even if you are not familiar with Newton's laws, you probably have an intuitive sense of them. For example, when you chase a baseball in the outfield, you visually predict where the ball will land by observing its path. You do this by noting its initial position and velocity, watching how these are affected by the forces acting on it (gravity, air resistance, wind), and then inferring its trajectory, as shown in Figure 7.17►, on the next page. If you knew only the ball's velocity, or only its position (imagine a still photo of the baseball in the air), you could not predict its landing spot. In classical mechanics, both position and velocity are required to predict a trajectory.

▲ Werner Heisenberg, a pioneer of quantum mechanics

► **FIGURE 7.17 The Concept of Trajectory** In classical mechanics, the position and velocity of a particle determine its future trajectory, or path. Thus, an outfielder can catch a baseball by observing its position and velocity, allowing for the effects of forces acting on it, such as gravity, and estimating its trajectory. (For simplicity, air resistance and wind are not shown.)

Remember that velocity includes speed as well as direction of travel.

Newton's laws of motion are **deterministic**—the present *determines* the future. This means that if two baseballs are hit consecutively with the same velocity from the same position under identical conditions, they will land in exactly the same place. The same is not true of electrons. We have just seen that we cannot simultaneously know the position and velocity of an electron; therefore, we cannot know its trajectory. In quantum mechanics, trajectories are replaced with *probability distribution maps* (Figure 7.18 ▼). A probability distribution map is a statistical map that shows where an electron is likely to be found under a given set of conditions.

▲ **FIGURE 7.18 Trajectory versus Probability** In quantum mechanics, we cannot calculate deterministic trajectories. Instead, it is necessary to think in terms of probability maps: statistical pictures of where a quantum-mechanical particle, such as an electron, is most likely to be found. In this hypothetical map, darker shading indicates greater probability.

To understand the concept of a probability distribution map, let us return to baseball. Imagine a baseball thrown from the pitcher's mound to a catcher behind home plate (Figure 7.19 ◀). The catcher can watch the baseball's path, predict exactly where it will cross home plate, and place his mitt in the correct place to catch it. As we have seen, the same predictions cannot be made for an electron. If an electron were thrown from the pitcher's mound to home plate, it would land in a different place every time, even if it were thrown in exactly the same way. This behavior is called **indeterminacy**. A baseball's future path is *determined* by its position and velocity when it leaves the pitcher's hand. In contrast, the future path of an electron is indeterminate and can only be described statistically.

In the quantum-mechanical world of the electron, the catcher cannot know where the electron will cross the plate for any given throw. However, if he were to record hundreds of identical electron throws, the catcher would observe a reproducible, *statistical pattern* of where the electron crosses the plate. He could even draw a map of the strike zone

◀ **FIGURE 7.19 Trajectory of a Macroscopic Object** A baseball follows a well-defined trajectory from the hand of the pitcher to the mitt of the catcher.

The Quantum-Mechanical Strike Zone

**FIGURE 7.20 The Quantum-Mechanical Strike Zone** An electron does not have a well-defined trajectory. However, we can construct a probability distribution map to show the relative probability of it crossing home plate at different points.

showing the probability of an electron crossing a certain area, as shown in Figure 7.20▲. This is a probability distribution map. In the sections that follow, we discuss quantum-mechanical electron *orbitals*, which are essentially probability distribution maps for electrons as they exist within atoms.

## 7.5 Quantum Mechanics and the Atom

As we have seen, the position and velocity of the electron are complementary properties—if we know one accurately, the other becomes indeterminate. Since velocity is directly related to energy (recall that kinetic energy equals  $\frac{1}{2}mv^2$ ), position and *energy* are also complementary properties—the more we know about one, the less we know about the other. Many of the properties of an element, however, depend on the energies of its electrons. For example, whether an electron is transferred from one atom to another to form an ionic bond depends in part on the relative energies of the electron in the two atoms.

In the following paragraphs, we describe the probability distribution maps for electron states in which the electron has well-defined energy but not well-defined position. In other words, for each of these states, we can specify the *energy* of the electron precisely, but not its location at a given instant. Instead, the electron's position is described in terms of an **orbital**, a probability distribution map showing where the electron is likely to be found. Since chemical bonding often involves the sharing of electrons between atoms to form covalent bonds, the spatial distribution of atomic electrons is important to bonding.

The mathematical derivation of energies and orbitals for electrons in atoms comes from solving the Schrödinger equation for the atom of interest. The general form of the Schrödinger equation is:

$$\mathcal{H}\psi = E\psi \quad [7.6]$$

The symbol  $\mathcal{H}$  is the Hamiltonian operator, a set of mathematical operations that represents the total energy (kinetic and potential) of the electron within the atom. The symbol  $E$  is the actual energy of the electron. The symbol  $\psi$  is the **wave function**, a mathematical function that describes the wavelike nature of the electron. A plot of the wave function squared ( $\psi^2$ ) represents an orbital, a position probability distribution map of the electron.

### Solutions to the Schrödinger Equation for the Hydrogen Atom

When the Schrödinger equation is solved, it yields many solutions—many possible wave functions. The wave functions themselves are fairly complicated mathematical functions, and we do not examine them in detail in this book. Instead, we introduce graphical representations (or plots) of the orbitals that correspond to the wave functions. Each orbital is specified by three interrelated **quantum numbers**:  $n$ , the **principal quantum number**;  $l$ , the **angular momentum quantum number**

**Quantum Mechanics and the Atom: Orbitals and Quantum Numbers**

These states are known as energy *eigenstates*.

An operator is different from a normal algebraic entity. In general, an operator transforms a mathematical function into another mathematical function. For example,  $d/dx$  is an operator that means “take the derivative of.” When  $d/dx$  operates on a function (such as  $x^2$ ), it returns another function ( $2x$ ).

The symbol  $\psi$  is the Greek letter psi, pronounced “sigh.”

(sometimes called the *azimuthal quantum number*); and  $m_l$ , the **magnetic quantum number**. These quantum numbers all have integer values, as had been hinted at by both the Rydberg equation and Bohr’s model. A fourth quantum number,  $m_s$ , the **spin quantum number**, specifies the orientation of the spin of the electron. We examine each of these quantum numbers individually.

The Principal Quantum Number ( $n$ )

The principal quantum number is an integer that determines the overall size and energy of an orbital. Its possible values are  $n = 1, 2, 3, \dots$  and so on. For the hydrogen atom, the energy of an electron in an orbital with quantum number  $n$  is given by the equation:

$$E_n = -2.18 \times 10^{-18} \text{ J} \left( \frac{1}{n^2} \right) \quad (n = 1, 2, 3, \dots)$$

[7.7]

The energy is negative because the electron’s energy is lowered (made more negative) by its interaction with the nucleus (see the description of Coulomb’s law in Section 8.3). The constant,  $2.18 \times 10^{-18} \text{ J}$ , is known as the Rydberg constant for hydrogen ( $R_H$ ). Notice that orbitals with higher values of  $n$  have greater (less negative) energies, as shown in the energy-level diagram at left. Notice also that, as  $n$  increases, the spacing between the energy levels decreases.

The Angular Momentum Quantum Number ( $l$ )

The angular momentum quantum number is an integer that determines the shape of the orbital. We will consider these shapes in Section 7.6. The possible values of  $l$  are  $0, 1, 2, \dots, (n - 1)$ . In other words, for a given value of  $n$ ,  $l$  can be any integer (including 0) up to  $n - 1$ . For example, if  $n = 1$ , then the only possible value of  $l$  is 0; if  $n = 2$ , the possible values of  $l$  are 0 and 1. To avoid confusion between  $n$  and  $l$ , values of  $l$  are often assigned letters as follows:

Value of $l$	Letter Designation
$l = 0$	s
$l = 1$	p
$l = 2$	d
$l = 3$	f

The values of  $l$  beyond 3 are designated with letters in alphabetical order so that  $l = 4$  is designated g,  $l = 5$  is designated h, and so on.

CONCEPTUAL CONNECTION 7.4

**The Relationship between  $n$  and  $l$**

What values of  $l$  are possible for  $n = 3$ ?

(a) 0 (or s)

(b) 0 and 1 (or s and p)

(c) 0, 1, and 2 (or s, p, and d)

(d) 0, 1, 2, and 3 (or s, p, d, and f)

The Magnetic Quantum Number ( $m_l$ )

The magnetic quantum number is an integer that specifies the orientation of the orbital. We will consider these orientations in Section 7.6. The possible values of  $m_l$  are the integer values (including zero) ranging from  $-l$  to  $+l$ . For example, if  $l = 0$ , then the only possible value of  $m_l$  is 0; if  $l = 1$ , the possible values of  $m_l$  are  $-1, 0$ , and  $+1$ .

CONCEPTUAL CONNECTION 7.5

**The Relationship between  $l$  and  $m_l$**

What values of  $m_l$  are possible for  $l = 2$ ?

(a) 0, 1, and 2

(b) 0

(c)  $-1, 0$ , and  $+1$

(d)  $-2, -1, 0, +1$ , and  $+2$

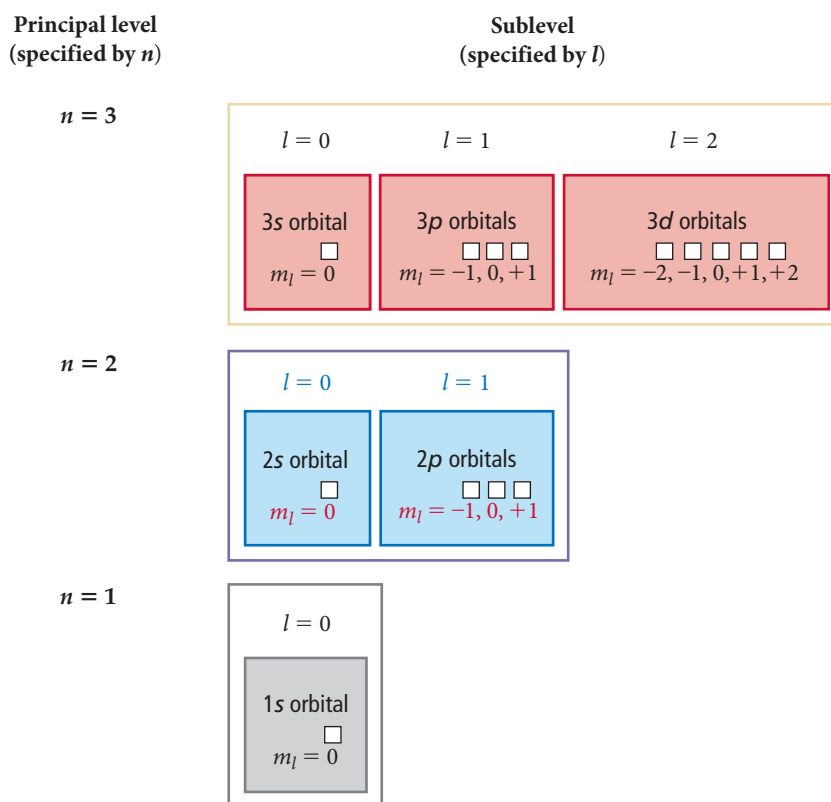

## The Spin Quantum Number ( $m_s$ )

The spin quantum number specifies the orientation of the *spin* of the electron. Electron spin is a fundamental property of an electron (like its negative charge). One electron does not have more or less spin than another—all electrons have the same amount of spin. The orientation of the electron's spin is quantized, with only two possibilities: that we can call spin up ( $m_s = +1/2$ ) and spin down ( $m_s = -1/2$ ). The spin quantum number becomes important in Section 8.3 when we begin to consider how electrons occupy orbitals. Here, we focus only on the first three quantum numbers.

Each specific combination of the first three quantum numbers ( $n$ ,  $l$ , and  $m_l$ ) specifies one atomic orbital. For example, the orbital with  $n = 1$ ,  $l = 0$ , and  $m_l = 0$  is known as the 1s orbital. The 1 in 1s is the value of  $n$ , and the s specifies that  $l = 0$ . There is only one 1s orbital in an atom, and its  $m_l$  value is zero. Orbitals with the same value of  $n$  are said to be in the same **principal level (or principal shell)**. Orbitals with the same value of  $n$  and  $l$  are said to be in the same **sublevel (or subshell)**. The following diagram shows all of the orbitals (each represented by a small square) in the first three principal levels:

The idea of a “spinning” electron is something of a metaphor. A more correct way to express the same idea is to say that an electron has inherent angular momentum.

For example, the  $n = 2$  level contains the  $l = 0$  and  $l = 1$  sublevels. Within the  $n = 2$  level, the  $l = 0$  sublevel—called the 2s sublevel—contains only one orbital (the 2s orbital), with  $m_l = 0$ . The  $l = 1$  sublevel—called the 2p sublevel—contains three 2p orbitals, with  $m_l = -1, 0, +1$ .

### Summarizing Orbitals:

- ▶ The number of sublevels in any level is equal to  $n$ , the principal quantum number. Therefore, the  $n = 1$  level has one sublevel, the  $n = 2$  level has two sublevels, and so on.
- ▶ The number of orbitals in any sublevel is equal to  $2l + 1$ . Therefore, the s sublevel ( $l = 0$ ) has one orbital, the p sublevel ( $l = 1$ ) has three orbitals, the d sublevel ( $l = 2$ ) has five orbitals, and so on.
- ▶ The number of orbitals in a level is equal to  $n^2$ . Therefore, the  $n = 1$  level has one orbital, the  $n = 2$  level has four orbitals, the  $n = 3$  level has nine orbitals, and so on.

**Example 7.5** Quantum Numbers I

What are the quantum numbers and names (for example,  $2s$ ,  $2p$ ) of the orbitals in the  $n = 4$  principal level? How many  $n = 4$  orbitals exist?

**SOLUTION**

First, determine the possible values of  $l$  (from the given value of  $n$ ). For a given value of  $n$ , the possible values of  $l$  are  $0, 1, 2, \dots, (n - 1)$ .

$n = 4$ ; therefore,  $l = 0, 1, 2$ , and  $3$

Next, determine the possible values of  $m_l$  for each value of  $l$ . For a given value of  $l$ , the possible values of  $m_l$  are the integer values, including zero, ranging from  $-l$  to  $+l$ . The name of an orbital is its principal quantum number ( $n$ ) followed by the letter corresponding to the value  $l$ . The total number of orbitals is given by  $n^2$ .

$l$	Possible $m_l$ Values	Orbital Name
0	0	4s (1 orbital)
1	-1, 0, +1	4p (3 orbitals)
2	-2, -1, 0, +1, +2	4d (5 orbitals)
3	-3, -2, -1, 0, +1, +2, +3	4f (7 orbitals)
Total number of orbitals = $4^2 = 16$		

**FOR PRACTICE 7.5** List the quantum numbers associated with all of the  $5d$  orbitals. How many  $5d$  orbitals exist?

**Example 7.6** Quantum Numbers II

These sets of quantum numbers are each supposed to specify an orbital. One set, however, is erroneous. Which one and why?

(a)  $n = 3$ ;  $l = 0$ ;  $m_l = 0$

(b)  $n = 2$ ;  $l = 1$ ;  $m_l = -1$

(c)  $n = 1$ ;  $l = 0$ ;  $m_l = 0$

(d)  $n = 4$ ;  $l = 1$ ;  $m_l = -2$

**SOLUTION**

Choice (d) is erroneous because for  $l = 1$ , the possible values of  $m_l$  are only  $-1, 0$ , and  $+1$ .

**FOR PRACTICE 7.6** Each set of quantum numbers is supposed to specify an orbital. However, each set contains one quantum number that is not allowed. Replace the quantum number that is not allowed with one that is allowed.

(a)  $n = 3$ ;  $l = 3$ ;  $m_l = +2$

(b)  $n = 2$ ;  $l = 1$ ;  $m_l = -2$

(c)  $n = 1$ ;  $l = 1$ ;  $m_l = 0$

**Atomic Spectroscopy Explained**

Quantum theory explains the atomic spectra of atoms we discussed in Section 7.3. Each wavelength in the emission spectrum of an atom corresponds to an electron *transition* between quantum-mechanical orbitals. When an atom absorbs energy, an electron in a lower-energy orbital is *excited* or promoted to a higher-energy orbital, as shown in Figure 7.21. In this new configuration, however, the atom is unstable,

**FIGURE 7.21** Excitation and

**Radiation** When an atom absorbs energy, an electron can be excited from an orbital in a lower-energy level to an orbital in a higher-energy level. The electron in this “excited state” is unstable, however, and relaxes to a lower-energy level, releasing energy in the form of electromagnetic radiation.

and the electron quickly falls back or *relaxes* to a lower-energy orbital. As it does so, it releases a photon of light containing an amount of energy precisely equal to the energy difference between the two energy levels. We saw previously (see Equation 7.7) that the energy of an orbital in a hydrogen atom with principal quantum number  $n$  is given by  $E_n = -2.18 \times 10^{-18} \text{ J } (1/n^2)$ , where  $n = 1, 2, 3, \dots$ . The *difference* in energy between two levels  $n_{\text{initial}}$  and  $n_{\text{final}}$  is given by  $\Delta E = E_{\text{final}} - E_{\text{initial}}$ . If we substitute the expression for  $E_n$  into the expression for  $\Delta E$ , we get the following important expression for the change in energy that occurs in a hydrogen atom when an electron changes energy levels:

$$\begin{aligned}\Delta E &= E_{\text{final}} - E_{\text{initial}} \\ &= -2.18 \times 10^{-18} \text{ J} \left( \frac{1}{n_f^2} \right) - \left[ -2.18 \times 10^{-18} \text{ J} \left( \frac{1}{n_i^2} \right) \right] \\ \Delta E &= -2.18 \times 10^{-18} \text{ J} \left( \frac{1}{n_f^2} - \frac{1}{n_i^2} \right) \quad [7.8]\end{aligned}$$

For example, suppose that an electron in a hydrogen atom relaxes from an orbital in the  $n = 3$  level to an orbital in the  $n = 2$  level. We determine  $\Delta E$ , the energy difference corresponding to the transition from  $n = 3$  to  $n = 2$ , as follows:

$$\begin{aligned}\Delta E_{\text{atom}} &= E_2 - E_3 \\ &= -2.18 \times 10^{-18} \text{ J} \left( \frac{1}{2^2} \right) - \left[ -2.18 \times 10^{-18} \text{ J} \left( \frac{1}{3^2} \right) \right] \\ &= -2.18 \times 10^{-18} \text{ J} \left( \frac{1}{2^2} - \frac{1}{3^2} \right) \\ &= -3.03 \times 10^{-19} \text{ J}\end{aligned}$$

The Rydberg equation,  $1/\lambda = R(1/m^2 - 1/n^2)$ , can be derived from the relationships just covered. We leave this derivation to an exercise (see Problem 7.98).

The energy carries a negative sign because the atom *emits* the energy as it relaxes from  $n = 3$  to  $n = 2$ . Since energy must be conserved, the exact amount of energy emitted by the atom is carried away by the photon:

$$\Delta E_{\text{atom}} = -E_{\text{photon}}$$

This energy determines the frequency and wavelength of the photon. Since the wavelength of the photon is related to its energy as  $E = hc/\lambda$ , we calculate the wavelength of the photon as:

$$\begin{aligned}\lambda &= \frac{hc}{E} \\ &= \frac{(6.626 \times 10^{-34} \text{ J} \cdot \text{s})(3.00 \times 10^8 \text{ m/s})}{3.03 \times 10^{-19} \text{ J}} \\ &= 6.56 \times 10^{-7} \text{ m} \quad \text{or} \quad 656 \text{ nm}\end{aligned}$$

Consequently, the light emitted by an excited hydrogen atom as it relaxes from an orbital in the  $n = 3$  level to an orbital in the  $n = 2$  level has a wavelength of 656 nm (red). Similarly, we can calculate the light emitted due to a transition from  $n = 4$  to  $n = 2$ , which is 486 nm (green). Notice that transitions between orbitals that are further apart in energy produce light that is higher in energy, and therefore shorter in wavelength, than transitions between orbitals that are closer together. Figure 7.22 on the next page shows several of the transitions in the hydrogen atom and their corresponding wavelengths.

### Emission Spectra Which transition emits light with the shortest wavelength?

(a)  $n = 5 \longrightarrow n = 4$

(b)  $n = 4 \longrightarrow n = 3$

(c)  $n = 3 \longrightarrow n = 2$

CONCEPTUAL  
CONNECTION 7.6

## ► FIGURE 7.22 Hydrogen Energy

**Transitions and Radiation** An atomic energy level diagram for hydrogen, showing some possible electron transitions between levels and the corresponding wavelengths of emitted light.

### Example 7.7 Wavelength of Light for a Transition in the Hydrogen Atom

Determine the wavelength of light emitted when an electron in a hydrogen atom makes a transition from an orbital in  $n = 6$  to an orbital in  $n = 5$ .

**SORT** You are given the energy levels of an atomic transition and asked to find the wavelength of emitted light.

**STRATEGIZE** In the first part of the conceptual plan, calculate the energy of the electron in the  $n = 6$  and  $n = 5$  orbitals using Equation 7.7 and subtract to find  $\Delta E_{\text{atom}}$ .

In the second part, find  $E_{\text{photon}}$  by taking the negative of  $\Delta E_{\text{atom}}$  and then calculate the wavelength corresponding to a photon of this energy using Equation 7.3. (The difference in sign between  $E_{\text{photon}}$  and  $\Delta E_{\text{atom}}$  applies only to emission. *The energy of a photon must always be positive.*)

**SOLVE** Follow the conceptual plan. Begin by calculating  $\Delta E_{\text{atom}}$ .

**GIVEN:**  $n = 6 \longrightarrow n = 5$

**FIND:**  $\lambda$

#### CONCEPTUAL PLAN

#### RELATIONSHIPS USED

$$E_n = -2.18 \times 10^{-18} \text{ J}(1/n^2)$$

$$E = hc/\lambda$$

#### SOLUTION

$$\begin{aligned} \Delta E_{\text{atom}} &= E_5 - E_6 \\ &= -2.18 \times 10^{-18} \text{ J} \left( \frac{1}{5^2} \right) - \left[ -2.18 \times 10^{-18} \text{ J} \left( \frac{1}{6^2} \right) \right] \\ &= -2.18 \times 10^{-18} \text{ J} \left( \frac{1}{5^2} - \frac{1}{6^2} \right) \\ &= -2.6644 \times 10^{-20} \text{ J} \end{aligned}$$

Calculate $E_{\text{photon}}$ by changing the sign of $\Delta E_{\text{atom}}$ .	$E_{\text{photon}} = -\Delta E_{\text{atom}} = +2.6644 \times 10^{-20} \text{ J}$
Solve the equation relating the energy of a photon to its wavelength for $\lambda$ . Substitute the energy of the photon and calculate $\lambda$ .	$E = \frac{hc}{\lambda}$ $\lambda = \frac{hc}{E}$ $= \frac{(6.626 \times 10^{-34} \text{ J}\cdot\text{s}) (3.00 \times 10^8 \text{ m/s})}{2.6644 \times 10^{-20} \text{ J}}$ $= 7.46 \times 10^{-6} \text{ m or } 7460 \text{ nm}$

**CHECK** The units of the answer (m) are correct for wavelength. The magnitude is reasonable because  $10^{-6} \text{ m}$  is in the infrared region of the electromagnetic spectrum. You know that transitions from  $n = 3$  or  $n = 4$  to  $n = 2$  lie in the visible region, so it makes sense that a transition between levels of higher  $n$  value (which are energetically closer to one another) results in light of longer wavelength.

**FOR PRACTICE 7.7** Determine the wavelength of the light absorbed when an electron in a hydrogen atom makes a transition from an orbital in the  $n = 2$  level to an orbital in the  $n = 7$  level.

**FOR MORE PRACTICE 7.7** An electron in the  $n = 6$  level of the hydrogen atom relaxes to a lower-energy level, emitting light of  $\lambda = 93.8 \text{ nm}$ . Find the principal level to which the electron relaxed.

## 7.6 The Shapes of Atomic Orbitals

As we noted previously, the shapes of atomic orbitals are important because covalent chemical bonds depend on the sharing of the electrons that occupy these orbitals. In one model of chemical bonding, for example, a bond consists of the overlap of atomic orbitals on adjacent atoms. The shapes of the overlapping orbitals determine the shape of the molecule. Although we limit ourselves in this chapter to the orbitals of the hydrogen atom, we will see in Chapter 8 that the orbitals of all atoms can be approximated as being hydrogen-like and therefore having very similar shapes to those of hydrogen.

The shape of an atomic orbital is determined primarily by  $l$ , the angular momentum quantum number. Recall that each value of  $l$  is assigned a letter that corresponds to particular orbitals. For example, the orbitals with  $l = 0$  are called  $s$  orbitals; those with  $l = 1$ ,  $p$  orbitals; those with  $l = 2$ ,  $d$  orbitals, and so on. We now examine the shape of each of these orbitals.

### s Orbitals ( $l = 0$ )

The lowest energy orbital is the spherically symmetrical  $1s$  orbital shown in Figure 7.23(a)▼. This image is actually a three-dimensional plot of the wave function squared ( $\psi^2$ ), which represents **probability density**, the probability (per unit volume) of finding the electron at a point in space.

**▲ FIGURE 7.24 The 1s Orbital Surface** In this representation, the surface of the sphere encompasses the volume where the electron is found 90% of the time when the electron is in the 1s orbital.

**▲ FIGURE 7.25 The Radial Distribution Function for the 1s Orbital** The curve shows the total probability of finding the electron within a thin shell at a distance  $r$  from the nucleus.

The magnitude of  $\psi^2$  in this plot is proportional to the density of the dots shown in the image. The high dot density near the nucleus (at the very center of the plot) indicates a higher probability density for the electron. As you move away from the nucleus, the probability density decreases. Figure 7.23(b) on the previous page shows a plot of probability density ( $\psi^2$ ) versus  $r$ , the distance from the nucleus. The plot represents a slice through the three-dimensional plot of  $\psi^2$  and illustrates how the probability density decreases as  $r$  increases.

We can better understand probability density with the help of a thought experiment. Imagine an electron in the 1s orbital located within the volume surrounding the nucleus. Imagine also taking a photograph of the electron every second for 10 or 15 minutes. In one photograph, the electron is very close to the nucleus, in another it is farther away, and so on. Each photo has a dot showing the electron's position relative to the nucleus when the photo was taken. Remember that we can never predict where the electron will be for any one photo. However, if we took hundreds of photos and superimposed all of them, we would have a plot similar to Figure 7.23(a)—a statistical representation of how likely the electron is to be found at each point.

This thought experiment can result in a possible misunderstanding: that the electron is moving around (like a moth near a flame) between photographs. However, in the quantum-mechanical model, that is not the case. Between photographs, the location of the electron is uncertain—in a sense its location is spread out over the entire volume of the orbital. Only when the photograph is taken (that is, when a measurement of the electron's location is made) does the location of the electron become localized to one spot. Between measurements, the electron has no single location. Recall from Section 7.1 that the measurement affects the outcome of any quantum system.

We can also represent an atomic orbital as a geometrical shape that encompasses the volume where the electron is likely to be found most frequently—typically, 90% of the time. For example, we represent the 1s orbital as the three-dimensional sphere shown in Figure 7.24. If we were to superimpose the dot-density representation of the 1s orbital on the shape representation, 90% of the dots would be within the sphere, meaning that when the electron is in the 1s orbital it has a 90% chance of being found within the sphere.

The plots we have just seen in Figures 7.23 and 7.24 represent probability *density*. However, they are a bit misleading because they seem to imply that the electron is most likely to be found *at the nucleus*. To get a better idea of where the electron is most likely to be found, we use a plot called the **radial distribution function**, shown in Figure 7.25 for the 1s orbital. The radial distribution function represents the *total probability of finding the electron within a thin spherical shell at a distance  $r$  from the nucleus*:

$$\text{Total radial probability (at a given } r) = \frac{\text{probability}}{\text{unit volume}} \times \text{volume of shell at } r$$

The radial distribution function represents, not probability density *at a point*  $r$ , but total probability *at a radius*  $r$ . In contrast to probability density, which has a maximum at the nucleus, the radial distribution function has a value of *zero* at the nucleus. It increases to a maximum at 52.9 pm and then decreases again with increasing  $r$ .

The shape of the radial distribution function is the result of multiplying together two functions with opposite trends in  $r$ . The two functions are:

1. the probability density function ( $\psi^2$ ), which is the probability per unit volume, has a maximum at the nucleus, and decreases with increasing  $r$ ; and
2. the volume of the thin shell, which is zero at the nucleus and increases with increasing  $r$ .

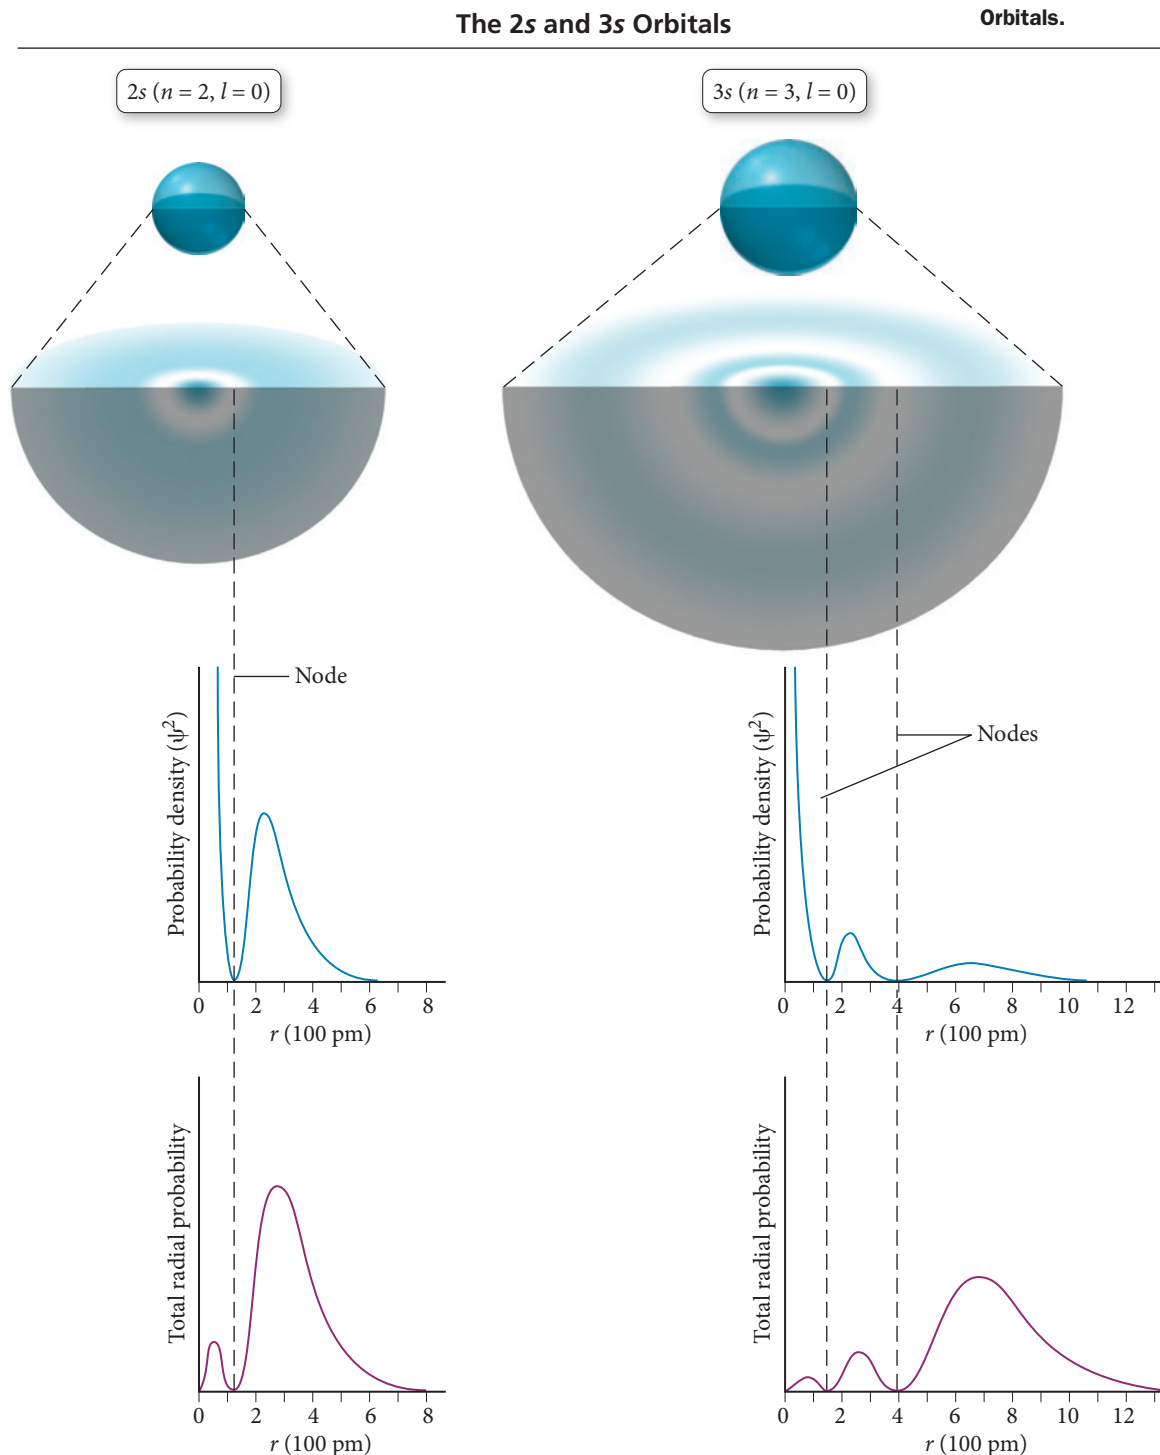

At the nucleus ( $r = 0$ ), for example, the probability *density* is at a maximum; however, the volume of a thin spherical shell is zero, so the radial distribution function is zero. As  $r$  increases, the volume of the thin spherical shell increases. We can understand this by making an analogy to an onion. A spherical shell at a distance  $r$  from the nucleus is like a layer in an onion at a distance  $r$  from its center. If the layers of the onion all have the same thickness, then the volume of any one layer—think of this as the total amount of onion in the layer—is greater as  $r$  increases. Similarly, the volume of any one spherical shell in the radial distribution function increases with increasing distance from the

nucleus, resulting in a greater total probability of finding the electron within that shell. Close to the nucleus, this increase in volume with increasing  $r$  outpaces the decrease in probability density, reaching a maximum at 52.9 pm. Farther out, however, the density tapers off faster than the volume increases.

The maximum in the radial distribution function, 52.9 pm, turns out to be the very same radius that Bohr had predicted for the innermost orbit of the hydrogen atom. However, there is a significant conceptual difference between the two radii. In the Bohr model, every time you probe the atom (in its lowest energy state), you would find the electron at a radius of 52.9 pm. In the quantum-mechanical model, you would generally find the electron at various radii, with 52.9 pm having the greatest probability.

The probability densities and radial distribution functions for the 2s and 3s orbitals are shown in Figure 7.26. Like the 1s orbital, these orbitals are spherically symmetric.

▼ **FIGURE 7.26** Probability Densities and Radial Distribution Functions for the 2s and 3s Orbitals.

These orbitals are larger in size than the 1s orbital, and, unlike the 1s orbital, they contain at least one **node**. A **node** is a point where the wave function ( $\psi$ ), and therefore the probability density ( $\psi^2$ ) and radial distribution function, all pass through zero. A node in a wave function is much like a node in a standing wave on a vibrating string. We can see nodes in an orbital most clearly by looking at a slice through the orbital. Plots of probability density and the radial distribution function as a function of  $r$  both reveal the presence of nodes. The probability of finding the electron at a node is zero.

▲ The nodes in quantum-mechanical atomic orbitals are three-dimensional analogs of the nodes on a vibrating string.

### **p Orbitals ( $l = 1$ )**

Each principal level with  $n = 2$  or greater contains three  $p$  orbitals ( $m_l = -1, 0, +1$ ). The three  $2p$  orbitals and their radial distribution functions are shown in Figure 7.27▼. The  $p$  orbitals are not spherically symmetric like the  $s$  orbitals, but they have two *lobes* of electron density on either side of the nucleus and a node located at the nucleus. The three  $p$  orbitals differ only in their orientation and are orthogonal (mutually perpendicular) to one another. It is convenient to define an  $x$ -,  $y$ -, and  $z$ -axis system and then label each  $p$  orbital as  $p_x$ ,  $p_y$ , and  $p_z$ . The  $3p$ ,  $4p$ ,  $5p$ , and higher  $p$  orbitals are all similar in shape to the  $2p$  orbitals, but they contain additional nodes (like the higher  $s$  orbitals) and are progressively larger in size.

▲ **FIGURE 7.27 The  $2p$  Orbitals and Their Radial Distribution Function** The radial distribution function is the same for each of the three  $2p$  orbitals when the  $x$ -axis of the graph is taken as the axis containing the lobes of the orbital.

### **d Orbitals ( $l = 2$ )**

Each principal level with  $n = 3$  or greater contains five  $d$  orbitals ( $m_l = -2, -1, 0, +1, +2$ ). The five  $3d$  orbitals are shown in Figure 7.28►. Four of these orbitals have a cloverleaf shape, with four lobes of electron density around the nucleus and two perpendicular nodal planes. The  $d_{xy}$ ,  $d_{xz}$ , and  $d_{yz}$  orbitals are oriented along the  $xy$ ,  $xz$ , and  $yz$  planes, respectively, and their lobes are oriented *between* the corresponding axes. The four lobes of the  $d_{x^2-y^2}$  orbital are oriented along the  $x$ - and  $y$ -axes. The  $d_{z^2}$  orbital is different in shape from the other four, having two lobes oriented along the  $z$ -axis and a donut-shaped ring along the  $xy$  plane. The  $4d$ ,  $5d$ ,  $6d$ , ..., orbitals are all similar in shape to the  $3d$  orbitals, but they contain additional nodes and are progressively larger in size.

### **f Orbitals ( $l = 3$ )**

Each principal level with  $n = 4$  or greater contains seven  $f$  orbitals ( $m_l = -3, -2, -1, 0, +1, +2, +3$ ), as shown in Figure 7.29►. These  $f$  orbitals have more lobes and nodes than  $d$  orbitals.

A nodal plane is a plane where the electron probability density is zero. For example, in the  $d_{xy}$  orbitals, the nodal planes lie in the  $xz$  and  $yz$  planes.

## The Phase of Orbitals

The orbitals we have just shown are three-dimensional waves. We can understand an important property of these orbitals by analogy to one-dimensional waves. Consider the following one-dimensional waves:

The wave on the left has a positive amplitude over its entire length, whereas the wave on the right has a positive amplitude over half of its length and a negative amplitude over the other half. The sign of the amplitude of a wave—positive or negative—is known as its **phase**. In these images, blue indicates positive phase and red indicates negative phase. The phase of a wave determines how it interferes with another wave as we saw in Section 7.2.

Just as a one-dimensional wave has a phase, so does a three-dimensional wave. We often represent the phase of a quantum-mechanical orbital with color. For example, the phases of a  $1s$  and  $2p$  orbital are represented as follows:

In these depictions, blue represents positive phase and red represents negative phase. The  $1s$  orbital is all one phase, whereas the  $2p$  orbital exhibits two different phases. The phase of quantum-mechanical orbitals is important in bonding, as we shall see in Chapter 10.

**▲ FIGURE 7.30 Why Atoms Are Spherical** Atoms are depicted as roughly spherical because all the orbitals together make up a roughly spherical shape.

## The Shape of Atoms

If some orbitals are shaped like dumbbells and three-dimensional cloverleaves, and if most of the volume of an atom is empty space diffusely occupied by electrons in these orbitals, then why do we often depict atoms as spheres? Atoms are drawn as spheres because most atoms contain many electrons occupying a number of different orbitals. Therefore, the shape of an atom is obtained by superimposing all of its orbitals. If we superimpose the  $s$ ,  $p$ , and  $d$  orbitals, we get a roughly spherical shape, as shown in Figure 7.30.

## Self-Assessment Quiz

- Q1.** Which wavelength of light has the highest frequency?  
a) 10 nm    b) 10 mm    c) 1 nm    d) 1 mm
- Q2.** Which kind of electromagnetic radiation contains the greatest energy per photon?  
a) microwaves                      b) gamma rays  
c) X-rays                              d) visible light
- Q3.** How much energy (in J) is contained in 1.00 mole of 552-nm photons?  
a)  $3.60 \times 10^{-19}$  J                      b)  $2.17 \times 10^5$  J  
c)  $3.60 \times 10^{-28}$  J                      d)  $5.98 \times 10^{-43}$  J
- Q4.** Light from three different lasers (A, B, and C), each with a different wavelength, was shined onto the same metal surface. Laser A produced no photoelectrons. Lasers B and C both produced photoelectrons, but the photoelectrons produced by laser B had a greater velocity than those produced by laser C. Arrange the lasers in order of increasing wavelength.  
a)  $A < B < C$                       b)  $B < C < A$   
c)  $C < B < A$                       d)  $A < C < B$
- Q5.** Calculate the wavelength of an electron traveling at  $1.85 \times 10^7$  m/s.  
a)  $2.54 \times 10^{13}$  m  
b)  $3.93 \times 10^{-14}$  m  
c)  $2.54 \times 10^{10}$  m  
d)  $3.93 \times 10^{-11}$  m
- Q6.** Which set of three quantum numbers *does not* specify an orbital in the hydrogen atom?  
a)  $n = 2; l = 1; m_l = -1$                       b)  $n = 3; l = 3; m_l = -2$   
c)  $n = 2; l = 0; m_l = 0$                       d)  $n = 3; l = 2; m_l = 2$
- Q7.** Calculate the wavelength of light emitted when an electron in the hydrogen atom makes a transition from an orbital with  $n = 5$  to an orbital with  $n = 3$ .  
a)  $1.28 \times 10^{-6}$  m                      b)  $6.04 \times 10^{-7}$  m  
c)  $2.28 \times 10^{-6}$  m                      d)  $1.55 \times 10^{-19}$  m
- Q8.** Which electron transition produces light of the highest frequency in the hydrogen atom?  
a)  $5p \longrightarrow 1s$                       b)  $4p \longrightarrow 1s$   
c)  $3p \longrightarrow 1s$                       d)  $2p \longrightarrow 1s$
- Q9.** How much time (in seconds) does it take light in a vacuum to travel 1.00 billion km?  
a)  $3.00 \times 10^{17}$  s                      b) 3.33 s  
c)  $3.33 \times 10^3$  s                      d)  $3.00 \times 10^{20}$  s
- Q10.** Which orbital is a  $d$  orbital?  
a)   
b)   
c)   
d) None of the above

Answers: 1. (c) 2. (b) 3. (b) 4. (b) 5. (d) 6. (b) 7. (a) 8. (a) 9. (c) 10. (b)

## Chapter 7 IN REVIEW

### Key Terms

#### Section 7.1

quantum-mechanical model (298)

 radial distribution function (324)  
 node (326)  
 phase (327)

### Key Concepts

#### The Realm of Quantum Mechanics (7.1)

- ▶ The theory of quantum mechanics explains the behavior of particles, such as photons (particles of light) and electrons, in the atomic and subatomic realms.
- ▶ Since the electrons of an atom determine many of its chemical and physical properties, quantum mechanics is foundational to understanding chemistry.

#### The Nature of Light (7.2)

- ▶ Light is a type of electromagnetic radiation—a form of energy embodied in oscillating electric and magnetic fields that travels through space at  $3.00 \times 10^8$  m/s.
- ▶ The wave nature of light is characterized by its wavelength—the distance between wave crests—and its ability to experience interference (constructive or destructive) and diffraction.
- ▶ The particle nature of light is characterized by the specific quantity of energy carried in each photon.
- ▶ The electromagnetic spectrum includes all wavelengths of electromagnetic radiation from gamma rays (high energy per photon, short wavelength) to radio waves (low energy per photon, long wavelength). Visible light is a tiny sliver in the middle of the electromagnetic spectrum.

#### Atomic Spectroscopy (7.3)

- ▶ Atomic spectroscopy is the study of the light absorbed and emitted by atoms when an electron makes a transition from one energy level to another.
- ▶ The wavelengths absorbed or emitted in atomic spectra depend on the energy differences between the levels involved in the transition; large energy differences result in short wavelengths, and small energy differences result in long wavelengths.

#### The Wave Nature of Matter (7.4)

- ▶ Electrons have a wave nature with an associated wavelength; the de Broglie relation quantifies the wavelength of an electron.

- ▶ The wave nature and particle nature of matter are complementary—the more we know of one, the less we know of the other.
- ▶ The wave-particle duality of electrons is quantified in Heisenberg's uncertainty principle, which states that there is a limit to how well we can know both the position of an electron (associated with the electron's particle nature) and the velocity times the mass of an electron (associated with the electron's wave nature)—the more accurately one is measured, the greater the uncertainty in measurement of the other.
- ▶ The inability to simultaneously know both the position and the velocity of an electron results in indeterminacy, the inability to predict a trajectory for an electron. Consequently, electron behavior is described differently than the behavior of everyday-sized particles.
- ▶ The trajectory we normally associate with macroscopic objects is replaced, for electrons, with statistical descriptions that show not the electron's path, but the region where it is most likely to be found.

#### The Quantum-Mechanical Model of the Atom (7.5, 7.6)

- ▶ The most common way to describe electrons in atoms according to quantum mechanics is to solve the Schrödinger equation for the energy states of the electrons within the atom. When the electron is in these states, its energy is well defined but its position is not. The position of an electron is described by a probability distribution map called an orbital.
- ▶ The solutions to the Schrödinger equation (including the energies and orbitals) are characterized by four quantum numbers:  $n$ ,  $l$ ,  $m_l$ , and  $m_s$ .
- ▶ The principal quantum number ( $n$ ) determines the energy of the electron and the size of the orbital; the angular momentum quantum number ( $l$ ) determines the shape of the orbital; the magnetic quantum number ( $m_l$ ) determines the orientation of the orbital; and the spin quantum number ( $m_s$ ) specifies the orientation of the spin of the electron.

Key Equations and Relationships

Relationship between Frequency ( $\nu$ ), Wavelength ( $\lambda$ ), and the Speed of Light ( $c$ ) (7.2)

$$\nu = \frac{c}{\lambda}$$

Relationship between Energy ( $E$ ), Frequency ( $\nu$ ), Wavelength ( $\lambda$ ), and Planck's Constant ( $h$ ) (7.2)

$$E = h\nu$$
$$E = \frac{hc}{\lambda}$$

De Broglie Relation: Relationship between Wavelength ( $\lambda$ ), Mass ( $m$ ), and Velocity ( $v$ ) of a Particle (7.4)

$$\lambda = \frac{h}{mv}$$

Heisenberg's Uncertainty Principle: Relationship between a Particle's Uncertainty in Position ( $\Delta x$ ) and Uncertainty in Velocity ( $\Delta v$ ) (7.4)

$$\Delta x \times m\Delta v \geq \frac{h}{4\pi}$$

Energy of an Electron in an Orbital with Quantum Number  $n$  in a Hydrogen Atom (7.5)

$$E_n = -2.18 \times 10^{-18} \text{ J} \left( \frac{1}{n^2} \right) \quad (n = 1, 2, 3, \dots)$$

Change in Energy That Occurs in an Atom When It Undergoes a Transition between Levels  $n_{\text{initial}}$  and  $n_{\text{final}}$  (7.5)

$$\Delta E = -2.18 \times 10^{-18} \text{ J} \left( \frac{1}{n_f^2} - \frac{1}{n_i^2} \right)$$

Key Learning Outcomes

CHAPTER OBJECTIVES	ASSESSMENT
Calculating the Wavelength and Frequency of Light (7.2) 	Example 7.1 For Practice 7.1 Exercises 39, 40
Calculating the Energy of a Photon (7.2)	Example 7.2 For Practice 7.2 For More Practice 7.4 Exercises 41–46
Relating Wavelength, Energy, and Frequency to the Electromagnetic Spectrum (7.2)	Example 7.3 For Practice 7.3 Exercises 37, 42
Using the de Broglie Relation to Calculate Wavelength (7.4)	Example 7.4 For Practice 7.4 Exercises 49–54
Relating Quantum Numbers to One Another and to Their Corresponding Orbitals (7.5)	Examples 7.5, 7.6 For Practice 7.5, 7.6 Exercises 59–62
Relating the Wavelength of Light to Transitions in the Hydrogen Atom (7.5)	Example 7.7 For Practice 7.7 For More Practice 7.7 Exercises 69–72

EXERCISES

Review Questions

1. Why is the quantum-mechanical model of the atom important for understanding chemistry?

2. What is light? How fast does it travel in a vacuum?

3. Define the wavelength and amplitude of a wave. How are these related to the energy of the wave?

4. Define the frequency of electromagnetic radiation. How is frequency related to wavelength?

5. What determines the color of light? Describe the difference between red light and blue light.

6. What determines the color of a colored object? Explain why grass appears green.
7. Give an approximate range of wavelengths for each type of electromagnetic radiation and summarize the characteristics and/or the uses of each.

a. gamma rays

b. X-rays

c. ultraviolet radiation

d. visible light

e. infrared radiation

f. microwave radiation

g. radio waves

8. Explain the wave behavior known as interference. Explain the difference between constructive and destructive interference.

9. Explain the wave behavior known as diffraction. Draw the diffraction pattern that occurs when light travels through two slits comparable in size and separation to the light's wavelength.

10. Describe the photoelectric effect. How did experimental observations of this phenomenon differ from the predictions of classical electromagnetic theory?
11. How did the photoelectric effect lead Einstein to propose that light is quantized?
12. What is a photon? How is the energy of a photon related to its wavelength? Its frequency?
13. What is an emission spectrum? How does an emission spectrum of a gas in a discharge tube differ from a white light spectrum?
14. Describe the Bohr model for the atom. How did the Bohr model account for the emission spectra of atoms?
15. Explain electron diffraction.
16. What is the de Broglie wavelength of an electron? What determines the value of the de Broglie wavelength for an electron?
17. What are complementary properties? How does electron diffraction demonstrate the complementarity of the wave nature and particle nature of the electron?
18. Explain Heisenberg's uncertainty principle. What paradox is at least partially solved by the uncertainty principle?
19. What is a trajectory? What kind of information do you need to predict the trajectory of a particle?
20. Why does the uncertainty principle make it impossible to predict a trajectory for the electron?
21. Newton's laws of motion are *deterministic*. Explain this statement.
22. An electron behaves in ways that are at least partially indeterminate. Explain this statement.
23. What is a probability distribution map?
24. For each solution to the Schrödinger equation, what can be precisely specified: the electron's energy or its position? Explain.
25. What is a quantum-mechanical orbital?
26. What is the Schrödinger equation? What is a wave function? How is a wave function related to an orbital?
27. What are the possible values of the principal quantum number  $n$ ? What does the principal quantum number determine?
28. What are the possible values of the angular momentum quantum number  $l$ ? What does the angular momentum quantum number determine?
29. What are the possible values of the magnetic quantum number  $m_l$ ? What does the magnetic quantum number determine?
30. List all the orbitals in each principal level. Specify the three quantum numbers for each orbital.  
a.  $n = 1$     b.  $n = 2$     c.  $n = 3$     d.  $n = 4$
31. Explain the difference between a plot showing the probability density for an orbital and one showing the radial distribution function.
32. Make sketches of the general shapes of the  $s$ ,  $p$ , and  $d$  orbitals.
33. List the four different sublevels. Given that only a maximum of two electrons can occupy an orbital, determine the maximum number of electrons that can exist in each sublevel.
34. Why are atoms usually portrayed as spheres when most orbitals are not spherically shaped?

## Problems by Topic

### Electromagnetic Radiation

35. The distance from the sun to Earth is  $1.496 \times 10^8$  km. How long does it take light to travel from the sun to Earth?
36. The nearest star to our sun is Proxima Centauri, at a distance of 4.3 light-years from the sun. A light-year is the distance that light travels in one year (365 days). How far away, in km, is Proxima Centauri from the sun?
37. List these types of electromagnetic radiation in order of (i) increasing wavelength and (ii) increasing energy per photon.  
a. radio waves  
b. microwaves  
c. infrared radiation  
d. ultraviolet radiation
38. List these types of electromagnetic radiation in order of (i) increasing frequency and (ii) decreasing energy per photon.  
a. gamma rays  
b. radio waves  
c. microwaves  
d. visible light
39. Calculate the frequency of each wavelength of electromagnetic radiation.  
a. 632.8 nm (wavelength of red light from helium–neon laser)  
b. 503 nm (wavelength of maximum solar radiation)  
c. 0.052 nm (a wavelength contained in medical X-rays)
40. Calculate the wavelength of each frequency of electromagnetic radiation.  
a. 100.2 MHz (typical frequency for FM radio broadcasting)  
b. 1070 kHz (typical frequency for AM radio broadcasting) (assume four significant figures)  
c. 835.6 MHz (common frequency used for cell phone communication)
41. Calculate the energy of a photon of electromagnetic radiation at each of the wavelengths indicated in Problem 39.
42. Calculate the energy of a photon of electromagnetic radiation at each of the frequencies indicated in Problem 40.
43. A laser pulse with wavelength 532 nm contains 3.85 mJ of energy. How many photons are in the laser pulse?
44. A heat lamp produces 32.8 watts of power at a wavelength of  $6.5 \mu\text{m}$ . How many photons are emitted per second? (1 watt = 1 J/s)
45. Determine the energy of 1 mol of photons for each kind of light. (Assume three significant figures.)  
a. infrared radiation (1500 nm)  
b. visible light (500 nm)  
c. ultraviolet radiation (150 nm)
46. How much energy is contained in 1 mol of each?  
a. X-ray photons with a wavelength of 0.135 nm  
b.  $\gamma$ -ray photons with a wavelength of  $2.15 \times 10^{-5}$  nm

### The Wave Nature of Matter and the Uncertainty Principle

47. Sketch the interference pattern that results from the diffraction of electrons passing through two closely spaced slits.
48. What happens to the interference pattern described in Problem 47 if the rate of electrons going through the slits is decreased to one electron per hour? What happens to the pattern if we try to determine which slit the electron goes through by using a laser placed directly behind the slits?

49. The resolution limit of a microscope is roughly equal to the wavelength of light used in producing the image. Electron microscopes use an electron beam (in place of photons) to produce much higher resolution images, about 0.20 nm in modern instruments. Assuming that the resolution of an electron microscope is equal to the de Broglie wavelength of the electrons used, to what speed must the electrons be accelerated to obtain a resolution of 0.20 nm?
50. The smallest atoms can themselves exhibit quantum-mechanical behavior. Calculate the de Broglie wavelength (in pm) of a hydrogen atom traveling at 475 m/s.
51. What is the de Broglie wavelength of an electron traveling at  $1.35 \times 10^5$  m/s?
52. A proton in a linear accelerator has a de Broglie wavelength of 122 pm. What is the speed of the proton?
53. Calculate the de Broglie wavelength of a 143-g baseball traveling at 95 mph. Why is the wave nature of matter not important for a baseball?
54. A 0.22-caliber handgun fires a 1.9-g bullet at a velocity of 765 m/s. Calculate the de Broglie wavelength of the bullet. Is the wave nature of matter significant for bullets?
55. An electron has an uncertainty in its position of 552 pm. What is the uncertainty in its velocity?
56. An electron traveling at  $3.7 \times 10^5$  m/s has an uncertainty in its velocity of  $1.88 \times 10^5$  m/s. What is the uncertainty in its position?

### Orbitals and Quantum Numbers

57. Which electron is, on average, closer to the nucleus: an electron in a 2s orbital or an electron in a 3s orbital?
58. Which electron is, on average, farther from the nucleus: an electron in a 3p orbital or an electron in a 4p orbital?
59. What are the possible values of  $l$  for each value of  $n$ ?  
a. 1      b. 2      c. 3      d. 4
60. What are the possible values of  $m_l$  for each value of  $l$ ?  
a. 0      b. 1      c. 2      d. 3
61. Which set of quantum numbers *cannot* specify an orbital?  
a.  $n = 2, l = 1, m_l = -1$       b.  $n = 3, l = 2, m_l = 0$   
c.  $n = 3, l = 3, m_l = 2$       d.  $n = 4, l = 3, m_l = 0$
62. Which combinations of  $n$  and  $l$  represent real orbitals, and which do not exist?  
a. 1s      b. 2p      c. 4s      d. 2d
63. Sketch the 1s and 2p orbitals. How do the 2s and 3p orbitals differ from the 1s and 2p orbitals?
64. Sketch the 3d orbitals. How do the 4d orbitals differ from the 3d orbitals?

### Atomic Spectroscopy

65. An electron in a hydrogen atom is excited with electrical energy to an excited state with  $n = 2$ . The atom then emits a photon. What is the value of  $n$  for the electron following the emission?
66. Determine whether each transition in the hydrogen atom corresponds to absorption or emission of energy.  
a.  $n = 3 \rightarrow n = 1$   
b.  $n = 2 \rightarrow n = 4$   
c.  $n = 4 \rightarrow n = 3$
67. According to the quantum-mechanical model for the hydrogen atom, which electron transitions produces light with the longer wavelength:  $2p \rightarrow 1s$  or  $3p \rightarrow 1s$ ?
68. According to the quantum-mechanical model for the hydrogen atom, which electron transition produces light with the longer wavelength:  $3p \rightarrow 2s$  or  $4p \rightarrow 3p$ ?
69. Calculate the wavelength of the light emitted when an electron in a hydrogen atom makes each transition and indicate the region of the electromagnetic spectrum (infrared, visible, ultraviolet, etc.) where the light is found.  
a.  $n = 2 \rightarrow n = 1$       b.  $n = 3 \rightarrow n = 1$   
c.  $n = 4 \rightarrow n = 2$       d.  $n = 5 \rightarrow n = 2$
70. Calculate the frequency of the light emitted when an electron in a hydrogen atom makes each transition.  
a.  $n = 4 \rightarrow n = 3$       b.  $n = 5 \rightarrow n = 1$   
c.  $n = 5 \rightarrow n = 4$       d.  $n = 6 \rightarrow n = 5$
71. An electron in the  $n = 7$  level of the hydrogen atom relaxes to a lower-energy level, emitting light of 397 nm. What is the value of  $n$  for the level to which the electron relaxed?
72. An electron in a hydrogen atom relaxes to the  $n = 4$  level, emitting light of 114 THz. What is the value of  $n$  for the level in which the electron originated?

## Cumulative Problems

73. Ultraviolet radiation and radiation of shorter wavelengths can damage biological molecules because these kinds of radiation carry enough energy to break bonds within the molecules. A typical carbon-carbon bond requires 348 kJ/mol to break. What is the longest wavelength of radiation with enough energy to break carbon-carbon bonds?
74. The human eye contains a molecule called 11-*cis*-retinal that changes shape when struck with light of sufficient energy. The change in shape triggers a series of events that results in an electrical signal being sent to the brain that results in vision. The minimum energy required to change the conformation of 11-*cis*-retinal within the eye is about 164 kJ/mol. Calculate the longest wavelength visible to the human eye.
75. An argon ion laser puts out 5.0 W of continuous power at a wavelength of 532 nm. The diameter of the laser beam is

5.5 mm. If the laser is pointed toward a pinhole with a diameter of 1.2 mm, how many photons travel through the pinhole per second? Assume that the light intensity is equally distributed throughout the entire cross-sectional area of the beam. ( $1 \text{ W} = 1 \text{ J/s}$ )

76. A green leaf has a surface area of  $2.50 \text{ cm}^2$ . If solar radiation is  $1000 \text{ W/m}^2$ , how many photons strike the leaf every second? Assume three significant figures and an average wavelength of 504 nm for solar radiation.
77. In a technique used for surface analysis called Auger electron spectroscopy (AES), electrons are accelerated toward a metal surface. These electrons cause the emissions of secondary electrons—called Auger electrons—from the metal surface. The kinetic energy of the Auger electrons depends on the composition of the surface. The presence of oxygen atoms on the surface results in

Auger electrons with a kinetic energy of approximately 506 eV. What is the de Broglie wavelength of one of these electrons?

$$[\text{KE} = \frac{1}{2}mv^2; 1 \text{ electron volt (eV)} = 1.602 \times 10^{-19} \text{ J}]$$

78. An X-ray photon of wavelength 0.989 nm strikes a surface. The emitted electron has a kinetic energy of 969 eV. What is the binding energy of the electron in kJ/mol?

$$[\text{KE} = \frac{1}{2}mv^2; 1 \text{ electron volt (eV)} = 1.602 \times 10^{-19} \text{ J}]$$

79. Ionization involves completely removing an electron from an atom. How much energy is required to ionize a hydrogen atom in its ground (or lowest energy) state? What wavelength of light contains enough energy in a single photon to ionize a hydrogen atom?
80. The energy required to ionize sodium is 496 kJ/mol. What minimum frequency of light is required to ionize sodium?
81. Suppose that in an alternate universe, the possible values of  $l$  are the integer values from 0 to  $n$  (instead of 0 to  $n - 1$ ). Assuming no other differences between this imaginary universe and ours, how many orbitals exist in each level in the alternate universe?  
a.  $n = 1$       b.  $n = 2$       c.  $n = 3$
82. Suppose that, in an alternate universe, the possible values of  $m_l$  are the integer values including 0 ranging from  $-l - 1$  to  $l + 1$  (instead of simply  $-l$  to  $+l$ ). How many orbitals exist in each sublevel in the alternate universe?  
a.  $s$  sublevel      b.  $p$  sublevel      c.  $d$  sublevel
83. An atomic emission spectrum of hydrogen shows three wavelengths: 1875 nm, 1282 nm, and 1093 nm. Assign these wavelengths to transitions in the hydrogen atom.
84. An atomic emission spectrum of hydrogen shows three wavelengths: 121.5 nm, 102.6 nm, and 97.23 nm. Assign these wavelengths to transitions in the hydrogen atom.
85. The binding energy of electrons in a metal is 193 kJ/mol. Find the threshold frequency of the metal.
86. In order for a thermonuclear fusion reaction of two deuterons ( ${}^2_1\text{H}^+$ ) to take place, the deuterons must collide and each must have a velocity of about  $1 \times 10^6$  m/s. Find the wavelength of such a deuteron.
87. The speed of sound in air is 344 m/s at room temperature. The lowest frequency of a large organ pipe is  $30 \text{ s}^{-1}$  and the highest

frequency of a piccolo is  $1.5 \times 10^4 \text{ s}^{-1}$ . Find the difference in wavelength between these two sounds.

88. The distance from Earth to the sun is  $1.5 \times 10^8$  km. Find the number of crests in a light wave of frequency  $1.0 \times 10^{14} \text{ s}^{-1}$  traveling from the sun to Earth.
89. The iodine molecule can be photodissociated (broken apart with light) into iodine atoms in the gas phase with light of wavelengths shorter than about 792 nm. A 100.0-mL glass tube contains 55.7 mtorr of gaseous iodine at  $25.0^\circ\text{C}$ . What minimum amount of light energy must be absorbed by the iodine in the tube to dissociate 15.0% of the molecules?
90. A 5.00-mL ampule of a 0.100-M solution of naphthalene in hexane is excited with a flash of light. The naphthalene emits 15.5 J of energy at an average wavelength of 349 nm. What percentage of the naphthalene molecules emitted a photon?
91. A laser produces 20.0 mW of red light. In 1.00 hr, the laser emits  $2.29 \times 10^{20}$  photons. What is the wavelength of the laser?
92. A particular laser consumes 150.0 watts of electrical power and produces a stream of  $1.33 \times 10^{19}$  1064-nm photons per second. What is the percent efficiency of the laser in converting electrical power to light?
93. The quantum yield of light-induced chemical reactions (called photochemical reactions) measures the efficiency of the process. The quantum yield,  $\phi$ , is defined as:  
$$\phi = \frac{\text{number of reaction events}}{\text{number of photons absorbed}}$$
Suppose the quantum yield for the reaction  $\text{CH}_3\text{X} \longrightarrow \text{CH}_3 + \text{X}$  is  $\phi = 0.24$ . A cuvette containing a solution of  $\text{CH}_3\text{X}$  is irradiated with 280-nm light with a power of 885 mW for 10.0 minutes. Assuming total absorption of the light by the sample, what is the maximum amount (in moles) of  $\text{CH}_3\text{X}$  that breaks apart?
94. A student is studying the photodissociation (dissociation with light) of  $\text{I}_2 \longrightarrow 2\text{I}$ . When a sample of  $\text{I}_2$  is irradiated with a power of 255 mW at 590 nm for 35 seconds, 0.0256 mmol of I forms. Assuming complete absorption of the incident radiation, what is the quantum yield,  $\phi$ , of the reaction? (See Problem 93 for definition of quantum yield.)

## Challenge Problems

95. An electron confined to a one-dimensional box has energy levels given by the equation:

$$E_n = n^2 h^2 / 8 m L^2$$

where  $n$  is a quantum number with possible values of 1, 2, 3, ...,  $m$  is the mass of the particle, and  $L$  is the length of the box.

- a. Calculate the energies of the  $n = 1$ ,  $n = 2$ , and  $n = 3$  levels for an electron in a box with a length of 155 pm.
- b. Calculate the wavelength of light required to make a transition from  $n = 1 \longrightarrow n = 2$  and from  $n = 2 \longrightarrow n = 3$ . In what region of the electromagnetic spectrum do these wavelengths lie?
96. The energy of a vibrating molecule is quantized much like the energy of an electron in the hydrogen atom. The energy levels of a vibrating molecule are given by the equation:

$$E_n = \left(n + \frac{1}{2}\right) h \nu$$

where  $n$  is a quantum number with possible values of 1, 2, ..., and  $\nu$  is the frequency of vibration. The vibration frequency of HCl is approximately  $8.85 \times 10^{13} \text{ s}^{-1}$ . What minimum energy is required to excite a vibration in HCl? What wavelength of light is required to excite this vibration?

97. The wave functions for the 1s and 2s orbitals are as follows:

$$1s \quad \psi = (1/\pi)^{1/2} (1/a_0^{3/2}) \exp(-r/a_0)$$

$$2s \quad \psi = (1/32\pi)^{1/2} (1/a_0^{3/2}) (-2r/a_0) \exp(-r/a_0)$$

where  $a_0$  is a constant ( $a_0 = 53 \text{ pm}$ ) and  $r$  is the distance from the nucleus. Use a spreadsheet to make a plot of each of these wave functions for values of  $r$  ranging from 0 pm to 200 pm. Describe the differences in the plots and identify the node in the 2s wave function.

98. Before quantum mechanics was developed, Johannes Rydberg developed an equation that predicted the wavelengths ( $\lambda$ ) in the atomic spectrum of hydrogen:

$$1/\lambda = R(1/m^2 - 1/n^2)$$

In this equation  $R$  is a constant and  $m$  and  $n$  are integers. Use the quantum-mechanical model for the hydrogen atom to derive the Rydberg equation.

99. Find the velocity of an electron emitted by a metal with a threshold frequency of  $2.25 \times 10^{14} \text{ s}^{-1}$  when it is exposed to visible light of wavelength  $5.00 \times 10^{-7} \text{ m}$ .
100. Water is exposed to infrared radiation of wavelength  $2.8 \times 10^{-4} \text{ cm}$ . Assume that all the radiation is absorbed and converted to heat. How many photons are required to raise the temperature of 2.0 g of water by 2.0 K?
101. The 2005 Nobel Prize in Physics was given, in part, to scientists who had made ultrashort pulses of light. These pulses are important in making measurements involving very short time

periods. One challenge in making such pulses is the uncertainty principle, which can be stated with respect to energy and time as  $\Delta E \cdot \Delta t \geq h/4\pi$ . What is the energy uncertainty ( $\Delta E$ ) associated with a short pulse of laser light that lasts for only 5.0 femtoseconds (fs)? Suppose the low-energy end of the pulse had a wavelength of 722 nm. What is the wavelength of the high-energy end of the pulse that is limited only by the uncertainty principle?

102. A metal with a threshold frequency of  $6.71 \times 10^{14} \text{ s}^{-1}$  emits an electron with a velocity of  $6.95 \times 10^5 \text{ m/s}$  when radiation of  $1.01 \times 10^{15} \text{ s}^{-1}$  strikes the metal. Calculate the mass of the electron.
103. Find the longest wavelength of a wave that can travel around in a circular orbit of radius 1.8 m.
104. The heat of fusion of ice is 6.00 kJ/mol. Find the number of photons of wavelength  $= 6.42 \times 10^{-6} \text{ m}$  that must be absorbed to melt 1.00 g of ice.

## Conceptual Problems

105. Explain the difference between the Bohr model for the hydrogen atom and the quantum-mechanical model. Is the Bohr model consistent with Heisenberg's uncertainty principle?
106. The light emitted from one of the following electronic transitions ( $n = 4 \rightarrow n = 3$  or  $n = 3 \rightarrow n = 2$ ) in the hydrogen atom causes the photoelectric effect in a particular metal, while light from the other transition does not. Which transition causes the photoelectric effect and why?
107. Determine whether an interference pattern is observed on the other side of the slits in each experiment.
- An electron beam is aimed at two closely spaced slits. The beam produces only one electron per minute.
  - An electron beam is aimed at two closely spaced slits. A light beam is placed at each slit to determine when an electron goes through the slit.
  - A high-intensity light beam is aimed at two closely spaced slits.
  - A gun is fired at a solid wall containing two closely spaced slits. (Will the bullets that pass through the slits form an interference pattern on the other side of the solid wall?)
108. Which transition in the hydrogen atom produces emitted light with the longest wavelength?
- $n = 4 \rightarrow n = 3$
  - $n = 2 \rightarrow n = 1$
  - $n = 3 \rightarrow n = 2$

## Active Classroom Learning

## Questions for Group Work

Discuss these questions with the group and record your consensus answer.

109. Discuss the nature of light with your group. Ask each member of your group to transcribe one complete sentence about the physical nature of light.
110. How are electrons like baseballs? How are they unlike baseballs?
111. What are all the possible values of  $m_l$  if  $l = 0$  (an  $s$  orbital)? If  $l = 1$  (a  $p$  orbital)? If  $l = 2$  (a  $d$  orbital)? How many possible values of  $m_l$  would there be if  $l = 20$ ? Write an equation to determine the number of possible values of  $m_l$  from the value of  $l$ .

112. Have each group member choose a set of quantum numbers for an electron in a hydrogen atom. Calculate the wavelength of light produced if an electron moves from your state to each state of the other group members. Make a table comparing all possible combinations, and list all wavelengths in order of increasing energy.
113. How many nodes are there in the  $1s$ ,  $2p$ , and  $3d$  orbitals? How many nodes are in a  $4f$  orbital?

## Data Interpretation and Analysis

### UV Radiation and Sunscreen

114. On average sunlight shines on the surface of Earth with an intensity of 910 Watts/ $\text{m}^2$ . Some of this energy is in the form of ultraviolet (UV) radiation. The compounds in chemical sunscreens absorb ultraviolet rays and release the energy as lower-energy infrared (IR) rays, thereby preventing the skin-damaging UV rays from reaching the skin. You may have noticed

references to UV-A (320–400 nm) and UV-B (280–320 nm) protection in sunscreen packaging and advertisements. Figure a► lists the chemical formula and molar mass of two compounds, 2-ethylhexyl  $p$ -methoxycinnamate (2-EHMC), a UV-B sunscreen, and terephthalylidenedicamphor sulfonic acid (TDSA), a UV-A sunscreen.

Sunscreen Compound	Chemical Formula	$\mathcal{M}$ (g/mol)
terephthalylidenedicamphor sulfonic acid (TDSA)	$\text{C}_{28}\text{H}_{34}\text{O}_8\text{S}_2$	562.70
2-ethylhexyl <i>p</i> -methoxycinnamate (2-EHMC)	$\text{C}_{18}\text{H}_{26}\text{O}_3$	290.39

**▲ FIGURE a Chemical Formula and Molar Mass ( $\mathcal{M}$ ) of Chemicals Commonly Found in Sunscreens**

Organic molecules have groups of atoms bonded together that can vibrate and rotate, making more energy states available. As a result, instead of absorbing exact wavelengths of radiation as elements do, organic molecules absorb over a broad range of wavelengths. Figure b plots absorbance versus wavelength for 2-EHMC and TDSA. Greater absorbance indicates that the compound absorbs more light.

**▲ FIGURE b Sunscreen Absorption**

<http://mycpss.com/critical-wavelength-broad-spectrum-uv-protection/>

Use the information provided in the figures to answer the following questions:

- Calculate the energy absorbed by TDSA at its maximum absorption for one photon of UV radiation.
- Calculate the energy absorbed by 2-EHMC at its maximum absorption for one photon of UV radiation.
- Which absorbs more energy, 2-EHMC or TDSA, at their respective maximum wavelengths?
- Why are these two compounds commonly included in sunscreen products?
- A person does not apply sunscreen and has  $0.42 \text{ m}^2$  of skin exposed to the sun for 1.00 hour. Calculate the total energy (in Joules) absorbed by the skin. Assume there are  $3.066 \times 10^{21}$  photons/meter<sup>2</sup>/sec. Assume an average wavelength of 330 nm in order to calculate the energy of a UV photon. Assume half of the photons that strike the skin are reflected.
- In order for a sunscreen product with equal amounts of TDSA and 2-EHMC to provide adequate protection from UV-A and UV-B rays for 1.00 hour, how many molecules of TDSA and 2-EHMC must be present on the skin? Assume one molecule of TDSA and one molecule 2-EHMC can each absorb 10,000 photons per hour. Assume the photon rate is the same as in part e.
- Calculate the mass of TDSA and 2-EHMC in grams that must be present on the exposed skin referenced in parts e and f in order to protect the skin.

## Answers to Conceptual Connections

### Frequency of Light

- 7.1 (b)** Infrared light has a lower frequency range than visible light, which in turn has a lower frequency range than ultraviolet light.

### The Photoelectric Effect

- 7.2** Observation A corresponds to 632 nm, observation B corresponds to 325 nm, and observation C corresponds to 455 nm. The shortest wavelength of light (highest energy per photon) corresponds to the photoelectrons with the greatest kinetic energy. The longest wavelength of light (lowest energy per photon) corresponds to the instance in which no photoelectrons were observed.

### The de Broglie Wavelength of Macroscopic Objects

- 7.3** Because of the baseball's large mass, its de Broglie wavelength is minuscule. (For a 150-g baseball,  $\lambda$  is on the order of  $10^{-34} \text{ m}$ .) This minuscule wavelength is insignificant compared to the size of the baseball itself, and therefore its effects are not observable.

### The Relationship between $n$ and $l$

- 7.4 (c)** Since  $l$  can have a maximum value of  $n - 1$  and since  $n = 3$ ,  $l$  can have a maximum value of 2.

### The Relationship between $l$ and $m_l$

- 7.5 (d)** Since  $m_l$  can have the integer values (including 0) between  $-l$  and  $+l$  and since  $l = 2$ , the possible values of  $m_l$  are  $-2, -1, 0, +1$ , and  $+2$ .

### Emission Spectra

- 7.6 (c)** The energy difference between  $n = 3$  and  $n = 2$  is greatest because the energy differences become closer together with increasing  $n$ . The greater energy difference results in an emitted photon of greater energy and therefore shorter wavelength.

# Periodic Properties of the Elements

Beginning students of chemistry often think of the science as a mere collection of disconnected data to be memorized by brute force. Not at all! Just look at it properly and everything hangs together and makes sense.

**KEY LEARNING OUTCOMES 375**

**G**reat advances in science occur not only when a scientist sees something new, but also when a scientist sees what everyone else has seen in a new way. In other words, great scientists often see patterns where others have seen only disjointed facts. Such was the case in 1869 when Dmitri Mendeleev (1834–1907), a Russian chemist, saw a pattern in the properties of elements. Mendeleev’s insight led to the periodic table, arguably the single most important tool for chemists. Recall that scientists devise theories that explain the underlying reasons for observations. Mendeleev’s periodic table is a compact way to summarize a large number of observations; quantum mechanics (covered in Chapter 7) is the theory that explains the underlying reasons for the periodic table. Quantum mechanics explains how electrons are arranged in atoms, which in turn determines the element’s properties. Since the periodic table is organized according to those properties, quantum mechanics beautifully accounts for Mendeleev’s periodic table. In this chapter, we see a continuation of the theme we have been developing since page one of this book—the properties of macroscopic substances (in this case, the elements in the periodic table) are explained by the properties of the particles that compose them (in this case, atoms and their electrons).

▲ *In order for a nerve cell to transmit a signal, sodium and potassium ions must flow in opposite directions through specific ion channels in the cell membrane.*

## 8.1 Nerve Signal Transmission

As you sit reading this book, tiny pumps in the membranes of your cells are working hard to transport ions—especially sodium ( $\text{Na}^+$ ) and potassium ( $\text{K}^+$ )—through those membranes. Amazingly, the ions are pumped in opposite directions. Sodium ions are

3 <b>Li</b> 6.94
11 <b>Na</b> 22.99
19 <b>K</b> 39.10
37 <b>Rb</b> 85.47
55 <b>Cs</b> 132.91
87 <b>Fr</b> (223.02)

▲ The group 1A metals. Potassium is directly beneath sodium in the periodic table.

▲ Dmitri Mendeleev is credited with the arrangement of the periodic table.

pumped *out of cells*, while potassium ions are pumped *into cells*. The result is a *chemical gradient* for each ion: the concentration of sodium is higher outside the cell than within, whereas just the opposite is true for potassium. These ion pumps are analogous to the water pumps in a high-rise building that pump water against the force of gravity to a tank on the roof. Other structures within the membrane, called ion channels, are like the building's faucets. When these open, sodium and potassium ions flow back down their gradients—sodium flowing in and potassium flowing out. This movement of ions is the basis for the transmission of nerve signals in the brain and throughout the body. Every move you make, every thought you have, and every sensation you experience is mediated by these ion movements.

How do the pumps and channels differentiate between sodium and potassium ions to selectively move one out of the cell and the other into the cell? To answer this question, we must examine the ions more closely. Both ions are cations of group 1A metals. All group 1A metals tend to lose one electron to form cations with a 1+ charge, so that cannot be the decisive factor. Potassium (atomic number 19) lies directly below sodium in the periodic table (atomic number 11), indicating that it has more protons, neutrons, and electrons than sodium. How do these additional subatomic particles affect the properties of potassium? As we will see in this chapter, although a higher atomic number does not always result in a larger ion (or atom), it does in the case of potassium (relative to sodium). The potassium ion has a radius of 133 pm whereas the sodium ion has a radius of 95 pm. (Recall that 1 pm =  $10^{-12}$  m.) The pumps and channels within cell membranes are so sensitive that they distinguish between the sizes of these two ions and selectively allow only one or the other to pass.

The relative size of sodium and potassium ions is an example of a **periodic property**: one that is predictable based on an element's position within the periodic table. In this chapter, we examine several periodic properties of elements, including atomic radius, ionization energy, and electron affinity. We will see that these properties, as well as the overall arrangement of the periodic table, are explained by quantum-mechanical theory, which we examined in Chapter 7. The arrangement of elements in the periodic table—originally based on similarities in the properties of the elements—reflects how electrons fill quantum-mechanical orbitals.

## 8.2 The Development of the Periodic Table

Prior to the 1700s, the number of known elements was relatively small, consisting mostly of the metals that had long been used for coinage, jewelry, and weapons. From the early 1700s to the mid-1800s, however, chemists discovered over 50 new elements. The first attempt to organize these elements according to similarities in their properties was made by the German chemist Johann Döbereiner (1780–1849), who grouped elements into *triads*: three elements with similar properties. For example, Döbereiner formed a triad out of barium, calcium, and strontium, three fairly reactive metals. About 50 years later, English chemist John Newlands (1837–1898) organized elements into *octaves*, in analogy to musical notes. When arranged this way, the properties of every eighth element were similar, much as every eighth note in the musical scale is similar. Newlands endured some ridicule for drawing an analogy between chemistry and music, including the derisive comments of one colleague who asked Newlands if he had ever tried ordering the elements according to the first letters of their names.

The modern periodic table is credited primarily to the Russian chemist Dmitri Mendeleev, even though a similar organization had been suggested by the German chemist Julius Lothar Meyer (1830–1895). Recall from Chapter 2 that Mendeleev's table is based

Gallium (eka-aluminum)			Germanium (eka-silicon)		
	Mendeleev's predicted properties	Actual properties		Mendeleev's predicted properties	Actual properties
Atomic mass	About 68 amu	69.72 amu	Atomic mass	About 72 amu	72.64 amu
Melting point	Low	29.8 °C	Density	5.5 g/cm <sup>3</sup>	5.35 g/cm <sup>3</sup>
Density	5.9 g/cm <sup>3</sup>	5.90 g/cm <sup>3</sup>	Formula of oxide	XO <sub>2</sub>	GeO <sub>2</sub>
Formula of oxide	X <sub>2</sub> O <sub>3</sub>	Ga <sub>2</sub> O <sub>3</sub>	Formula of chloride	XCl <sub>4</sub>	GeCl <sub>4</sub>
Formula of chloride	XCl <sub>3</sub>	GaCl <sub>3</sub>			

on the periodic law, which states that when elements are arranged in order of increasing mass, certain properties recur periodically. Mendeleev arranged the elements in a table in which mass increases from left to right and elements with similar properties fall in the same columns.

Mendeleev's arrangement was a huge success, allowing him to predict the existence and properties of yet undiscovered elements such as eka-aluminum (later discovered and named gallium) and eka-silicon (later discovered and named germanium). The properties of these two elements are summarized in Figure 8.1▲. (As noted in Chapter 2, *eka* means “the one beyond” or “the next one” in a family of elements.) However, Mendeleev did encounter some difficulties. For example, according to accepted values of atomic masses, tellurium (with higher mass) should come *after* iodine. But based on their properties, Mendeleev placed tellurium *before* iodine and suggested that the mass of tellurium was erroneous. The mass was correct; later work by the English physicist Henry Moseley (1887–1915) showed that listing elements according to *atomic number*, rather than atomic mass, resolves this problem and results in even better correlation with elemental properties.

Notice the scientific approach in practice in the history of the periodic table. A number of related observations led to a scientific law—the periodic law. Mendeleev's table, an expression of the periodic law, had predictive power as laws usually do. However, it did not explain *why* the properties of elements recurred or *why* certain elements had similar properties. Recall from Chapter 1 that laws *summarize* behavior while theories *explain* behavior. The theory that explains the reasons behind the periodic law is quantum-mechanical theory. In this chapter, we explore the connection between the periodic table and quantum-mechanical theory.

▲ **FIGURE 8.1 Eka-aluminum and Eka-silicon** Mendeleev's arrangement of elements in the periodic table allowed him to predict the existence of these elements, now known as gallium and germanium, and anticipate their properties.

## 8.3 Electron Configurations: How Electrons Occupy Orbitals

Electron Configurations

Quantum-mechanical theory describes the behavior of electrons in atoms. Since chemical bonding involves the transfer or sharing of electrons, quantum-mechanical theory helps us understand and describe chemical behavior. As we saw in Chapter 7, electrons in atoms exist within orbitals. An **electron configuration** for an atom shows the particular orbitals that electrons occupy for that atom. For example, consider the **ground state**—or lowest energy state—electron configuration for a hydrogen atom:

The electron configuration indicates that hydrogen's one electron is in the  $1s$  orbital. Electrons generally occupy the lowest energy orbitals available. Since the  $1s$  orbital is the lowest energy orbital in hydrogen (see Section 7.5), hydrogen's electron occupies that orbital. If we could write electron configurations for all the elements, we could see how the arrangements of the electrons within their atoms correlate with the element's chemical properties. However, the Schrödinger equation solutions (the atomic orbitals and their energies) that we described in Chapter 7 are for the hydrogen atom. What do the atomic orbitals of *other atoms* look like? What are their relative energies?

The Schrödinger equation for multielectron atoms has terms to account for the interactions of the electrons with one another that make it too complicated to solve exactly. However, approximate solutions indicate that the orbitals in multielectron atoms are hydrogen-like—they are similar to the  $s$ ,  $p$ ,  $d$ , and  $f$  orbitals that we examined in Chapter 7. In order to see how the electrons in multielectron atoms occupy these hydrogen-like orbitals, we must examine two additional concepts: *the effects of electron spin*, a fundamental property of all electrons that affects the number of electrons allowed in any one orbital; and *sublevel energy splitting*, which determines the order of orbital filling within a level.

## Electron Spin and the Pauli Exclusion Principle

We can represent the electron configuration of hydrogen ( $1s^1$ ) in a slightly different way with an **orbital diagram**, which gives similar information but symbolizes the electron as an arrow and the orbital as a box. The orbital diagram for a hydrogen atom is:

In an orbital diagram, the direction of the arrow (pointing up or pointing down) represents the orientation of the *electron's spin*. Recall from Section 7.5 that the orientation of the electron's spin is quantized, with only two possibilities—spin up ( $m_s = +\frac{1}{2}$ ) and spin down ( $m_s = -\frac{1}{2}$ ). In an orbital diagram,  $m_s = +\frac{1}{2}$  is represented with a half-arrow pointing up ( $\uparrow$ ) and  $m_s = -\frac{1}{2}$  is represented with a half-arrow pointing down ( $\downarrow$ ). In a collection of hydrogen atoms, the electrons in about half of the atoms are spin up and the electrons in the other half are spin down. Since no additional electrons are present within the hydrogen atom, we conventionally represent the hydrogen atom electron configuration with its one electron as spin up.

Helium is the first element on the periodic table that contains two electrons. Its two electrons occupy the  $1s$  orbital:

How do the spins of the two electrons in helium align relative to each other? The answer to this question is addressed by the **Pauli exclusion principle**, formulated by Wolfgang Pauli (1900–1958) in 1925:

**Pauli exclusion principle: no two electrons in an atom can have the same four quantum numbers.**

Since two electrons occupying the same orbital have three identical quantum numbers ( $n$ ,  $l$ , and  $m_l$ ), they must have different spin quantum numbers. Because there are only two possible spin quantum numbers ( $+\frac{1}{2}$  and  $-\frac{1}{2}$ ), the Pauli exclusion principle implies that *each orbital can have a maximum of only two electrons, with opposing spins*.

By applying the exclusion principle, we write an electron configuration and orbital diagram for helium as follows:

The following table shows the four quantum numbers for each of the two electrons in helium:

$n$	$l$	$m_l$	$m_s$
1	0	0	$+\frac{1}{2}$
1	0	0	$-\frac{1}{2}$

The two electrons have three quantum numbers in common (because they are in the same orbital) but have different spin quantum numbers (as indicated by the opposing half-arrows in the orbital diagram).

## Sublevel Energy Splitting in Multielectron Atoms

A major difference in the (approximate) solutions to the Schrödinger equation for multi-electron atoms compared to the solutions for the hydrogen atom is the energy ordering of the orbitals. In the hydrogen atom, the energy of an orbital depends only on  $n$ , the principal quantum number. For example, the  $3s$ ,  $3p$ , and  $3d$  orbitals (which are empty for hydrogen in its lowest energy state) all have the same energy—they are **degenerate**. The orbitals within a principal level of a *multielectron atom*, in contrast, are not degenerate—their energy depends on the value of  $l$ . We say that the energies of the sublevels are *split*. In general, the lower the value of  $l$  *within a principal level*, the lower the energy ( $E$ ) of the corresponding orbital. Thus, for a given value of  $n$ :

$$E(s \text{ orbital}) < E(p \text{ orbital}) < E(d \text{ orbital}) < E(f \text{ orbital})$$

In order to understand why the sublevels split in this way, we must examine three key concepts associated with the energy of an electron in the vicinity of a nucleus: (1) Coulomb's law, which describes the interactions between charged particles; (2) shielding, which describes how one electron can shield another electron from the full charge of the nucleus; and (3) penetration, which describes how one atomic orbital can overlap spatially with another, thus penetrating into a region that is close to the nucleus (and therefore less shielded from nuclear charge). We then discuss how these concepts, together with the spatial distributions of electron probability for each orbital, result in the energy ordering that we just saw.

### Coulomb's Law

The attractions and repulsions between charged particles, first introduced in Section 2.4, are described by **Coulomb's law**, which states that the potential energy ( $E$ ) of two charged particles depends on their charges ( $q_1$  and  $q_2$ ) and on their separation ( $r$ ):

$$E = \frac{1}{4\pi\epsilon_0} \frac{q_1 q_2}{r} \quad [8.1]$$

In this equation,  $\epsilon_0$  is a constant ( $\epsilon_0 = 8.85 \times 10^{-12} \text{ C}^2/\text{J} \cdot \text{m}$ ). The potential energy is positive for charges of the same sign (plus  $\times$  plus, or minus  $\times$  minus) and negative for charges of opposite sign (plus  $\times$  minus, or minus  $\times$  plus). The *magnitude* of the potential energy depends inversely on the separation between the charged particles. We can draw three important conclusions from Coulomb's law:

- For like charges, the potential energy ( $E$ ) is positive and decreases as the particles get *farther apart* (as  $r$  increases). Since systems tend toward lower potential energy, like charges repel each other (in much the same way that like poles of two magnets repel each other).
- For opposite charges, the potential energy is negative and becomes more negative as the particles get *closer together* (as  $r$  decreases). Therefore, opposite charges (like opposite poles on a magnet) *attract each other*.
- The *magnitude* of the interaction between charged particles increases as the charges of the particles increase. Consequently, an electron with a charge of  $1-$  is more strongly attracted to a nucleus with a charge of  $2+$  than it is to a nucleus with a charge of  $1+$ .

CONCEPTUAL  
CONNECTION 8.1

**Coulomb's Law** According to Coulomb's law, what happens to the potential energy of two oppositely charged particles as they get closer together?

- (a) Their potential energy decreases.
- (b) Their potential energy increases.
- (c) Their potential energy does not change.

### Shielding

In multielectron atoms, any one electron experiences both the positive charge of the nucleus (which is attractive) and the negative charges of the other electrons (which are repulsive). We can think of the repulsion of one electron by other electrons as *screening* or **shielding** that electron from the full effects of the nuclear charge. For example, consider a lithium ion ( $\text{Li}^+$ ). The lithium ion contains two electrons, so its electron configuration is identical to that of helium:

Imagine bringing a third electron toward the lithium ion. When the third electron is far from the nucleus, it experiences the  $3+$  charge of the nucleus through the *screen* or *shield* of the  $2-$  charge of the two  $1s$  electrons, as shown in Figure 8.2(a)▼. We can think of the third electron as experiencing an **effective nuclear charge ( $Z_{\text{eff}}$ )** of approximately  $1+$  ( $3+$  from the nucleus and  $2-$  from the electrons, for a net charge of  $1+$ ). The inner electrons in effect *shield* the outer electron from the full nuclear charge.

**▲ FIGURE 8.2 Shielding and Penetration** (a) An electron far from the nucleus is partly shielded by the electrons in the  $1s$  orbital, reducing the effective net nuclear charge that it experiences. (b) An electron that penetrates the electron cloud of the  $1s$  orbital experiences more of the nuclear charge.

### Penetration

Now imagine allowing this third electron to come closer to the nucleus. As the third electron *penetrates* the electron cloud of the  $1s$  electrons, it begins to experience the  $3+$  charge of the nucleus more fully because it is less shielded by the intervening electrons. If the electron could somehow get closer to the nucleus than the  $1s$  electrons, it would experience the full  $3+$  charge, as shown in Figure 8.2(b)▲. In other words, as the outer electron undergoes **penetration** into the region occupied by the inner electrons, it experiences a greater nuclear charge and therefore (according to Coulomb's law) a lower energy.

### Electron Spatial Distributions and Sublevel Splitting

We now have examined the concepts we need to understand the energy splitting of the sublevels within a principal level. The splitting is a result of the spatial distributions of

electrons within a sublevel. Recall from Section 7.6 that the radial distribution function for an atomic orbital shows the total probability of finding the electron within a thin spherical shell at a distance  $r$  from the nucleus.

Figure 8.3 shows the radial distribution functions of the  $2s$  and  $2p$  orbitals superimposed on one another (the radial distribution function of the  $1s$  orbital is also shown). Notice that, in general, an electron in a  $2p$  orbital has a greater probability of being found closer to the nucleus than an electron in a  $2s$  orbital. We might initially expect, therefore, that the  $2p$  orbital would be lower in energy. However, exactly the opposite is true—the  $2s$  orbital is actually lower in energy, *but only when the  $1s$  orbital is occupied*. (When the  $1s$  orbital is empty, the  $2s$  and  $2p$  orbitals are degenerate.) Why? The reason is the bump near  $r = 0$  (near the nucleus) for the  $2s$  orbital. This bump represents a significant probability of the electron being found very close to the nucleus. Even more importantly, this area of the probability penetrates into the  $1s$  orbital—it gets into the region where shielding by the  $1s$  electrons is less effective. In contrast, most of the probability in the radial distribution function of the  $2p$  orbital lies *outside* the radial distribution function of the  $1s$  orbital. Consequently, almost all of the  $2p$  orbital is shielded from nuclear charge by the  $1s$  orbital. The end result is that the  $2s$  orbital—since it experiences more of the nuclear charge due to its greater *penetration*—is lower in energy than the  $2p$  orbital. The results are similar when we compare the  $3s$ ,  $3p$ , and  $3d$  orbitals. The  $s$  orbitals penetrate more fully than the  $p$  orbitals, which in turn penetrate more fully than the  $d$  orbitals, as shown in Figure 8.4.

Figure 8.5 shows the energy ordering of a number of orbitals in multi-electron atoms. Notice these features of Figure 8.5:

- Because of penetration, the sublevels of each principal level are *not* degenerate for multielectron atoms.
- In the fourth and fifth principal levels, the effects of penetration become so important that the  $4s$  orbital lies lower in energy than the  $3d$  orbitals and the  $5s$  orbital lies lower in energy than the  $4d$  orbitals.
- The energy separations between one set of orbitals and the next become smaller for  $4s$  orbitals and beyond, and the relative energy ordering of these orbitals can actually vary among elements. These variations result in irregularities in the electron configurations of the transition metals and their ions (as we shall see later).

▲ **FIGURE 8.3** Radial Distribution Functions for the  $1s$ ,  $2s$ , and  $2p$  Orbitals.

▲ **FIGURE 8.4** Radial Distribution Functions for the  $3s$ ,  $3p$ , and  $3d$  Orbitals The  $3s$  electrons penetrate most deeply into the inner orbitals, are least shielded, and experience the “greatest” effective nuclear charge. The  $3d$  electrons penetrate least. This accounts for the energy ordering of the sublevels:  $s < p < d$ .

### General Energy Ordering of Orbitals for Multielectron Atoms

▲ **FIGURE 8.5** General Energy Ordering of Orbitals for Multielectron Atoms.

## CONCEPTUAL CONNECTION 8.2

### Penetration and Shielding Which statement is true?

- (a) An orbital that penetrates into the region occupied by core electrons is more shielded from nuclear charge than an orbital that does not penetrate and therefore has a higher energy.
- (b) An orbital that penetrates into the region occupied by core electrons is less shielded from nuclear charge than an orbital that does not penetrate and therefore has a higher energy.
- (c) An orbital that penetrates into the region occupied by core electrons is less shielded from nuclear charge than an orbital that does not penetrate and therefore has a lower energy.
- (d) An orbital that penetrates into the region occupied by core electrons is more shielded from nuclear charge than an orbital that does not penetrate and therefore has a lower energy.

Unless otherwise specified, we use the term *electron configuration* to mean the ground state (or lowest energy) configuration.

Remember that the number of electrons in a neutral atom is equal to its atomic number.

Electrons with parallel spins have correlated motion that minimizes their mutual repulsion.

## Electron Configurations for Multielectron Atoms

Now that we know the energy ordering of orbitals in multielectron atoms, we can determine ground state electron configurations for the rest of the elements. Since we know that electrons occupy the lowest energy orbitals available when the atom is in its ground state and that only two electrons (with opposing spins) are allowed in each orbital, we can systematically build up the electron configurations for the elements. This pattern of orbital filling is known as the **aufbau principle** (the German word *aufbau* means “build up”). For lithium, with three electrons, the electron configuration and orbital diagram are:

For carbon, which has six electrons, the electron configuration and orbital diagram are:

Notice that the  $2p$  electrons occupy the  $p$  orbitals (of equal energy) singly, rather than pairing in one orbital. This way of filling orbitals is known as **Hund's rule**, which states that *when filling degenerate orbitals, electrons fill them singly first, with parallel spins*. Hund's rule is a result of an atom's tendency to find the lowest energy state possible. When two electrons occupy separate orbitals of equal energy, the repulsive interaction between them is lower than when they occupy the same orbital because the electrons are spread out over different regions of space. By convention we denote these parallel spins with half arrows pointing up.

### Summarizing Orbital Filling:

- ▶ Electrons occupy orbitals so as to minimize the energy of the atom; therefore, lower energy orbitals fill before higher energy orbitals. Orbitals fill in the following order:  $1s\ 2s\ 2p\ 3s\ 3p\ 4s\ 3d\ 4p\ 5s\ 4d\ 5p\ 6s$ .
- ▶ Orbitals can hold no more than two electrons each. When two electrons occupy the same orbital, their spins are opposite. This is another way of expressing the Pauli exclusion principle (no two electrons in one atom can have the same four quantum numbers).
- ▶ When orbitals of identical energy are available, electrons first occupy these orbitals singly with parallel spins rather than in pairs. Once the orbitals of equal energy are half full, the electrons start to pair (Hund's rule).

Consider the electron configurations and orbital diagrams for elements with atomic numbers 3–10:

Symbol	Number of electrons	Electron configuration	Orbital diagram		
Li	3	$1s^2 2s^1$			
Be	4	$1s^2 2s^2$			
B	5	$1s^2 2s^2 2p^1$			
C	6	$1s^2 2s^2 2p^2$			

Notice that, as a result of Hund's rule, the  $p$  orbitals fill with single electrons before the electrons pair:

N	7	$1s^2 2s^2 2p^3$	
O	8	$1s^2 2s^2 2p^4$	
F	9	$1s^2 2s^2 2p^5$	
Ne	10	$1s^2 2s^2 2p^6$	

The electron configuration of neon represents the complete filling of the  $n = 2$  principal level. When writing electron configurations for elements beyond neon, or beyond any other noble gas, we can abbreviate the electron configuration of the previous noble gas—sometimes called the *inner electron configuration*—by the symbol for the noble gas in square brackets. For example, the electron configuration of sodium is:

We can write this configuration more compactly by using [Ne] to represent the inner electrons:

[Ne] represents  $1s^2 2s^2 2p^6$ , the electron configuration for neon.

To write an electron configuration for an element, first find its atomic number from the periodic table—this number equals the number of electrons. Then use the order of filling to distribute the electrons in the appropriate orbitals. Remember that each orbital can hold a maximum of two electrons. Consequently,

- the  $s$  sublevel has only one orbital and can therefore hold only 2 electrons.
- the  $p$  sublevel has three orbitals and can hold 6 electrons.
- the  $d$  sublevel has five orbitals and can hold 10 electrons.
- the  $f$  sublevel has seven orbitals and can hold 14 electrons.

**Example 8.1** Electron Configurations

Write electron configurations for each element.

(a) Mg (b) P (c) Br (d) Al

**SOLUTION**

<b>(a) Mg</b> Magnesium has 12 electrons. Distribute 2 of these into the 1s orbital, 2 into the 2s orbital, 6 into the 2p orbitals, and 2 into the 3s orbital.	Mg $1s^2 2s^2 2p^6 3s^2$ or [Ne] $3s^2$
<b>(b) P</b> Phosphorus has 15 electrons. Distribute 2 of these into the 1s orbital, 2 into the 2s orbital, 6 into the 2p orbitals, 2 into the 3s orbital, and 3 into the 3p orbitals.	P $1s^2 2s^2 2p^6 3s^2 3p^3$ or [Ne] $3s^2 3p^3$
<b>(c) Br</b> Bromine has 35 electrons. Distribute 2 of these into the 1s orbital, 2 into the 2s orbital, 6 into the 2p orbitals, 2 into the 3s orbital, 6 into the 3p orbitals, 2 into the 4s orbital, 10 into the 3d orbitals, and 5 into the 4p orbitals.	Br $1s^2 2s^2 2p^6 3s^2 3p^6 4s^2 3d^{10} 4p^5$ or [Ar] $4s^2 3d^{10} 4p^5$
<b>(d) Al</b> Aluminum has 13 electrons. Distribute 2 of these into the 1s orbital, 2 into the 2s orbital, 6 into the 2p orbitals, 2 into the 3s orbital, and 1 into the 3p orbital.	Al $1s^2 2s^2 2p^6 3s^2 3p^1$ or [Ne] $3s^2 3p^1$

**FOR PRACTICE 8.1** Write electron configurations for each element.

(a) Cl (b) Si (c) Sr (d) O

**Example 8.2** Writing Orbital Diagrams

Write the orbital diagram for sulfur and determine the number of unpaired electrons.

**SOLUTION**

Sulfur's atomic number is 16; it therefore has 16 electrons and the electron configuration $1s^2 2s^2 2p^6 3s^2 3p^4$ . Draw a box for each orbital, putting the lowest energy orbital (1s) on the far left and proceeding to orbitals of higher energy to the right.	
Distribute the 16 electrons into the boxes representing the orbitals, allowing a maximum of two electrons per orbital and remembering Hund's rule. You can see from the diagram that sulfur has two unpaired electrons.	

Two unpaired electrons

**FOR PRACTICE 8.2** Write the orbital diagram for Ar and determine the number of unpaired electrons.

## 8.4 Electron Configurations, Valence Electrons, and the Periodic Table

Writing an Electron Configuration based on an Element's Position on the Periodic Table

Recall that Mendeleev arranged the periodic table so that elements with similar chemical properties lie in the same column. We can begin to make the connection between an element's properties and its electron configuration by superimposing the electron configurations of the first 18 elements onto a partial periodic table, as shown in Figure 8.6. As we move to the right across a row, the orbitals fill in the correct order. With each subsequent row, the highest principal quantum number increases by one. Notice that as we move down a column, the number of electrons in the outermost principal energy level (highest  $n$  value) remains the same. The key connection between the macroscopic world (an element's chemical properties) and the atomic world (an atom's electronic structure) lies in these outermost electrons.

An atom's **valence electrons** are those that are important in chemical bonding. For main-group elements, the valence electrons are those in the outermost principal energy level. For transition elements, we also count the outermost  $d$  electrons among the valence electrons (even though they are not in an outermost principal energy level). The chemical properties of an element depend on its valence electrons, which are instrumental in bonding because they are held most loosely (and are therefore the easiest to lose or share). We can now see why the elements in a column of the periodic table have similar chemical properties: they have the same number of valence electrons.

We distinguish between valence electrons and all the other electrons in an atom, which are called **core electrons**. For example, silicon, with the electron configuration  $1s^2 2s^2 2p^6 3s^2 3p^2$ , has four valence electrons (those in the  $n = 3$  principal level) and ten core electrons as shown in the right margin.

Outer Electron Configurations of Elements 1–18

1A							8A
1 H $1s^1$							2 He $1s^2$
3 Li $2s^1$	4 Be $2s^2$	5 B $2s^2 2p^1$	6 C $2s^2 2p^2$	7 N $2s^2 2p^3$	8 O $2s^2 2p^4$	9 F $2s^2 2p^5$	10 Ne $2s^2 2p^6$
11 Na $3s^1$	12 Mg $3s^2$	13 Al $3s^2 3p^1$	14 Si $3s^2 3p^2$	15 P $3s^2 3p^3$	16 S $3s^2 3p^4$	17 Cl $3s^2 3p^5$	18 Ar $3s^2 3p^6$

▲ FIGURE 8.6 Outer Electron Configurations of the First 18 Elements in the Periodic Table.

### Example 8.3 Valence Electrons and Core Electrons

Write the electron configuration for Ge. Identify the valence electrons and the core electrons.

#### SOLUTION

Determine the total number of electrons from germanium's atomic number (32). Distribute the electrons into the appropriate orbitals according to the information in *Summarizing Orbital Filling* on p. 344.

Since germanium is a main-group element, its valence electrons are those in the outermost principal energy level. For germanium the  $n = 4$  principal level is outermost. Consequently, the  $n = 4$  electrons are valence electrons and the rest are core electrons.

*Note:* In this book, we write electron configurations with the orbitals in the order of filling. However, electron configurations are sometimes written in order of increasing principal quantum number. The electron configuration of germanium written in order of increasing principal quantum number is Ge  $1s^2 2s^2 2p^6 3s^2 3p^6 3d^{10} 4s^2 4p^2$ .

**FOR PRACTICE 8.3** Write the electron configuration for phosphorus. Identify the valence electrons and core electrons.

Orbital Blocks in the Periodic Table

A pattern similar to what we just saw for the first 18 elements exists for the entire periodic table, as shown in Figure 8.7. Note that because of the filling order of orbitals, we can divide the periodic table into blocks representing the filling of particular sublevels. The first two columns on the left side of the periodic table comprise the *s* block, with outer electron configurations of *ns*<sup>1</sup> (the alkali metals) and *ns*<sup>2</sup> (the alkaline earth metals). The six columns on the right side of the periodic table comprise the *p* block, with outer electron configurations of *ns*<sup>2</sup> *np*<sup>1</sup>, *ns*<sup>2</sup> *np*<sup>2</sup>, *ns*<sup>2</sup> *np*<sup>3</sup>, *ns*<sup>2</sup> *np*<sup>4</sup>, *ns*<sup>2</sup> *np*<sup>5</sup> (halogens), and *ns*<sup>2</sup> *np*<sup>6</sup> (noble gases). The transition elements comprise the *d* block, and the lanthanides and actinides (also called the inner transition elements) comprise the *f* block. (For compactness, the *f* block is normally printed below the *d* block instead of being embedded within it.)

You can see that the number of columns in a block corresponds to the maximum number of electrons that can occupy the particular sublevel of that block. The *s* block has two columns (corresponding to one *s* orbital holding a maximum of two electrons); the *p* block has six columns (corresponding to three *p* orbitals with two electrons each); the *d* block has 10 columns (corresponding to five *d* orbitals with two electrons each); and the *f* block has 14 columns (corresponding to seven *f* orbitals with two electrons each).

Notice also that, except for helium, the number of valence electrons in any main-group element is equal to its lettered group number. For example, we know that chlorine has seven valence electrons because it is in group 7A.

Lastly, note that, for main-group elements, the row number in the periodic table is equal to the number (or *n* value) of the highest occupied principal level. For example, because chlorine is in row 3, its highest principal level is the *n* = 3 level.

Helium is an exception. Even though it lies in the column with an outer electron configuration of *ns*<sup>2</sup> *np*<sup>6</sup>, its electron configuration is simply 1*s*<sup>2</sup>.

Orbital Blocks of the Periodic Table

▲ FIGURE 8.7 The s, p, d, and f Blocks of the Periodic Table.

Recall from Chapter 2 that main-group elements are those in the two far left columns (groups 1A, 2A) and the six far right columns (groups 3A–8A) of the periodic table.

**Summarizing Periodic Table Organization:**

- ▶ The periodic table is divisible into four blocks corresponding to the filling of the four quantum sublevels (*s*, *p*, *d*, and *f*).
- ▶ The group number of a main-group element is equal to the number of valence electrons in that element.
- ▶ The row number of a main-group element is equal to the highest principal quantum number of that element.

**Valence Electrons and Group Number** Without writing an electron configuration, determine the number of valence electrons in nitrogen.

CONCEPTUAL  
CONNECTION 8.4

## Writing an Electron Configuration for an Element from Its Position in the Periodic Table

The organization of the periodic table allows us to write the electron configuration for an element based on its position in the periodic table. For example, suppose we want to write an electron configuration for Cl. The *inner electron configuration* of Cl is that of the noble gas that precedes it in the periodic table, Ne. So we can represent the inner electron configuration with [Ne]. We can determine the *outer electron configuration*—the configuration of the electrons beyond the previous noble gas—by tracing the elements between Ne and Cl and assigning electrons to the appropriate orbitals, as shown here. Remember that the highest *n* value is indicated by the row number (in this case, 3 for chlorine).

1A	2A							3A	4A	5A	6A	7A	8A
1													
2													
3	3s <sup>2</sup>												Ne
4	s												
5		d											
6													
7													
f													

We begin with [Ne], then add in the two 3*s* electrons as we trace across the *s* block, followed by five 3*p* electrons as we trace across the *p* block to Cl, which is in the fifth column of the *p* block. The electron configuration is:

Notice that Cl is in column 7A and therefore has seven valence electrons and an outer electron configuration of  $ns^2np^5$ .

**Example 8.4** Writing Electron Configurations from the Periodic Table

Refer to the periodic table to write the electron configuration for selenium (Se).

**SOLUTION**

The atomic number of Se is 34. The noble gas that precedes Se in the periodic table is argon, so the inner electron configuration is [Ar]. Obtain the outer electron configuration by tracing the elements between Ar and Se and assigning electrons to the appropriate orbitals. Begin with [Ar]. Because Se is in row 4, add two  $4s$  electrons as you trace across the  $s$  block ( $n = \text{row number}$ ). Next, add ten  $3d$  electrons as you trace across the  $d$  block ( $n = \text{row number} - 1$ ). Lastly, add four  $4p$  electrons as you trace across the  $p$  block to Se, which is in the fourth column of the  $p$  block ( $n = \text{row number}$ ).

**FOR PRACTICE 8.4** Refer to the periodic table to write the electron configuration of bismuth (Bi).

**FOR MORE PRACTICE 8.4** Refer to the periodic table to write the electron configuration for iodine (I).

**The Transition and Inner Transition Elements**

The electron configurations of the transition elements ( $d$  block) and inner transition elements ( $f$  block) exhibit trends that differ somewhat from those of the main-group elements. As we move to the right across a row in the  $d$  block, the  $d$  orbitals fill as shown here:

21 <b>Sc</b> $4s^2 3d^1$	22 <b>Ti</b> $4s^2 3d^2$	23 <b>V</b> $4s^2 3d^3$	24 <b>Cr</b> $4s^1 3d^5$	25 <b>Mn</b> $4s^2 3d^5$	26 <b>Fe</b> $4s^2 3d^6$	27 <b>Co</b> $4s^2 3d^7$	28 <b>Ni</b> $4s^2 3d^8$	29 <b>Cu</b> $4s^1 3d^{10}$	30 <b>Zn</b> $4s^2 3d^{10}$
39 <b>Y</b> $5s^2 4d^1$	40 <b>Zr</b> $5s^2 4d^2$	41 <b>Nb</b> $5s^1 4d^4$	42 <b>Mo</b> $5s^1 4d^5$	43 <b>Tc</b> $5s^2 4d^5$	44 <b>Ru</b> $5s^1 4d^7$	45 <b>Rh</b> $5s^1 4d^8$	46 <b>Pd</b> $4d^{10}$	47 <b>Ag</b> $5s^1 4d^{10}$	48 <b>Cd</b> $5s^2 4d^{10}$

Notice that *the principal quantum number of the  $d$  orbitals that fill across each row in the transition series is equal to the row number minus one*. In the fourth row, the  $3d$  orbitals fill; in the fifth row, the  $4d$  orbitals fill; and so on. This happens because, as we discussed in Section 8.3, the  $4s$  orbital is generally lower in energy than the  $3d$  orbital (because it more efficiently penetrates into the region occupied by the core electrons). The result is that the  $4s$  orbital fills before the  $3d$  orbital, even though the  $4s$  orbital's principal quantum number ( $n = 4$ ) is higher.

Keep in mind, however, that the  $4s$  and the  $3d$  orbitals are extremely close to each other in energy so their relative energy ordering depends on the exact species under consideration; this causes some irregular behavior in the transition metals. For example, in the first transition series of the  $d$  block, the outer configuration is  $4s^2 3d^x$  with two exceptions: Cr is  $4s^1 3d^5$  and Cu is  $4s^1 3d^{10}$ . This behavior is related to the closely spaced  $3d$  and  $4s$  energy levels and the stability associated with a half-filled (as in Cr) or completely filled (as in Cu) sublevel. Actual electron configurations are definitively determined experimentally (through spectroscopy) and do not always conform to the general pattern. Nonetheless, the patterns described here allow us to accurately predict electron configurations for most of the elements in the periodic table.

As we move across the  $f$  block (the inner transition series), the  $f$  orbitals fill. For these elements, the principal quantum number of the  $f$  orbitals that fill across each

row is the row number *minus two*. (In the sixth row, the  $4f$  orbitals fill, and in the seventh row, the  $5f$  orbitals fill.) In addition, within the inner transition series, the close energy spacing of the  $5d$  and  $4f$  orbitals sometimes causes an electron to enter a  $5d$  orbital instead of the expected  $4f$  orbital. For example, the electron configuration of gadolinium is  $[\text{Xe}] 6s^2 4f^7 5d^1$  (instead of the expected  $[\text{Xe}] 6s^2 4f^8$ ).

## 8.5 The Explanatory Power of the Quantum-Mechanical Model

We can now see how the quantum-mechanical model accounts for the chemical properties of the elements, such as the inertness of helium or the reactivity of hydrogen, and (more generally) how it accounts for the periodic law. *The chemical properties of elements are largely determined by the number of valence electrons they contain.* Their properties are periodic because the number of valence electrons is periodic.

Because elements within a column in the periodic table have the same number of valence electrons, they have similar chemical properties. The noble gases, for example, all have eight valence electrons, except for helium, which has two. Although we do not cover the quantitative (or numerical) aspects of the quantum-mechanical model in this book, calculations of the overall energy of the electrons within atoms with eight valence electrons (or two, in the case of helium) show that they are particularly stable. In other words, when  $s$  and  $p$  quantum sublevels are completely full, the overall energy of the electrons that occupy that level is particularly low. Therefore, those electrons *cannot* lower their energy by reacting with other atoms or molecules, so the corresponding atom is relatively unreactive or inert. The noble gases are the most chemically stable and relatively unreactive family in the periodic table.

Elements with electron configurations *close* to those of the noble gases are the most reactive because they can attain noble gas electron configurations by losing or gaining a small number of electrons. For example, alkali metals (group 1A) are among the most reactive metals because their outer electron configuration ( $ns^1$ ) is one electron beyond a noble gas configuration. They readily react to lose the  $ns^1$  electron, obtaining a noble gas configuration. This explains why—as we saw in Chapter 2—the group 1A metals tend to form  $1+$  cations. Similarly, alkaline earth metals, with an outer electron configuration of  $ns^2$ , also tend to be reactive metals, losing their  $ns^2$  electrons to form  $2+$  cations. This does not mean that forming an ion with a noble gas configuration is in itself energetically favorable. In fact, forming cations always *requires energy*. But when the cation formed has a noble gas configuration, the energy cost of forming the cation is often less than the energy payback that occurs when that cation forms ionic bonds with anions, as we shall see in Chapter 9.

On the right side of the periodic table, halogens are among the most reactive nonmetals because of their  $ns^2 np^5$  electron configurations. They are only one electron short of a noble gas configuration and tend to react to gain that one electron, forming  $1-$  ions. Figure 8.8▼, which is similar to Figure 2.14 in Chapter 2,

8A	1A

### Periodic Trends in the Size of Atomic Effective Nuclear Charge

▲ The van der Waals radius of an atom is one-half the distance between adjacent nuclei in the atomic solid.

▲ The covalent radius of bromine is one-half the distance between two bonded bromine atoms.

The bonding radii of some elements, such as helium and neon, must be approximated because they do not form chemical bonds or metallic crystals.

## 8.6 Periodic Trends in the Size of Atoms and Effective Nuclear Charge

In previous chapters, we saw that the volume of an atom is taken up primarily by its electrons (Chapter 2) occupying quantum-mechanical orbitals (Chapter 7). We also discussed how these orbitals do not have a definite boundary but represent only a statistical probability distribution for where the electron is found. So how do we define the size of an atom? One way to define atomic radii is to consider the distance between *non-bonding* atoms that are in direct contact. For example, krypton can be frozen into a solid in which the krypton atoms are touching each other but are not bonded together. The distance between the centers of adjacent krypton atoms—which we can determine from the solid's density—is then twice the radius of a krypton atom. An atomic radius determined in this way is called the **nonbonding atomic radius** or the **van der Waals radius**. The van der Waals radius represents the radius of an atom when it is not bonded to another atom.

Another way to define the size of an atom—the **bonding atomic radius** or **covalent radius**—is defined differently for nonmetals and metals, as follows:

Nonmetals: one-half the distance between two of the atoms bonded together

Metals: one-half the distance between two of the atoms next to each other in a crystal of the metal

For example, the distance between Br atoms in Br<sub>2</sub> is 228 pm; therefore, the Br covalent radius is one-half of 228 pm or 114 pm.

Using this method, we can assign radii to all elements in the periodic table that form chemical bonds or form metallic crystals. A more general term, the **atomic radius**, refers to a set of average bonding radii determined from measurements on a large number of elements and compounds. The atomic radius represents the radius of an atom when it is bonded to another atom and is always smaller than the van der Waals radius. The approximate bond length of any two covalently bonded atoms is the sum of their atomic radii. For example, the approximate bond length for ICl is iodine's atomic radius (133 pm) plus chlorine's atomic radius (99 pm), a bond length of 232 pm. (The actual experimentally measured bond length in ICl is 232.07 pm.)

Figure 8.9 plots atomic radius as a function of atomic number for the first 57 elements in the periodic table. Notice the periodic trend in the radii. Atomic radii peak with each alkali metal. Figure 8.10 is a relief map of atomic radii for most of the elements in the periodic table. The general trends in the atomic radii of main-group elements, which are the same as trends observed in van der Waals radii, are:

1. As we move down a column (or family) in the periodic table, atomic radius increases.
2. As we move to the right across a period (or row) in the periodic table, atomic radius decreases.

We can understand the observed trend in radii as we move down a column based on the trends in the sizes of atomic orbitals. Atomic radius is largely determined by the valence electrons, the electrons farthest from the nucleus. As we move down a column in the periodic table, the highest principal quantum number (*n*) of the valence electrons increases. Consequently, the valence electrons occupy larger orbitals, resulting in larger atoms.

The observed trend in atomic radii as we move to the right across a row, however, is a bit more complex. To understand this trend, we must revisit some concepts from Section 8.3, including effective nuclear charge and shielding.

**▲ FIGURE 8.9 Atomic Radius versus Atomic Number** Notice the periodic trend in atomic radius, starting at a peak with each alkali metal and falling to a minimum with each noble gas.

### Trends in Atomic Radius

**▲ FIGURE 8.10 Trends in Atomic Radius** In general, atomic radii increase as we move down a column and decrease as we move to the right across a period in the periodic table.

## Effective Nuclear Charge

The trend in atomic radius as we move to the right across a row in the periodic table is determined by the inward pull of the nucleus on the electrons in the outermost principal energy level (highest  $n$  value). According to Coulomb's law, the attraction between

a nucleus and an electron increases with increasing magnitude of nuclear charge. For example, compare the H atom to the  $\text{He}^+$  ion:

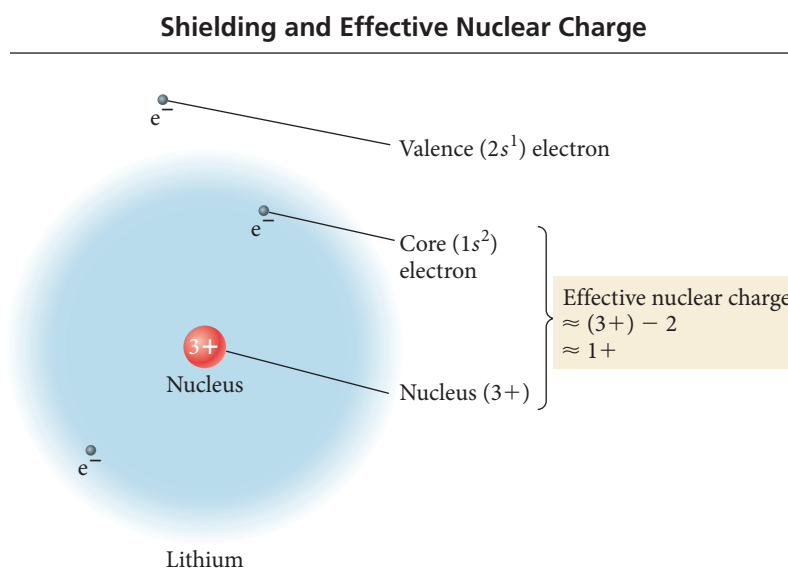

It takes 1312 kJ/mol of energy to remove the 1s electron from hydrogen but 5251 kJ/mol of energy to remove it from  $\text{He}^+$ . Why? Although each electron is in a 1s orbital, the electron in the helium ion is attracted to the nucleus by a 2+ charge, while the electron in the hydrogen atom is attracted to the nucleus by only a 1+ charge. Therefore, the electron in the helium ion is held more tightly (it has lower potential energy according to Coulomb's law), making it more difficult to remove and making the helium ion smaller than the hydrogen atom.

As we saw in Section 8.3, any one electron in a multielectron atom experiences both the positive charge of the nucleus (which is attractive) and the negative charges of the other electrons (which are repulsive). Consider again the outermost electron in the lithium atom:

Even though the 2s orbital penetrates into the 1s orbital to some degree, the majority of the 2s orbital is outside of the 1s orbital. Therefore the electron in the 2s orbital is partially *screened* or *shielded* from the 3+ charge of the nucleus by the 2− charge of the 1s (core) electrons. This reduces the net charge experienced by the 2s electron as shown in Figure 8.11 ▼.

**▲ FIGURE 8.11 Shielding and Effective Nuclear Charge** The valence electron in lithium experiences the 3+ charge of the nucleus through the screen of the 2− charge of the core electrons. The effective nuclear charge acting on the valence electron is approximately 1+.

As we have seen, we can define the average or net charge experienced by an electron as the *effective nuclear charge*. The effective nuclear charge experienced by a particular electron in an atom is the *actual nuclear charge* ( $Z$ ) minus the *charge shielded by other electrons* ( $S$ ):

$$Z_{\text{eff}} = Z - S$$

Effective nuclear charge      Actual nuclear charge      Charge screened by other electrons

For lithium, we estimate that the two core electrons shield the valence electron from the nuclear charge with high efficiency ( $S$  is nearly 2). The effective nuclear charge experienced by lithium's valence electron is therefore slightly greater than  $1+$ .

Now consider the valence electrons in beryllium (Be), with atomic number 4. Its electron configuration is:

To estimate the effective nuclear charge experienced by the  $2s$  electrons in beryllium, we must distinguish between two different types of shielding: (1) the shielding of the outermost electrons by the core electrons and (2) the shielding of the outermost electrons by *each other*. The key to understanding the trend in atomic radius is the difference between these two types of shielding:

**Core electrons efficiently shield electrons in the outermost principal energy level from nuclear charge, but outermost electrons do not efficiently shield one another from nuclear charge.**

For example, the two outermost electrons in beryllium experience the  $4+$  charge of the nucleus through the shield of the two  $1s$  core electrons without shielding each other from that charge very much. We estimate that the shielding ( $S$ ) experienced by any one of the outermost electrons due to the core electrons is nearly 2, but that the shielding due to the other outermost electron is nearly 0. The effective nuclear charge experienced by beryllium's outermost electrons is therefore slightly greater than  $2+$ .

The effective nuclear charge experienced by *beryllium's* outermost electrons is greater than that experienced by *lithium's* outermost electron. Consequently, beryllium's outermost electrons are held more tightly than lithium's, resulting in a smaller atomic radius for beryllium. The effective nuclear charge experienced by an atom's outermost electrons continues to become more positive as we move to the right across the rest of the second row in the periodic table, resulting in successively smaller atomic radii. The same trend is generally observed in all main-group elements.

#### Summarizing Atomic Radii for Main-Group Elements:

- ▶ As we move down a column in the periodic table, the principal quantum number ( $n$ ) of the electrons in the outermost principal energy level increases, resulting in larger orbitals and therefore larger atomic radii.
- ▶ As we move to the right across a row in the periodic table, the effective nuclear charge ( $Z_{\text{eff}}$ ) experienced by the electrons in the outermost principal energy level increases, resulting in a stronger attraction between the outermost electrons and the nucleus, and smaller atomic radii.

**Effective Nuclear Charge** Which electrons experience the greatest effective nuclear charge?

- (a) the valence electrons in Mg
- (b) the valence electrons in Al
- (c) the valence electrons in S

CONCEPTUAL  
CONNECTION 8.5

## Atomic Radii and the Transition Elements

In Figure 8.10, we can see that as we move down the first two rows of a column within the transition metals, the elements follow the same general trend in atomic radii as the main-group elements (the radii get larger). However, with the exception of the first couple of elements in each transition series, the atomic radii of the transition elements *do not* follow the same trend as the main-group elements as we move to the right across a row. Instead of decreasing in size, *the radii of transition elements stay roughly constant across each row*. Why? The difference is that, across a row of transition elements, the number of electrons in the outermost principal energy level (highest  $n$  value) is nearly constant

(recall from Section 8.3, for example, that the 4s orbital fills before the 3d). As another proton is added to the nucleus of each successive element, another electron is added as well, but the electron goes into an  $n_{\text{highest}} - 1$  orbital. The number of outermost electrons stays constant, and they experience a roughly constant effective nuclear charge, keeping the radius approximately constant.

### Example 8.5 Atomic Size

On the basis of periodic trends, choose the larger atom in each pair (if possible). Explain your choices.

- (a) C or F
- (b) C or Ge
- (c) N or Al
- (d) Al or Ge

#### SOLUTION

- (a) C atoms are larger than F atoms because as you trace the path between C and F on the periodic table, you move to the right within the same period. As you move to the right across a period, the effective nuclear charge experienced by the outermost electrons increases, resulting in a smaller radius.

- (b) Ge atoms are larger than C atoms because as you trace the path between C and Ge on the periodic table, you move down a column. Atomic size increases as you move down a column because the outermost electrons occupy orbitals with a higher principal quantum number that are therefore larger, resulting in a larger atom.

- (c) Al atoms are larger than N atoms because as you trace the path between N and Al on the periodic table, you move down a column (atomic size increases) and then to the left across a period (atomic size increases). These effects add together for an overall increase.

- (d) Based on periodic trends alone, you cannot tell which atom is larger because as you trace the path between Al and Ge you move to the right across a period (atomic size decreases) and then down a column (atomic size increases). These effects tend to counter each other, and it is not easy to tell which will predominate.

**FOR PRACTICE 8.5** On the basis of periodic trends, choose the larger atom in each pair (if possible):

- (a) Sn or I
- (b) Ge or Po
- (c) Cr or W
- (d) F or Se

**FOR MORE PRACTICE 8.5** Arrange the elements in order of decreasing radius: S, Ca, F, Rb, Si.

## 8.7 Ions: Electron Configurations, Magnetic Properties, Ionic Radii, and Ionization Energy

Recall that ions are atoms (or groups of atoms) that have lost or gained electrons. In this section, we examine periodic trends in ionic electron configurations, magnetic properties, ionic radii, and ionization energies.

### Electron Configurations and Magnetic Properties of Ions

We can deduce the electron configuration of a main-group monoatomic ion from the electron configuration of the neutral atom and the charge of the ion. For anions, we *add* the number of electrons indicated by the magnitude of the charge of the anion. For example, the electron configuration of fluorine (F) is  $1s^2 2s^2 2p^5$  and that of the fluoride ion ( $F^-$ ) is  $1s^2 2s^2 2p^6$ .

We determine the electron configuration of cations by *subtracting* the number of electrons indicated by the magnitude of the charge. For example, the electron configuration of lithium (Li) is  $1s^2 2s^1$  and that of the lithium ion ( $Li^+$ ) is  $1s^2 2s^0$  (or simply  $1s^2$ ). For main-group cations, we remove the required number of electrons in the reverse order of filling. However, for transition metal cations, the trend is different. When writing the electron configuration of a transition metal cation, we *remove the electrons in the highest  $n$ -value orbitals first, even if this does not correspond to the reverse order of filling*. For example, the electron configuration of vanadium is:

The  $V^{2+}$  ion, however, has the following electron configuration:

In other words, for transition metal cations, the order in which electrons are removed upon ionization is *not* the reverse of the filling order. During filling, the  $4s$  orbital normally fills before the  $3d$  orbital. When a fourth period transition metal ionizes, however, it loses its  $4s$  electrons before its  $3d$  electrons. Why this unexpected behavior? The full answer to this question is beyond our scope, but the following two factors contribute to this phenomenon:

- As discussed previously, the  $ns$  and  $(n - 1)d$  orbitals are extremely close in energy and, depending on the exact configuration, can vary in relative energy ordering.
- As the  $(n - 1)d$  orbitals begin to fill in the first transition series, the increasing nuclear charge stabilizes the  $(n - 1)d$  orbitals relative to the  $ns$  orbitals. This happens because the  $(n - 1)d$  orbitals are not the outermost (or highest  $n$ ) orbitals and are therefore not effectively shielded from the increasing nuclear charge by the  $ns$  orbitals.

The bottom-line experimental observation is that an  $ns^0(n - 1)d^x$  configuration is lower in energy than an  $ns^2(n - 1)d^{x-2}$  configuration for transition metal ions. Therefore, we remove the  $ns$  electrons before the  $(n - 1)d$  electrons when we write electron configurations for transition metal ions.

The magnetic properties of transition metal ions support these assignments. Recall from Section 8.3 that an unpaired electron generates a magnetic field due to its spin. Consequently, an atom or ion that contains unpaired electrons is attracted to an external magnetic field, and we say that the atom or ion is **paramagnetic**. For example, consider the electron configuration of silver:

Silver's unpaired  $5s$  electron causes silver to be paramagnetic. In fact, an early demonstration of electron spin—called the Stern–Gerlach experiment—involved the interaction of a beam of silver atoms with a magnetic field.

The order of removing electrons is not the reverse of the filling order because the energy levels in a cation shift relative to the neutral atom.

An atom or ion in which all electrons are paired is not attracted to an external magnetic field—it is instead slightly repelled—and we say that the atom or ion is **diamagnetic**. The zinc atom is diamagnetic:

The magnetic properties of the zinc ion provide confirmation that the 4s electrons are indeed lost before 3d electrons in the ionization of zinc. If zinc lost two 3d electrons upon ionization, then the  $\text{Zn}^{2+}$  would be paramagnetic (because the two electrons would come out of two different filled d orbitals, leaving each of them with one unpaired electron). That does not happen and the zinc ion, like the zinc atom, is diamagnetic because the 4s electrons are lost instead:

Observations in other transition metals confirm that the  $ns$  electrons are lost before the  $(n - 1)d$  electrons upon ionization.

### Example 8.6 Electron Configurations and Magnetic Properties for Ions

Write the electron configuration and orbital diagram for each ion and determine whether each is diamagnetic or paramagnetic.

- (a)  $\text{Al}^{3+}$       (b)  $\text{S}^{2-}$       (c)  $\text{Fe}^{3+}$

#### SOLUTION

- (a)  $\text{Al}^{3+}$

Begin by writing the electron configuration of the neutral atom. This ion has a 3+ charge, so you remove three electrons to write the electron configuration of the ion. Write the orbital diagram by drawing half-arrows to represent each electron in boxes representing the orbitals. Because there are no unpaired electrons,  $\text{Al}^{3+}$  is diamagnetic.

Diamagnetic

- (b)  $\text{S}^{2-}$

Begin by writing the electron configuration of the neutral atom. Because this ion has a 2− charge, add two electrons to write the electron configuration of the ion. Write the orbital diagram by drawing half-arrows to represent each electron in boxes representing the orbitals. Because there are no unpaired electrons,  $\text{S}^{2-}$  is diamagnetic.

Diamagnetic

- (c)  $\text{Fe}^{3+}$

Begin by writing the electron configuration of the neutral atom. Since this ion has a 3+ charge, remove three electrons to write the electron configuration of the ion. Because it is a transition metal, remove the electrons from the 4s orbital before removing electrons from the 3d orbitals. Write the orbital diagram by drawing half-arrows to represent each electron in boxes representing the orbitals. There are unpaired electrons, so  $\text{Fe}^{3+}$  is paramagnetic.

Paramagnetic

**FOR PRACTICE 8.6** Write the electron configuration and orbital diagram for each ion and predict whether each is paramagnetic or diamagnetic.

- (a)  $\text{Co}^{2+}$       (b)  $\text{N}^{3-}$       (c)  $\text{Ca}^{2+}$

## Ionic Radii

What happens to the radius of an atom when it becomes a cation? An anion? Consider, for example, the difference between the Na atom and the  $\text{Na}^+$  ion. Their electron configurations are:

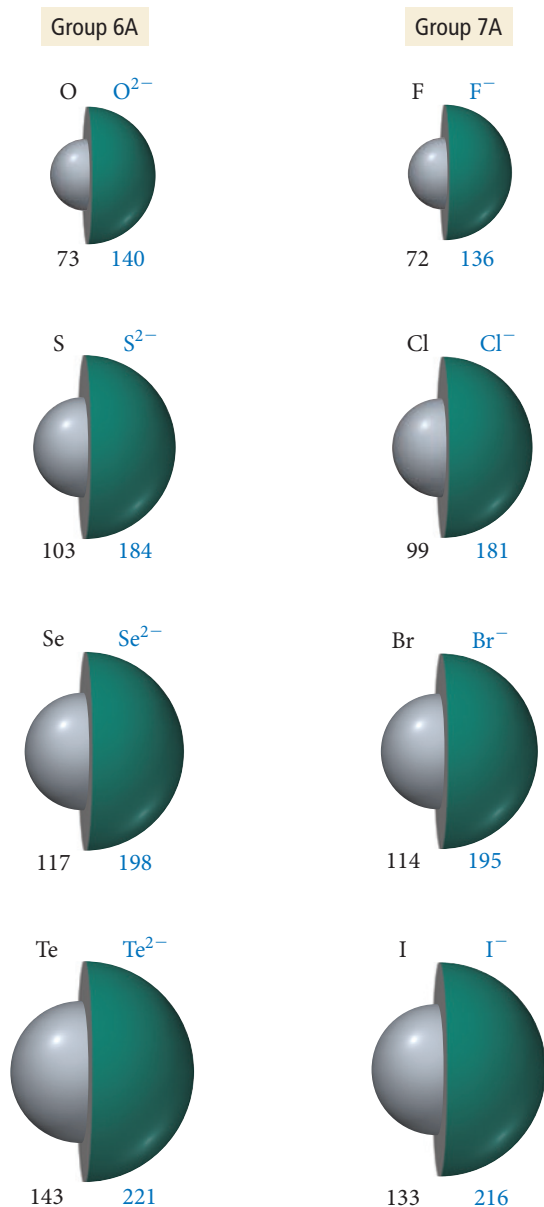

The sodium atom has an outer 3s electron and a neon core. Because the 3s electron is the outermost electron and it is shielded from the nuclear charge by the core electrons, it contributes greatly to the size of the sodium atom. The sodium cation, having lost the outermost 3s electron, has only the neon core and carries a charge of 1+. Without the 3s electron, the sodium cation (ionic radius = 95 pm) is much smaller than the sodium atom (covalent radius = 186 pm). The trend is the same with all cations and their atoms, as shown in Figure 8.12▼:

**Cations are much smaller than their corresponding atoms.**

Radii of Atoms and Their Cations (pm)	
Group 1A	Group 2A
Li $\text{Li}^+$  152    60	Be $\text{Be}^{2+}$  112    31
Na $\text{Na}^+$  186    95	Mg $\text{Mg}^{2+}$  160    65
K $\text{K}^+$  227    133	Ca $\text{Ca}^{2+}$  197    99
Rb $\text{Rb}^+$  248    148	Sr $\text{Sr}^{2+}$  215    113
	Group 3A
	B $\text{B}^{3+}$  85    23
	Al $\text{Al}^{3+}$  143    50
	Ga $\text{Ga}^{3+}$  135    62
	In $\text{In}^{3+}$  166    81

◀ **FIGURE 8.12** Sizes of Atoms and Their Cations Atomic and ionic radii (pm) for the first three columns of main-group elements.

## Radii of Atoms and Their Anions (pm)

What about anions? Consider the difference between Cl and  $\text{Cl}^-$ . Their electron configurations are:

The chlorine anion has one additional outermost electron but no additional proton to increase the nuclear charge. The extra electron increases the repulsions among the outermost electrons, resulting in a chloride anion that is larger than the chlorine atom. The trend is the same with all anions and their atoms, as shown in Figure 8.13 ◀.

**Anions are much larger than their corresponding atoms.**

We can observe an interesting trend in ionic size when we examine the radii of an *isoelectronic* series of ions—ions with the same number of electrons. Consider the following ions and their radii:

$\text{S}^{2-}$ (184 pm)	$\text{Cl}^-$ (181 pm)	$\text{K}^+$ (133 pm)	$\text{Ca}^{2+}$ (99 pm)
18 electrons	18 electrons	18 electrons	18 electrons
16 protons	17 protons	19 protons	20 protons

All of these ions have 18 electrons in exactly the same orbitals, but the radius of each ion gets successively smaller. Why? The reason is the progressively greater number of protons. The  $\text{S}^{2-}$  ion has 16 protons and therefore a charge of 16+ pulling on 18 electrons. The  $\text{Ca}^{2+}$  ion, in contrast, has 20 protons, and therefore a charge of 20+ pulling on the same 18 electrons. The result is a much smaller radius for the calcium ion. For a given number of electrons, a greater nuclear charge results in a smaller atom or ion.

◀ **FIGURE 8.13** Sizes of Atoms and Their Anions Atomic and ionic radii for groups 6A and 7A in the periodic table.

### Example 8.7 Ion Size

Choose the larger atom or ion from each pair.

- (a) S or  $\text{S}^{2-}$       (b) Ca or  $\text{Ca}^{2+}$       (c)  $\text{Br}^-$  or Kr

**SOLUTION**

- (a) The  $\text{S}^{2-}$  ion is larger than an S atom because anions are larger than the atoms from which they are formed.  
 (b) A Ca atom is larger than  $\text{Ca}^{2+}$  because cations are smaller than the atoms from which they are formed.  
 (c) A  $\text{Br}^-$  ion is larger than a Kr atom because, although they are isoelectronic,  $\text{Br}^-$  has one fewer proton than Kr, resulting in less pull on the electrons and therefore a larger radius.

**FOR PRACTICE 8.7** Choose the larger atom or ion from each pair.

- (a) K or  $\text{K}^+$       (b) F or  $\text{F}^-$       (c)  $\text{Ca}^{2+}$  or  $\text{Cl}^-$

## CONCEPTUAL CONNECTION 8.6

**Ions, Isotopes, and Atomic Size** In the previous sections, we have seen how the number of electrons and the number of protons affect the size of an atom or ion. However, we have not considered how the number of neutrons affects the size of an atom. Why not? Would you expect isotopes—for example, C-12 and C-13—to have different atomic radii?

## Ionization Energy

The **ionization energy (IE)** of an atom or ion is the energy required to remove an electron from the atom or ion in the gaseous state. Ionization energy is always positive because removing an electron always takes energy. (The process is similar to an endothermic reaction, which absorbs heat and therefore has a positive  $\Delta H$ .) The energy required to remove the first electron is the *first ionization energy* ( $IE_1$ ). For example, we represent the first ionization of sodium with the equation:

The energy required to remove the second electron is the *second ionization energy* ( $IE_2$ ), the energy required to remove the third electron is the *third ionization energy* ( $IE_3$ ), and so on. We represent the second ionization energy of sodium as:

Notice that the second ionization energy is not the energy required to remove *two* electrons from sodium (that quantity is the sum of  $IE_1$  and  $IE_2$ ), but rather the energy required to remove one electron from  $\text{Na}^+$ . We look at trends in  $IE_1$  and  $IE_2$  separately.

## Trends in First Ionization Energy

The first ionization energies of the elements through Xe are shown in Figure 8.14. Notice the periodic trend in ionization energy, peaking at each noble gas and bottoming at each alkali metal. Based on what we have learned about electron configurations and effective nuclear charge, how can we account for the observed trend? As we have seen,

**FIGURE 8.14** First Ionization Energy versus Atomic Number for the Elements through Xenon First ionization energy starts at a minimum with each alkali metal and rises to a peak with each noble gas.

the principal quantum number,  $n$ , increases as we move down a column. Within a given sublevel, orbitals with higher principal quantum numbers are larger than orbitals with smaller principal quantum numbers. Consequently, electrons in the outermost principal level are farther away from the positively charged nucleus—and are therefore held less tightly—as we move down a column. This results in a lower ionization energy as we move down a column, as shown in Figure 8.15 ▼.

▲ **FIGURE 8.15 Trends in Ionization Energy** First ionization energy increases as we move to the right across a period and decreases as we move down a column in the periodic table.

What about the trend as we move to the right across a row? For example, would it take more energy to remove an electron from Na or from Cl, two elements on either end of the third row in the periodic table? We know that Na has an outer electron configuration of  $3s^1$  and Cl has an outer electron configuration of  $3s^23p^5$ . As discussed previously, the outermost electrons in chlorine experience a higher effective nuclear charge than the outermost electrons in sodium (which is why chlorine has a smaller atomic radius than sodium). Consequently, we would expect chlorine to have a higher ionization energy than sodium, which is indeed the case. We can make a similar argument for the other main-group elements: first ionization energy generally increases as we move to the right across a row in the periodic table, as shown in Figure 8.15.

#### Summarizing First Ionization Energy for Main-Group Elements:

- ▶ First ionization energy generally *decreases* as we move down a column (or family) in the periodic table because electrons in the outermost principal level are increasingly farther away from the positively charged nucleus and are therefore held less tightly.
- ▶ First ionization energy generally *increases* as we move to the right across a row (or period) in the periodic table because electrons in the outermost principal energy level generally experience a greater effective nuclear charge ( $Z_{\text{eff}}$ ).

**Example 8.8** First Ionization Energy

On the basis of periodic trends, determine which element in each pair has the higher first ionization energy (if possible).

- (a) Al or S      (b) As or Sb      (c) N or Si      (d) O or Cl

**SOLUTION**

- (a) Al or S

S has a higher ionization energy than Al because as you trace the path between Al and S on the periodic table, you move to the right within the same row. Ionization energy increases as you go to the right due to increasing effective nuclear charge.

- (b) As or Sb

As has a higher ionization energy than Sb because as you trace the path between As and Sb on the periodic table, you move down a column. Ionization energy decreases as you go down a column as a result of the increasing size of orbitals with increasing  $n$ .

- (c) N or Si

N has a higher ionization energy than Si because as you trace the path between N and Si on the periodic table, you move down a column (ionization energy decreases) and then to the left across a row (ionization energy decreases). These effects sum together for an overall decrease.

- (d) O or Cl

Based on periodic trends alone, it is impossible to tell which has a higher ionization energy because, as you trace the path between O and Cl, you go to the right across a row (ionization energy increases) and then down a column (ionization energy decreases). These effects tend to counter each other, and it is not obvious which will dominate.

**FOR PRACTICE 8.8** On the basis of periodic trends, determine the element in each pair with the higher first ionization energy (if possible).

- (a) Sn or I      (b) Ca or Sr      (c) C or P      (d) F or S

**FOR MORE PRACTICE 8.8** Arrange the following elements in order of decreasing first ionization energy: S, Ca, F, Rb, Si.

**Exceptions to Trends in First Ionization Energy**

If we carefully examine Figure 8.15, we can see some exceptions to the trends in first ionization energies. For example, boron has a smaller ionization energy than beryllium, even though it lies to the right of beryllium in the same row. This exception is caused by the difference between the  $s$  block and the  $p$  block. Recall from Section 8.3 that the  $2p$  orbital penetrates into the nuclear region *less than* the  $2s$  orbital. Consequently, the  $1s$  electrons shield the electron in the  $2p$  orbital from nuclear charge more than they shield the electrons in the  $2s$  orbital. The result, as we saw in Section 8.3, is that the  $2p$  orbitals are higher in energy, and therefore the electron is easier to remove (it has a lower first ionization energy). Similar exceptions occur for aluminum and gallium, both directly below boron in group 3A.

Another exception occurs between nitrogen and oxygen. Although oxygen is to the right of nitrogen in the same row, it has a lower first ionization energy. This exception is caused by the repulsion between electrons when they occupy the same orbital. Examine the electron configurations and orbital diagrams of nitrogen and oxygen shown here:

Nitrogen has three electrons in three  $p$  orbitals, whereas oxygen has four. In nitrogen, the  $2p$  orbitals are half-filled (which makes the configuration particularly stable). One of oxygen's four  $2p$  electrons must pair with another electron, making it easier to remove (and less stable). Exceptions for similar reasons occur for S and Se, directly below oxygen in group 6A.

## Trends in Second and Successive Ionization Energies

Notice the trends in the first, second, and third ionization energies of sodium (group 1A) and magnesium (group 2A), as shown at left.

For sodium, there is a huge jump between the first and second ionization energies. For magnesium, the ionization energy roughly doubles from the first to the second, but then a huge jump occurs between the second and third ionization energies. What is the reason for these jumps?

We can understand these trends by examining the electron configurations of sodium and magnesium:

The first ionization of sodium involves removing the valence electron in the  $3s$  orbital. Recall that these valence electrons are held more loosely than the core electrons and that the resulting ion has a noble gas configuration, which is particularly stable. Consequently, the first ionization energy is fairly low. The second ionization of sodium, however, involves removing a core electron from an ion with a noble gas configuration. This requires a tremendous amount of energy, making the value of  $\text{IE}_2$  very high.

As with sodium, the first ionization of magnesium involves removing a valence electron in the  $3s$  orbital. This requires a bit more energy than the corresponding ionization of sodium because of the trends in  $Z_{\text{eff}}$  that we discussed earlier ( $Z_{\text{eff}}$  increases as we move to the right across a row). The second ionization of magnesium also involves removing an outer electron in the  $3s$  orbital, but this time from an ion with a  $1+$  charge (instead of from a neutral atom). This requires roughly twice the energy as removing the electron from the neutral atom. The third ionization of magnesium is analogous to the second ionization of sodium—it requires removing a core electron from an ion with a noble gas configuration. This requires a tremendous amount of energy, making the value of  $\text{IE}_3$  very high.

As shown in Table 8.1, similar trends exist for the successive ionization energies of many elements. The ionization energy increases fairly uniformly with each successive removal of an outermost electron, but then takes a large jump with the removal of the first core electron.

**TABLE 8.1** Successive Ionization Energies for the Elements Sodium through Argon (kJ/mol)

Element	IE <sub>1</sub>	IE <sub>2</sub>	IE <sub>3</sub>	IE <sub>4</sub>	IE <sub>5</sub>	IE <sub>6</sub>	IE <sub>7</sub>		
Na	496	4560	Core electrons						
Mg	738	1450						7730	
Al	578	1820						2750	11,600
Si	786	1580						3230	4360
P	1012	1900	2910	4960	6270	22,200	27,100		
S	1000	2250	3360	4560	7010	8500			
Cl	1251	2300	3820	5160	6540	9460	11,000		
Ar	1521	2670	3930	5770	7240	8780	12,000		

**Ionization Energies and Chemical Bonding** Based on what you just learned about ionization energies, explain why valence electrons are more important than core electrons in determining the reactivity and bonding in atoms.

### CONCEPTUAL CONNECTION 8.7

## 8.8 Electron Affinities and Metallic Character

Electron affinity and metallic character also exhibit periodic trends. Electron affinity is a measure of how easily an atom will accept an additional electron; it is crucial to chemical bonding because bonding involves the transfer or sharing of electrons. Metallic character is important because of the high proportion of metals in the periodic table and the large role they play in our lives. Of the roughly 110 elements, 87 are metals. We examine each of these periodic properties individually in this section.

### Electron Affinity

The **electron affinity (EA)** of an atom (or ion) is the energy change associated with the gaining of an electron by the atom in the gaseous state. Electron affinity is usually—though not always—negative because an atom or ion usually releases energy when it gains an electron. (The process is analogous to an exothermic reaction, which releases heat and therefore has a negative  $\Delta H$ .) In other words, the coulombic attraction between the nucleus of an atom and the incoming electron usually results in the release of energy as the electron is gained. For example, we represent the electron affinity of chlorine with the equation:

Figure 8.16 displays the electron affinities for a number of main-group elements. As you can see from this figure, the trends in electron affinity are not as regular as trends in other properties we examined in Sections 8.6 and 8.7. For instance, we might expect electron affinities to become relatively more positive (so that the addition of an electron is less exothermic) as we move down a column because the electron is located in orbitals with successively higher principal quantum numbers and therefore is farther from the

**Electron Affinities (kJ/mol)**

1A	2A	3A	4A	5A	6A	7A	8A
H -73							He >0
Li -60	Be >0	B -27	C -122	N >0	O -141	F -328	Ne >0

**▲ FIGURE 8.16** Electron Affinities of Selected Main-Group Elements.

nucleus. This trend applies to the group 1A metals but does not hold for the other columns in the periodic table.

A more regular trend in electron affinity occurs as we move to the right across a row, however. Based on the periodic properties we have learned so far, would you expect more energy to be released by Na or Cl when an electron is gained? We know that Na has an outer electron configuration of  $3s^1$  and Cl has an outer electron configuration of  $3s^23p^5$ . Since adding an electron to chlorine gives it a noble gas configuration and adding an electron to sodium does not, and since the outermost electrons in chlorine experience a higher  $Z_{\text{eff}}$  than the outermost electrons in sodium, we would expect chlorine to have a more negative electron affinity—the process should be more exothermic for chlorine. This is in fact the case. For main-group elements, electron affinity generally becomes more negative (more exothermic) as we move to the right across a row in the periodic table. The halogens (group 7A) therefore have the most negative electron affinities. But exceptions do occur. For example, notice that nitrogen and the other group 5A elements do not follow the general trend. These elements have  $ns^2np^3$  outer electron configurations. When an electron is added to this configuration, it must pair with another electron in an already occupied  $p$  orbital. The repulsion between two electrons occupying the same orbital causes the electron affinity to be more positive than for elements in the previous column.

**Summarizing Electron Affinity for Main-Group Elements:**

- ▶ Most groups (columns) of the periodic table do not exhibit any definite trend in electron affinity. Among the group 1A metals, however, electron affinity becomes more positive as we move down a column (adding an electron becomes less exothermic).
- ▶ Electron affinity generally becomes more negative (adding an electron becomes more exothermic) as we move to the right across a period (row) in the periodic table.

## Metallic Character

As we discussed in Chapter 2, metals are good conductors of heat and electricity: they can be pounded into flat sheets (malleability), they can be drawn into wires (ductility), they are often shiny, and they tend to lose electrons in chemical reactions. Nonmetals, in contrast, have more varied physical properties; some are solids at room temperature, others are gases. However, in general, nonmetals are typically poor conductors of heat and electricity, and they all tend to gain electrons in chemical reactions.

As we move to the right across a row in the periodic table, ionization energy increases and electron affinity becomes more negative; therefore, elements on the left side of the periodic table are more likely to lose electrons than elements on the right side (which are more likely to gain them). The other properties associated with metals follow the same general trend (even though we do not quantify them here). Consequently, as shown in Figure 8.17▶:

**As we move to the right across a row (or period) in the periodic table, metallic character decreases.**

As we move down a column in the periodic table, ionization energy decreases, making electrons more likely to be lost in chemical reactions. Therefore,

**As we move down a column (or family) in the periodic table, metallic character increases.**

These trends, based on the quantum-mechanical model, explain the distribution of metals and nonmetals in the periodic table discussed in Chapter 2. Metals are found on the left side and toward the center and nonmetals on the upper right side. The change in chemical behavior from metallic to nonmetallic can be seen most clearly as we proceed to the right across period 3, or down along group 5A as we can see in Figure 8.18▶.

**▲ FIGURE 8.17 Trends in Metallic Character I** Metallic character decreases as we move to the right across a period and increases as we move down a column in the periodic table.

## Trends in Metallic Character

**▲ FIGURE 8.18 Trends in Metallic Character II** As we move down group 5A in the periodic table, metallic character increases. As we move across period 3, metallic character decreases.

**Example 8.9** Metallic Character

On the basis of periodic trends, choose the more metallic element from each pair (if possible).

- (a) Sn or Te
- (b) P or Sb
- (c) Ge or In
- (d) S or Br

**SOLUTION**

- (a) Sn or Te

Sn is more metallic than Te because as you trace the path between Sn and Te on the periodic table, you move to the right within the same period. Metallic character decreases as we move to the right.

- (b) P or Sb

Sb is more metallic than P because as you trace the path between P and Sb on the periodic table, you move down a column. Metallic character increases as we move down a column.

- (c) Ge or In

In is more metallic than Ge because as you trace the path between Ge and In on the periodic table, you move down a column (metallic character increases) and then to the left across a period (metallic character increases). These effects add together for an overall increase.

- (d) S or Br

Based on periodic trends alone, we cannot tell which is more metallic because as you trace the path between S and Br, you move to the right across a period (metallic character decreases) and then down a column (metallic character increases). These effects tend to counter each other, and it is not easy to tell which will predominate.

**FOR PRACTICE 8.9** On the basis of periodic trends, choose the more metallic element from each pair (if possible).

- (a) Ge or Sn
- (b) Ga or Sn
- (c) P or Bi
- (d) B or N

**FOR MORE PRACTICE 8.9** Arrange the following elements in order of increasing metallic character: Si, Cl, Na, Rb.

## 8.9 Some Examples of Periodic Chemical Behavior: The Alkali Metals, the Halogens, and the Noble Gases

In this section, we explore some of the properties and chemical reactions of three families in the periodic table: the alkali metals, the halogens, and the noble gases. These families exemplify the connection between chemical behavior and electron configuration.

The alkali metals (group 1A) have  $ns^1$  outer electron configurations. The single valence electron that keeps these metals from having noble gas configurations is easily removed (the metals have low ionization energies), making these elements the most active metals in the periodic table. The halogens (group 7A) have  $ns^2np^5$  outer electron configurations. The one electron needed to attain noble gas configurations is easily acquired (the halogens have highly negative electron affinities), making these elements among the most active nonmetals in the periodic table. The noble gases (group 8A) have electron configurations with full outer  $s$  and  $p$  sublevels ( $ns^2np^6$ ) and so are the most chemically inert family in the periodic table.

In this section of the chapter, we examine the properties of each of these groups separately. (Even though hydrogen is often listed in group 1A, it behaves like a nonmetal because of its high ionization energy: 1312 kJ/mol. We therefore do not include hydrogen in our discussion of the group 1A metals.)

### The Alkali Metals (Group 1A)

Table 8.2 lists some selected properties of the alkali metals. Notice that, in general, the properties of the alkali metals vary fairly regularly as we proceed down the column. As expected from periodic trends, the atomic radius increases steadily while the first ionization energy decreases steadily.

With the exception of potassium, density increases as we move down the column. This is a general trend that occurs in other columns within the periodic table. As we move down a column, the increase in mass (due to the additional protons and neutrons) outpaces the increase in volume caused by greater atomic radii. The result is successively greater densities. The melting points of the alkali metals as a group are anomalously low for metals, and they steadily decrease as we move down the column. (This is not a general trend for the rest of the periodic table, which shows more irregular patterns in melting points.)

Because of their generally low first ionization energies, the alkali metals are excellent reducing agents—they are readily oxidized, losing electrons to other substances. Consequently, the alkali metals exist naturally in their oxidized state, either in compounds or as dissolved ions in seawater. Since first ionization energy *decreases* as we go down the column, the relative reactivities of the alkali metals tend to *increase* as we move down the column. In other words, the lower the first ionization energy of an alkali metal, the greater tendency it will have to lose its electron and the more reactive it is.

**TABLE 8.2** Properties of the Alkali Metals\*

Element	Electron Configuration	Atomic Radius (pm)	IE <sub>1</sub> (kJ/mol)	Density at 25 °C (g/cm <sup>3</sup> )	Melting Point (°C)
Li	[He] 2s <sup>1</sup>	152	520	0.535	181
Na	[Ne] 3s <sup>1</sup>	186	496	0.968	102
K	[Ar] 4s <sup>1</sup>	227	419	0.856	98
Rb	[Kr] 5s <sup>1</sup>	248	403	1.532	39
Cs	[Xe] 6s <sup>1</sup>	265	376	1.879	29

\*Francium is omitted because it has no stable isotopes.

▲ **FIGURE 8.19** Reaction of Sodium and Chlorine to Form Sodium Chloride.

► **FIGURE 8.20** Reactions of the Alkali Metals with Water The reactions become progressively more vigorous as we move down the group. (The rate of the alkali metal reaction with water, and therefore its vigor, are enhanced by the successively lower melting points of the alkali metals as we move down the column. The low melting points of the heavier metals allow the emitted heat to actually melt the metal, increasing the reaction rate.)

The reactions of the alkali metals with nonmetals are vigorous. For example, the alkali metals (M) react with halogens (X) according to the reaction:

The reaction of sodium and chlorine to form sodium chloride is typical:

This reaction emits heat and sparks as it occurs (Figure 8.19◀). Each successive alkali metal reacts even more vigorously with chlorine.

The alkali metals also react with water to form the dissolved alkali metal ion, the hydroxide ion, and hydrogen gas:

The reaction is highly exothermic and can be explosive because the heat from the reaction can ignite the hydrogen gas. The reaction becomes more explosive as we move down the column from one metal to the next, as shown in Figure 8.20▼.

Reactions of the Alkali Metals with Water

Lithium

Sodium

Potassium

The Halogens (Group 7A)

Table 8.3 lists selected properties of the first four halogens. Notice that the properties of the halogens, like those of the alkali metals, vary fairly regularly as we proceed down the column. As expected from periodic trends, the atomic radius and the density increase for each successive halogen. We can see from the melting and boiling points that fluorine and chlorine are both gases at room temperature, bromine is a liquid, and iodine is a solid.

All of the halogens are powerful oxidizing agents—they are readily reduced, gaining electrons from other substances in their reactions. Fluorine is the most powerful oxidizing agent of the group—reacting with almost everything, including the heavier noble gases—and iodine is the least. The halogens all react with metals to form *metal halides* according to the equation:

TABLE 8.3 Properties of the Halogens*						
Element	Electron Configuration	Atomic Radius (pm)	EA (kJ/mol)	Melting Point (°C)	Boiling Point (°C)	Density of Liquid (g/cm <sup>3</sup> )
F	[He] 2s <sup>2</sup> 2p <sup>5</sup>	72	−328	−219	−188	1.51
Cl	[Ne] 3s <sup>2</sup> 3p <sup>5</sup>	99	−349	−101	−34	2.03
Br	[Ar] 4s <sup>2</sup> 4p <sup>5</sup>	114	−325	−7	59	3.19
I	[Kr] 5s <sup>2</sup> 5p <sup>5</sup>	133	−295	114	184	3.96

\*At is omitted because it is rare and radioactive.

where M is the metal, X is the halogen, and  $\text{MX}_n$  is the metal halide. For example, chlorine reacts with iron according to the equation:

Since metals tend to lose electrons and the halogens tend to gain them, the metal halides—like all compounds that form between metals and nonmetals—contain ionic bonds.

The halogens also react with hydrogen to form *hydrogen halides* according to the equation:

The hydrogen halides—like all compounds that form between two nonmetals—contain covalent bonds. All of the hydrogen halides form acidic solutions when combined with water.

The halogens also react with each other to form *interhalogen compounds*. For example, bromine reacts with fluorine according to the equation:

Again, like all compounds that form between two nonmetals, the interhalogen compounds contain covalent bonds.

### Example 8.10 Alkali Metal and Halogen Reactions

Write a balanced chemical equation for each reaction.

- (a) the reaction between potassium metal and bromine gas
- (b) the reaction between rubidium metal and liquid water
- (c) the reaction between gaseous chlorine and solid iodine

#### SOLUTION

(a) Alkali metals react with halogens to form metal halides. Write the formulas for the reactants and the metal halide product (making sure to write the correct ionic chemical formula for the metal halide, as outlined in Section 3.5), and then balance the equation.	$2 \text{K}(s) + \text{Br}_2(g) \longrightarrow 2 \text{KBr}(s)$
(b) Alkali metals react with water to form the dissolved metal ion, the hydroxide ion, and hydrogen gas. Write the skeletal equation including each of these and then balance it.	$2 \text{Rb}(s) + 2 \text{H}_2\text{O}(l) \longrightarrow 2 \text{Rb}^+(aq) + 2 \text{OH}^-(aq) + \text{H}_2(g)$
(c) Halogens react with each other to form interhalogen compounds. Write the skeletal equation with each of the halogens as the reactants and the interhalogen compound as the product and balance the equation.	$\text{Cl}_2(g) + \text{I}_2(s) \longrightarrow 2 \text{ICl}(g)$

**FOR PRACTICE 8.10** Write a balanced chemical equation for each reaction.

- (a) the reaction between aluminum metal and chlorine gas
- (b) the reaction between lithium metal and liquid water
- (c) the reaction between gaseous hydrogen and liquid bromine

## The Noble Gases (Group 8A)

Table 8.4 lists selected properties of the noble gases. Notice that the properties of the noble gases, like those of the alkali metals and halogens, vary fairly regularly as we proceed down the column. As expected from periodic trends, the atomic radius and the density increase

**TABLE 8.4** Properties of the Noble Gases \*

Element	Electron Configuration	Atomic Radius (pm)**	IE <sub>1</sub> (kJ/mol)	Boiling Point (K)	Density of Gas (g/L at STP)
He	1s <sup>2</sup>	32	2372	4.2	0.18
Ne	[He] 2s <sup>2</sup> 2p <sup>6</sup>	70	2081	27.1	0.90
Ar	[Ne] 3s <sup>2</sup> 3p <sup>6</sup>	98	1521	87.3	1.78
Kr	[Ar] 4s <sup>2</sup> 4p <sup>6</sup>	112	1351	119.9	3.74
Xe	[Kr] 5s <sup>2</sup> 5p <sup>6</sup>	130	1170	165.1	5.86

\*Radon is omitted because it is radioactive.

\*\*Since only the heavier noble gases form compounds, covalent radii for the smaller noble gases are estimated.

▲ Liquid helium, a cryogenic liquid, cools substances to temperatures as low as 1.2 K.

for each successive noble gas, and the first ionization energy decreases. As their boiling points indicate, all of the noble gases are gases at room temperature and must be cooled to extremely low temperatures before they liquefy. For this reason, some noble gases can be cryogenic liquids—liquids used to cool other substances to low temperatures. For example, researchers often submerge samples of interest in boiling liquid helium to cool them down to 4.2 K (or lower) and study their properties at this extremely low temperature.

The high first ionization energies of the noble gases and their completely full *s* and *p* sublevels make them exceptionally unreactive. In fact, before the 1960s, no noble gas compounds were known. Since then, two of the noble gases have been shown to react with fluorine (the most reactive nonmetal on the periodic table) under fairly extreme conditions. For instance, krypton reacts with fluorine to form KrF<sub>2</sub>:

Similarly, Xe reacts with fluorine to form three different xenon fluorides:

The inertness of the noble gases has led to their use in situations where reactions are undesirable. For example, argon is used in lightbulbs to prevent the hot tungsten filament from oxidizing, and helium is part of the mixture breathed by deep-sea divers to prevent the toxicity caused by too much oxygen and nitrogen under high pressures. (The helium replaces some of the oxygen and nitrogen in the tank, lowering the concentrations of oxygen and nitrogen in the blood.)

Xenon can also be forced to react with oxygen to form XeO<sub>3</sub> and XeO<sub>4</sub>.

## Self-Assessment Quiz

- Q1.** According to Coulomb's law, if the separation between two particles of the same charge is doubled, what happens to the potential energy of the two particles?
- It is twice as high as it was before the distance separation.
  - It is one-half as high as it was before the separation.
  - It does not change.
  - It is one-fourth as high as it was before the separation.
- Q2.** Which electron in sulfur is most shielded from nuclear charge?
- an electron in the 1*s* orbital
  - an electron in a 2*p* orbital
  - an electron in a 3*p* orbital
  - none of the above (All of these electrons are equally shielded from nuclear charge.)

- Q3.** Choose the correct electron configuration for Se.

- 1s<sup>2</sup>2s<sup>2</sup>2p<sup>6</sup>3s<sup>2</sup>3p<sup>4</sup>
- 1s<sup>2</sup>2s<sup>2</sup>2p<sup>6</sup>3s<sup>2</sup>3p<sup>6</sup>4s<sup>2</sup>3d<sup>10</sup>4p<sup>4</sup>
- 1s<sup>2</sup>2s<sup>2</sup>2p<sup>6</sup>3s<sup>2</sup>3p<sup>6</sup>4s<sup>2</sup>4p<sup>4</sup>
- 1s<sup>2</sup>2s<sup>2</sup>2p<sup>6</sup>3s<sup>2</sup>3p<sup>6</sup>4s<sup>2</sup>3d<sup>4</sup>

- Q4.** Choose the correct orbital diagram for vanadium.

- [Ar] 

4s
3d
- [Ar] 

4s
3d
- [Ar] 

4s
3d
- [Ar]

- Q5.** Which set of four quantum numbers corresponds to an electron in a  $4p$  orbital?
- $n = 4, l = 1, m_l = 0, m_s = \frac{1}{2}$
  - $n = 4, l = 3, m_l = 3, m_s = -\frac{1}{2}$
  - $n = 4, l = 2, m_l = 0, m_s = \frac{1}{2}$
  - $n = 4, l = 4, m_l = 3, m_s = -\frac{1}{2}$
- Q6.** Which element has the smallest atomic radius?
- C
  - Si
  - Be
  - F
- Q7.** Which statement is true about electron shielding of nuclear charge?
- Outermost electrons efficiently shield one another from nuclear charge.
  - Core electrons efficiently shield one another from nuclear charge.
  - Outermost electrons efficiently shield core electrons from nuclear charge.
  - Core electrons efficiently shield outermost electrons from nuclear charge.
- Q8.** Which statement is true about effective nuclear charge?
- Effective nuclear charge *decreases* as you move to the right across a row in the periodic table.
  - Effective nuclear charge *increases* as you move to the right across a row in the periodic table.
  - Effective nuclear charge *remains constant* as you move to the right across a row in the periodic table.
  - Effective nuclear charge *increases and decreases* at regular intervals as you move to the right across a row in the periodic table.
- Q9.** Which is the correct electron configuration for  $\text{Fe}^{2+}$ ?
- $[\text{Ar}]4s^23d^6$
  - $[\text{Ar}]4s^23d^4$
  - $[\text{Ar}]4s^03d^6$
  - $[\text{Ar}]4s^23d^8$
- Q10.** Which species is diamagnetic?
- $\text{Cr}^{2+}$
  - Zn
  - Mn
  - C
- Q11.** Arrange these atoms and ions in order of increasing radius:  $\text{Cs}^+, \text{Ba}^{2+}, \text{I}^-$ .
- $\text{I}^- < \text{Ba}^{2+} < \text{Cs}^+$
  - $\text{Cs}^+ < \text{Ba}^{2+} < \text{I}^-$
  - $\text{Ba}^{2+} < \text{Cs}^+ < \text{I}^-$
  - $\text{I}^- < \text{Cs}^+ < \text{Ba}^{2+}$
- Q12.** Arrange these elements in order of increasing first ionization energy: Cl, Sn, Si.
- $\text{Cl} < \text{Si} < \text{Sn}$
  - $\text{Sn} < \text{Si} < \text{Cl}$
  - $\text{Si} < \text{Cl} < \text{Sn}$
  - $\text{Sn} < \text{Cl} < \text{Si}$
- Q13.** The ionization energies of an unknown third period element are listed here. Identify the element.  
 $\text{IE}_1 = 786 \text{ kJ/mol}$ ;  $\text{IE}_2 = 1580 \text{ kJ/mol}$ ;  $\text{IE}_3 = 3230 \text{ kJ/mol}$ ;  
 $\text{IE}_4 = 4360 \text{ kJ/mol}$ ;  $\text{IE}_5 = 16,100 \text{ kJ/mol}$
- Mg
  - Al
  - Si
  - P
- Q14.** Which statement is true about trends in metallic character?
- Metallic character *increases* as you move to the right across a row in the periodic table and *increases* as you move down a column.
  - Metallic character *decreases* as you move to the right across a row in the periodic table and *increases* as you move down a column.
  - Metallic character *decreases* as you move to the right across a row in the periodic table and *decreases* as you move down a column.
  - Metallic character *increases* as you move to the right across a row in the periodic table and *decreases* as you move down a column.
- Q15.** For which element is the gaining of an electron most exothermic?
- Li
  - N
  - F
  - B

Answers: 1. (b) 2. (c) 3. (b) 4. (d) 5. (a) 6. (d) 7. (d) 8. (b) 9. (c) 10. (b) 11. (b) 12. (c) 13. (c) 14. (b) 15. (c)

## Chapter 8 IN REVIEW

### Key Terms

#### Section 8.1

periodic property (338)

#### Section 8.3

electron configuration (339)  
 ground state (339)  
 orbital diagram (340)  
 Pauli exclusion principle (340)  
 degenerate (341)  
 Coulomb's law (341)  
 shielding (342)  
 effective nuclear charge ( $Z_{\text{eff}}$ ) (342)  
 penetration (342)

aufbau principle (344)

Hund's rule (344)

#### Section 8.4

valence electrons (347)  
 core electrons (347)

#### Section 8.6

van der Waals radius (nonbonding  
 atomic radius) (352)  
 covalent radius (bonding atomic  
 radius) (352)  
 atomic radius (352)

#### Section 8.7

paramagnetic (357)  
 diamagnetic (358)  
 ionization energy (IE) (361)

#### Section 8.8

electron affinity (EA) (365)

## Key Concepts

### Periodic Properties and the Development of the Periodic Table (8.1, 8.2)

- ▶ In the nineteenth century, Dmitri Mendeleev arranged the elements in an early version of the periodic table so that atomic mass increased from left to right in a row and elements with similar properties fell in the same columns.
- ▶ Periodic properties are predictable based on an element's position within the periodic table. Periodic properties include atomic radius, ionization energy, electron affinity, density, and metallic character.
- ▶ Quantum mechanics explains the periodic table by describing how electrons fill the quantum-mechanical orbitals within the atoms that compose the elements.

### Electron Configurations (8.3)

- ▶ An electron configuration for an atom shows which quantum-mechanical orbitals the atom's electrons occupy. For example, the electron configuration of helium ( $1s^2$ ) indicates that helium's two electrons occupy the  $1s$  orbital.
- ▶ The order of filling quantum-mechanical orbitals in multielectron atoms is  $1s\ 2s\ 2p\ 3s\ 3p\ 4s\ 3d\ 4p\ 5s\ 4d\ 5p\ 6s$ .
- ▶ According to the Pauli exclusion principle, each orbital can hold a maximum of two electrons and those electrons have opposing spins.
- ▶ According to Hund's rule, orbitals of the same energy first fill singly with electrons having parallel spins before pairing.

### Electron Configurations and the Periodic Table (8.4, 8.5)

- ▶ Because quantum-mechanical orbitals fill sequentially with increasing atomic number, we can infer the electron configuration of an element from its position in the periodic table.
- ▶ The most stable electron configurations are those with completely full  $s$  and  $p$  sublevels. Therefore, the most stable and unreactive elements—those with the lowest energy electron configurations—are the noble gases.
- ▶ Elements with one or two valence electrons are among the most active metals, readily losing their valence electrons to attain noble gas configurations.
- ▶ Elements with six or seven valence electrons are among the most active nonmetals, readily gaining enough electrons to attain a noble gas configuration.

### Effective Nuclear Charge and Periodic Trends in Atomic Size (8.6)

- ▶ The size of an atom is largely determined by its outermost electrons. As we move down a column in the periodic table, the principal quantum number ( $n$ ) of the outermost electrons increases, resulting in successively larger orbitals and therefore larger atomic radii.
- ▶ As we move across a row in the periodic table, atomic radii decrease because the effective nuclear charge—the net or average

charge experienced by the atom's outermost electrons—increases.

- ▶ The atomic radii of the transition elements stay roughly constant as we move across each row because electrons are added to the  $n_{\text{highest}} - 1$  orbitals while the number of highest  $n$  electrons stays roughly constant.

### Ion Properties (8.7)

- ▶ We determine the electron configuration of an ion by adding or subtracting the corresponding number of electrons to the electron configuration of the neutral atom.
- ▶ For main-group ions, the order in which electrons are removed is the same as the order in which they are added in building up the electron configuration.
- ▶ For transition metal atoms, the  $ns$  electrons are removed before the  $(n - 1)d$  electrons.
- ▶ The radius of a cation is much *smaller* than that of the corresponding atom, and the radius of an anion is much *larger* than that of the corresponding atom.
- ▶ The first ionization energy—the energy required to remove the first electron from an atom in the gaseous state—generally decreases as we move down a column in the periodic table and increases when we move to the right across a row.
- ▶ Successive ionization energies increase smoothly from one valence electron to the next, but the ionization energy increases dramatically for the first core electron.

### Electron Affinities and Metallic Character (8.8)

- ▶ Electron affinity—the energy associated with an atom in its gaseous state gaining an electron—does not show a general trend as we move down a column in the periodic table, but it generally becomes more negative (more exothermic) to the right across a row.
- ▶ Metallic character—the tendency to lose electrons in a chemical reaction—generally increases down a column in the periodic table and decreases to the right across a row.

### The Alkali Metals, Halogens, and Noble Gases (8.9)

- ▶ The most active metals are the alkali metals (group 1A), and the most active nonmetals are the halogens (group 7A).
- ▶ The alkali metals are powerful reducing agents, reacting with many nonmetals—including the halogens and water—to form ionic compounds.
- ▶ The halogens are powerful oxidizing agents, reacting with many metals to form ionic compounds. The halogens also react with many nonmetals to form covalent compounds.
- ▶ The noble gases are relatively unreactive; only krypton and xenon form compounds, typically only with fluorine, the most reactive element in the periodic table.

## Key Equations and Relationships

### Order of Filling Quantum-Mechanical Orbitals (8.3)

$$1s\ 2s\ 2p\ 3s\ 3p\ 4s\ 3d\ 4p\ 5s\ 4d\ 5p\ 6s$$

## Key Learning Outcomes

CHAPTER OBJECTIVES	ASSESSMENT
Writing Electron Configurations (8.3)	Example 8.1 For Practice 8.1 Exercises 41, 42
Writing Orbital Diagrams (8.3) 	Example 8.2 For Practice 8.2 Exercises 43, 44
Valence Electrons and Core Electrons (8.4)	Example 8.3 For Practice 8.3 Exercises 51, 52
Electron Configurations from the Periodic Table (8.4)	Example 8.4 For Practice 8.4 For More Practice 8.4 Exercises 45, 46
Using Periodic Trends to Predict Atomic Size (8.6) 	Example 8.5 For Practice 8.5 For More Practice 8.5 Exercises 61–64
Writing Electron Configurations for Ions (8.7)	Example 8.6 For Practice 8.6 Exercises 65, 66
Using Periodic Trends to Predict Ion Size (8.7)	Example 8.7 For Practice 8.7 Exercises 69–72
Using Periodic Trends to Predict Relative Ionization Energies (8.7)	Example 8.8 For Practice 8.8 For More Practice 8.8 Exercises 73–76
Predicting Metallic Character Based on Periodic Trends (8.8) 	Example 8.9 For Practice 8.9 For More Practice 8.9 Exercises 81–84
Writing Reactions for Alkali Metal and Halogen Reactions (8.9)	Example 8.10 For Practice 8.10 Exercises 85–90

## EXERCISES

### Review Questions

- What are periodic properties?
- Which periodic property is particularly important to nerve signal transmission? Why?
- Explain the contributions of Johann Döbereiner and John Newlands to the organization of elements according to their properties.
- Who is credited with arranging the periodic table? How are the elements arranged in the modern periodic table?
- Explain the contributions of Meyer and Moseley to the periodic table.
- The periodic table is a result of the periodic law. What observations led to the periodic law? What theory explains the underlying reasons for the periodic law?
- What is an electron configuration? Give an example.
- What is Coulomb's law? Explain how the potential energy of two charged particles depends on the distance between the charged particles and on the magnitude and sign of their charges.
- What is shielding? In an atom, which electrons tend to do the most shielding (core electrons or valence electrons)?
- What is penetration? How does the penetration of an orbital into the region occupied by core electrons affect the energy of an electron in that orbital?
- Why are the sublevels within a principal level split into different energies for multielectron atoms but not for the hydrogen atom?
- What is an orbital diagram? Provide an example.
- Why is electron spin important when writing electron configurations? Explain in terms of the Pauli exclusion principle.
- What are degenerate orbitals? According to Hund's rule, how are degenerate orbitals occupied?
- List all orbitals from 1s through 5s according to increasing energy for multielectron atoms.
- What are valence electrons? Why are they important?
- Copy this blank periodic table onto a sheet of paper and label each of the blocks within the table: *s* block, *p* block, *d* block, and *f* block.
- Explain why the *s* block in the periodic table has only two columns while the *p* block has six.

	Actinides																													

19. Why do the rows in the periodic table get progressively longer as you move down the table? For example, the first row contains 2 elements, the second and third rows each contain 8 elements, and the fourth and fifth rows each contain 18 elements. Explain.
20. Describe the relationship between a main-group element's lettered group number (the number of the element's column) and its valence electrons.
21. Describe the relationship between an element's row number in the periodic table and the highest principal quantum number in the element's electron configuration. How does this relationship differ for main-group elements, transition elements, and inner transition elements?
22. Which of the transition elements in the first transition series have anomalous electron configurations?
23. Describe how to write the electron configuration for an element based on its position in the periodic table.
24. Describe the relationship between the properties of an element and the number of valence electrons that it contains.
25. List the number of valence electrons for each family, and explain the relationship between the number of valence electrons and the resulting chemistry of the elements in the family.
  - a. alkali metals                      b. alkaline earth metals
  - c. halogens                              d. oxygen family
26. Define atomic radius. For main-group elements, describe the observed trends in atomic radius as you move:
  - a. across a period in the periodic table
  - b. down a column in the periodic table
27. What is effective nuclear charge? What is shielding?
28. Use the concepts of effective nuclear charge, shielding, and  $n$  value of the valence orbital to explain the trend in atomic radius as you move across a period in the periodic table.
29. For transition elements, describe and explain the observed trends in atomic radius as you move:
  - a. across a period in the periodic table
  - b. down a column in the periodic table
30. How is the electron configuration of an anion different from that of the corresponding neutral atom? How is the electron configuration of a cation different?
31. Describe how to write an electron configuration for a transition metal cation. Is the order of electron removal upon ionization simply the reverse of electron addition upon filling? Why or why not?
32. Describe the relationship between
  - a. the radius of a cation and that of the atom from which it forms
  - b. the radius of an anion and that of the atom from which it forms
33. What is ionization energy? What is the difference between first ionization energy and second ionization energy?
34. What is the general trend in first ionization energy as you move down a column in the periodic table? As you move across a row?
35. What are the exceptions to the periodic trends in first ionization energy? Why do they occur?
36. Examination of the first few successive ionization energies for a given element usually reveals a large jump between two ionization energies. For example, the successive ionization energies of magnesium show a large jump between  $IE_2$  and  $IE_3$ . The successive ionization energies of aluminum show a large jump between  $IE_3$  and  $IE_4$ . Explain why these jumps occur and how you might predict them.
37. What is electron affinity? What are the observed periodic trends in electron affinity?
38. What is metallic character? What are the observed periodic trends in metallic character?
39. Write a general equation for the reaction of an alkali metal with each substance.
  - a. a halogen                              b. water
40. Write a general equation for the reaction of a halogen with each substance.
  - a. a metal                              b. hydrogen                      c. another halogen

## Problems by Topic

### Electron Configurations

41. Write the full electron configuration for each element.
  - a. Si    b. O    c. K    d. Ne
42. Write the full electron configuration for each element.
  - a. C    b. P    c. Ar    d. Na
43. Write the full orbital diagram for each element.
  - a. N    b. F    c. Mg    d. Al
44. Write the full orbital diagram for each element.
  - a. S    b. Ca    c. Ne    d. He
45. Use the periodic table to write an electron configuration for each element. Represent core electrons with the symbol of the previous noble gas in brackets.
  - a. P    b. Ge    c. Zr    d. I
46. Use the periodic table to determine the element corresponding to each electron configuration.
  - a.  $[\text{Ar}] 4s^2 3d^{10} 4p^6$                       b.  $[\text{Ar}] 4s^2 3d^2$
  - c.  $[\text{Kr}] 5s^2 4d^{10} 5p^2$                       d.  $[\text{Kr}] 5s^2$
47. Use the periodic table to determine each quantity.
  - a. the number of  $2s$  electrons in Li
  - b. the number of  $3d$  electrons in Cu
  - c. the number of  $4p$  electrons in Br
  - d. the number of  $4d$  electrons in Zr
48. Use the periodic table to determine each quantity.
  - a. the number of  $3s$  electrons in Mg
  - b. the number of  $3d$  electrons in Cr
  - c. the number of  $4d$  electrons in Y
  - d. the number of  $6p$  electrons in Pb
49. Name an element in the fourth period (row) of the periodic table with the following:
  - a. five valence electrons
  - b. four  $4p$  electrons
  - c. three  $3d$  electrons
  - d. full  $s$  and  $p$  sublevels
50. Name an element in the third period (row) of the periodic table with the following:
  - a. three valence electrons
  - b. four  $3p$  electrons
  - c. six  $3p$  electrons
  - d. two  $3s$  electrons and no  $3p$  electrons

### Valence Electrons and Simple Chemical Behavior from the Periodic Table

51. Determine the number of valence electrons in an atom of each element.
  - a. Ba    b. Cs    c. Ni    d. S

52. Determine the number of valence electrons in an atom of each element. Which elements do you expect to lose electrons in their chemical reactions? Which do you expect to gain electrons?
- a. Al      b. Sn      c. Br      d. Se
53. Which outer electron configuration would you expect to belong to a reactive metal? To a reactive nonmetal?
- a.  $ns^2$       b.  $ns^2np^6$       c.  $ns^2np^5$       d.  $ns^2np^2$
54. Which outer electron configurations would you expect to belong to a noble gas? To a metalloid?
- a.  $ns^2$       b.  $ns^2np^6$       c.  $ns^2np^5$       d.  $ns^2np^2$

### Coulomb's Law and Effective Nuclear Charge

55. According to Coulomb's law, which pair of charged particles has the lowest potential energy?
- a. a particle with a 1− charge separated by 150 pm from a particle with a 2+ charge  
b. a particle with a 1− charge separated by 150 pm from a particle with a 1+ charge  
c. a particle with a 1− charge separated by 100 pm from a particle with a 3+ charge
56. According to Coulomb's law, rank the interactions between charged particles from lowest potential energy to highest potential energy.
- a. a 1+ charge and a 1− charge separated by 100 pm  
b. a 2+ charge and a 1− charge separated by 100 pm  
c. a 1+ charge and a 1+ charge separated by 100 pm  
d. a 1+ charge and a 1− charge separated by 200 pm
57. Which experience a greater effective nuclear charge: the valence electrons in beryllium or the valence electrons in nitrogen? Why?
58. Arrange the atoms according to decreasing effective nuclear charge experienced by their valence electrons: S, Mg, Al, Si.
59. If core electrons completely shielded valence electrons from nuclear charge (i.e., if each core electron reduced nuclear charge by 1 unit) and if valence electrons did not shield one another from nuclear charge at all, what would be the effective nuclear charge experienced by the valence electrons of each atom?
- a. K      b. Ca      c. O      d. C
60. In Section 8.6, we estimated the effective nuclear charge on beryllium's valence electrons to be slightly greater than 2+. What would a similar process predict for the effective nuclear charge on boron's valence electrons? Would you expect the effective nuclear charge to be different for boron's 2s electrons compared to its 2p electron? In what way? (Hint: Consider the shape of the 2p orbital compared to that of the 2s orbital.)

### Atomic Radius

61. Choose the larger atom from each pair.
- a. Al or In      b. Si or N      c. P or Pb      d. C or F
62. Choose the larger atom from each pair, if possible.
- a. Sn or Si      b. Br or Ga      c. Sn or Bi      d. Se or Sn
63. Arrange these elements in order of increasing atomic radius: Ca, Rb, S, Si, Ge, F.
64. Arrange these elements in order of decreasing atomic radius: Cs, Sb, S, Pb, Se.

### Ionic Electron Configurations, Ionic Radii, Magnetic Properties, and Ionization Energy

65. Write the electron configuration for each ion.
- a.  $O^{2-}$       b.  $Br^-$       c.  $Sr^{2+}$       d.  $Co^{3+}$       e.  $Cu^{2+}$
66. Write the electron configuration for each ion.
- a.  $Cl^-$       b.  $P^{3-}$       c.  $K^+$       d.  $Mo^{3+}$       e.  $V^{3+}$

67. Write orbital diagrams for each ion and indicate whether the ion is diamagnetic or paramagnetic.
- a.  $V^{5+}$       b.  $Cr^{3+}$       c.  $Ni^{2+}$       d.  $Fe^{3+}$
68. Write orbital diagrams for each ion and indicate whether the ion is diamagnetic or paramagnetic.
- a.  $Cd^{2+}$       b.  $Au^+$       c.  $Mo^{3+}$       d.  $Zr^{2+}$
69. Which is the larger species in each pair?
- a. Li or  $Li^+$       b.  $I^-$  or  $Cs^+$       c. Cr or  $Cr^{3+}$       d. O or  $O^{2-}$
70. Which is the larger species in each pair?
- a. Sr or  $Sr^{2+}$       b. N or  $N^{3-}$       c. Ni or  $Ni^{2+}$       d.  $S^{2-}$  or  $Ca^{2+}$
71. Arrange this isoelectronic series in order of decreasing radius:  $F^-$ ,  $O^{2-}$ ,  $Mg^{2+}$ ,  $Na^+$ .
72. Arrange this isoelectronic series in order of increasing atomic radius:  $Se^{2-}$ ,  $Sr^{2+}$ ,  $Rb^+$ ,  $Br^-$ .
73. Choose the element with the higher first ionization energy from each pair.
- a. Br or Bi      b. Na or Rb      c. As or At      d. P or Sn
74. Choose the element with the higher first ionization energy from each pair.
- a. P or I      b. Si or Cl      c. P or Sb      d. Ga or Ge
75. Arrange these elements in order of increasing first ionization energy: Si, F, In, N.
76. Arrange these elements in order of decreasing first ionization energy: Cl, S, Sn, Pb.
77. For each element, predict where the “jump” occurs for successive ionization energies. (For example, does the jump occur between the first and second ionization energies, the second and third, or the third and fourth?)
- a. Be      b. N      c. O      d. Li
78. Consider this set of ionization energies.
- $IE_1 = 578 \text{ kJ/mol}$   
 $IE_2 = 1820 \text{ kJ/mol}$   
 $IE_3 = 2750 \text{ kJ/mol}$   
 $IE_4 = 11,600 \text{ kJ/mol}$

To which third-period element do these ionization values belong?

### Electron Affinities and Metallic Character

79. Choose the element with the more negative (more exothermic) electron affinity from each pair.
- a. Na or Rb      b. B or S      c. C or N      d. Li or F
80. Choose the element with the more negative (more exothermic) electron affinity from each pair.
- a. Mg or S      b. K or Cs      c. Si or P      d. Ga or Br
81. Choose the more metallic element from each pair.
- a. Sr or Sb      b. As or Bi      c. Cl or O      d. S or As
82. Choose the more metallic element from each pair.
- a. Sb or Pb      b. K or Ge      c. Ge or Sb      d. As or Sn
83. Arrange these elements in order of increasing metallic character: Fr, Sb, In, S, Ba, Se.
84. Arrange these elements in order of decreasing metallic character: Sr, N, Si, P, Ga, Al.

### Chemical Behavior of the Alkali Metals and the Halogens

85. Write the balanced chemical equation for the reaction of solid strontium with iodine gas.
86. Based on the ionization energies of the alkali metals, which alkali metal would you expect to undergo the most exothermic reaction with chlorine gas? Write a balanced chemical equation for the reaction.

87. Write the balanced chemical equation for the reaction of solid lithium with liquid water.
88. Write the balanced chemical equation for the reaction of solid potassium with liquid water.

89. Write the balanced equation for the reaction of hydrogen gas with bromine gas.
90. Write the balanced equation for the reaction of chlorine gas with fluorine gas.

## Cumulative Problems

91. Bromine is a highly reactive liquid while krypton is an inert gas. Explain this difference based on their electron configurations.
92. Potassium is a highly reactive metal while argon is an inert gas. Explain this difference based on their electron configurations.
93. Both vanadium and its  $3+$  ion are paramagnetic. Refer to their electron configurations to explain this statement.
94. Refer to their electron configurations to explain why copper is paramagnetic while its  $1+$  ion is not.
95. Suppose you were trying to find a substitute for  $K^+$  in nerve signal transmission. Where would you begin your search? What ions would be most like  $K^+$ ? For each ion you propose, explain the ways in which it would be similar to  $K^+$  and the ways it would be different. Refer to periodic trends in your discussion.
96. Suppose you were trying to find a substitute for  $Na^+$  in nerve signal transmission. Where would you begin your search? What ions would be most like  $Na^+$ ? For each ion you propose, explain the ways in which it would be similar to  $Na^+$  and the ways it would be different. Use periodic trends in your discussion.
97. Life on Earth evolved based on the element carbon. Based on periodic properties, what two or three elements would you expect to be most like carbon?
98. Which pair of elements would you expect to have the most similar atomic radii, and why?
- Si and Ga
  - Si and Ge
  - Si and As
99. Consider these elements: N, Mg, O, F, Al.
- Write the electron configuration for each element.
  - Arrange the elements in order of decreasing atomic radius.
  - Arrange the elements in order of increasing ionization energy.
  - Use the electron configurations in part a to explain the differences between your answers to parts b and c.
100. Consider these elements: P, Ca, Si, S, Ga.
- Write the electron configuration for each element.
  - Arrange the elements in order of decreasing atomic radius.
  - Arrange the elements in order of increasing ionization energy.
  - Use the electron configurations in part a to explain the differences between your answers to parts b and c.
101. Explain why atomic radius decreases as you move to the right across a period for main-group elements but not for transition elements.
102. Explain why vanadium (radius = 134 pm) and copper (radius = 128 pm) have nearly identical atomic radii, even though the atomic number of copper is about 25% higher than that of vanadium. What would you predict about the relative densities of these two metals? Look up the densities in a reference book, periodic table, or on the Internet. Are your predictions correct?
103. The lightest noble gases, such as helium and neon, are completely inert—they do not form any chemical compounds whatsoever. The heavier noble gases, in contrast, do form a limited number of compounds. Explain this difference in terms of trends in fundamental periodic properties.
104. The lightest halogen is also the most chemically reactive, and reactivity generally decreases as you move down the column of halogens in the periodic table. Explain this trend in terms of periodic properties.
105. Write general outer electron configurations ( $ns^xnp^y$ ) for groups 6A and 7A in the periodic table. The electron affinity of each group 7A element is more negative than that of each corresponding group 6A element. Use the electron configurations to explain why this is so.
106. The electron affinity of each group 5A element is more positive than that of each corresponding group 4A element. Use the outer electron configurations for these columns to suggest a reason for this observation.
107. The elements with atomic numbers 35 and 53 have similar chemical properties. Based on their electronic configurations, predict the atomic number of a heavier element that also should share these chemical properties.
108. Write the electron configurations of the six cations that form from sulfur by the loss of one to six electrons. For those cations that have unpaired electrons, write orbital diagrams.
109. You have cracked a secret code that uses elemental symbols to spell words. The code uses numbers to designate the elemental symbols. Each number is the sum of the atomic number and the highest principal quantum number of the highest occupied orbital of the element whose symbol is to be used. The message may be written forward or backward. Decode the following messages:
- 10, 12, 58, 11, 7, 44, 63, 66
  - 9, 99, 30, 95, 19, 47, 79
110. The electron affinity of sodium is lower than that of lithium, while the electron affinity of chlorine is higher than that of fluorine. Suggest an explanation for this observation.
111. Use Coulomb's law to calculate the ionization energy in kJ/mol of an atom composed of a proton and an electron separated by 100.00 pm. What wavelength of light has sufficient energy to ionize the atom?
112. The first ionization energy of sodium is 496 kJ/mol. Use Coulomb's law to estimate the average distance between the sodium nucleus and the 3s electron. How does this distance compare to the atomic radius of sodium? Explain the difference.
113. Consider the elements: B, C, N, O, F.
- Which element has the highest first ionization energy?
  - Which element has the largest atomic radius?
  - Which element is most metallic?
  - Which element has three unpaired electrons?
114. Consider the elements: Na, Mg, Al, Si, P.
- Which element has the highest second ionization energy?
  - Which element has the smallest atomic radius?
  - Which element is least metallic?
  - Which element is diamagnetic?

## Challenge Problems

- 115.** Consider the densities and atomic radii of the noble gases at 25 °C:

Element	Atomic Radius (pm)	Density (g/L)
He	32	0.18
Ne	70	0.90
Ar	98	-
Kr	112	3.75
Xe	130	-
Rn	-	9.73

- Estimate the densities of argon and xenon by interpolation from the data.
  - Estimate the density of the element with atomic number 118 by extrapolation from the data.
  - Use the molar mass of neon to estimate the mass of a neon atom. Then use the atomic radius of neon to calculate the average density of a neon atom. How does this density compare to the density of neon gas? What does this comparison suggest about the nature of neon gas?
  - Use the densities and molar masses of krypton and neon to calculate the number of atoms of each element found in a volume of 1.0 L. Use these values to estimate the number of atoms present in 1.0 L of Ar. Now use the molar mass of argon to estimate the density of Ar. How does this estimate compare to that in part a?
- 116.** As you have seen, the periodic table is a result of empirical observation (i.e., the periodic law), but quantum-mechanical theory explains *why* the table is so arranged. Suppose that, in another universe, quantum theory was such that there were one *s* orbital but only two *p* orbitals (instead of three) and only three *d* orbitals (instead of five). Draw out the first four periods of the periodic table in this alternative universe. Which elements would be the equivalent of the noble gases? Halogens? Alkali metals?
- 117.** Consider the metals in the first transition series. Use periodic trends to predict a trend in density as you move to the right across the series.
- 118.** Imagine a universe in which the value of  $m_s$  can be  $+\frac{1}{2}$ , 0, and  $-\frac{1}{2}$ . Assuming that all the other quantum numbers can take only the values possible in our world and that the Pauli exclusion principle applies, determine:
- the new electronic configuration of neon
  - the atomic number of the element with a completed  $n = 2$  shell
  - the number of unpaired electrons in fluorine
- 119.** A carbon atom can absorb radiation of various wavelengths with resulting changes in its electron configuration. Write orbital diagrams for the electron configuration of carbon that results from absorption of the three longest wavelengths of radiation it can absorb.
- 120.** Only trace amounts of the synthetic element darmstadtium, atomic number 110, have been obtained. The element is so highly unstable that no observations of its properties have been possible. Based on its position in the periodic table, propose three different reasonable valence electron configurations for this element.
- 121.** What is the atomic number of the as yet undiscovered element in which the 8*s* and 8*p* electron energy levels fill? Predict the chemical behavior of this element.
- 122.** The trend in second ionization energy for the elements from lithium to fluorine is not a regular one. Predict which of these elements has the highest second ionization energy and which has the lowest and explain. Of the elements N, O, and F, O has the highest and N the lowest second ionization energy. Explain.
- 123.** Unlike the elements in groups 1A and 2A, those in group 3A do not show a regular decrease in first ionization energy as you move down the column. Explain the irregularities.
- 124.** Using the data in Figures 8.15 and 8.16, calculate  $\Delta E$  for the reaction  $\text{Na(g)} + \text{Cl(g)} \longrightarrow \text{Na}^+(\text{g}) + \text{Cl}^-(\text{g})$ .
- 125.** Even though adding two electrons to O or S forms an ion with a noble gas electron configuration, the second electron affinity of both of these elements is positive. Explain.
- 126.** In Section 2.7 we discussed the metalloids, which form a diagonal band separating the metals from the nonmetals. There are other instances in which elements such as lithium and magnesium that are diagonal to each other have comparable metallic character. Suggest an explanation for this observation.
- 127.** The heaviest known alkaline earth metal is radium, atomic number 88. Find the atomic numbers of the as yet undiscovered next two members of the series.
- 128.** Predict the electronic configurations of the first two excited states (next higher-energy states beyond the ground state) of Pd.
- 129.** Table 8.2 does not include francium because none of francium's isotopes are stable. Predict the values of the entries for Fr in Table 8.2. Predict the nature of the products of the reaction of Fr with: (a) water, (b) oxygen, and (c) chlorine.
- 130.** From its electronic configuration, predict which of the first 10 elements would be most similar in chemical behavior to the as yet undiscovered element 165.

## Conceptual Problems

- 131.** Imagine that in another universe atoms and elements are identical to ours, except that atoms with six valence electrons have particular stability (in contrast to our universe where atoms with eight valence electrons have particular stability). Give an example of an element in the alternative universe that corresponds to each of the following:
- a noble gas
  - a reactive nonmetal
  - a reactive metal
- 132.** The outermost valence electron in atom A experiences an effective nuclear charge of 2+ and is on average 225 pm from the nucleus. The outermost valence electron in atom B experiences an effective nuclear charge of 1+ and is on average 175 pm from the nucleus. Which atom (A or B) has the higher first ionization energy? Explain.

- 133.** Determine whether each statement regarding penetration and shielding is true or false. (Assume that all lower-energy orbitals are fully occupied.)
- An electron in a 3s orbital is more shielded than an electron in a 2s orbital.
  - An electron in a 3s orbital penetrates into the region occupied by core electrons more than electrons in a 3p orbital penetrates into the region occupied by core electrons.
  - An electron in an orbital that penetrates closer to the nucleus always experiences more shielding than an electron in an orbital that does not penetrate as far.

- An electron in an orbital that penetrates close to the nucleus tends to experience a higher effective nuclear charge than an electron in an orbital that does not penetrate close to the nucleus.

- 134.** Give a combination of four quantum numbers that could be assigned to an electron occupying a 5p orbital. Do the same for an electron occupying a 6d orbital.

- 135.** Use the trends in ionization energy and electron affinity to explain why calcium fluoride has the formula  $\text{CaF}_2$  and not  $\text{Ca}_2\text{F}$  or  $\text{CaF}$ .

### Active Classroom Learning

## Questions for Group Work

Discuss these questions with the group and record your consensus answer.

- 136.** In a complete sentence describe the relationship between shielding and penetration.
- 137.** Play a game to memorize the order in which orbitals fill. Have each group member in turn state the name of the next orbital to fill and the maximum number of electrons it can hold (for example, “1s two,” “2s two,” “2p six,” etc.). If a member gets stuck, other group members can help, consulting Figure 8.5 and the accompanying text summary if necessary. However, when a member gets stuck, the next player starts back at “1s two.” Keep going until each group member can list all the orbitals in order up to “6s two.”

- 138.** Sketch a periodic table (without element symbols). Include the correct number of rows and columns in the s, p, d, and f blocks. Shade in the squares for elements that have irregular electron configurations.

- 139.** In complete sentences, explain: (a) why  $\text{Se}^{2-}$  and  $\text{Br}^-$  are about the same size; (b) why  $\text{Br}^-$  is slightly smaller than  $\text{Se}^{2-}$ ; and (c) which singly charged cation you would expect to be approximately the same size as  $\text{Se}^{2-}$  and  $\text{Br}^-$  and why.

- 140.** Have each member of your group sketch a periodic table indicating a periodic trend (atomic size, first ionization energy, metallic character, etc.). Have each member present his or her table to the rest of the group and explain the trend based on concepts such as orbital size or effective nuclear charge.

## Data Interpretation and Analysis

### Periodic Properties of Period 3 Elements

- 141.** Figure a plots the first ionization energies of the elements in period 3. Figure b lists some of the binary compounds that form between fluorine and the elements in period 3. Figure c plots the electron affinities of the elements in period 3.

▲ **FIGURE a** First Ionization Energies of Period 3 Elements

Element	Na	Mg	Al	Si	P	S	Cl	Ar
Compound	NaF	MgF <sub>2</sub>	AlF <sub>3</sub>		PF <sub>3</sub>	SF <sub>2</sub>	ClF	

▲ **FIGURE b** Binary Compounds That Form between Fluorine and Period 3 Elements

▲ **FIGURE c** Electron Affinities of Period 3 Elements

Use the information provided in the figures to answer the following questions:

- In general, first ionization energy increases as we move from left to right across the third period. Explain.
- There is a decrease in first ionization from Mg to Al. There is an increase in electron affinity from Mg to Al. Explain.
- The first ionization energy of S is slightly less than that of P. Explain.
- After reviewing the information in Figures a, b, and c, Student X offers the following hypothesis: The number of fluorine atoms that bond to a metal atom is equal to the number of valence electrons of the metal. The number of

fluorine atoms that bond to a nonmetal atom is equal to 8 minus the number of valence electrons of the nonmetal. Student Y offers the following hypothesis: In general, there is an inverse relationship between the electron affinities of the period 3 elements and the number of fluorine atoms that bond to the metal or nonmetal atoms.

Do you agree with Student X's hypothesis, with Student Y's hypothesis, both of them, or neither of them? Explain.

- Write the formula for a compound that forms between silicon and fluorine. Does this compound support Student X's hypothesis, Student Y's hypothesis, or neither hypothesis? Explain.

## Answers to Conceptual Connections

### Coulomb's Law

- 8.1 (a)** Since the charges are opposite, the potential energy of the interaction is negative. As the charges get closer together,  $r$  becomes smaller and the potential energy decreases (becomes more negative).

### Penetration and Shielding

- 8.2 (c)** Penetration results in less shielding from nuclear charge and therefore lower energy.

### Electron Configurations and Quantum Numbers

- 8.3**  $n = 4, l = 0, m_l = 0, m_s = +\frac{1}{2}$ ;  $n = 4, l = 0, m_l = 0, m_s = -\frac{1}{2}$

### Valence Electrons and Group Number

- 8.4** Nitrogen has five valence electrons. Since nitrogen is a main-group element, it has the same number of valence electrons as its group number in the periodic table.

### Effective Nuclear Charge

- 8.5 (c)** Since  $Z_{\text{eff}}$  increases from left to right across a row in the periodic table, the valence electrons in S experience a greater effective nuclear charge than the valence electrons in Al or in Mg.

### Ions, Isotopes, and Atomic Size

- 8.6** The isotopes of an element all have the same radius for two reasons: (1) neutrons are negligibly small compared to the size of an atom and therefore extra neutrons do not increase atomic

size, and (2) neutrons have no charge and therefore do not attract electrons in the way that protons do.

### Ionization Energies and Chemical Bonding

- 8.7** As you can see from the successive ionization energies of any element, valence electrons are held most loosely and can therefore be transferred or shared most easily. Core electrons, on the other hand, are held tightly and are not easily transferred or shared. Consequently, valence electrons are most important to chemical bonding.

### Periodic Trends

- 8.8** The 3s electron in sodium has a relatively low first ionization energy (496 kJ/mol) because it is a valence electron. The energetic cost for sodium to lose a second electron is extraordinarily high (4560 kJ/mol) because the next electron to be lost is a core electron (2p). Similarly, the electron affinity of chlorine to gain one electron (−349 kJ/mol) is highly exothermic because the added electron completes chlorine's valence shell. The gain of a second electron by the negatively charged chlorine anion is not so favorable. Therefore, we expect sodium and chlorine to combine in a 1:1 ratio.

# Chemical Bonding I: The Lewis Model

Theories are nets cast to catch what we call “the world”: to rationalize, to explain, and to master it. We endeavor to make the mesh ever finer and finer.

KEY LEARNING OUTCOMES 419

**C**hemical bonding is at the heart of chemistry. The bonding theories that we are about to examine are—as Karl Popper, a philosopher of science, eloquently states in the chapter-opening quote—nets cast to understand the world. In the next two chapters, we will examine three theories with successively finer “meshes.” The first is the Lewis model, a simple model of chemical bonding, which can be sketched out on the back of an envelope. With just a few dots, dashes, and chemical symbols, the Lewis model can help us to understand and predict many chemical observations. The second is valence bond theory, which treats electrons in a more quantum-mechanical manner but stops short of viewing them as belonging to the entire molecule. The third is molecular orbital theory, essentially a full quantum-mechanical treatment of the molecule and its electrons as a whole. Molecular orbital theory has great predictive power, but at the expense of great complexity and intensive computational requirements. Which theory is “correct”? Remember that theories are models that help us understand and predict behavior. All three of these theories are extremely useful, depending on exactly what aspect of chemical bonding we want to predict or understand.

▲ The AIDS drug Indinavir—shown here as the missing piece in a puzzle depicting the protein HIV-protease—was developed with the help of chemical bonding theories.

## 9.1 Bonding Models and AIDS Drugs

In 1989, researchers using X-ray crystallography—a technique in which X-rays are scattered from crystals of the molecule of interest—determined the structure of a molecule called HIV-protease. HIV-protease is a protein (a class of large biological molecules) synthesized by

We discuss X-ray crystallography in more detail in Section 12.2.

We discuss proteins in more detail in Chapter 22.

▲ G. N. Lewis

the human immunodeficiency virus (HIV). This particular protein is crucial to the virus's ability to multiply and cause acquired immune deficiency syndrome, or AIDS. Without HIV-protease, HIV cannot spread in the human body because the virus cannot replicate. In other words, without HIV-protease, AIDS can't develop.

With knowledge of the HIV-protease structure, pharmaceutical companies set out to create a molecule that would disable HIV-protease by attaching to the working part of the molecule, called the active site. To design such a molecule, researchers used *bonding theories*—models that predict how atoms bond together to form molecules—to simulate the shape of potential drug molecules and determine how they would interact with the protease molecule. By the early 1990s, pharmaceutical companies had developed several drug molecules that seemed to work. Since these molecules inhibit the action of HIV-protease, they were named *protease inhibitors*. Protease inhibitors, when given in combination with other drugs, decrease the viral count in HIV-infected individuals to undetectable levels. Although protease inhibitors do not cure AIDS, many AIDS patients are still alive today because of these drugs.

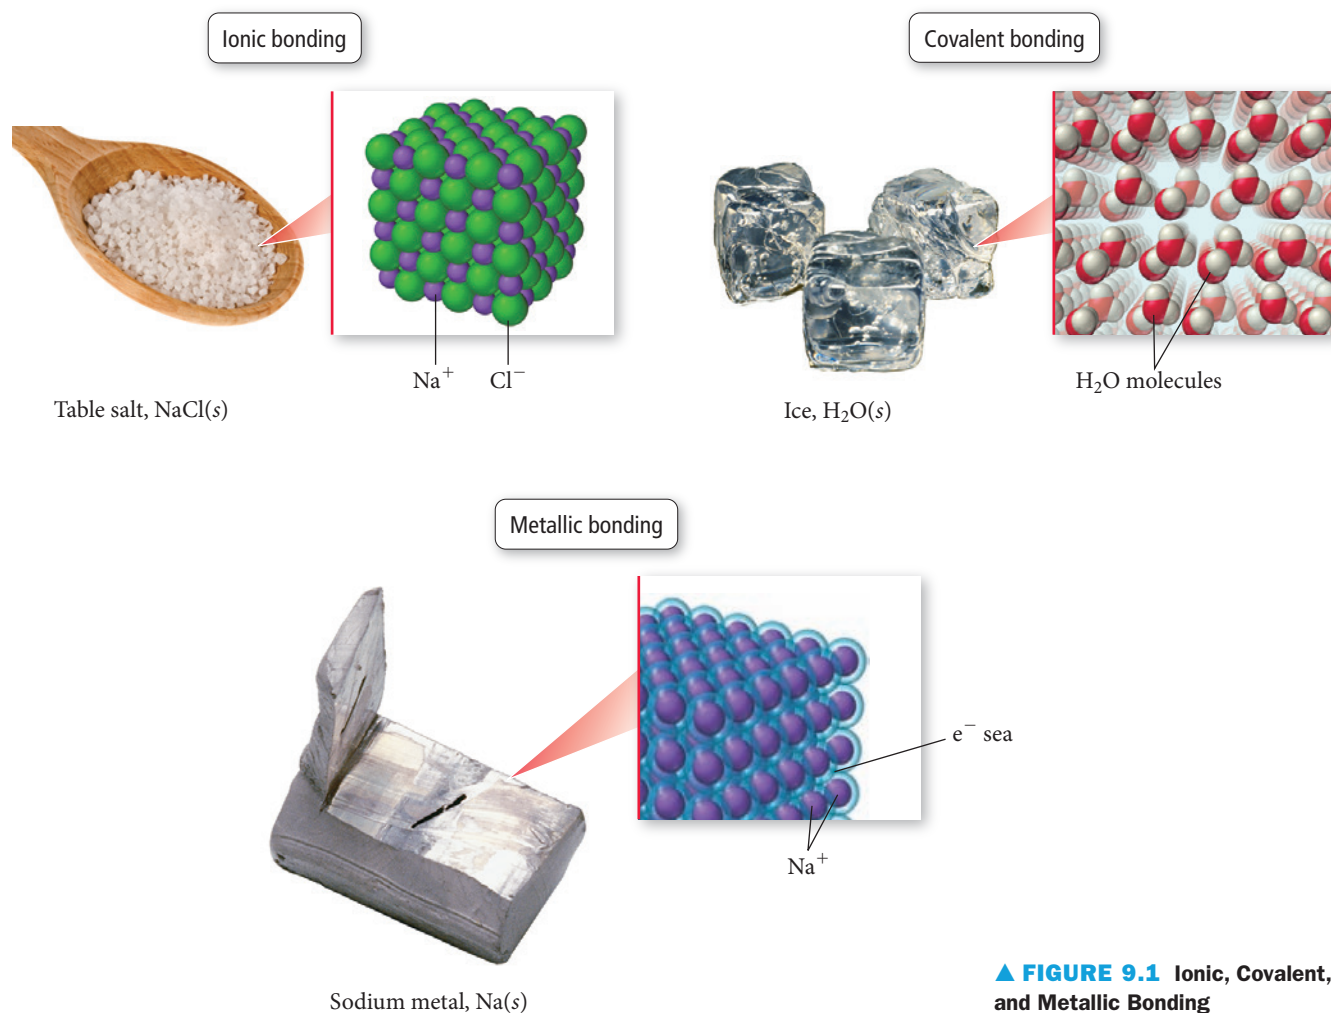

Bonding theories are central to chemistry because they explain how atoms bond together to form molecules. They explain why some combinations of atoms are stable and others are not. For example, bonding theories explain why table salt is NaCl and not NaCl<sub>2</sub> and why water is H<sub>2</sub>O and not H<sub>3</sub>O. Bonding theories also predict the shapes of molecules—a topic in the next chapter—which in turn determine many of the physical and chemical properties of compounds.

The bonding model we examine in this chapter is the **Lewis model**, named after the American chemist G. N. Lewis (1875–1946). In the Lewis model, valence electrons are represented as dots, and we draw **Lewis electron-dot structures** (or simply **Lewis structures**) to depict molecules. These structures, which are fairly simple to draw, have tremendous predictive power. With minimal computation, the Lewis model can be used to predict whether a particular set of atoms will form a stable molecule and what that molecule might look like. Although we will also examine more advanced theories in the following chapter, the Lewis model remains the simplest model for making quick, everyday predictions about most molecules.

## 9.2 Types of Chemical Bonds

We begin our discussion of chemical bonding by asking why bonds form in the first place. This seemingly simple question is vitally important. Imagine our universe without chemical bonding. Such a universe would contain only 91 different kinds of substances (the 91 naturally occurring elements). With such a poor diversity of substances, life would be impossible, and we would not be around to wonder why. The *answer* to the question of why bonds form, however, is not simple and involves not only quantum mechanics but also some thermodynamics that we do not introduce until Chapter 18. Nonetheless, we can address an important *aspect* of the answer now: *Chemical bonds form because they lower the potential energy between the charged particles that compose atoms.*

As you already know, atoms are composed of particles with positive charges (the protons in the nucleus) and negative charges (the electrons). When two atoms approach each other, the electrons of one atom are attracted to the nucleus of the other according to Coulomb's law (see Section 8.3) and vice versa. However, at the same time, the electrons of each atom repel the electrons of the other, and the nucleus of each atom repels the nucleus of the other. The result is a complex set of interactions among a potentially large number of charged particles. If these interactions lead to an overall net reduction of energy between the charged particles, a chemical bond forms. Bonding theories help us to predict the circumstances under which bonds form and also the properties of the resultant molecules.

**▲ FIGURE 9.1** Ionic, Covalent, and Metallic Bonding

We broadly classify chemical bonds into three types depending on the kind of atoms involved in the bonding (Figure 9.1▲):

Types of Atoms	Type of Bond	Characteristic of Bond
Metal and nonmetal	Ionic	Electrons transferred
Nonmetal and nonmetal	Covalent	Electrons shared
Metal and metal	Metallic	Electrons pooled

Recall from Chapter 8 that metals tend to have low ionization energies (their electrons are relatively easy to remove) and that nonmetals tend to have negative electron affinities (they readily gain electrons). When a metal atom bonds with a nonmetal atom, it transfers one or more electrons to the nonmetal. The metal atom becomes a cation and the nonmetal atom an anion. These oppositely charged ions attract one another, lowering their overall potential energy as described by Coulomb's law. The resulting bond is an **ionic bond**.

We also discussed in Chapter 8 that nonmetals tend to have high ionization energies (their electrons are relatively difficult to remove). Therefore, when a nonmetal bonds with another nonmetal, neither atom transfers electrons to the other. Instead, the two atoms *share* some electrons. The shared electrons interact with the nuclei of both of the bonding atoms, lowering their potential energy in accordance with Coulomb's law. The resulting bond is a **covalent bond**.

Recall from Section 3.2 that we can understand the stability of a covalent bond by considering the most stable arrangement (the one with the lowest potential energy) of two positively charged particles separated by a small distance and a negatively charged particle. As we can see in Figure 9.2▶ on the next page, the arrangement in which the negatively charged particle lies *between* the two positively charged ones has the lowest potential energy because in this arrangement, the negatively charged particle interacts

► **FIGURE 9.2** Possible Configurations of One Negatively Charged Particle and Two Positively Charged Ones

most strongly with *both of the positively charged ones*. In a sense, the negatively charged particle holds the two positively charged ones together. Similarly, shared electrons in a covalent chemical bond *hold* the bonding atoms together by attracting the positive charges of their nuclei.

A third type of bonding, **metallic bonding**, occurs in metals. Since metals have low ionization energies, they tend to lose electrons easily. In the simplest model for metallic bonding—called the *electron sea* model—all of the atoms in a metal lattice pool their valence electrons. These pooled electrons are no longer localized on a single atom, but delocalized over the entire metal. The positively charged metal atoms are then attracted to the sea of electrons, holding the metal together. We discuss metallic bonding in more detail in Section 9.11.

## CONCEPTUAL CONNECTION 9.1

**Bond Types** Which compound is most likely to contain ionic bonds?  
 (a)  $\text{CH}_4$  (b)  $\text{N}_2\text{O}$  (c)  $\text{MgF}_2$

Remember, the number of valence electrons for any main group is equal to the group number of the element (except for helium, which is in group 8A but has only two valence electrons).

## 9.3 Representing Valence Electrons with Dots

In Chapter 8, we saw that, for main-group elements, valence electrons are those electrons in the outermost principal energy level. Because valence electrons are held most loosely, and chemical bonding involves the transfer or sharing of electrons between two or more atoms, valence electrons are most important in bonding, so the Lewis model focuses on these. In a **Lewis symbol**, we represent the valence electrons of main-group elements as dots surrounding the element symbol. For example, the electron configuration of O is:

The Lewis symbol for oxygen is:

Although the exact location of dots is not critical, in this book we first place dots singly before pairing (except for helium, which always has two paired dots signifying its duet).

Each dot in a Lewis symbol represents a valence electron. The dots are placed around the element's symbol with a maximum of two dots per side. We draw the Lewis symbols for all of the period 2 elements similarly.

Lewis symbols provide a simple way to visualize the number of valence electrons in a main-group atom. Notice that atoms with eight valence electrons—which are particularly stable because they have full *s* and *p* sublevels—are easily identified because they have eight dots, an **octet**.

Helium is somewhat of an exception. Its electron configuration and Lewis symbol are:

The Lewis symbol of helium contains only two dots (a **duet**). For helium, a duet represents a stable electron configuration because the  $n = 1$  quantum level fills with only two electrons.

In the Lewis model, a **chemical bond** is the sharing or transfer of electrons to attain stable electron configurations for the bonding atoms. If electrons are transferred, as occurs between a metal and a nonmetal, the bond is an *ionic bond*. If the electrons are shared, as occurs between two nonmetals, the bond is a *covalent bond*. In either case, the bonding atoms attain stable electron configurations; since the stable configuration is usually eight electrons in the outermost shell, this is known as the **octet rule**.

When applying the Lewis model, we do not try to calculate the energies associated with the attractions and repulsions between electrons and nuclei on neighboring atoms. The energy changes that occur because of these interactions are central to chemical bonding (as we saw in Section 9.2), yet the Lewis model ignores them because calculating these energy changes is extremely complicated. Instead the Lewis model uses the simple octet rule, a practical approach that accurately predicts what we see in nature for a large number of compounds—hence the success and longevity of the Lewis model.

## 9.4 Ionic Bonding: Lewis Symbols and Lattice Energies

Although the Lewis model's strength is in modeling covalent bonding, it can also be applied to ionic bonding. To represent ionic bonding, we move electron dots from the Lewis symbol of the metal to the Lewis symbol of the nonmetal and allow the resultant ions to form a crystalline lattice composed of alternating cations and anions.

### Ionic Bonding and Electron Transfer

Consider potassium and chlorine, which have the following Lewis symbols:

When these atoms bond, potassium transfers its valence electron to chlorine:

The transfer of the electron gives chlorine an octet (shown as eight dots around chlorine) and leaves potassium without any valence electrons but with an octet in the *previous* principal energy level (which is now the outermost level):

Octet in previous level

The potassium, having lost an electron, becomes positively charged (a cation), while the chlorine, which has gained an electron, becomes negatively charged (an anion). We typically write the Lewis symbol of an anion within brackets with the charge in the upper right-hand corner, outside the brackets. The positive and negative charges attract one another, resulting in the compound KCl.

This example shows how we can use the Lewis model to predict the correct chemical formulas for ionic compounds. For the compound that forms between K and Cl, for example, the Lewis model predicts a ratio of one potassium cation to every one chloride anion, KCl. In nature, when we examine the compound formed between potassium and chlorine, we indeed find one potassium ion to every chloride ion.

As another example, consider the ionic compound formed between sodium and sulfur. The Lewis symbols for sodium and sulfur are:

Sodium must lose its one valence electron in order to have an octet (in the previous principal shell), while sulfur must gain two electrons to attain an octet. Consequently, the compound that forms between sodium and sulfur requires a ratio of two sodium atoms to every one sulfur atom:

Recall that solid ionic compounds do not contain distinct molecules; they are composed of alternating positive and negative ions in a three-dimensional crystalline array.

The two sodium atoms each lose their one valence electron, while the sulfur atom gains two electrons and attains an octet. The Lewis model predicts that the correct chemical formula is  $\text{Na}_2\text{S}$ , which is exactly what we see in nature.

### Example 9.1 Using Lewis Symbols to Predict the Chemical Formula of an Ionic Compound

Use Lewis symbols to predict the formula for the compound that forms between calcium and chlorine.

#### SOLUTION

Draw Lewis symbols for calcium and chlorine based on their respective numbers of valence electrons, which you can determine from their group number in the periodic table.

Calcium must lose its two valence electrons (to end up with an octet in its previous principal shell), while chlorine only needs to gain one electron to attain an octet. Draw two chlorine anions, each with an octet and a 1<sup>−</sup> charge, and one calcium cation with a 2<sup>+</sup> charge. Place brackets around the chlorine anions and indicate the charges on each ion.

Finally, write the formula with subscripts to indicate the number of each ion.

**FOR PRACTICE 9.1** Use Lewis symbols to predict the formula for the compound that forms between magnesium and nitrogen.

## Lattice Energy: The Rest of the Story

The formation of an ionic compound from its constituent elements is usually quite exothermic. For example, when sodium chloride (table salt) forms from elemental sodium and chlorine, 411 kJ of heat evolves in the following violent reaction:

Where does this energy come from? It might seem that it comes solely from the tendency of metals to lose electrons and nonmetals to gain electrons—but it does not. In fact, the transfer of an electron from sodium to chlorine—by itself—actually *absorbs* energy. The first ionization energy of sodium is +496 kJ/mol, and the electron affinity of Cl is only −349 kJ/mol. Based only on these energies, the reaction should be *endothermic* by +147 kJ/mol. So why is the reaction so *exothermic*?

The answer lies in the **lattice energy**—the energy associated with the formation of a crystalline lattice of alternating cations and anions from the gaseous ions. Because the sodium ions are positively charged and the chlorine ions are negatively charged, the potential energy decreases—as prescribed by Coulomb's law—when these ions come together to form a lattice. That energy is emitted as heat when the lattice forms, as shown in Figure 9.3. The exact value of the lattice energy, however, is not simple to determine because it involves a large number of interactions among many charged particles in a lattice. The most straightforward way to calculate lattice energy is with the *Born–Haber cycle*.

## The Born–Haber Cycle

The **Born–Haber cycle** is a hypothetical series of steps that represents the formation of an ionic compound from its constituent elements. The steps are chosen so that the change in enthalpy of each step is known except for the last one, which is the lattice energy. The change in enthalpy for the overall process is also known. Using Hess's law (see Section 6.8), we can therefore determine the enthalpy change for the unknown last step, the lattice energy.

Consider the formation of NaCl from its constituent elements in their standard states. The enthalpy change for the overall reaction is simply the standard enthalpy of formation of NaCl(s):

Recall that Hess's law states that the change in the overall enthalpy of a stepwise process is the sum of the enthalpy changes of the steps.

### Lattice Energy of an Ionic Compound

**▲ FIGURE 9.3 Lattice Energy** The lattice energy of an ionic compound is the energy associated with the formation of a crystalline lattice of the compound from the gaseous ions.

Now consider the following set of steps—the Born–Haber cycle—from which  $\text{NaCl}(\text{s})$  can also be made from  $\text{Na}(\text{s})$  and  $\text{Cl}_2(\text{g})$ :

- The first step is the formation of gaseous sodium from solid sodium.

- The second step is the formation of a chlorine atom from a chlorine molecule.

- The third step is the ionization of gaseous sodium. The enthalpy change for this step is the ionization energy of sodium.

- The fourth step is the addition of an electron to gaseous chlorine. The enthalpy change for this step is the electron affinity of chlorine.

- The fifth and final step is the formation of the crystalline solid from the gaseous ions. The enthalpy change for this step is the lattice energy, the unknown quantity.

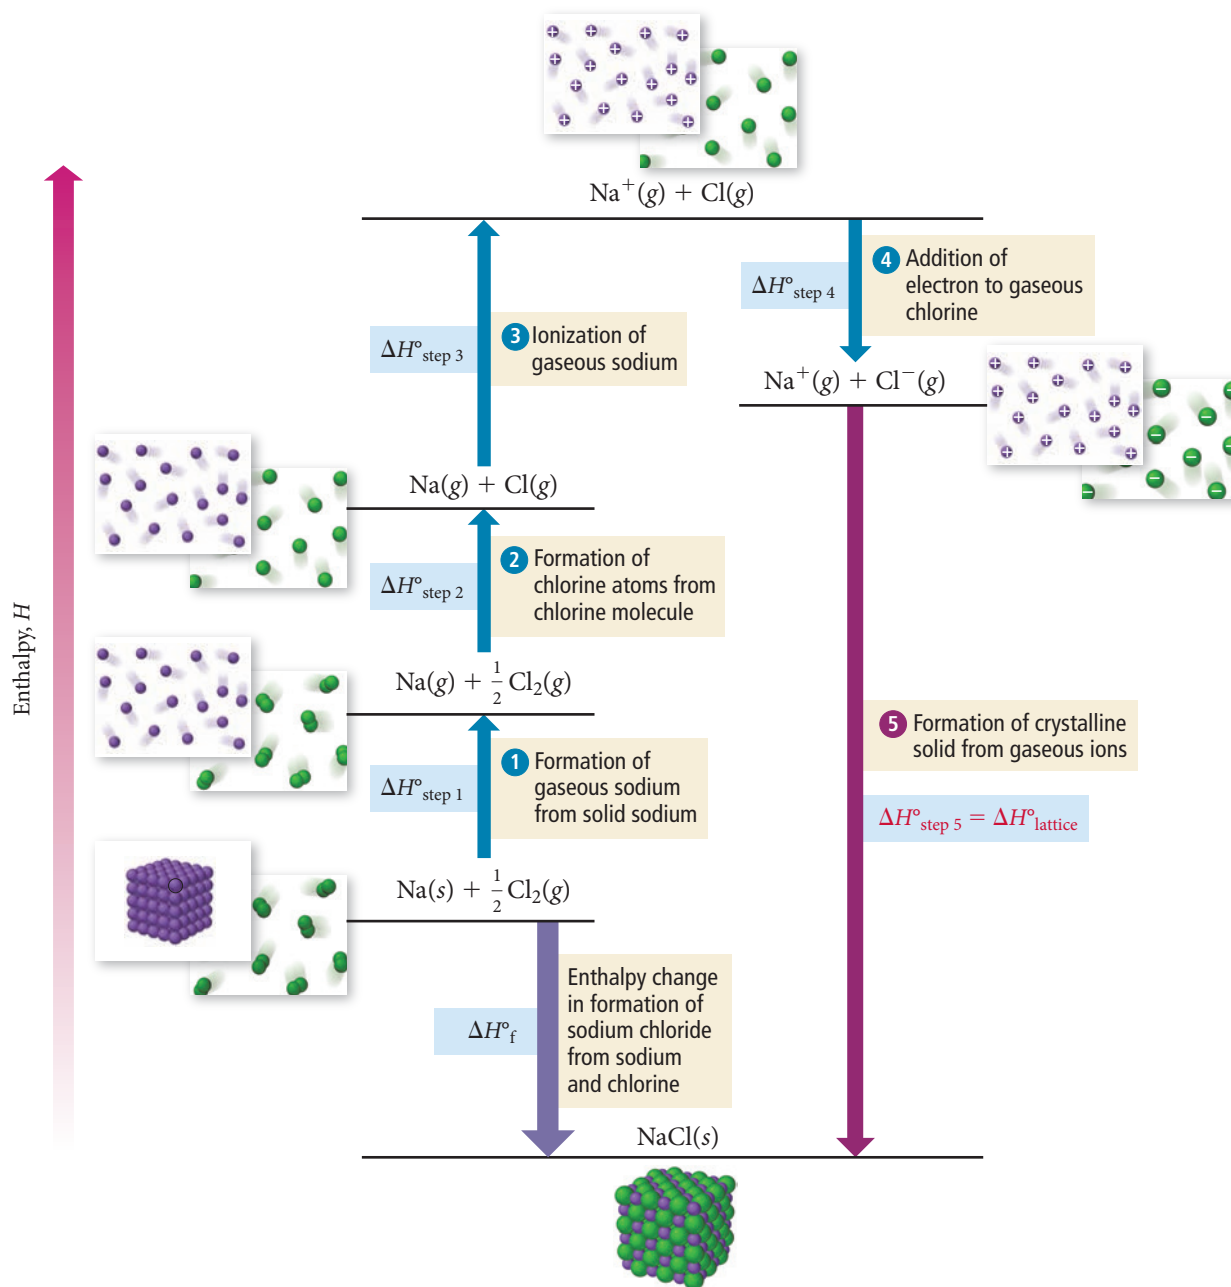

Figure 9.4, on the next page, illustrates the entire Born–Haber cycle for  $\text{NaCl}$ .

Since the overall reaction obtained by summing the steps in the Born–Haber cycle is equivalent to the formation of  $\text{NaCl}$  from its constituent elements, we use Hess's law to set the overall enthalpy of formation for  $\text{NaCl}(\text{s})$  equal to the sum of the steps in the Born–Haber cycle:

$$\Delta H_{\text{f}}^\circ = \Delta H_{\text{step 1}}^\circ + \Delta H_{\text{step 2}}^\circ + \Delta H_{\text{step 3}}^\circ + \Delta H_{\text{step 4}}^\circ + \Delta H_{\text{step 5}}^\circ$$

Lattice energy  
↓

Born–Haber Cycle for Production of NaCl from Na(s) and Cl<sub>2</sub>(g)

**▲ FIGURE 9.4 Born–Haber Cycle for Sodium Chloride** The sum of the steps is the formation of NaCl from elemental Na and Cl<sub>2</sub>. The enthalpy change of the last step (step 5) is the lattice energy.

We then solve this equation for  $\Delta H^\circ_{\text{step 5}}$ , which is  $\Delta H^\circ_{\text{lattice}}$ , and substitute the appropriate values to calculate the lattice energy:

$$\begin{aligned}\Delta H^\circ_{\text{lattice}} &= \Delta H^\circ_{\text{step 5}} = \Delta H^\circ_f - (\Delta H^\circ_{\text{step 1}} + \Delta H^\circ_{\text{step 2}} + \Delta H^\circ_{\text{step 3}} + \Delta H^\circ_{\text{step 4}}) \\ &= -411 \text{ kJ} - (+108 \text{ kJ} + 122 \text{ kJ} + 496 \text{ kJ} - 349 \text{ kJ}) \\ &= -788 \text{ kJ}\end{aligned}$$

Some books define the lattice energy as the energy associated with separating one mole of an ionic lattice into its gaseous constituents, which makes the sign of the lattice energy positive instead of negative.

The value of the lattice energy is a large negative number. The formation of the crystalline NaCl lattice from sodium cations and chloride anions is highly exothermic and more than compensates for the endothermicity of the electron transfer process.

In other words, the formation of ionic compounds is not exothermic because sodium “wants” to lose electrons and chlorine “wants” to gain them; rather, it is exothermic because of the large amount of heat released when sodium and chlorine ions coalesce to form a crystalline lattice.

## Trends in Lattice Energies: Ion Size

Consider the lattice energies of the following alkali metal chlorides:

Metal Chloride	Lattice Energy (kJ/mol)
LiCl	−834
NaCl	−788
KCl	−701
CsCl	−657

Why does the magnitude of the lattice energy decrease as we move down the column? We know from the periodic trends discussed in Chapter 8 that ionic radius increases as we move down a column in the periodic table (see Section 8.7). We also know, from our discussion of Coulomb’s law in Section 8.3, that the potential energy of oppositely charged ions becomes less negative (or more positive) as the distance between the ions increases. As the size of the alkali metal ions increases down the column, so does the distance between the metal cations and the chloride anions. The magnitude of each successive lattice energy of the chlorides decreases accordingly, making the formation of the chlorides less exothermic as you move down the column. In other words, *as the ionic radii increase as we move down the column, the ions cannot get as close to each other and therefore do not release as much energy when the lattice forms.*

▲ Bond lengths of the group 1A metal chlorides.

## Trends in Lattice Energies: Ion Charge

Consider the lattice energies of the following two compounds:

Compound	Lattice Energy (kJ/mol)
NaF	−910
CaO	−3414

Why is the magnitude of the lattice energy of CaO so much greater than the lattice energy of NaF?  $\text{Na}^+$  has a radius of 95 pm and  $\text{F}^-$  has a radius of 136 pm, resulting in a distance between ions of 231 pm.  $\text{Ca}^{2+}$  has a radius of 99 pm and  $\text{O}^{2-}$  has a radius of 140 pm, resulting in a distance between ions of 239 pm. Even though the separation between the calcium and oxygen is slightly greater (which would tend to lower the lattice energy), the lattice energy for CaO is almost four times *greater*.

The explanation lies in the charges of the ions. Recall from Coulomb’s law that the magnitude of the potential energy of two interacting charges depends not only on the distance between the charges, but also on the product of the charges:

$$E = \frac{1}{4\pi\epsilon_0} \frac{q_1 q_2}{r}$$

For NaF,  $E$  is proportional to  $(1+)(1-) = 1-$ , while for CaO,  $E$  is proportional to  $(2+)(2-) = 4-$ , so the relative stabilization for CaO relative to NaF is roughly four times greater, as observed in the lattice energy.

### Summarizing Trends in Lattice Energies:

- ▶ Lattice energies become less exothermic (less negative) with increasing ionic radius.
- ▶ Lattice energies become more exothermic (more negative) with increasing magnitude of ionic charge.

**Example 9.2** Predicting Relative Lattice Energies

Arrange these ionic compounds in order of increasing *magnitude* of lattice energy: CaO, KBr, KCl, SrO.

**SOLUTION**

KBr and KCl have lattice energies of smaller magnitude than CaO and SrO because of their lower ionic charges ( $1+$ ,  $1-$  compared to  $2+$ ,  $2-$ ). When you compare KBr and KCl, you expect KBr to have a lattice energy of lower magnitude due to the larger ionic radius of the bromide ion relative to the chloride ion. Between CaO and SrO, you expect SrO to have a lower magnitude lattice energy due to the larger ionic radius of the strontium ion relative to the calcium ion.

Order of increasing *magnitude* of lattice energy:

Actual lattice energy values:

Compound	Lattice Energy (kJ/mol)
KBr	-671
KCl	-701
SrO	-3217
CaO	-3414

**FOR PRACTICE 9.2** Arrange the following in order of increasing magnitude of lattice energy: LiBr, KI, and CaO.

**FOR MORE PRACTICE 9.2** Which compound has a higher magnitude lattice energy: NaCl or  $\text{MgCl}_2$ ?

**Ionic Bonding: Models and Reality**

In this section, we have developed a model for ionic bonding. The value of a model is in how well it accounts for what we see in nature (through experiments). Does our ionic bonding model explain the properties of ionic compounds, including their high melting and boiling points, their tendency *not to conduct* electricity as solids, and their tendency *to conduct* electricity when dissolved in water?

We modeled an ionic solid as a lattice of individual ions held together by coulombic forces that are *nondirectional* (which means that, as we move away from the center of an ion, the forces are equally strong in all directions). To melt the solid, these forces must be overcome, which requires a significant amount of heat. Therefore, our model accounts for the high melting points of ionic solids. In the model, electrons transfer from the metal to the nonmetal, but the transferred electrons remain localized on one atom. In other words, our model does not include any free electrons that might conduct electricity (the movement or flow of electrons or other charged particles in response to an electric potential, or voltage, is electrical current). In addition, the ions themselves are fixed in place; therefore, our model accounts for the nonconductivity of ionic solids. When our idealized ionic solid dissolves in water, however, the cations and anions dissociate, forming free ions in solution. These ions can move in response to electrical forces, creating an electrical current. Thus, our model predicts that solutions of ionic compounds conduct electricity (which in fact they do).

► The melting of solid ionic compounds such as sodium chloride requires enough heat to overcome the electrical forces holding the anions and cations together in a lattice. Thus, the melting points of ionic compounds are relatively high.

NaCl(s)

▲ Solid sodium chloride does not conduct electricity.

NaCl(aq)

▲ Aqueous sodium chloride conducts electricity.

**Melting Points of Ionic Solids** Use the ionic bonding model to determine which has the higher melting point: NaCl or MgO. Explain the relative ordering.

## Chemistry AND Medicine

### Ionic Compounds in Medicine

**A**lthough most drugs are molecular compounds, a number of ionic compounds have medical uses. Consider the following partial list of ionic compounds used in medicine. Notice that many of these compounds contain polyatomic ions. The bonding between a metal and a polyatomic ion is ionic. However, the bonding within a polyatomic ion is covalent, the topic of our next section.

Formula	Name	Medical Use
AgNO <sub>3</sub>	Silver nitrate	Topical anti-infective agent; in solution, used to treat and prevent eye infection, especially in newborn infants
BaSO <sub>4</sub>	Barium sulfate	Given as a contrast medium—or image enhancer—in X-rays
CaSO <sub>4</sub>	Calcium sulfate	Used to make plaster casts
KMnO <sub>4</sub>	Potassium permanganate	Topical anti-infective agent; often used to treat fungal infections on the feet
KI	Potassium iodide	Antiseptic and disinfectant; given orally to prevent radiation sickness
Li <sub>2</sub> CO <sub>3</sub>	Lithium carbonate	Used to treat bipolar (manic-depressive) disorders
MgSO <sub>4</sub>	Magnesium sulfate	Used to treat eclampsia (a condition that can occur during pregnancy in which elevated blood pressure leads to convulsions)
Mg(OH) <sub>2</sub>	Magnesium hydroxide	Antacid and mild laxative
NaHCO <sub>3</sub>	Sodium bicarbonate	Oral antacid used to treat heartburn and acid stomach; injected into blood to treat severe acidosis (acidification of the blood)
NaF	Sodium fluoride	Used to strengthen teeth
ZnO	Zinc oxide	Used as protection from ultraviolet light in sun

## 9.5 Covalent Bonding: Lewis Structures

The Lewis model provides us with a simple and useful model for covalent bonding. In this model, we represent molecular compounds with *Lewis structures*, which depict neighboring atoms as sharing some (or all) of their valence electrons in order to attain octets (or duets for hydrogen).

### Single Covalent Bonds

To see how covalent bonding is conceived in terms of the Lewis model, consider hydrogen and oxygen, which have the following Lewis symbols:

In water, these atoms share their unpaired valence electrons so that each hydrogen atom gets a duet and the oxygen atom gets an octet as represented with this Lewis structure:

The shared electrons—those that appear in the space between the two atoms—count toward the octets (or duets) of *both of the atoms* (shown at left).

A shared pair of electrons is called a **bonding pair**, whereas a pair that is associated with only one atom—and therefore not involved in bonding—is a **lone pair** (shown at left). Lone pair electrons are also called **nonbonding electrons**.

We often represent a bonding pair of electrons by a dash to emphasize that it constitutes a chemical bond:

The Lewis model also shows why the halogens form diatomic molecules. Consider the Lewis symbol for chlorine:

If two Cl atoms pair together, they can each have an octet:

Elemental chlorine does indeed exist as a diatomic molecule in nature, just as the Lewis model predicts. The same is true for the other halogens.

Similarly, the Lewis model predicts that hydrogen, which has the Lewis symbol:

should exist as  $\text{H}_2$ . When two hydrogen atoms share their valence electrons, each gets a duet, a stable configuration for hydrogen:

Again, the Lewis model predicts correctly. In nature, elemental hydrogen exists as  $\text{H}_2$  molecules.

### Double and Triple Covalent Bonds

In the Lewis model, two atoms may share more than one electron pair to get octets. For example, two oxygen atoms share two electron pairs in order for each oxygen atom to have an octet:

Each oxygen atom has an octet because *the additional bonding pair counts toward the octet of both oxygen atoms*. When two atoms share two electron pairs, the resulting bond is a **double bond**. In general, double bonds are shorter and stronger than single bonds. Atoms can also share three electron pairs. Consider the Lewis structure of  $\text{N}_2$ . Since each N atom has five valence electrons, the Lewis structure for  $\text{N}_2$  has 10 electrons. Both nitrogen atoms attain octets by sharing three electron pairs:

Keep in mind that one dash always stands for two electrons (a single bonding pair).

The bond is a **triple bond**. Triple bonds are even shorter and stronger than double bonds. When we examine nitrogen in nature, we find that it exists as a diatomic molecule with a very strong bond between the two nitrogen atoms. The bond is so strong that it is difficult to break, making  $\text{N}_2$  a relatively unreactive molecule.

We explore the characteristics of multiple bonds more fully in Section 9.10.

## Covalent Bonding: Models and Reality

The Lewis model predicts the properties of molecular compounds in many ways. First, it accounts for why particular combinations of atoms form molecules and others do not. For example, why is water  $\text{H}_2\text{O}$  and not  $\text{H}_3\text{O}$ ? We can write a good Lewis structure for  $\text{H}_2\text{O}$ , but not for  $\text{H}_3\text{O}$ .

In this way, the Lewis model predicts that  $\text{H}_2\text{O}$  should be stable, while  $\text{H}_3\text{O}$  should not be, and that is in fact the case. However, if we remove an electron from  $\text{H}_3\text{O}$ , we get  $\text{H}_3\text{O}^+$ , which should be stable (according to the Lewis model) because, when we remove the extra electron, oxygen attains an octet:

This ion, called the hydronium ion, is in fact stable in aqueous solutions (see Section 4.8).

The Lewis model predicts other possible combinations for hydrogen and oxygen as well. For example, we can write a Lewis structure for  $\text{H}_2\text{O}_2$  as follows:

Indeed,  $\text{H}_2\text{O}_2$ , or hydrogen peroxide, exists and is often used as a disinfectant and a bleach.

The Lewis model also accounts for why covalent bonds are highly *directional*. The attraction between two covalently bonded atoms is due to the sharing of one or more electron pairs in the space between them. Thus, each bond links just one specific pair of atoms—in contrast to ionic bonds, which are *nondirectional* and hold together an entire array of ions. As a result, the fundamental units of covalently bonded compounds are individual molecules. These molecules can interact with one another in a number of different ways that we cover in Chapter 11. However, in covalently bonded molecular compounds the interactions *between* molecules (intermolecular forces) are generally much weaker than the bonding interactions within a molecule (intramolecular forces), as shown in Figure 9.5▼.

### Molecular Compound

◀ **FIGURE 9.5 Intermolecular and Intramolecular Forces** The covalent bonds between atoms of a molecule are much stronger than the interactions between molecules. To boil a molecular substance, we simply have to overcome the relatively weak intermolecular forces, so molecular compounds generally have low boiling points.

When a molecular compound melts or boils, the molecules themselves remain intact—only the relatively weak interactions between molecules must be overcome. Consequently, molecular compounds tend to have lower melting and boiling points than ionic compounds.

## CONCEPTUAL CONNECTION 9.3

**Energy and the Octet Rule** What is wrong with the following statement?  
*Atoms form bonds in order to satisfy the octet rule.*

## 9.6 Electronegativity and Bond Polarity

We know from Chapter 7 that representing electrons with dots, as we do in the Lewis model, is a drastic oversimplification. As we have already discussed, this does not invalidate the Lewis model—which is an extremely useful theory—but we must recognize and compensate for its inherent limitations. One limitation of representing electrons as dots, and covalent bonds as two dots shared between two atoms, is that the shared electrons always appear to be *equally* shared. Such is not the case.

For example, consider the Lewis structure of hydrogen fluoride:

The two shared electron dots sitting between the H and the F atoms appear to be equally shared between hydrogen and fluorine. However, based on laboratory measurements, we know they are not. When HF is put in an electric field, the molecules orient as shown in Figure 9.6. From this observation, we know that the hydrogen side of the molecule

► **FIGURE 9.6** Orientation of Gaseous Hydrogen Fluoride in an Electric Field **Field** Because one side of the HF molecule has a slight positive charge and the other side a slight negative charge, the molecules align themselves with an external electric field.

must have a slight positive charge and the fluorine side of the molecule must have a slight negative charge. We represent this partial separation of charge as follows:

The red arrow on the left, with a positive sign on the tail, indicates that the left side of the molecule has a partial positive charge and that the right side of the molecule (the side the arrow is pointing *toward*) has a partial negative charge. Similarly, the  $\delta^+$  (delta plus) represents a partial positive charge and the  $\delta^-$  (delta minus) represents a partial negative charge. Does this make the bond ionic? No. In an ionic bond, the electron is essentially *transferred* from one atom to another. In HF, the electron is *unequally shared*. In other words, even though the Lewis structure of HF portrays the bonding electrons as residing *between* the two atoms, in reality the electron density is greater on the fluorine atom than on the hydrogen atom (Figure 9.7). The bond is said to be *polar*—having a positive pole and a negative pole. A **polar covalent bond** is intermediate in nature between a pure covalent bond and an ionic bond. In fact, the categories of pure covalent and ionic are really two extremes within a broad continuum. Most covalent bonds between dissimilar atoms are actually *polar covalent*—somewhere between the two extremes.

▲ **FIGURE 9.7** Electrostatic Potential Map for the HF Molecule The F end of the molecule, with its partial negative charge, is yellow/pink; the H end, with its partial positive charge, is blue.

## Electronegativity

The ability of an atom to attract electrons to itself in a chemical bond (which results in polar and ionic bonds) is called **electronegativity**. We say that fluorine is more *electronegative* than hydrogen because it takes a greater share of the electron density in HF.

The American chemist Linus Pauling (1901–1994) quantified electronegativity in his classic book, *The Nature of the Chemical Bond*. Pauling compared the bond energy—the energy required to break a bond—of a heteronuclear diatomic molecule such as HF with the bond energies of its homonuclear counterparts, in this case  $\text{H}_2$  and  $\text{F}_2$ . The bond energies of  $\text{H}_2$  and  $\text{F}_2$  are 436 kJ/mol and 155 kJ/mol, respectively. Pauling reasoned that if the HF bond were purely covalent—that is, if the electrons were shared exactly equally—the bond energy of HF should simply be an average of the bond energies of  $\text{H}_2$  and  $\text{F}_2$ , which would be 296 kJ/mol. However, the bond energy of HF is experimentally measured to be 565 kJ/mol. Pauling suggested that the additional bond energy was due to the *ionic character* of the bond. Based on many such comparisons of bond energies, and by arbitrarily assigning an electronegativity of 4.0 to fluorine (the most electronegative element on the periodic table), Pauling developed the electronegativity values shown in Figure 9.8▼.

For main-group elements, notice the following periodic trends in electronegativity from Figure 9.8:

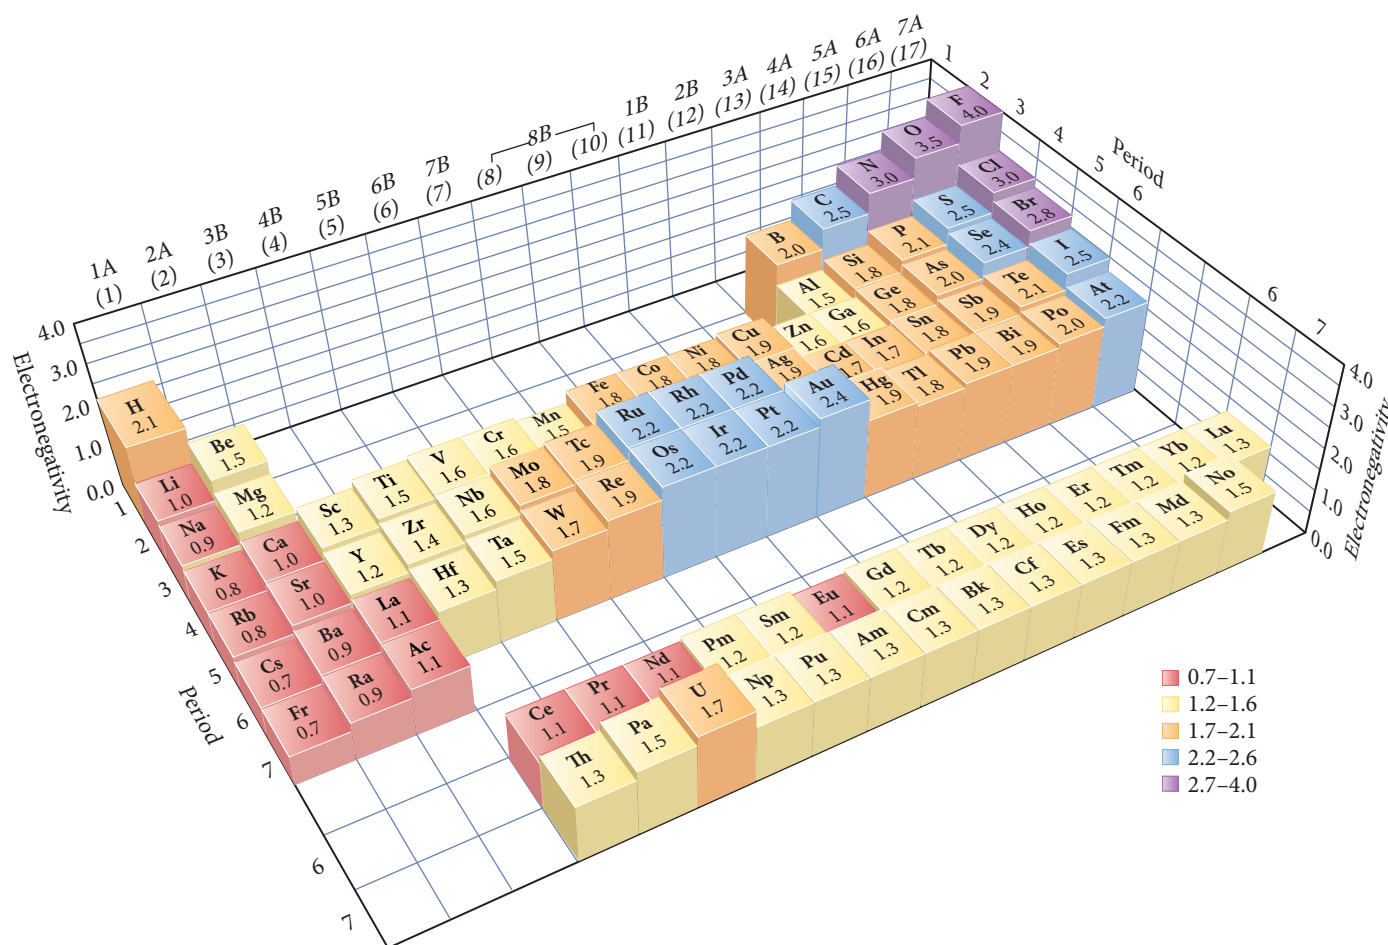

- Electronegativity generally increases across a period in the periodic table.
- Electronegativity generally decreases down a column in the periodic table.
- Fluorine is the most electronegative element.
- Francium is the least electronegative element (sometimes called the most *electropositive*).

We cover the concept of bond energy in more detail in Section 9.10.

Pauling's “average” bond energy was actually calculated a little bit differently than the normal average shown here. He took the square root of the product of the bond energies of the homonuclear counterparts as the “average.”

▼ **FIGURE 9.8 Electronegativities of the Elements** Electronegativity generally increases as we move across a row in the periodic table and decreases as we move down a column.

### Trends in Electronegativity

The periodic trends in electronegativity are consistent with other periodic trends we have seen. In general, electronegativity is inversely related to atomic size—the larger the atom, the less ability it has to attract electrons to itself in a chemical bond.

## CONCEPTUAL CONNECTION 9.4

**Periodic Trends in Electronegativity** Arrange these elements in order of decreasing electronegativity: P, Na, N, Al.

### Bond Polarity, Dipole Moment, and Percent Ionic Character

The degree of polarity in a chemical bond depends on the electronegativity difference (sometimes abbreviated  $\Delta\text{EN}$ ) between the two bonding atoms. The greater the electronegativity difference, the more polar the bond. If two atoms with identical electronegativities form a covalent bond, they share the electrons equally, and the bond is purely covalent or *nonpolar*. For example, the chlorine molecule, composed of two chlorine atoms (which necessarily have identical electronegativities), has a covalent bond in which electrons are evenly shared:

If there is a large electronegativity difference between the two atoms in a bond, such as normally occurs between a metal and a nonmetal, the electron from the metal is almost completely transferred to the nonmetal, and the bond is ionic. For example, sodium and chlorine form an ionic bond:

If there is an intermediate electronegativity difference between the two atoms, such as between two different nonmetals, then the bond is polar covalent. For example, HCl has a polar covalent bond:

Although all attempts to divide the bond polarity continuum into specific regions are necessarily arbitrary, it is helpful to classify bonds as covalent, polar covalent, and ionic, based on the electronegativity difference between the bonding atoms as shown in Table 9.1 and Figure 9.9►.

**TABLE 9.1** The Effect of Electronegativity Difference on Bond Type

Electronegativity Difference ( $\Delta\text{EN}$ )	Bond Type	Example
Small (0–0.4)	Covalent	$\text{Cl}_2$
Intermediate (0.4–2.0)	Polar covalent	HCl
Large (2.0+)	Ionic	NaCl

We quantify the polarity of a bond by the size of its dipole moment. A **dipole moment** ( $\mu$ ) occurs any time there is a separation of positive and negative charge. The magnitude of a dipole moment created by separating two particles of equal but opposite charges of magnitude  $q$  by a distance  $r$  is given by the equation:

$$\mu = qr \quad [9.1]$$

## The Continuum of Bond Types

◀ **FIGURE 9.9** Electronegativity Difference ( $\Delta EN$ ) and Bond Type

We can get a sense for the dipole moment of a completely ionic bond by calculating the dipole moment that results from separating a proton and an electron ( $q = 1.6 \times 10^{-19} \text{ C}$ ) by a distance of  $r = 130 \text{ pm}$  (the approximate length of a short chemical bond):

$$\begin{aligned}\mu &= qr \\ &= (1.6 \times 10^{-19} \text{ C})(130 \times 10^{-12} \text{ m}) \\ &= 2.1 \times 10^{-29} \text{ C} \cdot \text{m} \\ &= 6.2 \text{ D}\end{aligned}$$

The debye (D) is the unit commonly used for reporting dipole moments ( $1 \text{ D} = 3.34 \times 10^{-30} \text{ C} \cdot \text{m}$ ). Based on this calculation, we would expect the dipole moment of completely ionic bonds with bond lengths close to  $130 \text{ pm}$  to be about  $6 \text{ D}$ . The smaller the magnitude of the charge separation, and the smaller the distance between the charges, the smaller the dipole moment. Table 9.2 lists the dipole moments of several molecules along with the electronegativity differences of their atoms.

**TABLE 9.2** Dipole Moments of Several Molecules in the Gas Phase

Molecule	$\Delta EN$	Dipole Moment (D)
$\text{Cl}_2$	0	0
$\text{ClF}$	1.0	0.88
$\text{HF}$	1.9	1.82
$\text{LiF}$	3.0	6.33

By comparing the *actual* dipole moment of a bond to what the dipole moment would be if the electron were completely transferred from one atom to the other, we can get a sense of the degree to which the electron is transferred (or the degree to which the bond is ionic). The **percent ionic character** is the ratio of a bond's actual dipole moment to the dipole moment it would have if the electron were completely transferred from one atom to the other, multiplied by 100%:

$$\text{Percent ionic character} = \frac{\text{measured dipole moment of bond}}{\text{dipole moment if electron were completely transferred}} \times 100\%$$

For example, suppose a diatomic molecule with a bond length of  $130 \text{ pm}$  has a dipole moment of  $3.5 \text{ D}$ . We previously calculated that separating a proton and an electron by  $130 \text{ pm}$  results in a dipole moment of  $6.2 \text{ D}$ . Therefore, the percent ionic character of the bond is 56%:

$$\begin{aligned}\text{Percent ionic character} &= \frac{3.5 \text{ D}}{6.2 \text{ D}} \times 100\% \\ &= 56\%\end{aligned}$$

A bond in which an electron is completely transferred from one atom to another would have 100% ionic character (although even the most ionic bonds do not reach this ideal). Figure 9.10 shows the percent ionic character of a number of diatomic gas-phase molecules plotted against the electronegativity difference between the bonding atoms. As expected, the percent ionic character generally increases as the electronegativity difference increases. However, as we can see, no bond is 100% ionic. In general, bonds with greater than 50% ionic character are referred to as ionic bonds.

▼ **FIGURE 9.10** Percent Ionic Character versus Electronegativity Difference for Some Compounds

**Example 9.3** Classifying Bonds as Pure Covalent, Polar Covalent, or Ionic

Classify the bond formed between each pair of atoms as covalent, polar covalent, or ionic.

- (a) Sr and F                      (b) N and Cl                      (c) N and O

**SOLUTION**

- (a) In Figure 9.8, find the electronegativity of Sr (1.0) and of F (4.0). The electronegativity difference ( $\Delta\text{EN}$ ) is  $\Delta\text{EN} = 4.0 - 1.0 = 3.0$ . Using Table 9.1, classify this bond as ionic.
- (b) In Figure 9.8, find the electronegativity of N (3.0) and of Cl (3.0). The electronegativity difference ( $\Delta\text{EN}$ ) is  $\Delta\text{EN} = 3.0 - 3.0 = 0$ . Using Table 9.1, classify this bond as covalent.
- (c) In Figure 9.8, find the electronegativity of N (3.0) and of O (3.5). The electronegativity difference ( $\Delta\text{EN}$ ) is  $\Delta\text{EN} = 3.5 - 3.0 = 0.5$ . Using Table 9.1, classify this bond as polar covalent.

**FOR PRACTICE 9.3** Determine if the bond formed between each pair of atoms is pure covalent, polar covalent, or ionic.

- (a) I and I                      (b) Cs and Br                      (c) P and O

**CONCEPTUAL CONNECTION 9.5**

**Percent Ionic Character** The  $\text{HCl(g)}$  molecule has a bond length of 127 pm and a dipole moment of 1.08 D. Without doing detailed calculations, identify the best estimate for its percent ionic character.

- (a) 5%                      (b) 15%                      (c) 50%                      (d) 80%

**Writing Lewis Structures for Molecular Compound**

**9.7 Lewis Structures of Molecular Compounds and Polyatomic Ions**

We now turn to the basic sequence of steps involved in actually writing Lewis structures for given combinations of atoms.

**Writing Lewis Structures for Molecular Compounds**

To write a Lewis structure for a molecular compound, follow these steps:

- 1. Write the correct skeletal structure for the molecule.** The Lewis structure of a molecule must have the atoms in the correct positions. For example, you could not write a Lewis structure for water if you started with the hydrogen atoms next to each other and the oxygen atom at the end ( $\text{H H O}$ ). In nature, oxygen is the central atom and the hydrogen atoms are *terminal* (at the ends). The correct skeletal structure is  $\text{H O H}$ . The only way to determine the skeletal structure of a molecule with absolute certainty is to examine its structure experimentally. However, you can write likely skeletal structures by remembering two guidelines. First, *hydrogen atoms are always terminal*. Hydrogen does not ordinarily occur as a central atom because central atoms must form at least two bonds, and hydrogen, which has only a single valence electron to share and requires only a duet, can form just one bond. Second, *put the more electronegative elements in terminal positions* and the less electronegative elements (other than hydrogen) in the central position. Later in this section, you will learn how to distinguish between competing skeletal structures by applying the concept of formal charge.
- 2. Calculate the total number of electrons for the Lewis structure by summing the valence electrons of each atom in the molecule.** Remember that the number of valence electrons for any main-group element is equal to its group number in the periodic table. *If you are writing a Lewis structure for a polyatomic ion, you must consider the charge of the ion when calculating the total number of electrons.* Add one electron for each negative charge and subtract one electron for each positive charge. Don't worry about which electron comes from which atom—only the total number is important.

Often, chemical formulas provide clues to how the atoms are bonded together. For example,  $\text{CH}_3\text{OH}$  indicates that three hydrogen atoms and the oxygen atom are bonded to the carbon atom, but the fourth hydrogen atom is bonded to the oxygen atom.

There are a few exceptions to this rule, such as diborane ( $\text{B}_2\text{H}_6$ ), which contains *bridging hydrogens*, but these are rare and cannot be adequately addressed by the Lewis model.

- 3. Distribute the electrons among the atoms, giving octets (or duets in the case of hydrogen) to as many atoms as possible.** Begin by placing two electrons between every two atoms. These represent the minimum number of bonding electrons. Then distribute the remaining electrons as lone pairs, first to terminal atoms and then to the central atom, giving octets (or duets for hydrogen) to as many atoms as possible.
- 4. If any atoms lack an octet, form double or triple bonds as necessary to give them octets.** Do this by moving lone electron pairs from terminal atoms into the bonding region with the central atom.

Sometimes distributing all the remaining electrons to the central atom results in more than an octet. This is called an expanded octet, which we discuss in Section 9.9.

In the left column that follows, there is an abbreviated version of the procedure for writing Lewis structures; the center and right columns feature two examples of applying the procedure.

### Procedure for ...

Writing Lewis Structures for Molecular Compounds	<b>Example 9.4</b>  <b>Writing Lewis Structures</b> Write the Lewis structure for CO <sub>2</sub> .	<b>Example 9.5</b> <b>Writing Lewis Structures</b> Write the Lewis structure for NH <sub>3</sub> .
1. Write the correct skeletal structure for the molecule.	<b>SOLUTION</b> Because carbon is the less electronegative atom, put it in the central position. $\text{O C O}$	<b>SOLUTION</b> Since hydrogen is always terminal, put nitrogen in the central position. $\begin{array}{c} \text{H N H} \\   \\ \text{H} \end{array}$
2. Calculate the total number of electrons for the Lewis structure by summing the valence electrons of each atom in the molecule.	Total number of electrons for Lewis structure = $\left( \begin{array}{c} \text{number of} \\ \text{valence} \\ \text{e}^- \text{ for C} \end{array} \right) + 2 \left( \begin{array}{c} \text{number of} \\ \text{valence} \\ \text{e}^- \text{ for O} \end{array} \right)$ $= 4 + 2(6) = 16$	Total number of electrons for Lewis structure = $\left( \begin{array}{c} \text{number of} \\ \text{valence} \\ \text{e}^- \text{ for N} \end{array} \right) + 3 \left( \begin{array}{c} \text{number of} \\ \text{valence} \\ \text{e}^- \text{ for H} \end{array} \right)$ $= 5 + 3(1) = 8$
3. Distribute the electrons among the atoms, giving octets (or duets for hydrogen) to as many atoms as possible. Begin with the bonding electrons, and then proceed to lone pairs on terminal atoms, and finally to lone pairs on the central atom.	Bonding electrons are first. $\text{O}:\text{C}:\text{O}$ (4 of 16 electrons used) Lone pairs on terminal atoms are next. $:\ddot{\text{O}}:\text{C}:\ddot{\text{O}}:$ (16 of 16 electrons used)	Bonding electrons are first. $\begin{array}{c} \text{H}:\text{N}:\text{H} \\   \\ \text{H} \end{array}$ (6 of 8 electrons used) Lone pairs on terminal atoms are next, but none is needed on hydrogen. Lone pairs on the central atom are last. $\begin{array}{c} \text{H}-\ddot{\text{N}}-\text{H} \\   \\ \text{H} \end{array}$ (8 of 8 electrons used)
4. If any atom lacks an octet, form double or triple bonds as necessary until all atoms have octets.	Since carbon lacks an octet, move lone pairs from the oxygen atoms to bonding regions to form double bonds. $\begin{array}{c} :\ddot{\text{O}}:\text{C}:\ddot{\text{O}}: \\ \downarrow \\ :\text{O}=\text{C}=\text{O}: \end{array}$	Since all of the atoms have octets (or duets for hydrogen), the Lewis structure for NH <sub>3</sub> is complete as shown in the previous step.
	<b>FOR PRACTICE 9.4</b> Write the Lewis structure for CO.	<b>FOR PRACTICE 9.5</b> Write the Lewis structure for H <sub>2</sub> CO.

## Writing Lewis Structures for Polyatomic Ions

Write Lewis structures for polyatomic ions by following the same procedure, but pay special attention to the charge of the ion when calculating the number of electrons for the Lewis structure. Add one electron for each negative charge and subtract one electron for each positive charge. Write the Lewis structure for a polyatomic ion within brackets with the charge of the ion in the upper right-hand corner, outside the bracket.

### Example 9.6 Writing Lewis Structures for Polyatomic Ions

Write the Lewis structure for the  $\text{NH}_4^+$  ion.

#### SOLUTION

Begin by writing the skeletal structure. Since hydrogen is always terminal, put the nitrogen atom in the central position.

Calculate the total number of electrons for the Lewis structure by summing the number of valence electrons for each atom and subtracting 1 for the  $1+$  charge.

$$\begin{aligned} &\text{Total number of electrons for Lewis structure} \\ &= (\text{number of valence } e^- \text{ in N}) + 4 (\text{number of valence } e^- \text{ in H}) - 1 \\ &= 5 + 4(1) - 1 \\ &= 8 \end{aligned}$$

Subtract  $1 e^-$  to account for  $1+$  charge of ion.

Place two bonding electrons between every two atoms. Since all of the atoms have complete octets, no double bonds are necessary.

(8 of 8 electrons used)

Lastly, write the Lewis structure in brackets with the charge of the ion in the upper right-hand corner.

**FOR PRACTICE 9.6** Write the Lewis structure for the hypochlorite ion,  $\text{ClO}^-$ .

#### Resonance and Formal Charge

## 9.8 Resonance and Formal Charge

We need two additional concepts to write the best possible Lewis structures for a large number of compounds. The concepts are *resonance*, which is relevant when two or more valid Lewis structures can be drawn for the same compound, and *formal charge*, an electron bookkeeping system that allows us to discriminate between alternative Lewis structures.

### Resonance

For some molecules, we can write more than one valid Lewis structure. For example, consider writing a Lewis structure for  $\text{O}_3$ . The following two Lewis structures, with the double bond on alternate sides, are equally correct:

In cases such as this—where there are two or more valid Lewis structures for the same molecule—we find that, in nature, the molecule is an *average* of the two Lewis structures. Both of the two Lewis structures for  $\text{O}_3$  predict that  $\text{O}_3$  contains two

different bonds (one double bond and one single bond). However, when we experimentally examine the structure of  $\text{O}_3$ , we find that the bonds in the  $\text{O}_3$  molecule are equivalent and each is intermediate in strength and length between a double bond and single bond. We account for this by representing the molecule with both structures, called *resonance structures*, with a double-headed arrow between them:

A **resonance structure** is one of two or more Lewis structures that have the same skeletal formula (the atoms are in the same locations), but different electron arrangements. The actual structure of the molecule is intermediate between the two (or more) resonance structures and is called a **resonance hybrid**. The term *hybrid* comes from breeding and means the offspring of two animals or plants of different varieties or breeds. If we breed a Labrador retriever with a German shepherd, we get a *hybrid* that is intermediate between the two breeds (Figure 9.11(a) ▼). Similarly, the actual structure of a resonance hybrid is intermediate between the two (or more) resonance structures (Figure 9.11(b) ▼). The only structure that actually exists is the hybrid structure—the individual resonance structures do not exist and are merely a way to describe the actual structure. Notice that the actual structure of ozone has two equivalent bonds and a bent geometry (we discuss molecular geometries in Chapter 10).

▲ **FIGURE 9.11 Hybridization** Just as the offspring of two different dog breeds is a hybrid that is intermediate between the two breeds (a), the structure of a resonance hybrid is intermediate between that of the contributing resonance structures (b).

The concept of resonance is an adaptation of the Lewis model that helps account for the complexity of actual molecules. In the Lewis model, electrons are *localized* either on one atom (lone pair) or between atoms (bonding pair). However, in nature, the electrons in molecules are often *delocalized* over several atoms or bonds. The delocalization of electrons lowers their energy; it stabilizes them (for reasons that are beyond the scope of this book). Resonance depicts two or more structures with the electrons in different places in an attempt to more accurately reflect the delocalization of electrons. In the real hybrid structure, an average between the resonance structures, the electrons are more spread out (or delocalized) than in any of the resonance structures. The resulting stabilization of the electrons (that is, the lowering of their potential energy due to delocalization) is sometimes called *resonance stabilization*. Resonance stabilization makes an important contribution to the stability of many molecules.

**Example 9.7** Writing Resonance Structures

Write a Lewis structure for the  $\text{NO}_3^-$  ion. Include resonance structures.

**SOLUTION**

Begin by writing the skeletal structure. Since nitrogen is the least electronegative atom, put it in the central position.	$\begin{array}{c} \text{O} \\ \text{O N O} \end{array}$
Calculate the total number of electrons for the Lewis structure by summing the number of valence electrons for each atom and adding 1 for the 1- charge.	<p>Total number of electrons for Lewis structure  <math>= (\text{number of valence } e^- \text{ in N}) + 3 (\text{number of valence } e^- \text{ in O}) + 1</math>  <math>= 5 + 3(6) + 1</math>  <math>= 24</math></p> <p style="text-align: right;">Add 1 <math>e^-</math> to account for 1- charge of ion.</p>
Place two bonding electrons between each pair of atoms.	$\begin{array}{c} \text{O} \\ \text{O}:\ddot{\text{N}}:\text{O} \end{array}$ <p>(6 of 24 electrons used)</p>
Distribute the remaining electrons, first to terminal atoms. There are not enough electrons to complete the octet on the central atom.	$\begin{array}{c} :\ddot{\text{O}}: \\ :\ddot{\text{O}}:\ddot{\text{N}}:\ddot{\text{O}}: \end{array}$ <p>(24 of 24 electrons used)</p>
Form a double bond by moving a lone pair from one of the oxygen atoms into the bonding region with nitrogen. Enclose the structure in brackets and include the charge.	$\left[ \begin{array}{c} :\ddot{\text{O}}: \\ :\ddot{\text{O}}:\ddot{\text{N}}:\ddot{\text{O}}: \end{array} \right]^-$ <p style="text-align: center;">or</p> $\left[ \begin{array}{c} :\ddot{\text{O}}: \\ :\ddot{\text{O}}-\text{N}=\ddot{\text{O}}: \end{array} \right]^-$
Since the double bond can form equally well with any of the three oxygen atoms, write all three structures as resonance structures. (The actual space-filling model of $\text{NO}_3^-$ is shown here for comparison. Note that all three bonds are equal in length.)	$\left[ \begin{array}{c} :\ddot{\text{O}}: \\ :\ddot{\text{O}}-\text{N}=\ddot{\text{O}}: \end{array} \right]^- \longleftrightarrow \left[ \begin{array}{c} :\text{O}: \\ :\ddot{\text{O}}=\text{N}-\ddot{\text{O}}: \end{array} \right]^- \longleftrightarrow \left[ \begin{array}{c} :\ddot{\text{O}}: \\ :\ddot{\text{O}}=\text{N}-\ddot{\text{O}}: \end{array} \right]^-$ <div style="text-align: center;">  <p><math>\text{NO}_3^-</math></p> </div>

**FOR PRACTICE 9.7** Write a Lewis structure for the  $\text{NO}_2^-$  ion. Include resonance structures.

In the examples of resonance hybrids that we have examined so far, the contributing structures have been equivalent (or equally valid) Lewis structures. In these cases, the true structure is an equally weighted average of the resonance structures. In some cases, however, we can write resonance structures that are not equivalent. For reasons that we cover in the material that follows—such as formal charge—one resonance structure may be somewhat better than another. In such cases, the true structure is still an average of the resonance structures, but the better resonance structure contributes more to the true structure. In other words, multiple nonequivalent resonance structures may be weighted differently in their contributions to the true overall structure of a molecule (see Example 9.8).

**Formal Charge**

*Formal charge* is a fictitious charge assigned to each atom in a Lewis structure that helps us to distinguish among competing Lewis structures. The **formal charge** of an atom

in a Lewis structure is *the charge it would have if all bonding electrons were shared equally between the bonded atoms*. In other words, formal charge is the calculated charge for an atom if we completely ignore the effects of electronegativity. For example, we know that because fluorine is more electronegative than hydrogen, HF has a dipole moment—the hydrogen atom has a slight positive charge and the fluorine atom has a slight negative charge. However, the *formal charges* of hydrogen and fluorine in HF (the calculated charges if we ignore their differences in electronegativity) are both zero:

We can calculate the formal charge on any atom as the difference between the number of valence electrons in the atom and the number of electrons that it “owns” in a Lewis structure. An atom in a Lewis structure can be thought of as “owning” all of its nonbonding electrons and one-half of its bonding electrons:

$$\text{Formal charge} = \text{number of valence electrons} - (\text{number of nonbonding electrons} + \frac{1}{2} \text{ number of bonding electrons})$$

So the formal charge of hydrogen in HF is 0:

$$\text{Formal charge} = 1 - [0 + \frac{1}{2}(2)] = 0$$

Number of valence electrons for H      Number of electrons that H “owns” in the Lewis structure

Similarly, we calculate the formal charge of fluorine in HF as 0:

$$\text{Formal charge} = 7 - [6 + \frac{1}{2}(2)] = 0$$

Number of valence electrons for F      Number of electrons that F “owns” in the Lewis structure

The concept of formal charge is useful because it can help us distinguish between competing skeletal structures or competing resonance structures. In general, when we calculate formal charges, these four rules apply:

1. The sum of all formal charges in a neutral molecule must be zero.
2. The sum of all formal charges in an ion must equal the charge of the ion.
3. Small (or zero) formal charges on individual atoms are better than large ones.
4. When formal charge cannot be avoided, negative formal charge should reside on the most electronegative atom.

We can use formal charge to determine which of the competing skeletal structures for hydrogen cyanide shown here is best (or most stable). Notice that both skeletal structures satisfy the octet rule equally. The formal charge of each atom in the structure is calculated below it.

	Structure A			Structure B		
	H	— C	≡ N:	H	— N	≡ C:
number of valence e <sup>−</sup>	1	4	5	1	5	4
−number of nonbonding e <sup>−</sup>	−0	−0	−2	−0	−0	−2
− $\frac{1}{2}$ (number of bonding e <sup>−</sup> )	− $\frac{1}{2}$ (2)	− $\frac{1}{2}$ (8)	− $\frac{1}{2}$ (6)	− $\frac{1}{2}$ (2)	− $\frac{1}{2}$ (8)	− $\frac{1}{2}$ (6)
Formal charge	0	0	0	0	+1	−1

As required, the sum of the formal charges for each of these structures is zero (as it always must be for neutral molecules). However, structure B has formal charges on both the N atom and the C atom, while structure A has no formal charges on any atom. Furthermore, in structure B, the negative formal charge is not on the most electronegative element (nitrogen is more electronegative than carbon). Consequently, structure A is the better skeletal structure. Since atoms in the middle of a molecule tend to have more bonding electrons and fewer nonbonding electrons, they also tend to have more positive formal charges. Consequently, the best skeletal structure usually has the least electronegative atom in the central position, as we learned in step 1 of our procedure for writing Lewis structures.

Both HCN and HNC exist, but—as predicted by formal charge—HCN is more stable than HNC.

### Example 9.8 Assigning Formal Charges

Assign formal charges to each atom in the resonance structures of the cyanate ion ( $\text{OCN}^-$ ). Which resonance structure is likely to contribute most to the correct structure of  $\text{OCN}^-$ ?

#### SOLUTION

Calculate the formal charge on each atom by finding the number of valence electrons and subtracting the number of nonbonding electrons and one-half the number of bonding electrons.

	A [ $\ddot{\text{O}}-\text{C}\equiv\text{N}]^-$			B [ $\ddot{\text{O}}=\text{C}=\ddot{\text{N}}:]^-$			C [ $\text{O}\equiv\text{C}-\ddot{\text{N}}:]^-$		
Number of valence $e^-$	6	4	5	6	4	5	6	4	5
–number of nonbonding $e^-$	–6	–0	–2	–4	–0	–4	–2	–0	–6
$-\frac{1}{2}(\text{number of bonding } e^-)$	–1	–4	–3	–2	–4	–2	–3	–4	–1
Formal charge	–1	0	0	0	0	–1	+1	0	–2

The sum of all formal charges for each structure is  $-1$ , as it should be for a  $1^-$  ion. Structures A and B have the fewest non-zero formal charges and are preferred over structure C. Structure A is preferable to B because it has the negative formal charge on the more electronegative atom. You therefore expect structure A to make the biggest contribution to the resonance forms of the cyanate ion.

**FOR PRACTICE 9.8** Assign formal charges to each atom in the resonance structures of  $\text{N}_2\text{O}$ . Which resonance structure is likely to contribute most to the correct structure of  $\text{N}_2\text{O}$ ?

**FOR MORE PRACTICE 9.8** Assign formal charges to each of the atoms in the nitrate ion ( $\text{NO}_3^-$ ). The Lewis structure for the nitrate ion is shown in Example 9.7.

### Example 9.9 Drawing Resonance Structures and Assigning Formal Charge for Organic Compounds

Draw the Lewis structure (including resonance structures) for nitromethane ( $\text{CH}_3\text{NO}_2$ ). For each resonance structure, assign formal charges to all atoms that have formal charge.

#### SOLUTION

Begin by writing the skeletal structure. For organic compounds, the condensed structural formula (in this case  $\text{CH}_3\text{NO}_2$ ) indicates how the atoms are connected.

Calculate the total number of electrons for the Lewis structure by summing the number of valence electrons for each atom.	Total number of electrons for Lewis structure $= (\# \text{ valence } e^- \text{ in C}) + 3(\# \text{ valence } e^- \text{ in H})$ $+ (\# \text{ valence } e^- \text{ in N}) + 2(\# \text{ valence } e^- \text{ in O})$ $= 4 + 3(1) + 5 + 2(6)$ $= 24$
Place a dash between each pair of atoms to indicate a bond. Each dash represents two electrons.	$\begin{array}{c} \text{H} \quad \text{O} \\   \quad   \\ \text{H}-\text{C}-\text{N}-\text{O} \\   \\ \text{H} \end{array}$ (12 of 24 electrons used)
Distribute the remaining electrons, first to terminal atoms then to interior atoms.	$\begin{array}{c} \text{H} \quad :\ddot{\text{O}}: \\   \quad   \\ \text{H}-\text{C}-\text{N}-\ddot{\text{O}}: \\   \\ \text{H} \end{array}$ (24 of 24 electrons used)
If there are not enough electrons to complete the octets on the interior atoms, form double bonds by moving lone pair electrons from terminal atoms into the bonding region with interior atoms.	$\begin{array}{c} \text{H} \quad :\ddot{\text{O}}: \\   \quad    \\ \text{H}-\text{C}-\text{N}-\ddot{\text{O}}: \\   \\ \text{H} \end{array}$
Draw any necessary resonance structures by moving only electron dots. (In this case, you can form a double bond between the nitrogen atom and the other oxygen atom.)	$\begin{array}{c} \text{H} \quad :\ddot{\text{O}}: \\   \quad    \\ \text{H}-\text{C}-\text{N}-\ddot{\text{O}}: \end{array} \longleftrightarrow \begin{array}{c} \text{H} \quad :\ddot{\text{O}}: \\   \quad   \\ \text{H}-\text{C}-\text{N}=\ddot{\text{O}}: \end{array}$
Assign formal charges (FC) to each atom. $\text{FC} = \# \text{ valence } e^- - (\# \text{ nonbonding } e^- + \frac{1}{2} \# \text{ bonding } e^-)$	$\begin{array}{c} \text{H} \quad :\ddot{\text{O}}:^{-1} \\   \quad   \\ \text{H}-\text{C}-\text{N}^{+1}=\ddot{\text{O}}: \end{array} \longleftrightarrow \begin{array}{c} \text{H} \quad :\ddot{\text{O}}: \\   \quad    \\ \text{H}-\text{C}-\text{N}^{+1}-\ddot{\text{O}}:^{-1} \end{array}$ <p>Carbon, hydrogen, and the double-bonded oxygen atoms have formal charges of zero. Nitrogen has a +1 formal charge <math>[5 - \frac{1}{2}(8)]</math> and the singly bonded oxygen atom in each resonance structure has a -1 formal charge <math>[6 - (6 + \frac{1}{2}(2))]</math>.</p>

**FOR PRACTICE 9.9** Draw the Lewis structure (including resonance structures) for diazomethane ( $\text{CH}_2\text{N}_2$ ). For each resonance structure, assign formal charges to all atoms that have formal charge.

## 9.9 Exceptions to the Octet Rule: Odd-Electron Species, Incomplete Octets, and Expanded Octets

The octet rule in the Lewis model has some exceptions, which we examine in this section of the chapter. They include (1) *odd-electron species*, molecules or ions with an odd number of electrons; (2) *incomplete octets*, molecules or ions with *fewer than eight electrons* around an atom; and (3) *expanded octets*, molecules or ions with *more than eight electrons* around an atom.

## Odd-Electron Species

Molecules and ions with an odd number of electrons in their Lewis structures are **free radicals** (or simply *radicals*). For example, nitrogen monoxide—a pollutant found in motor vehicle exhaust—has 11 electrons. If we try to write a Lewis structure for nitrogen monoxide, we can't achieve octets for both atoms:

The nitrogen atom in nitrogen monoxide does not have an octet, so this Lewis structure does not satisfy the octet rule. Yet, nitrogen monoxide exists, especially in polluted air. Why? As with any simple theory, the Lewis model is not sophisticated enough to handle every single case. It is impossible to write good Lewis structures for free radicals; nevertheless, some of these molecules exist in nature. Perhaps it is a testament to the Lewis model, however, that *relatively few* such molecules exist and that, in general, they tend to be somewhat unstable and reactive. NO, for example, reacts with oxygen in the air to form NO<sub>2</sub>, another odd-electron molecule represented with the following 17-electron resonance structures:

In turn, NO<sub>2</sub> reacts with water to form nitric acid (a component of acid rain) and also reacts with other atmospheric pollutants to form peroxyacetylnitrate (PAN), an active component of photochemical smog. For free radicals, such as NO and NO<sub>2</sub>, we simply write the best Lewis structure that we can.

The unpaired electron in nitrogen monoxide is put on the nitrogen rather than the oxygen in order to minimize formal charges.

### CONCEPTUAL CONNECTION 9.6

**Odd-Electron Species** Which molecule would you expect to be a free radical?

- (a) CO
- (b) CO<sub>2</sub>
- (c) N<sub>2</sub>O
- (d) NO<sub>2</sub>

## Incomplete Octets

Another significant exception to the octet rule involves elements that tend to form *incomplete octets*. The most important of these is boron, which forms compounds with only six electrons around B, rather than eight. For example, BF<sub>3</sub> and BH<sub>3</sub> lack an octet for B.

Beryllium compounds, such as BeH<sub>2</sub>, also have incomplete octets.

You might be wondering why we don't just form double bonds to increase the number of electrons around B. For BH<sub>3</sub>, we can't because there are no additional electrons to move into the bonding region. For BF<sub>3</sub>, however, we could attempt to give B an octet by moving a lone pair from an F atom into the bonding region with B:

## Chemistry IN THE Environment

## Free Radicals and the Atmospheric Vacuum Cleaner

Free radicals play a key role in much of the chemistry of the atmosphere. The free radical that is most important to atmospheric reactions is the hydroxyl radical:

▲  $\text{NO}_2(\text{g})$  is a pollutant found in urban air.

Many free radical structures are abbreviated by writing a single dot with the formula. Thus, the hydroxyl radical is often abbreviated as:

In the atmosphere, the hydroxyl radical forms when excited oxygen atoms—formed from the photodecomposition of ozone—react with water vapor:

The \* next to the O indicates that the oxygen atom has excess energy.

The resulting hydroxyl radical reacts with a wide variety of molecules from both natural sources and from air pollution that are present in the atmosphere. For example, the hydroxyl radical reacts with carbon monoxide, an atmospheric pollutant that we first encountered in Chapter 1, in the following two-step process:

We can see from this reaction that the hydroxyl radical converts toxic CO into relatively nontoxic  $\text{CO}_2$ .

The  $\text{HOO} \cdot$  free radical generated by the second reaction is converted back into the hydroxyl radical when it reacts with other atmospheric substances, and the process repeats itself. Therefore, a single hydroxyl radical can convert a lot of CO into  $\text{CO}_2$ .

Do you ever wonder what happens to the hydrocarbons you accidentally spill when filling a car's gas tank or to the

natural gas that is released into the atmosphere as you light a kitchen stove? Hydrocarbons released into the atmosphere are converted to  $\text{CO}_2$  and  $\text{H}_2\text{O}$  in a series of steps initiated by the hydroxyl free radical. Consider the following representative reaction of methane, the main hydrocarbon in natural gas:

Notice the similarity between this reaction and the direct combustion (or burning) of methane:

As you can see, the free radical reaction initiates a slow “burning” of  $\text{CH}_4$  in a series of steps that produces carbon dioxide and water and some additional free radicals. The hydroxyl radical initiates similar reactions with other pollutants as well as undesirable naturally occurring atmospheric gases. Without the hydroxyl free radical—sometimes called *the atmospheric vacuum cleaner*—our atmosphere would be a much dirtier place.

▲ Hydrocarbons such as octane evaporate into the atmosphere when a motor vehicle is fueled. What happens to them?

## QUESTION

Draw the best possible Lewis structures for the free radicals important in atmospheric chemistry: NO,  $\text{NO}_2$ , HOO, OH,  $\text{CH}_3$ .

This Lewis structure has octets for all atoms, including boron. However, when we assign formal charges to this structure, we get a negative formal charge on B and a positive formal charge on F:

The positive formal charge on fluorine—the most electronegative element in the periodic table—makes this an unfavorable structure. This leaves us with some questions. Do we complete the octet on B at the expense of giving fluorine a positive formal charge? Or do we leave B without an octet in order to avoid the positive formal charge on fluorine? The answers to these kinds of questions are not always clear because we are pushing the limits of the Lewis model. In the case of boron, we usually accept the incomplete octet as the better Lewis structure. However, doing so does not rule out the possibility that the double-bonded Lewis structure might be a minor contributing resonance structure. The ultimate answers to these kinds of questions must be determined from experiments. Experimental measurements of the B—F bond length in  $\text{BF}_3$  suggest that the bond may be slightly shorter than expected for a single B—F bond, indicating that it may indeed have a small amount of double-bond character.

$\text{BF}_3$  can complete its octet in another way—via a chemical reaction. The Lewis model predicts that  $\text{BF}_3$  might react in ways that would complete its octet, and indeed it does. For example,  $\text{BF}_3$  reacts with  $\text{NH}_3$  as follows:

The product has complete octets for all atoms in the structure.

## Expanded Octets

Elements in the third row of the periodic table and beyond often exhibit *expanded octets* of up to 12 (and occasionally 14) electrons. Consider the Lewis structures of arsenic pentafluoride and sulfur hexafluoride:

In  $\text{AsF}_5$  arsenic has an expanded octet of 10 electrons, and in  $\text{SF}_6$  sulfur has an expanded octet of 12 electrons. Both of these compounds exist and are stable. In third-period elements and beyond, 10- and 12-electron expanded octets are common because the *d* orbitals in these elements are energetically accessible (they are not much higher in energy than the orbitals occupied by the valence electrons) and can accommodate the extra electrons (see Section 8.3). Expanded octets *never* occur in second-period elements.

In some Lewis structures, we must decide whether or not to expand an octet in order to lower formal charge. For example, consider the Lewis structure of  $\text{H}_2\text{SO}_4$ :

Notice that two of the oxygen atoms have a  $-1$  formal charge and that sulfur has a  $+2$  formal charge. While this amount of formal charge is acceptable, especially since the

When nitrogen bonds to boron, the nitrogen atom provides both of the electrons. This kind of bond is called a *coordinate covalent bond*, which we discuss in Chapter 25.

negative formal charge resides on the more electronegative atom, it is possible to eliminate the formal charge by expanding the octet on sulfur:

Which of these two Lewis structures for  $\text{H}_2\text{SO}_4$  is better? Again, the answer is not straightforward. Experiments show that the sulfur–oxygen bond lengths in the two sulfur–oxygen bonds without the hydrogen atoms are shorter than expected for sulfur–oxygen single bonds, indicating that the double-bonded Lewis structure plays an important role in describing the bonding in  $\text{H}_2\text{SO}_4$ . In general, we expand octets in third-row (or beyond) elements in order to lower formal charge. However, we should *never* expand the octets of second-row elements. Second-row elements do not have energetically accessible *d* orbitals and therefore never exhibit expanded octets.

### Example 9.10 Writing Lewis Structures for Compounds Having Expanded Octets

Write the Lewis structure for  $\text{XeF}_2$ .

#### SOLUTION

Begin by writing the skeletal structure. Since xenon is the less electronegative atom, put it in the central position.

F Xe F

Calculate the total number of electrons for the Lewis structure by summing the number of valence electrons for each atom.

Total number of electrons for Lewis structure = (number of valence  $e^-$  in Xe) + 2(number of valence  $e^-$  in F)  
 $= 8 + 2(7)$   
 $= 22$

Place two bonding electrons between the atoms of each pair of atoms.

F:Xe:F  
 (4 of 22 electrons used)

Distribute the remaining electrons to give octets to as many atoms as possible, beginning with terminal atoms and finishing with the central atom. Arrange additional electrons around the central atom, giving it an expanded octet of up to 12 electrons.

$:\ddot{\text{F}}:\text{Xe}:\ddot{\text{F}}:$   
 (16 of 22 electrons used)  
 $:\ddot{\text{F}}:\ddot{\text{X}}\text{e}:\ddot{\text{F}}:$  or  $:\ddot{\text{F}}-\ddot{\text{X}}\text{e}-\ddot{\text{F}}:$   
 (22 of 22 electrons used)

**FOR PRACTICE 9.10** Write the Lewis structure for  $\text{XeF}_4$ .

**FOR MORE PRACTICE 9.10** Write the Lewis structure for  $\text{H}_3\text{PO}_4$ . If necessary, expand the octet on any appropriate atoms to lower formal charge.

### Expanded Octets Which molecule could have an expanded octet?

(a)  $\text{H}_2\text{CO}_3$

(b)  $\text{H}_3\text{PO}_4$

(c)  $\text{HNO}_2$

CONCEPTUAL  
 CONNECTION 9.7

## 9.10 Bond Energies and Bond Lengths

In Chapter 6, we discussed how to calculate the standard enthalpy change for a chemical reaction ( $\Delta H_{\text{rxn}}^\circ$ ) from tabulated standard enthalpies of formation. However, sometimes we may not easily find standard enthalpies of formation for all of the reactants and products of a reaction. In such cases, we can use individual *bond energies* to estimate enthalpy

changes of reaction. In this section, we examine the concept of bond energy and how we can use bond energies to calculate enthalpy changes of reaction. We also look at average bond lengths for a number of commonly encountered bonds.

## Bond Energy

Bond energy is also called bond enthalpy or bond dissociation energy.

The **bond energy** of a chemical bond is the energy required to break 1 mole of the bonds in the gas phase. For example, the bond energy of the Cl—Cl bond in Cl<sub>2</sub> is 243 kJ/mol.

The bond energy of HCl is 431 kJ/mol.

Bond energies are always positive because it always takes energy to break a bond. We say that the HCl bond is *stronger* than the Cl<sub>2</sub> bond because it requires more energy to break it. In general, compounds with stronger bonds tend to be more chemically stable, and therefore less chemically reactive, than compounds with weaker bonds. The triple bond in N<sub>2</sub> has a bond energy of 946 kJ/mol.

It is a very strong and stable bond, which explains nitrogen's relative inertness.

The bond energy of a particular bond in a polyatomic molecule is a little more difficult to determine because a particular type of bond can have different bond energies in different molecules. For example, consider the C—H bond. In CH<sub>4</sub>, the energy required to break one C—H bond is 438 kJ/mol.

However, the energy required to break a C—H bond in other molecules varies slightly, as shown here:

TABLE 9.3 Average Bond Energies

Bond	Bond Energy (kJ/mol)	Bond	Bond Energy (kJ/mol)	Bond	Bond Energy (kJ/mol)
H—H	436	N—N	163	Br—F	237

\*799 in CO<sub>2</sub>.

We can calculate an *average bond energy* for a chemical bond, which is an average of the bond energies for that bond in a large number of compounds. For the four compounds just discussed, we calculate an average C—H bond energy of 422 kJ/mol. Table 9.3 lists average bond energies for a number of common chemical bonds averaged over a large number of compounds. Notice that the C—H bond energy listed is 414 kJ/mol, which is not too different from the value we calculated from our limited number of compounds. Notice also that bond energies depend, not only on the kind of atoms involved in the bond, but also on the type of bond: single, double, or triple. In general, for a given pair of atoms, triple bonds are stronger than double bonds, which are, in turn, stronger than single bonds. For example, consider the bond energies of carbon-carbon triple, double, and single bonds listed in Table 9.3.

## Using Average Bond Energies to Estimate Enthalpy Changes for Reactions

We can use average bond energies to *estimate* the enthalpy change of a reaction. For example, consider the reaction between methane and chlorine:

We can imagine this reaction occurring by the breaking of a C—H bond and a Cl—Cl bond and the forming of a C—Cl bond and an H—Cl bond. We know that when bonds break, the process is endothermic (positive bond energy) and when bonds form, the process is exothermic (negative bond energy). So we can calculate the overall enthalpy change as a sum of the enthalpy changes associated with breaking the required bonds in the reactants and forming the required bonds in the products, as shown in Figure 9.12▼.

Bonds Broken		Bonds Formed	
C—H break	+414 kJ	C—Cl form	−339 kJ
Cl—Cl break	+243 kJ	H—Cl form	−431 kJ
<i>Sum (Σ)ΔH's bonds broken: +657 kJ</i>		<i>Sum (Σ)ΔH's bonds formed: −770 kJ</i>	
$\Delta H_{\text{rxn}} = \Sigma(\Delta H\text{'s bonds broken}) + \Sigma(\Delta H\text{'s bonds formed})$			
$= +657 \text{ kJ} - 770 \text{ kJ}$			
$= -113 \text{ kJ}$			

We find that  $\Delta H_{\text{rxn}} = -113$  kJ. Calculating  $\Delta H_{\text{rxn}}^\circ$  from tabulated enthalpies of formation—the method we learned in Chapter 6—gives  $\Delta H_{\text{rxn}}^\circ = -101$  kJ, fairly close to the value we obtained from average bond energies.

In general, we can calculate  $\Delta H_{\text{rxn}}$  from average bond energies by summing the changes in enthalpy for all of the bonds that are broken and adding the sum of the enthalpy changes for all of the bonds that are formed. Remember that  $\Delta H$  is positive for breaking bonds and negative for forming them:

$$\Delta H_{\text{rxn}} = \underbrace{\Sigma(\Delta H\text{'s bonds broken})}_{\substack{\uparrow \\ \text{Positive}}} + \underbrace{\Sigma(\Delta H\text{'s bonds formed})}_{\substack{\uparrow \\ \text{Negative}}}$$

As we can see from the equation:

- A reaction is *exothermic* when weak bonds break and strong bonds form.
- A reaction is *endothermic* when strong bonds break and weak bonds form.

Scientists sometimes say that “energy is stored in chemical bonds or in a chemical compound,” which may make it sound as if breaking the bonds in the compound releases energy. For example, in biology we often hear that energy is stored in glucose or in ATP. However, *breaking a chemical bond always requires energy*. When we say that energy is stored in a compound, or that a compound is energy rich, we mean that the compound can undergo a reaction in which weak bonds break and strong bonds form, thereby releasing energy in the overall process. However, *it is always the forming of chemical bonds that releases energy*.

▼ **FIGURE 9.12** Estimating  $\Delta H_{\text{rxn}}$  from Bond Energies We can approximate the enthalpy change of a reaction by summing up the enthalpy changes involved in breaking old bonds and forming new ones.

### Estimating the Enthalpy Change of a Reaction from Bond Energies

## CONCEPTUAL CONNECTION 9.8

**Bond Energies and  $\Delta H_{\text{rxn}}$**  The reaction between hydrogen and oxygen to form water is highly exothermic. Which statement is true of the energies of the bonds that break and form during the reaction?

- (a) The energy needed to break the required bonds is greater than the energy released when the new bonds form.
- (b) The energy needed to break the required bonds is less than the energy released when the new bonds form.
- (c) The energy needed to break the required bonds is about the same as the energy released when the new bonds form.

### Example 9.11 Calculating $\Delta H_{\text{rxn}}$ from Bond Energies

Hydrogen gas, a potential fuel, can be made by the reaction of methane gas and steam.

Use bond energies to calculate  $\Delta H_{\text{rxn}}$  for this reaction.

#### SOLUTION

Begin by rewriting the reaction using the Lewis structures of the molecules involved.

Determine which bonds are broken in the reaction and sum the bond energies of these.

$$\begin{aligned} \Sigma(\Delta H^\circ \text{ bonds broken}) &= 4(\text{C}-\text{H}) + 4(\text{O}-\text{H}) \\ &= 4(414 \text{ kJ}) + 4(464 \text{ kJ}) \\ &= 3512 \text{ kJ} \end{aligned}$$

Determine which bonds are formed in the reaction and add the negatives of their bond energies.

$$\begin{aligned} 4 \text{H}-\text{H} + \ddot{\text{O}}=\text{C}=\ddot{\text{O}} \\ \Sigma(\Delta H^\circ \text{ bonds formed}) &= -4(\text{H}-\text{H}) - 2(\text{C}=\text{O}) \\ &= -4(436 \text{ kJ}) - 2(799 \text{ kJ}) \\ &= -3342 \text{ kJ} \end{aligned}$$

Find  $\Delta H_{\text{rxn}}$  by summing the results of the previous two steps.

$$\begin{aligned} \Delta H_{\text{rxn}} &= \Sigma(\Delta H^\circ \text{ bonds broken}) + \Sigma(\Delta H^\circ \text{ bonds formed}) \\ &= 3512 \text{ kJ} - 3342 \text{ kJ} \\ &= 1.70 \times 10^2 \text{ kJ} \end{aligned}$$

**FOR PRACTICE 9.11** Another potential future fuel is methanol ( $\text{CH}_3\text{OH}$ ). Write a balanced equation for the combustion of gaseous methanol and use bond energies to calculate the enthalpy of combustion of methanol in kJ/mol.

**FOR MORE PRACTICE 9.11** Use bond energies to calculate  $\Delta H_{\text{rxn}}$  for this reaction:  $\text{N}_2(\text{g}) + 3 \text{H}_2(\text{g}) \longrightarrow 2 \text{NH}_3(\text{g})$ .

## Bond Lengths

Just as we can tabulate average bond energies, which represent the average energy of a bond between two particular atoms in a large number of compounds, we can tabulate average bond lengths (Table 9.4). The average **bond length** represents the average

**TABLE 9.4** Average Bond Lengths

Bond	Bond Length (pm)	Bond	Bond Length (pm)	Bond	Bond Length (pm)
H—H	74	C—C	154	N—N	145
H—C	110	C=C	134	N=N	123
H—N	100	C≡C	120	N≡N	110
H—O	97	C—N	147	N—O	136
H—S	132	C=N	128	N=O	120
H—F	92	C≡N	116	O—O	145
H—Cl	127	C—O	143	O=O	121
H—Br	141	C=O	120	F—F	143
H—I	161	C—Cl	178	Cl—Cl	199
				Br—Br	228
				I—I	266

length of a bond between two particular atoms in a large number of compounds. Like bond energies, bond lengths depend not only on the kind of atoms involved in the bond, but also on the type of bond: single, double, or triple. In general, for a particular pair of atoms, triple bonds are shorter than double bonds, which are in turn shorter than single bonds. For example, consider the bond lengths (shown here with bond strengths) of carbon–carbon triple, double, and single bonds:

Bond	Bond Length (pm)	Bond Strength (kJ/mol)
C≡C	120 pm	837 kJ/mol
C=C	134 pm	611 kJ/mol
C—C	154 pm	347 kJ/mol

Notice that, as the bond gets longer, it also becomes weaker. This relationship between the length of a bond and the strength of a bond does not necessarily hold true for all bonds. Consider the following series of nitrogen–halogen single bonds:

Bond	Bond Length (pm)	Bond Strength (kJ/mol)
N—F	139	272
N—Cl	191	200
N—Br	214	243
N—I	222	159

Although the bonds generally get weaker as they get longer, the trend is not a smooth one.

## 9.11 Bonding in Metals: The Electron Sea Model

So far, we have explored simple models for bonding between a metal and a nonmetal (ionic bonding) and for bonding between two nonmetals (covalent bonding). We have seen how these models account for and predict the properties of ionic and molecular compounds. The last type of bonding that we examine in this chapter is metallic bonding, which occurs between metals.

As we have already discussed, metals have a tendency to lose electrons, which means that they have relatively low ionization energies. When metal atoms bond together to form a solid lattice, each metal atom donates one or more electrons to an *electron sea*. For example, we can think of sodium metal as an array of positively charged  $\text{Na}^+$  ions immersed in a sea of negatively charged electrons ( $e^-$ ), as shown in Figure 9.13►.

**Bond Lengths**

▲ Bond lengths in the diatomic halogen molecules.

▲ **FIGURE 9.13** The Electron Sea Model for Sodium In this model of metallic bonding,  $\text{Na}^+$  ions are immersed in a “sea” of electrons.

## Chemistry IN THE Environment | The Lewis Structure of Ozone

Ozone is a form of oxygen in which three oxygen atoms bond together. Its Lewis structure consists of the following resonance structures:

Compare the Lewis structure of ozone to the Lewis structure of  $\text{O}_2$ :

Since double bonds are stronger and shorter than single bonds,  $\text{O}_2$  must have a stronger bond because it is a double bond.  $\text{O}_3$ , on the other hand, has bonds that are intermediate between single and double, which are weaker bonds. The effects of this are significant. As we discussed in Section 6.10,  $\text{O}_3$  absorbs harmful ultraviolet light entering Earth's atmosphere. Ozone is ideally suited to do this because

photons at wavelengths of 280–320 nm (the most harmful components of sunlight) are just strong enough to break the bonds in the  $\text{O}_3$  molecule:

In this process, the photon is absorbed.  $\text{O}_2$  and O then recombine to re-form  $\text{O}_3$ , which can in turn absorb more UV light. The same wavelengths of UV light, however, do not have sufficient energy to break the stronger double bond of  $\text{O}_2$ . No other molecules in our atmosphere can do the job that ozone does. Consequently, we should continue, and even strengthen, the ban on ozone-depleting compounds.

### QUESTION

Calculate the average bond energy of one  $\text{O}_3$  bond. What wavelength of light has just the right amount of energy to break this bond?

▲ Ozone protects life on Earth from harmful ultraviolet light.

▲ Copper can easily be drawn into fine strands like those used in household electrical cords.

Each sodium atom donates its one valence electron to the “sea” and becomes a sodium ion. The sodium cations are held together by their attraction to the sea of electrons.

Although the electron sea model is simple, it accounts for many of the properties of metals. For example, metals conduct electricity because—in contrast to ionic solids, in which electrons are localized on an ion—the electrons in a metal are free to move. The movement or flow of electrons in response to an electric potential (or voltage) is an electric current. Metals are also excellent conductors of heat, again because of the highly mobile electrons, which help to disperse thermal energy throughout the metal.

The electron sea model also accounts for the *malleability* of metals (their capacity to be pounded into sheets) and the *ductility* of metals (their capacity to be drawn into wires). Since there are no localized or specific “bonds” in a metal, we can deform it relatively easily by forcing the metal ions to slide past one another. The electron sea easily accommodates deformations by flowing into the new shape.

# Self-Assessment Quiz

**Q1.** Which pair of elements is most likely to form an ionic bond?

- a) nitrogen and oxygen      b) carbon and hydrogen  
c) sulfur and oxygen      d) calcium and oxygen

**Q2.** Which set of elements is arranged in order of increasing electronegativity?

- a)  $O < S < As < Ge$       b)  $Ge < As < S < O$   
c)  $S < O < As < Ge$       d)  $As < O < Ge < S$

**Q3.** Which is the correct Lewis structure for magnesium bromide?

- a)  $2 \text{Mg}^{2+} [\text{:}\ddot{\text{Br}}\text{:}]^-$       b)  $\text{Mg}:\ddot{\text{Br}}:$   
c)  $\text{Mg}^{2+} 2 [\text{:}\ddot{\text{Br}}\text{:}]^-$       d)  $:\ddot{\text{Mg}}:\ddot{\text{Br}}:$

**Q4.** Which compound is likely to have an incomplete octet?

- a)  $\text{NH}_3$     b)  $\text{SO}_3$     c)  $\text{N}_2\text{O}$     d)  $\text{BH}_3$

**Q5.** Which compound has the lattice energy with the greatest magnitude?

- a)  $\text{MgS}$     b)  $\text{CaS}$     c)  $\text{SrS}$     d)  $\text{BaS}$

**Q6.** Which set of compounds is arranged in order of increasing magnitude of lattice energy?

- a)  $\text{CsI} < \text{NaCl} < \text{MgS}$       b)  $\text{NaCl} < \text{CsI} < \text{MgS}$   
c)  $\text{MgS} < \text{NaCl} < \text{CsI}$       d)  $\text{CsI} < \text{MgS} < \text{NaCl}$

**Q7.** Which pair of atoms forms the most polar bond?

- a) N and O    b) C and O    c) C and F    d) N and F

**Q8.** Which pair of atoms forms a nonpolar covalent bond?

- a) C and S    b) C and O    c) B and O    d) Na and Cl

**Q9.** Which is the correct Lewis structure for nitrogen trifluoride?

- a)  $\text{:}\ddot{\text{F}}=\ddot{\text{N}}-\ddot{\text{F}}\text{:}$       b)  $\text{:}\ddot{\text{F}}-\ddot{\text{N}}-\ddot{\text{F}}\text{:}$   
c)  $\text{:}\ddot{\text{F}}-\ddot{\text{N}}-\ddot{\text{F}}\text{:}$       d)  $\text{:}\ddot{\text{F}}-\ddot{\text{N}}-\ddot{\text{F}}-\ddot{\text{F}}\text{:}$

**Q10.** Which is the correct Lewis structure for  $\text{CO}_3^{2-}$ ?

- a)  $\left[ \begin{array}{c} \text{:}\ddot{\text{O}}\text{:} \\ \parallel \\ \text{:}\ddot{\text{O}}=\text{C}=\ddot{\text{O}}\text{:} \end{array} \right]^{2-}$   
b)  $\left[ \begin{array}{c} \text{:}\ddot{\text{O}}\text{:} \\ \parallel \\ \text{:}\ddot{\text{O}}-\text{C}-\ddot{\text{O}}\text{:} \end{array} \right]^{2-} \longleftrightarrow \left[ \begin{array}{c} \text{:}\ddot{\text{O}}\text{:} \\ \parallel \\ \text{:}\ddot{\text{O}}=\text{C}-\ddot{\text{O}}\text{:} \end{array} \right]^{2-} \longleftrightarrow \left[ \begin{array}{c} \text{:}\ddot{\text{O}}\text{:} \\ \parallel \\ \text{:}\ddot{\text{O}}-\text{C}=\ddot{\text{O}}\text{:} \end{array} \right]^{2-}$   
c)  $\left[ \begin{array}{c} \text{:}\ddot{\text{O}}\text{:} \\ \parallel \\ \text{:}\ddot{\text{O}}-\text{C}-\ddot{\text{O}}\text{:} \end{array} \right]^{2-}$   
d)  $\left[ \text{:}\ddot{\text{O}}-\text{C}=\ddot{\text{O}}-\ddot{\text{O}}\text{:} \right]^{2-}$

**Q11.** Determine the formal charge of nitrogen in the structure shown here:

- a) +1  
b) +2  
c) -1  
d) -2

**Q12.** A Lewis structure for the acetate ion is shown here:

Which structure is the best resonance structure for the acetate ion?

- a)  $\left[ \begin{array}{c} \text{H} \\ | \\ \text{H}-\text{C}-\ddot{\text{C}}-\ddot{\text{O}}-\ddot{\text{O}}\text{:} \\ | \\ \text{H} \end{array} \right]^-$   
b)  $\left[ \begin{array}{c} \text{H} \quad \text{:}\ddot{\text{O}}\text{:} \\ | \quad \parallel \\ \text{H}-\text{C}=\text{C}-\ddot{\text{O}}\text{:} \\ | \\ \text{H} \end{array} \right]^-$   
c)  $\left[ \begin{array}{c} \text{:}\ddot{\text{O}}-\text{H} \\ | \\ \text{H}-\text{C}-\ddot{\text{C}}-\ddot{\text{O}}\text{:} \\ | \\ \text{H} \end{array} \right]^-$   
d)  $\left[ \begin{array}{c} \text{H} \quad \text{:}\ddot{\text{O}}\text{:} \\ | \quad \parallel \\ \text{H}-\text{C}-\text{C}=\ddot{\text{O}}\text{:} \\ | \\ \text{H} \end{array} \right]^-$

**Q13.** Use formal charge to choose the best Lewis structure for  $\text{CH}_3\text{SOCH}_3$ .

- a)  $\begin{array}{c} \text{H} \quad \text{:}\ddot{\text{O}}\text{:} \quad \text{H} \\ | \quad \parallel \quad | \\ \text{H}-\text{C}=\text{S}-\text{C}-\text{H} \\ | \quad \quad | \\ \text{H} \quad \quad \text{H} \end{array}$       b)  $\begin{array}{c} \text{H} \quad \text{:}\ddot{\text{O}}\text{:} \quad \text{H} \\ | \quad \parallel \quad | \\ \text{H}-\text{C}-\text{S}-\text{C}-\text{H} \\ | \quad \quad | \\ \text{H} \quad \quad \text{H} \end{array}$   
c)  $\begin{array}{c} \text{H} \quad \text{:}\ddot{\text{O}}\text{:} \quad \text{H} \\ | \quad \parallel \quad | \\ \text{H}-\text{C}-\text{S}-\text{C}-\text{H} \\ | \quad \quad | \\ \text{H} \quad \quad \text{H} \end{array}$       d)  $\begin{array}{c} \text{H} \quad \text{:}\ddot{\text{O}}\text{:} \quad \text{H} \\ | \quad \parallel \quad | \\ \text{H}-\text{C}=\text{S}-\text{C}-\text{H} \\ | \quad \quad | \\ \text{H} \quad \quad \text{H} \end{array}$

Continued—

**Q14.** Use bond energies from Table 9.3 to determine  $\Delta H_{\text{rxn}}$  for the reaction between ethanol and hydrogen chloride.

- a) -1549 kJ                      b) 1549 kJ  
c) -12 kJ                        d) 12 kJ

**Q15.** Consider the halogenation of ethene, where X is a generic halogen:

Use bond energies to determine which halogen produces the most exothermic halogenation reaction with ethene. The C—F, C—Br, and C—I bond energies are 552 kJ/mol, 280 kJ/mol, and 209 kJ/mol, respectively. Look up all other necessary bond energies in Table 9.3.

- a) fluorine                      b) chlorine  
c) bromine                     d) iodine

Answers: 1. (d) 2. (b) 3. (c) 4. (d) 5. (a) 6. (a) 7. (c) 8. (a) 9. (c) 10. (b) 11. (a) 12. (d) 13. (b) 14. (c) 15. (a)

### Key Concepts

#### Bonding Models and AIDS Drugs (9.1)

- ▶ Theories that predict how and why atoms bond together are central to chemistry because they explain compound stability and molecule shape.
- ▶ Bonding theories have been useful in combating HIV because they help in the design of molecules that bind to the active site of a protein crucial for the development of AIDS.

#### Types of Chemical Bonds (9.2)

- ▶ We divide chemical bonds into three general types: ionic bonds, which occur between a metal and a nonmetal; covalent bonds, which occur between two nonmetals; and metallic bonds, which occur within metals.
- ▶ In an ionic bond, an electron transfers from the metal to the nonmetal and the resultant ions attract each other by coulombic forces.
- ▶ In a covalent bond, nonmetals share electrons that interact with the nuclei of both atoms via coulombic forces, holding the atoms together.

- ▶ In a metallic bond, the atoms form a lattice in which each metal loses electrons to an “electron sea.” The attraction of the positively charged metal ions to the electron sea holds the metal together.

#### The Lewis Model and Electron Dots (9.3)

- ▶ In the Lewis model, chemical bonds form when atoms transfer (ionic bonding) or share (covalent bonding) valence electrons to attain noble gas electron configurations.
- ▶ The Lewis model represents valence electrons as dots surrounding the symbol for an element. When two or more elements bond together, the dots are transferred or shared so that every atom has eight dots, an octet (or two dots, a duet, in the case of hydrogen).

#### Ionic Lewis Structures and Lattice Energy (9.4)

- ▶ In an ionic Lewis structure involving main-group metals, the metal transfers its valence electrons (dots) to the nonmetal.
- ▶ The formation of most ionic compounds is exothermic because of lattice energy, the energy released when metal cations and nonmetal anions coalesce to form the solid. The smaller the radius of the ions and the greater their charge, the more exothermic the lattice energy.

### Covalent Lewis Structures, Electronegativity, and Polarity (9.5, 9.6, 9.7)

- ▶ In a covalent Lewis structure, neighboring atoms share valence electrons to attain octets (or duets).
- ▶ A single shared electron pair constitutes a single bond, while two or three shared pairs constitute double or triple bonds, respectively.
- ▶ The shared electrons in a covalent bond are not always *equally* shared; when two dissimilar nonmetals form a covalent bond, the electron density is greater on the more electronegative element. The result is a polar bond, in which one element has a partial positive charge and the other a partial negative charge.
- ▶ Electronegativity—the ability of an atom to attract electrons to itself in chemical bonding—increases as we move to the right across a period in the periodic table and decreases as we move down a column.
- ▶ Elements with very dissimilar electronegativities form ionic bonds, those with very similar electronegativities form nonpolar covalent bonds, and those with intermediate electronegativity differences form polar covalent bonds.

### Resonance and Formal Charge (9.8)

- ▶ We can best represent some molecules not by a single Lewis structure, but by two or more resonance structures. The actual structure of these molecules is a resonance hybrid: a combination or average of the contributing structures.
- ▶ The formal charge of an atom in a Lewis structure is the charge the atom would have if all bonding electrons were shared equally between bonding atoms.
- ▶ In general, the best Lewis structures have the fewest atoms with formal charge, and any negative formal charges are on the most electronegative atom.

### Exceptions to the Octet Rule (9.9)

- ▶ Although the octet rule normally applies when we draw Lewis structures, some exceptions occur.
- ▶ These exceptions include odd-electron species, which necessarily have Lewis structures with only seven electrons around an atom. Such molecules, called free radicals, tend to be unstable and chemically reactive.
- ▶ Other exceptions to the octet rule include molecules with incomplete octets—usually totaling six electrons (especially important in compounds containing boron)—and molecules with expanded octets—usually 10 or 12 electrons (which can occur in compounds containing elements from the third row of the periodic table and below). Expanded octets never occur in second-period elements.

### Bond Energies and Bond Lengths (9.10)

- ▶ The bond energy of a chemical bond is the energy required to break one mole of the bonds in the gas phase.
- ▶ Average bond energies for a number of different bonds are tabulated, and we can use them to calculate enthalpies of reaction.
- ▶ Average bond lengths are also tabulated.
- ▶ In general, triple bonds are shorter and stronger than double bonds, which are in turn shorter and stronger than single bonds.

### Bonding in Metals (9.11)

- ▶ When metal atoms bond together to form a solid, each metal atom donates one or more electrons to an *electron sea*. The metal cations are held together by their attraction to the sea of electrons.
- ▶ The *electron sea* model accounts for the electrical conductivity, thermal conductivity, malleability, and ductility of metals.

## Key Equations and Relationships

Dipole Moment ( $\mu$ ): Separation of Two Particles of Equal but Opposite Charge of Magnitude  $q$  by a Distance  $r$  (9.6)

$$\mu = qr$$

Percent Ionic Character (9.6)

$$\text{Percent ionic character} = \frac{\text{measured dipole moment of bond}}{\text{dipole moment if electron were completely transferred}} \times 100\%$$

Formal Charge (9.8)

$$\text{Formal charge} = \text{number of valence electrons} - (\text{number of nonbonding electrons} + \frac{1}{2} \text{ number of shared electrons})$$

Enthalpy Change of a Reaction ( $\Delta H_{\text{rxn}}$ ): Relationship of Bond Energies (9.10)

$$\Delta H_{\text{rxn}} = \Sigma(\Delta H' \text{'s bonds broken}) + \Sigma(\Delta H' \text{'s bonds formed})$$

## Key Learning Outcomes

CHAPTER OBJECTIVES	ASSESSMENT
Predicting Chemical Formulas of an Ionic Compound (9.4)	Example 9.1 For Practice 9.1 Exercises 41–42
Predicting Relative Lattice Energies (9.4)	Example 9.2 For Practice 9.2 For More Practice 9.2 Exercise 46
	
Classifying Bonds: Pure Covalent, Polar Covalent, or Ionic (9.6)	Example 9.3 For Practice 9.3 Exercises 55–56
Writing Lewis Structures for Covalent Compounds (9.7)	Examples 9.4–9.5 For Practice 9.4–9.5 Exercises 51–52

Writing Lewis Structures for Polyatomic Ions (9.7)	Example 9.6	For Practice 9.6	Exercises 59–64
Writing Resonance Lewis Structures (9.8)	Example 9.7	For Practice 9.7	Exercises 63–64
Assigning Formal Charges to Assess Competing Resonance Structures (9.8)	Example 9.8	For Practice 9.8	For More Practice 9.8 Exercises 65–66
Drawing Resonance Structures and Assigning Formal Charge for Organic Compounds (9.8)	Example 9.9	For Practice 9.9	Exercises 69–72
Writing Lewis Structures for Compounds Having Expanded Octets (9.9)	Example 9.10	For Practice 9.10	For More Practice 9.10 Exercises 77–78
Calculating $\Delta H_{\text{rxn}}$ from Bond Energies (9.10)	Example 9.11	For Practice 9.11	For More Practice 9.11 Exercises 81–83

## EXERCISES

### Review Questions

- Why are bonding theories important? Provide some examples of what bonding theories can predict.
- Why do chemical bonds form? What basic forces are involved in bonding?
- What are the three basic types of chemical bonds? What happens to electrons in the bonding atoms in each type?
- How do you determine how many dots to put around the Lewis symbol of an element?
- Describe the octet rule in the Lewis model.
- According to the Lewis model, what is a chemical bond?
- How do you draw an ionic Lewis structure?
- How can Lewis structures be used to determine the formula of ionic compounds? Give an example.
- What is lattice energy?
- Why is the formation of solid sodium chloride from solid sodium and gaseous chlorine exothermic, even though it takes more energy to form the  $\text{Na}^+$  ion than the amount of energy released upon formation of  $\text{Cl}^-$ ?
- What is the Born–Haber cycle? List each step in the cycle and show how the cycle is used to calculate lattice energy.
- How does lattice energy relate to ionic radii? To ion charge?
- How does the ionic bonding model explain the relatively high melting points of ionic compounds?
- How does the ionic bonding model explain the nonconductivity of ionic solids, and at the same time the conductivity of ionic solutions?
- In a covalent Lewis structure, what is the difference between lone pair and bonding pair electrons?
- In what ways are double and triple covalent bonds different from single covalent bonds?
- How does the Lewis model for covalent bonding account for why certain combinations of atoms are stable while others are not?
- How does the Lewis model for covalent bonding account for the relatively low melting and boiling points of molecular compounds (compared to ionic compounds)?
- What is electronegativity? What are the periodic trends in electronegativity?
- How do a pure covalent bond, a polar covalent bond, and an ionic bond differ?
- Explain percent ionic character of a bond. Do any bonds have 100% ionic character?
- What is a dipole moment?
- What is the magnitude of the dipole moment formed by separating a proton and an electron by 100 pm? 200 pm?
- What is the basic procedure for writing a covalent Lewis structure?
- How do you determine the number of electrons in the Lewis structure of a molecule? A polyatomic ion?
- What are resonance structures? What is a resonance hybrid?
- Do resonance structures always contribute equally to the overall structure of a molecule? Explain.
- What is formal charge? How is formal charge calculated? How is it helpful?
- Why does the octet rule have exceptions? List the three major categories of exceptions and an example of each.
- Which elements can have expanded octets? Which elements should never have expanded octets?
- What is bond energy? How can you use average bond energies to calculate enthalpies of reaction?
- Explain the difference between endothermic reactions and exothermic reactions with respect to the bond energies of the bonds broken and formed.
- What is the electron sea model for bonding in metals?
- How does the electron sea model explain the conductivity of metals? The malleability and ductility of metals?

## Problems by Topic

### Valence Electrons and Dot Structures

35. Write the electron configuration for N. Then write the Lewis symbol for N and show which electrons from the electron configuration are included in the Lewis symbol.
36. Write the electron configuration for Ne. Then write the Lewis symbol for Ne and show which electrons from the electron configuration are included in the Lewis symbol.
37. Write the Lewis symbol for each atom or ion.  
a. Al      b.  $\text{Na}^+$       c. Cl      d.  $\text{Cl}^-$
38. Write the Lewis symbol for each atom or ion.  
a.  $\text{S}^{2-}$       b. Mg      c.  $\text{Mg}^{2+}$       d. P

### Ionic Lewis Symbols and Lattice Energy

39. Write the Lewis symbols for the ions in each ionic compound.  
a. NaF      b. CaO      c.  $\text{SrBr}_2$       d.  $\text{K}_2\text{O}$
40. Write the Lewis symbols for the ions in each ionic compound.  
a. SrO      b.  $\text{Li}_2\text{S}$       c.  $\text{CaI}_2$       d. RbF
41. Use Lewis symbols to determine the formula for the compound that forms between each pair of elements.  
a. Sr and Se      b. Ba and Cl      c. Na and S      d. Al and O
42. Use Lewis symbols to determine the formula for the compound that forms between each pair of elements:  
a. Ca and N      b. Mg and I      c. Ca and S      d. Cs and F
43. Explain the trend in the lattice energies of the alkaline earth metal oxides.

Metal Oxide	Lattice Energy (kJ/mol)
MgO	-3795
CaO	-3414
SrO	-3217
BaO	-3029

44. Rubidium iodide has a lattice energy of  $-617 \text{ kJ/mol}$ , while potassium bromide has a lattice energy of  $-671 \text{ kJ/mol}$ . Why is the lattice energy of potassium bromide more exothermic than the lattice energy of rubidium iodide?
45. The lattice energy of CsF is  $-744 \text{ kJ/mol}$ , whereas that of BaO is  $-3029 \text{ kJ/mol}$ . Explain this large difference in lattice energy.
46. Arrange these compounds in order of increasing magnitude of lattice energy: KCl, SrO, RbBr, CaO.
47. Use the Born-Haber cycle and data from Appendix IIB, Chapter 8 and this chapter to calculate the lattice energy of KCl. ( $\Delta H_{\text{sub}}$  for potassium is  $89.0 \text{ kJ/mol}$ .)
48. Use the Born-Haber cycle and data from Appendix IIB and Table 9.3 to calculate the lattice energy of CaO. ( $\Delta H_{\text{sub}}$  for calcium is  $178 \text{ kJ/mol}$ ;  $\text{IE}_1$  and  $\text{IE}_2$  for calcium are  $590 \text{ kJ/mol}$  and  $1145 \text{ kJ/mol}$ , respectively;  $\text{EA}_1$  and  $\text{EA}_2$  for O are  $-141 \text{ kJ/mol}$  and  $744 \text{ kJ/mol}$ , respectively.)

### Simple Covalent Lewis Structures, Electronegativity, and Bond Polarity

49. Use covalent Lewis structures to explain why each element (or family of elements) occurs as diatomic molecules.  
a. hydrogen      b. the halogens      c. oxygen      d. nitrogen
50. Use covalent Lewis structures to explain why the compound that forms between nitrogen and hydrogen has the formula  $\text{NH}_3$ . Show why  $\text{NH}_2$  and  $\text{NH}_4$  are not stable.

51. Write the Lewis structure for each molecule.  
a.  $\text{PH}_3$       b.  $\text{SCl}_2$       c. HI      d.  $\text{CH}_4$
52. Write the Lewis structure for each molecule.  
a.  $\text{NF}_3$       b. HBr      c.  $\text{SBr}_2$       d.  $\text{CCl}_4$
53. Write the Lewis structure for each molecule.  
a.  $\text{SF}_2$       b.  $\text{SiH}_4$   
c.  $\text{HCOOH}$  (both O bonded to C)      d.  $\text{CH}_3\text{SH}$  (C and S central)
54. Write the Lewis structure for each molecule.  
a.  $\text{CH}_2\text{O}$       b.  $\text{C}_2\text{Cl}_4$   
c.  $\text{CH}_3\text{NH}_2$       d.  $\text{CFCl}_3$  (C central)
55. Determine if a bond between each pair of atoms would be pure covalent, polar covalent, or ionic.  
a. Br and Br      b. C and Cl      c. C and S      d. Sr and O
56. Determine if a bond between each pair of atoms would be pure covalent, polar covalent, or ionic.  
a. C and N      b. N and S      c. K and F      d. N and N
57. Draw the Lewis structure for CO with an arrow representing the dipole moment. Refer to Figure 9.10 to estimate the percent ionic character of the CO bond.
58. Draw the Lewis structure for BrF with an arrow representing the dipole moment. Refer to Figure 9.10 to estimate the percent ionic character of the BrF bond.

### Covalent Lewis Structures, Resonance, and Formal Charge

59. Write the Lewis structure for each molecule or ion.  
a.  $\text{Cl}_4$       b.  $\text{N}_2\text{O}$       c.  $\text{SiH}_4$       d.  $\text{Cl}_2\text{CO}$
60. Write the Lewis structure for each molecule or ion.  
a.  $\text{H}_3\text{COH}$       b.  $\text{OH}^-$       c.  $\text{BrO}^-$       d.  $\text{O}_2^{2-}$
61. Write the Lewis structure for each molecule or ion.  
a.  $\text{N}_2\text{H}_2$       b.  $\text{N}_2\text{H}_4$       c.  $\text{C}_2\text{H}_2$       d.  $\text{C}_2\text{H}_4$
62. Write the Lewis structure for each molecule or ion.  
a.  $\text{H}_3\text{COCH}_3$       b.  $\text{CN}^-$       c.  $\text{NO}_2^-$       d.  $\text{ClO}^-$
63. Write a Lewis structure that obeys the octet rule for each molecule or ion. Include resonance structures if necessary and assign formal charges to each atom.  
a.  $\text{SeO}_2$       b.  $\text{CO}_3^{2-}$       c.  $\text{ClO}^-$       d.  $\text{NO}_2^-$
64. Write a Lewis structure that obeys the octet rule for each ion. Include resonance structures if necessary and assign formal charges to each atom.  
a.  $\text{ClO}_3^-$       b.  $\text{ClO}_4^-$       c.  $\text{NO}_3^-$       d.  $\text{NH}_4^+$
65. Use formal charge to identify the better Lewis structure.

66. Use formal charges to identify the better Lewis structure.

67. How important is the resonance structure shown here to the overall structure of carbon dioxide? Explain.

68. In  $\text{N}_2\text{O}$ , nitrogen is the central atom and the oxygen atom is terminal. In  $\text{OF}_2$ , however, oxygen is the central atom. Use formal charges to explain why.
69. Draw the Lewis structure (including resonance structures) for the acetate ion ( $\text{CH}_3\text{COO}^-$ ). For each resonance structure, assign formal charges to all atoms that have formal charge.
70. Draw the Lewis structure (including resonance structures) for methyl azide ( $\text{CH}_3\text{N}_3$ ). For each resonance structure, assign formal charges to all atoms that have formal charge.
71. What are the formal charges of the atoms shown in red?

72. What are the formal charges of the atoms shown in red?

### Odd-Electron Species, Incomplete Octets, and Expanded Octets

73. Write the Lewis structure for each molecule (octet rule not followed).  
a.  $\text{BCl}_3$       b.  $\text{NO}_2$       c.  $\text{BH}_3$
74. Write the Lewis structure for each molecule (octet rule not followed).  
a.  $\text{BBr}_3$       b.  $\text{NO}$       c.  $\text{ClO}_2$
75. Write the Lewis structure for each ion. Include resonance structures if necessary and assign formal charges to all atoms. If necessary, expand the octet on the central atom to lower formal charge.  
a.  $\text{PO}_4^{3-}$       b.  $\text{CN}^-$       c.  $\text{SO}_3^{2-}$       d.  $\text{ClO}_2^-$
76. Write Lewis structures for each molecule or ion. Include resonance structures if necessary and assign formal charges to all atoms. If necessary, expand the octet on the central atom to lower formal charge.  
a.  $\text{SO}_4^{2-}$       b.  $\text{HSO}_4^-$       c.  $\text{SO}_3$       d.  $\text{BrO}_2^-$

77. Write Lewis structures for each molecule or ion. Use expanded octets as necessary.  
a.  $\text{PF}_5$       b.  $\text{I}_3^-$       c.  $\text{SF}_4$       d.  $\text{GeF}_4$
78. Write Lewis structures for each molecule or ion. Use expanded octets as necessary.  
a.  $\text{ClF}_5$       b.  $\text{AsF}_6^-$       c.  $\text{Cl}_3\text{PO}$       d.  $\text{IF}_5$

### Bond Energies and Bond Lengths

79. Order these compounds in order of increasing carbon-carbon bond strength and in order of decreasing carbon-carbon bond length:  $\text{HCCH}$ ,  $\text{H}_2\text{CCH}_2$ ,  $\text{H}_3\text{CCH}_3$ .
80. Which compound shown here has the stronger nitrogen-nitrogen bond? The shorter nitrogen-nitrogen bond?  
 $\text{H}_2\text{NNH}_2$ ,  $\text{HNNH}$
81. Hydrogenation reactions are used to add hydrogen across double bonds in hydrocarbons and other organic compounds. Use average bond energies to calculate  $\Delta H_{\text{rxn}}$  for the hydrogenation reaction.  
$$\text{H}_2\text{C}=\text{CH}_2(\text{g}) + \text{H}_2(\text{g}) \longrightarrow \text{H}_3\text{C}-\text{CH}_3(\text{g})$$
82. Ethanol is a possible fuel. Use average bond energies to calculate  $\Delta H_{\text{rxn}}$  for the combustion of ethanol.  
$$\text{CH}_3\text{CH}_2\text{OH}(\text{g}) + 3 \text{O}_2(\text{g}) \longrightarrow 2 \text{CO}_2(\text{g}) + 3 \text{H}_2\text{O}(\text{g})$$
83. Hydrogen, a potential future fuel, can be produced from carbon (from coal) and steam by this reaction:  
$$\text{C}(\text{s}) + 2 \text{H}_2\text{O}(\text{g}) \longrightarrow \text{H}_2(\text{g}) + \text{CO}_2(\text{g})$$
  
Use average bond energies to calculate  $\Delta H_{\text{rxn}}$  for the reaction.
84. In the *Chemistry and the Environment* box on free radicals in this chapter, we discussed the importance of the hydroxyl radical in reacting with and eliminating many atmospheric pollutants. However, the hydroxyl radical does not clean up everything. For example, chlorofluorocarbons—which destroy stratospheric ozone—are not attacked by the hydroxyl radical. Consider the hypothetical reaction by which the hydroxyl radical might react with a chlorofluorocarbon:  
$$\text{OH}(\text{g}) + \text{CF}_2\text{Cl}_2(\text{g}) \longrightarrow \text{HOF}(\text{g}) + \text{CFCl}_2(\text{g})$$
  
Use bond energies to explain why this reaction is improbable. (The C—F bond energy is 552 kJ/mol.)

## Cumulative Problems

85. Write an appropriate Lewis structure for each compound. Make certain to distinguish between ionic and molecular compounds.  
a.  $\text{BI}_3$       b.  $\text{K}_2\text{S}$   
c.  $\text{HCFO}$       d.  $\text{PBr}_3$
86. Write an appropriate Lewis structure for each compound. Make certain to distinguish between ionic and molecular compounds.  
a.  $\text{Al}_2\text{O}_3$       b.  $\text{ClF}_5$   
c.  $\text{MgI}_2$       d.  $\text{XeO}_4$
87. Each compound contains both ionic and covalent bonds. Write ionic Lewis structures for each of them, including the covalent structure for the ion in brackets. Write resonance structures if necessary.  
a.  $\text{BaCO}_3$       b.  $\text{Ca}(\text{OH})_2$   
c.  $\text{KNO}_3$       d.  $\text{LiIO}$
88. Each compound contains both ionic and covalent bonds. Write ionic Lewis structures for each of them, including the covalent structure for the ion in brackets. Write resonance structures if necessary.  
a.  $\text{RbIO}_2$       b.  $\text{NH}_4\text{Cl}$   
c.  $\text{KOH}$       d.  $\text{Sr}(\text{CN})_2$
89. Carbon ring structures are common in organic chemistry. Draw a Lewis structure for each carbon ring structure, including any necessary resonance structures.  
a.  $\text{C}_4\text{H}_8$       b.  $\text{C}_4\text{H}_4$       c.  $\text{C}_6\text{H}_{12}$       d.  $\text{C}_6\text{H}_6$
90. Amino acids are the building blocks of proteins. The simplest amino acid is glycine ( $\text{H}_2\text{NCH}_2\text{COOH}$ ). Draw a Lewis structure for glycine. (Hint: The central atoms in the skeletal structure are nitrogen and the two carbon atoms. Each oxygen atom is bonded directly to the right-most carbon atom.)
91. Formic acid is responsible for the sting of ant bites. By mass, formic acid is 26.10% C, 4.38% H, and 69.52% O. The molar mass of formic acid is 46.02 g/mol. Determine the molecular formula of formic acid and draw its Lewis structure.
92. Diazomethane is a highly poisonous, explosive compound because it readily evolves  $\text{N}_2$ . Diazomethane has the following composition by mass: 28.57% C; 4.80% H; and 66.64% N. The molar mass of diazomethane is 42.04 g/mol. Find the molecular formula of diazomethane, draw its Lewis structure, and assign formal charges to each atom. Why is diazomethane not very stable? Explain.

93. The reaction of  $\text{Fe}_2\text{O}_3(\text{s})$  with  $\text{Al}(\text{s})$  to form  $\text{Al}_2\text{O}_3(\text{s})$  and  $\text{Fe}(\text{s})$  is called the thermite reaction and is highly exothermic. What role does lattice energy play in the exothermicity of the reaction?
94.  $\text{NaCl}$  has a lattice energy of  $-787 \text{ kJ/mol}$ . Consider a hypothetical salt  $\text{XY}$ .  $\text{X}^{3+}$  has the same radius of  $\text{Na}^+$  and  $\text{Y}^{3-}$  has the same radius as  $\text{Cl}^-$ . Estimate the lattice energy of  $\text{XY}$ .
95. Draw the Lewis structure for nitric acid (the hydrogen atom is attached to one of the oxygen atoms). Include all three resonance structures by alternating the double bond among the three oxygen atoms. Use formal charge to determine which of the resonance structures is most important to the structure of nitric acid.
96. Phosgene ( $\text{Cl}_2\text{CO}$ ) is a poisonous gas used as a chemical weapon during World War I. It is a potential agent for chemical terrorism today. Draw the Lewis structure of phosgene. Include all three resonance forms by alternating the double bond among the three terminal atoms. Which resonance structure is the best?
97. The cyanate ion ( $\text{OCN}^-$ ) and the fulminate ion ( $\text{CNO}^-$ ) share the same three atoms but have vastly different properties. The cyanate ion is stable, while the fulminate ion is unstable and forms explosive compounds. The resonance structures of the cyanate ion are explored in Example 9.8. Draw Lewis structures for the fulminate ion—including possible resonance forms—and use formal charge to explain why the fulminate ion is less stable (and therefore more reactive) than the cyanate ion.
98. Draw the Lewis structure for each organic compound from its condensed structural formula.
- $\text{C}_3\text{H}_8$
  - $\text{CH}_3\text{OCH}_3$
  - $\text{CH}_3\text{COCH}_3$
  - $\text{CH}_3\text{COOH}$
  - $\text{CH}_3\text{CHO}$
99. Draw the Lewis structure for each organic compound from its condensed structural formula.
- $\text{C}_2\text{H}_4$
  - $\text{CH}_3\text{NH}_2$
  - $\text{HCHO}$
  - $\text{CH}_3\text{CH}_2\text{OH}$
  - $\text{HCOOH}$
100. Use Lewis structures to explain why  $\text{Br}_3^-$  and  $\text{I}_3^-$  are stable, while  $\text{F}_3^-$  is not.
101. Draw the Lewis structure for  $\text{HCSNH}_2$ . (The carbon and nitrogen atoms are bonded together, and the sulfur atom is bonded to the carbon atom.) Label each bond in the molecule as polar or nonpolar.
102. Draw the Lewis structure for urea,  $\text{H}_2\text{NCONH}_2$ , one of the compounds responsible for the smell of urine. (The central carbon atom is bonded to both nitrogen atoms and to the oxygen atom.) Does urea contain polar bonds? Which bond in urea is most polar?
103. Some theories of aging suggest that free radicals cause certain diseases and perhaps aging in general. As you know from the Lewis model, such molecules are not chemically stable and will quickly react with other molecules. According to certain theories, free radicals may attack molecules within the cell, such as DNA, changing them and causing cancer or other diseases. Free radicals may also attack molecules on the surfaces of cells, making them appear foreign to the body's immune system. The immune system then attacks the cells and destroys them, weakening the body. Draw Lewis structures for each free radical implicated in this theory of aging.

- $\text{O}_2^-$
- $\text{O}^-$
- $\text{OH}$
- $\text{CH}_3\text{OO}$  (unpaired electron on terminal oxygen)

104. Free radicals are important in many environmentally significant reactions (see the *Chemistry in the Environment* box on free radicals in this chapter). For example, photochemical smog—smog that results from the action of sunlight on air pollutants—forms in part by these two steps:

The product of this reaction, ozone, is a pollutant in the lower atmosphere. (Upper atmospheric ozone is a natural part of the atmosphere that protects life on Earth from ultraviolet light.) Ozone is an eye and lung irritant and also accelerates the weathering of rubber products. Rewrite the given reactions using the Lewis structure of each reactant and product. Identify the free radicals.

105. If hydrogen were used as a fuel, it could be burned according to this reaction:

Use average bond energies to calculate  $\Delta H_{\text{rxn}}$  for this reaction and also for the combustion of methane ( $\text{CH}_4$ ). Which fuel yields more energy per mole? Per gram?

106. Calculate  $\Delta H_{\text{rxn}}$  for the combustion of octane ( $\text{C}_8\text{H}_{18}$ ), a component of gasoline, by using average bond energies and then calculate it using enthalpies of formation from Appendix IIB. What is the percent difference between your results? Which result would you expect to be more accurate?
107. Draw the Lewis structure for each compound.
- $\text{Cl}_2\text{O}_7$  (no  $\text{Cl}-\text{Cl}$  bond)
  - $\text{H}_3\text{PO}_3$  (two  $\text{OH}$  bonds)
  - $\text{H}_3\text{AsO}_4$
108. The azide ion,  $\text{N}_3^-$ , is a symmetrical ion, all of whose contributing resonance structures have formal charges. Draw three important contributing structures for this ion.
109. List the following gas-phase ion pairs in order of the quantity of energy released when they form from separated gas-phase ions. List the pair that releases the least energy first.  $\text{Na}^+\text{F}^-$ ,  $\text{Mg}^{2+}\text{F}^-$ ,  $\text{Na}^+\text{O}^{2-}$ ,  $\text{Mg}^{2+}\text{O}^{2-}$ ,  $\text{Al}^{3+}\text{O}^{2-}$ .
110. Calculate  $\Delta H^\circ$  for the reaction  $\text{H}_2(\text{g}) + \text{Br}_2(\text{g}) \longrightarrow 2\text{HBr}(\text{g})$  using the bond energy values. The  $\Delta H_f^\circ$  of  $\text{HBr}(\text{g})$  is not equal to one-half of the value calculated. Account for the difference.
111. The heat of atomization is the heat required to convert a molecule in the gas phase into its constituent atoms in the gas phase. The heat of atomization is used to calculate average bond energies. Without using any tabulated bond energies, calculate the average  $\text{C}-\text{Cl}$  bond energy from the following data: the heat of atomization of  $\text{CH}_4$  is  $1660 \text{ kJ/mol}$ , and the heat of atomization of  $\text{CH}_2\text{Cl}_2$  is  $1495 \text{ kJ/mol}$ .
112. Calculate the heat of atomization (see previous problem) of  $\text{C}_2\text{H}_3\text{Cl}$ , using the average bond energies in Table 9.3.
113. A compound composed of only carbon and hydrogen is 7.743% hydrogen by mass. Propose a Lewis structure for the compound.
114. A compound composed of only carbon and chlorine is 85.5% chlorine by mass. Propose a Lewis structure for the compound.

## Challenge Problems

- 115.** The main component of acid rain ( $\text{H}_2\text{SO}_4$ ) forms from  $\text{SO}_2$  pollutant in the atmosphere via these steps:

Draw the Lewis structure for each of the species in these steps and use bond energies and Hess's law to estimate  $\Delta H_{\text{rxn}}$  for the overall process. (Use 265 kJ/mol for the S—O single bond energy.)

- 116.** A 0.167-g sample of an unknown acid requires 27.8 mL of 0.100 M NaOH to titrate to the equivalence point. Elemental analysis of the acid gives the following percentages by mass: 40.00% C, 6.71% H, 53.29% O. Determine the molecular formula, molar mass, and Lewis structure of the unknown acid.

- 117.** Use the dipole moments of HF and HCl (given at the end of the problem) together with the percent ionic character of each bond (Figure 9.10) to estimate the bond length in each molecule. How well does your estimated bond length agree with the bond length in Table 9.4?

$$\text{HCl } \mu = 1.08 \text{ D}$$

$$\text{HF } \mu = 1.82 \text{ D}$$

- 118.** Use average bond energies together with the standard enthalpy of formation of  $\text{C(g)}$  (718.4 kJ/mol) to estimate the standard enthalpy of formation of gaseous benzene,  $\text{C}_6\text{H}_6(\text{g})$ . (Remember that average bond energies apply to the gas phase only.) Compare the value you obtain using average bond energies to the actual standard enthalpy of formation of gaseous benzene, 82.9 kJ/mol. What does the difference between these two values tell you about the stability of benzene?

- 119.** The standard state of phosphorus at 25 °C is  $\text{P}_4$ . This molecule has four equivalent P atoms, no double or triple bonds, and no expanded octets. Draw its Lewis structure.

- 120.** The standard heat of formation of  $\text{CaBr}_2$  is  $-675 \text{ kJ/mol}$ . The first ionization energy of Ca is 590 kJ/mol, and its second ionization energy is 1145 kJ/mol. The heat of sublimation of  $\text{Ca}[\text{Ca(s)} \longrightarrow \text{Ca(g)}]$  is 178 kJ/mol. The bond energy of  $\text{Br}_2$  is 193 kJ/mol, the heat of vaporization of  $\text{Br}_2(\text{l})$  is 31 kJ/mol, and the electron affinity of Br is  $-325 \text{ kJ/mol}$ . Calculate the lattice energy of  $\text{CaBr}_2$ .

- 121.** The standard heat of formation of  $\text{PI}_3(\text{s})$  is  $-24.7 \text{ kJ/mol}$ , and the PI bond energy in this molecule is 184 kJ/mol. The standard heat of formation of  $\text{P(g)}$  is 334 kJ/mol, and that of  $\text{I}_2(\text{g})$  is 62 kJ/mol. The  $\text{I}_2$  bond energy is 151 kJ/mol. Calculate the heat of sublimation of  $\text{PI}_3[\text{PI}_3(\text{s}) \longrightarrow \text{PI}_3(\text{g})]$ .

- 122.** A compound has the formula  $\text{C}_8\text{H}_8$  and does not contain any double or triple bonds. All the carbon atoms are chemically identical, and all the hydrogen atoms are chemically identical. Draw the Lewis structure for this molecule.

- 123.** Find the oxidation number of each sulfur in the molecule  $\text{H}_2\text{S}_4$ , which has a linear arrangement of its atoms.

- 124.** Ionic solids of the  $\text{O}^-$  and  $\text{O}^{3-}$  anions do not exist, while ionic solids of the  $\text{O}^{2-}$  anion are common. Explain.

- 125.** The standard state of sulfur is solid rhombic sulfur. Use the appropriate standard heats of formation given in Appendix II to find the average bond energy of the  $\text{S}=\text{O}$  in  $\text{SO}_2$ .

## Conceptual Problems

- 126.** Which statement is true of an endothermic reaction?
- Strong bonds break and weak bonds form.
  - Weak bonds break and strong bonds form.
  - The bonds that break and those that form are of approximately the same strength.
- 127.** When a firecracker explodes, energy is obviously released. The compounds in the firecracker can be viewed as being “energy rich.” What does this mean? Explain the source of the energy in terms of chemical bonds.

- 128.** A fundamental difference between compounds containing ionic bonds and those containing covalent bonds is the existence of molecules. Explain why molecules exist in solid covalent compounds but not in solid ionic compounds.

- 129.** In the very first chapter of this book, we described the scientific approach and put a special emphasis on scientific models or theories. In this chapter, we looked carefully at a model for chemical bonding (the Lewis model). Why is this theory successful? What are some of the limitations of the theory?

## Active Classroom Learning

## Questions for Group Work

Discuss these questions with the group and record your consensus answer.

- 130.** Have each member of your group represent an atom of a metal or an atom of a nonmetal. Each group member holds a coin to represent an electron. Which group members are most reluctant to give up their electrons? Which group members are most willing to give up their electrons? Determine which kind of bond could form between each pair of group members. Tabulate your results.
- 131.** Spend a few minutes reviewing the Lewis dot symbols for the atoms H through Ne. Form a circle and have each group member ask the group member on his or her right to draw the Lewis symbol for a specific atom. Keep going around until each group

member can write all the Lewis dot symbols for the atoms H through Ne. Determine the formal charge for each symbol. In a complete sentence or two, describe why they are all the same.

- 132.** Draw the Lewis dot symbols for the atoms Al and O. Use the Lewis model to determine the formula for the compound formed from these two atoms.

- 133.** Draft a list of step-by-step instructions for writing the correct Lewis dot structure for any molecule or polyatomic ion.

- 134.** Pass a piece of paper around the group and ask each group member in turn to perform the next step in the process of determining a correct Lewis structure (including formal charges on all atoms and resonance structures, if appropriate) for the following molecules and ions:  $\text{N}_2\text{H}_4$ ,  $\text{CCl}_4$ ,  $\text{CO}_3^{2-}$ , and  $\text{NH}_4^+$ .

## Data Interpretation and Analysis

### Lattice Energies of Period 4 Elements

**135.** Evidence for the additional stabilization of certain electron configurations comes from the experimental lattice energies of the metal fluorides— $\text{MF}_2$ . Figure a plots lattice energy for the 2+ metal cations for period 4 elements. Figure b plots the ionic radii of the 2+ metal cations of period 4 elements versus atomic number.

**▲ FIGURE a** Lattice Energy of Period 4 Metal Fluorides

Source: After C.S.G. Phillips, R. J. P Williams, *Inorganic Chemistry*, Volume 1, p. 179.

**▲ FIGURE b** Ionic Radius Versus Atomic Number of 2+ Metal Cations for Period 4 Elements

Use the information provided in the figures to answer the following questions:

- Explain the general trend in lattice energy observed in Figure a.
- Is there a correlation between ionic radius and lattice energy? Explain.
- What could account for the decrease in lattice energy between  $\text{CrF}_2$  and  $\text{MnF}_2$ ?
- Which has the higher lattice energy:  $\text{VF}_2$  or  $\text{VCl}_2$ ? Explain.

## Answers to Conceptual Connections

### Bond Types

**9.1 (c)** Because  $\text{MgF}_2$  is composed of a metal and a nonmetal, it is most likely to contain ionic bonds.

### Melting Points of Ionic Solids

**9.2** You would expect  $\text{MgO}$  to have the higher melting point because, in our bonding model, the magnesium and oxygen ions are held together in a crystalline lattice by charges of 2+ for magnesium and 2- for oxygen. In contrast, the  $\text{NaCl}$  lattice is held together by charges of 1+ for sodium and 1- for chlorine. The experimentally measured melting points of these compounds are 801 °C for  $\text{NaCl}$  and 2852 °C for  $\text{MgO}$ , in accordance with our model.

### Energy and the Octet Rule

**9.3** The reasons that atoms form bonds are complex. One contributing factor is the lowering of their potential energy. The octet rule is just a handy way to predict the combinations of atoms that have a lower potential energy when they bond.

### Periodic Trends in Electronegativity

**9.4**  $\text{N} > \text{P} > \text{Al} > \text{Na}$

### Percent Ionic Character

**9.5 (b)** You are given that the dipole moment of the  $\text{HCl}$  bond is about 1 D and that the bond length is 127 pm. Previously, we calculated the dipole moment for a 130-pm bond that is 100% ionic to be about 6.2 D. You can therefore estimate the bond's ionic character as  $1/6 \times 100$ , which is closest to 15%.

### Odd-Electron Species

**9.6 (d)**  $\text{NO}_2$  because the sum of the valence electrons of its atoms is an odd number.

### Expanded Octets

**9.7 (b)** The only molecule in this group that could have an expanded octet is  $\text{H}_3\text{PO}_4$  because phosphorus is a third-period element. Expanded octets *never* occur in second-period elements such as carbon and nitrogen.

### Bond Energies and $\Delta H_{\text{rxn}}$

**9.8 (b)** In a highly exothermic reaction, the energy needed to break bonds is less than the energy released when the new bonds form, resulting in a net release of energy.

# Chemical Bonding II: Molecular Shapes, Valence Bond Theory, and Molecular Orbital Theory

No theory ever solves all the puzzles with which it is confronted at a given time; nor are the solutions already achieved often perfect.

**KEY LEARNING OUTCOMES 475**

In Chapter 9, we examined a simple model for chemical bonding called the Lewis model. We saw how this model helps us to explain and predict the combinations of atoms that form stable molecules. When we combine the Lewis model with the idea that valence electron groups repel one another—the basis of an approach known as VSEPR theory—we can predict the general shape of a molecule from its Lewis structure. We address molecular shape and its importance in the first part of this chapter. We then move on to explore two additional bonding theories—called valence bond theory and molecular orbital theory—that are progressively more sophisticated, but at the cost of being more complex, than the Lewis model. As you work through this chapter, our second on chemical bonding, keep in mind the importance of this topic. In our universe, elements join together to form compounds, and that makes many things possible, including our own existence.

▲ Similarities in the shape of sucrose and aspartame give both molecules the ability to stimulate a sweet taste sensation.

## 10.1 Artificial Sweeteners: Fooled by Molecular Shape

Artificial sweeteners, such as aspartame (NutraSweet), taste sweet but have few or no calories. Why? *Because taste and caloric value are independent properties of foods.* The caloric value of a food depends on the amount of energy released when your body metabolizes the food. For example, sucrose (table sugar) is metabolized by oxidation to carbon dioxide and water:

When your body metabolizes a mole of sucrose, it obtains 5644 kJ of energy. Some artificial sweeteners, such as saccharin, for example, are not metabolized at all—they just pass through the body unchanged—and therefore have no caloric value. Other artificial sweeteners, such as aspartame, are metabolized but have a much lower caloric content (for a given amount of sweetness) than sucrose.

The *taste* of a food, however, is independent of its metabolism. The sensation of taste originates in the tongue, where specialized taste cells act as highly sensitive and specific molecular detectors. These cells discern sugar molecules from the thousands of different types of molecules present in a mouthful of food. The main factors for this discrimination are the sugar molecule's shape and charge distribution.

The surface of a taste cell contains specialized protein molecules called taste receptors. A particular *tastant*—a molecule that we can taste—fits snugly into a special pocket (just as a key fits into a lock) on the taste receptor protein called the *active site*. For example, a sugar molecule precisely fits into the active site of the sugar receptor protein called T1r3. When the sugar molecule (the key) enters the active site (the lock), the different subunits of the T1r3 protein split apart. This split opens ion channels in the cell membrane, resulting in nerve signal transmission (see Section 8.1) that reaches the brain and causes the sensation of sweetness.

Artificial sweeteners taste sweet because they fit into the receptor pocket that normally binds sucrose. In fact, both aspartame and saccharin bind to the active site in the T1r3 protein more strongly than sugar! For this reason, artificial sweeteners are “sweeter than sugar.” Aspartame, for example, is 200 times sweeter than sugar, meaning that it takes 200 times as much sugar as aspartame to trigger the same amount of nerve signal transmission from taste cells.

The lock-and-key fit between the active site of a protein and a particular molecule is important not only to taste but to many other biological functions as well. Immune response, the sense of smell, and many types of drug action all depend on shape-specific interactions between molecules and proteins. Our ability to determine the shapes of key biological molecules is largely responsible for the revolution in biology research that has occurred over the last 50 years.

In this chapter, we look at ways to predict and account for the shapes of molecules. The molecules we examine are much smaller than the protein molecules we just discussed, but the same principles apply to both. The simple model we examine to account for molecular shape is *valence shell electron pair repulsion* (VSEPR) theory, and we will use it in conjunction with the Lewis model. We then proceed to explore two additional bonding theories: valence bond theory and molecular orbital theory. These bonding theories are more complex, but also more powerful, than the Lewis model. They predict and account for molecular shape as well as other properties of molecules.

**▲ FIGURE 10.1 Repulsion between Electron Groups** The basic idea of VSEPR theory is that repulsions between electron groups determine molecular geometry.

## 10.2 VSEPR Theory: The Five Basic Shapes

**Valence shell electron pair repulsion (VSEPR) theory** is based on the simple idea that **electron groups**—which we define as lone pairs, single bonds, multiple bonds, and even single electrons—repel one another through coulombic forces. The electron groups are also attracted to the nucleus (otherwise the molecule would fall apart), but VSEPR theory focuses on the repulsions. According to VSEPR theory, the repulsions between electron groups on *interior atoms* of a molecule determine the geometry of the molecule (Figure 10.1◀). The preferred geometry of a molecule is the one in which the electron groups have the maximum separation (and therefore the minimum repulsion energy) possible. Consequently, for molecules having just one interior atom (the central atom), molecular geometry depends on (a) the number of electron groups around the central atom and (b) how many of those electron groups are bonding groups and how many are lone pairs. We first look at the molecular geometries associated with two to six electron groups around the central atom when all of those groups are bonding groups (single or multiple bonds). The resulting geometries constitute the five basic shapes of molecules. We then consider how these basic shapes are modified if one or more of the electron groups are lone pairs.

## Two Electron Groups: Linear Geometry

Consider the Lewis structure of  $\text{BeCl}_2$ , which has two electron groups (two single bonds) about the central atom:

According to VSEPR theory, the geometry of  $\text{BeCl}_2$  is determined by the repulsion between these two electron groups, which maximize their separation by assuming a  $180^\circ$  bond angle or a **linear geometry**. Experimental measurements of the geometry of  $\text{BeCl}_2$  indicate that the molecule is indeed linear, as predicted by the theory.

Molecules that form only two single bonds, with no lone pairs, are rare because they do not follow the octet rule. However, the same geometry is observed in all molecules that have two electron groups (and no lone pairs). Consider the Lewis structure of  $\text{CO}_2$ , which has two electron groups (the double bonds) around the central carbon atom:

According to VSEPR theory, the two double bonds repel each other (just as the two single bonds in  $\text{BeCl}_2$  repel each other), resulting in a linear geometry for  $\text{CO}_2$ . Experimental observations confirm that  $\text{CO}_2$  is indeed a linear molecule.

Beryllium often forms incomplete octets, as it does in this structure.

A double bond counts as one electron group.

## Three Electron Groups: Trigonal Planar Geometry

The Lewis structure of  $\text{BF}_3$  (another molecule with an incomplete octet) has three electron groups around the central atom:

These three electron groups can maximize their separation by assuming  $120^\circ$  bond angles in a plane—a **trigonal planar geometry**. Experimental observations of the structure of  $\text{BF}_3$  again confirm the predictions of VSEPR theory.

Another molecule with three electron groups, formaldehyde ( $\text{HCHO}$ ), has one double bond and two single bonds around the central atom:

Because formaldehyde has three electron groups around the central atom, we initially predict that the bond angles should also be  $120^\circ$ . However, experimental observations show that the  $\text{HCO}$  bond angles are  $121.9^\circ$  and the  $\text{HCH}$  bond angle is  $116.2^\circ$ . These bond angles are close to the idealized  $120^\circ$  that we originally predicted, but the  $\text{HCO}$  bond angles are slightly greater than the  $\text{HCH}$  bond angle because the double bond contains more electron density than the single bond and therefore exerts a slightly greater repulsion on the single bonds. In general, *different types of electron groups exert slightly different repulsions*—the resulting bond angles reflect these differences.

**Electron Groups and Molecular Geometry** In determining electron geometry, why do we consider only the electron groups on the central atom? In other words, why don't we consider electron groups on terminal atoms?

CONCEPTUAL  
**CONNECTION 10.1**

## Four Electron Groups: Tetrahedral Geometry

The VSEPR geometries of molecules with two or three electron groups around the central atom are two-dimensional, and we can therefore easily visualize and represent them on paper. For molecules with four or more electron groups around the central atom, the geometries are three-dimensional and therefore more difficult to imagine and draw. We can understand these basic shapes by analogy to balloons tied together.

## ► FIGURE 10.2 Representing

## Electron Geometry with

**Balloons** (a) The bulkiness of balloons causes them to assume a linear arrangement when two of them are tied together. Similarly, the repulsion between two electron groups produces a linear geometry. (b) Like three balloons tied together, three electron groups adopt a trigonal planar geometry.

In this analogy, each electron group around a central atom is like a balloon tied to a central point. The bulkiness of the balloons causes them to spread out as much as possible, much as the repulsion between electron groups causes them to position themselves as far apart as possible.

For example, if you tie two balloons together, they assume a roughly linear arrangement, as shown in Figure 10.2(a)▲, analogous to the linear geometry of  $\text{BeCl}_2$  that we just examined. Notice that the balloons do not represent atoms, but *electron groups*. Similarly, if you tie three balloons together—in analogy to three electron groups—they assume a trigonal planar geometry, as shown in Figure 10.2(b)▲, much like the  $\text{BF}_3$  molecule. If you tie *four* balloons together, however, they assume a three-dimensional **tetrahedral geometry** with  $109.5^\circ$  angles between the balloons. That is, the balloons point toward the vertices of a *tetrahedron*—a geometrical shape with four identical faces, each an equilateral triangle, as shown here:

Methane is an example of a molecule with four electron groups around the central atom:

For four electron groups, the tetrahedron is the three-dimensional shape that allows the maximum separation among the groups. The repulsions among the four electron groups in the  $\text{C—H}$  bonds cause the molecule to assume the tetrahedral shape. When we write the Lewis structure of  $\text{CH}_4$  on paper, it may seem that the molecule should be square planar, with bond angles of  $90^\circ$ . However, in three dimensions, the electron groups can get farther away from each other by forming the tetrahedral geometry, as illustrated by our balloon analogy.

## CONCEPTUAL CONNECTION 10.2

**Molecular Geometry** What is the geometry of the HCN molecule? The Lewis structure of HCN is  $\text{H}-\text{C}\equiv\text{N}:$

- (a) linear      (b) trigonal planar      (c) tetrahedral

### Five Electron Groups: Trigonal Bipyramidal Geometry

Five electron groups around a central atom assume a **trigonal bipyramidal geometry**, like five balloons tied together. In this structure, three of the groups lie in a single plane, as in the trigonal planar configuration, whereas the other two are positioned above and below this plane. The angles in the trigonal bipyramidal structure are not all the same. The angles between the *equatorial positions* (the three bonds in the trigonal plane) are  $120^\circ$ , whereas the angle between the *axial positions* (the two bonds on either side of the trigonal plane) and the trigonal plane is  $90^\circ$ .  $\text{PCl}_5$  is an example of a molecule with five electron groups around the central atom:

Trigonal bipyramidal geometry

Trigonal bipyramid

The three equatorial chlorine atoms are separated by  $120^\circ$  bond angles, and the two axial chlorine atoms are separated from the equatorial atoms by  $90^\circ$  bond angles.

### Six Electron Groups: Octahedral Geometry

Six electron groups around a central atom assume an **octahedral geometry**, like six balloons tied together. In this structure—named after the eight-sided geometrical shape called the octahedron—four of the groups lie in a single plane, with a fifth group above the plane and the sixth below it. The angles in this geometry are all  $90^\circ$ .  $\text{SF}_6$  is a molecule with six electron groups around the central atom:

Octahedral geometry

Octahedron

The structure of this molecule is highly symmetrical; all six bonds are equivalent.

**Example 10.1** VSEPR Theory and the Basic ShapesDetermine the molecular geometry of  $\text{NO}_3^-$ .**SOLUTION**

Determine the molecular geometry of  $\text{NO}_3^-$  by counting the number of electron groups around the central atom (N). Begin by drawing a Lewis structure for  $\text{NO}_3^-$ .

$\text{NO}_3^-$  has  $5 + 3(6) + 1 = 24$  valence electrons. The Lewis structure has three resonance structures:

The hybrid structure is intermediate between these three and has three equivalent bonds.

Use any one of the resonance structures to determine the number of electron groups around the central atom.

The nitrogen atom has three electron groups: two single bonds and one double bond.

Based on the number of electron groups, determine the geometry that minimizes the repulsions between the groups.

The electron geometry that minimizes the repulsions between three electron groups is trigonal planar.

The three bonds are equivalent (because of the resonance structures), so they each exert the same repulsion on the other two and the molecule has three equal bond angles of  $120^\circ$ .

**FOR PRACTICE 10.1** Determine the molecular geometry of  $\text{CCl}_4$ .

**VSEPR Theory: The Effect of Lone Pairs****10.3 VSEPR Theory: The Effect of Lone Pairs**

Each of the examples we have just seen has only bonding electron groups around the central atom. What happens in molecules that have lone pairs around the central atom as well? The lone pairs also repel other electron groups, as we see in the examples that follow.

**Four Electron Groups with Lone Pairs**

Consider the Lewis structure of ammonia:

Electron geometry:  
tetrahedral

Molecular geometry:  
trigonal pyramidal

The central nitrogen atom has four electron groups (one lone pair and three bonding pairs) that repel one another. If we do not distinguish between bonding electron groups and lone pairs, we find that the **electron geometry**—the geometrical arrangement of the *electron groups*—is still tetrahedral, as we expect for four electron groups. However, the **molecular geometry**—the geometrical arrangement of the atoms—is **trigonal pyramidal**, as shown at left.

Notice that although the electron geometry and the molecular geometry are different, *the electron geometry is relevant to the molecular geometry*. The lone pair exerts its influence on the bonding pairs.

As we noted previously, different kinds of electron groups generally result in different amounts of repulsion. Lone pair electrons typically exert slightly greater repulsions than bonding electrons. If all four electron groups in  $\text{NH}_3$  exerted equal repulsions on one another, the bond angles in the molecule would all be the ideal tetrahedral angle,  $109.5^\circ$ . However, the actual angle between  $\text{N}-\text{H}$  bonds in ammonia is slightly smaller,  $107^\circ$ . A lone electron pair is more spread out in space than a bonding electron pair because a lone pair is attracted to only one nucleus while a bonding pair is attracted to two (Figure 10.3). The lone pair occupies more of the angular space around a nucleus, exerting a greater repulsive force on neighboring electrons and compressing the  $\text{N}-\text{H}$  bond angles.

◀ **FIGURE 10.3** Lone Pair versus Bonding Electron Pairs

A lone electron pair occupies more space than a bonding pair.

A water molecule's Lewis structure is:

Because water has four electron groups (two bonding pairs and two lone pairs), its *electron geometry* is also tetrahedral, but its *molecular geometry* is **bent**, as shown at right. As in  $\text{NH}_3$ , the bond angles in  $\text{H}_2\text{O}$  are smaller ( $104.5^\circ$ ) than the ideal tetrahedral bond angles because of the greater repulsion exerted by the lone pair electrons. The bond angle in  $\text{H}_2\text{O}$  is even smaller than in  $\text{NH}_3$  because  $\text{H}_2\text{O}$  has *two* lone pairs of electrons on the central oxygen atom. These lone pairs compress the  $\text{H}_2\text{O}$  bond angle to a greater extent than in  $\text{NH}_3$ .

In general, electron group repulsions compare as follows:

Lone pair–lone pair > Lone pair–bonding pair > Bonding pair–bonding pair

Most repulsive

Least repulsive

We see the effects of this ordering in the progressively smaller bond angles of  $\text{CH}_4$ ,  $\text{NH}_3$ , and  $\text{H}_2\text{O}$ , shown in Figure 10.4. The relative ordering of repulsions also helps to determine the geometry of molecules with five and six electron groups when one or more of those groups are lone pairs.

◀ **FIGURE 10.4** The Effect of Lone Pairs on Molecular Geometry

The bond angles get progressively smaller as the number of lone pairs on the central atom increases from zero in  $\text{CH}_4$  to one in  $\text{NH}_3$  to two in  $\text{H}_2\text{O}$ .

### Effect of Lone Pairs on Molecular Geometry

## Five Electron Groups with Lone Pairs

Consider the Lewis structure of  $\text{SF}_4$ :

The central sulfur atom has five electron groups (one lone pair and four bonding pairs). The *electron geometry*, due to the five electron groups, is trigonal bipyramidal.

To determine the molecular geometry for sulfur tetrafluoride, notice that the lone pair could occupy either an equatorial position or an axial position within the trigonal bipyramidal electron geometry. Which position is more favorable? To answer this question, recall that, as we have just seen, lone pair–bonding pair repulsions are greater than bonding pair–bonding pair repulsions. Therefore, the lone pair occupies the position that minimizes its interaction with the bonding pairs. If the lone pair were in an axial position, it would have three  $90^\circ$  interactions with bonding pairs. In an equatorial position, however, it has only two  $90^\circ$  interactions. Consequently, the lone pair occupies an equatorial position. The resulting molecular geometry is called **seesaw** because it resembles a seesaw (or teeter-totter).

The seesaw molecular geometry is sometimes called an *irregular tetrahedron*.

When two of the five electron groups around the central atom are lone pairs, as in  $\text{BrF}_3$ , the lone pairs occupy two of the three equatorial positions—again minimizing  $90^\circ$  interactions with bonding pairs and also avoiding a lone pair–lone pair  $90^\circ$  repulsion. The resulting molecular geometry is **T-shaped**.

When three of the five electron groups around the central atom are lone pairs, as in  $\text{XeF}_2$ , the lone pairs occupy all three of the equatorial positions, and the resulting molecular geometry is linear.

### Six Electron Groups with Lone Pairs

Consider the Lewis structure of  $\text{BrF}_5$  shown here. The central bromine atom has six electron groups (one lone pair and five bonding pairs). The electron geometry, due to the six electron groups, is octahedral. Since all six positions in the octahedral geometry are equivalent, the lone pair can be situated in any one of these positions. The resulting molecular geometry is **square pyramidal**.

When two of the six electron groups around the central atom are lone pairs, as in  $\text{XeF}_4$ , the lone pairs occupy positions across from one another (to minimize lone pair-lone pair repulsions), and the resulting molecular geometry is **square planar**.

TABLE 10.1 Electron and Molecular Geometries

\*Count only electron groups around the central atom. Each of the following is considered one electron group: a lone pair, a single bond, a double bond, a triple bond, or a single electron.

### CONCEPTUAL CONNECTION 10.3

**Lone Pair Electrons and Molecular Geometry** Imagine that a molecule with six electron groups is confined to two dimensions and therefore has a hexagonal planar electron geometry. If two of the six groups are lone pairs, where are they located?

- (a) positions 1 and 2
- (b) positions 1 and 3
- (c) positions 1 and 4

#### Summarizing VSEPR Theory:

- ▶ The geometry of a molecule is determined by the number of electron groups on the central atom (or on all interior atoms, if there is more than one).
- ▶ The number of electron groups is determined from the Lewis structure of the molecule. If the Lewis structure contains resonance structures, use any one of the resonance structures to determine the number of electron groups.
- ▶ Each of the following counts as a single electron group: a lone pair, a single bond, a double bond, a triple bond, or a single electron (as in a free radical).
- ▶ The geometry of the electron groups is determined by their repulsions as summarized in Table 10.1. In general, electron group repulsions vary as follows:  
 Lone pair–lone pair > lone pair–bonding pair > bonding pair–bonding pair
- ▶ Bond angles can vary from the idealized angles because double and triple bonds occupy more space than single bonds (they are bulkier even though they are shorter), and lone pairs occupy more space than bonding groups. The presence of lone pairs usually makes bond angles smaller than the ideal angles for the particular geometry.

### CONCEPTUAL CONNECTION 10.4

**Molecular Geometry and Electron Group Repulsions** Which statement is *always* true according to VSEPR theory?

- (a) The shape of a molecule is determined only by repulsions among bonding electron groups.
- (b) The shape of a molecule is determined only by repulsions among nonbonding electron groups.
- (c) The shape of a molecule is determined by the polarity of its bonds.
- (d) The shape of a molecule is determined by repulsions among all electron groups on the central atom (or interior atoms, if there is more than one).

## 10.4 VSEPR Theory: Predicting Molecular Geometries

To determine the geometry of a molecule, follow the procedure presented on the following page. As in other examples, we provide the steps in the left column and two examples of applying the steps in the center and right columns.

## Procedure for...

<b>Predicting Molecular Geometries</b>	<b>Example 10.2</b> <b>Predicting Molecular Geometries</b> Predict the geometry and bond angles of $\text{PCl}_3$ .	<b>Example 10.3</b> <b>Predicting Molecular Geometries</b> Predict the geometry and bond angles of $\text{ICl}_4^-$ .
<b>1. Draw the Lewis structure for the molecule.</b>	$\text{PCl}_3$ has 26 valence electrons. 	$\text{ICl}_4^-$ has 36 valence electrons. 
<b>2. Determine the total number of electron groups around the central atom.</b> Lone pairs, single bonds, double bonds, triple bonds, and single electrons each count as one group.	The central atom (P) has four electron groups.	The central atom (I) has six electron groups.
<b>3. Determine the number of bonding groups and the number of lone pairs around the central atom.</b> These should sum to your result from step 2. Bonding groups include single bonds, double bonds, and triple bonds.	 Three of the four electron groups around P are bonding groups, and one is a lone pair.	 Four of the six electron groups around I are bonding groups, and two are lone pairs.
<b>4. Refer to Table 10.1 to determine the electron geometry and molecular geometry.</b> If no lone pairs are present around the central atom, the bond angles will be that of the ideal geometry. If lone pairs are present, the bond angles may be smaller than the ideal geometry.	The electron geometry is tetrahedral (four electron groups), and the molecular geometry—the shape of the molecule—is <i>trigonal pyramidal</i> (three bonding groups and one lone pair). Because of the presence of a lone pair, the bond angles are less than $109.5^\circ$ .  Trigonal pyramidal	The electron geometry is octahedral (six electron groups), and the molecular geometry—the shape of the molecule—is <i>square planar</i> (four bonding groups and two lone pairs). Even though lone pairs are present, the bond angles are $90^\circ$ because the lone pairs are symmetrically arranged and do not compress the I—Cl bond angles.  Square planar

## Representing Molecular Geometries on Paper

Since molecular geometries are three-dimensional, they are often difficult to represent on two-dimensional paper. Many chemists use the notation shown here for bonds to indicate three-dimensional structures on two-dimensional paper.

Some examples of the molecular geometries used in this book are shown below using this notation.

## Predicting the Shapes of Larger Molecules

Larger molecules may have two or more *interior* atoms. When predicting the shapes of these molecules, we apply the principles we just covered to each interior atom. Consider glycine, an amino acid found in many proteins (such as those involved in taste discussed in Section 10.1). Glycine, shown in the margin, contains four interior atoms: one nitrogen atom, two carbon atoms, and an oxygen atom. To determine the shape of glycine, we determine the geometry about each interior atom as follows:

Atom	Number of Electron Groups	Number of Lone Pairs	Molecular Geometry
Nitrogen	4	1	Trigonal pyramidal
Leftmost carbon	4	0	Tetrahedral
Rightmost carbon	3	0	Trigonal planar
Oxygen	4	2	Bent

Considering the geometries of each of these, we can determine the entire three-dimensional shape of the molecule as shown to the right.

**Example 10.4** Predicting the Shape of Larger Molecules

Predict the geometry about each interior atom in methanol ( $\text{CH}_3\text{OH}$ ) and make a sketch of the molecule.

**SOLUTION**

Begin by drawing the Lewis structure of  $\text{CH}_3\text{OH}$ .  $\text{CH}_3\text{OH}$  contains two interior atoms: one carbon atom and one oxygen atom. To determine the shape of methanol, determine the geometry about each interior atom as follows:

Atom	Number of Electron Groups	Number of Lone Pairs	Molecular Geometry
Carbon	4	0	Tetrahedral
Oxygen	4	2	Bent

Considering these interior atom geometries, draw a three-dimensional sketch of the molecule:

**FOR PRACTICE 10.4** Predict the geometry about each interior atom in acetic acid ( $\text{H}_3\text{C}-\text{C}(=\text{O})-\text{H}$ ) and make a sketch of the molecule.

**CONCEPTUAL CONNECTION 10.5**

**The Shape of Larger Molecules** What is the molecular geometry about nitrogen in  $\text{CH}_3\text{NH}_2$ ?

**10.5 Molecular Shape and Polarity**

In Chapter 9, we discussed polar bonds. Entire molecules can also be polar, depending on their shape and the nature of their bonds. For example, if a diatomic molecule has a polar bond, the molecule as a whole is polar:

The figure on the right is an electrostatic potential map of  $\text{HCl}$ . In these maps, red areas indicate electron-rich regions in the molecule and the blue areas indicate electron-poor regions. Yellow indicates moderate electron density. Notice that the region around the more electronegative atom (chlorine) is more electron-rich than the region around the hydrogen atom. Thus the molecule itself is polar. If the bond in a diatomic molecule is *nonpolar*, the molecule as a whole is *nonpolar*.

In polyatomic molecules, the presence of polar bonds may or may not result in a polar molecule, depending on the molecular geometry. If the molecular geometry is such

that the dipole moments of individual polar bonds sum together to a net dipole moment, then the molecule is polar. But, if the molecular geometry is such that the dipole moments of the individual polar bonds cancel each other (that is, sum to zero), then the molecule is nonpolar. It all depends on the geometry of the molecule. Consider carbon dioxide:

Each C=O bond in CO<sub>2</sub> is polar because oxygen and carbon have significantly different electronegativities (3.5 and 2.5, respectively). However, since CO<sub>2</sub> is a linear molecule, the polar bonds directly oppose one another and the dipole moment of one bond exactly opposes the dipole moment of the other—the two dipole moments sum to zero and the *molecule* is nonpolar.

Dipole moments can cancel each other because they are *vector quantities*; they have both a magnitude and a direction. Think of each polar bond as a vector, pointing in the direction of the more electronegative atom. The length of the vector is proportional to the electronegativity difference between the bonding atoms. In CO<sub>2</sub>, we have two identical vectors pointing in exactly opposite directions—the vectors sum to zero, much as +1 and −1 sum to zero:

Notice that the electrostatic potential map shows regions of moderately high electron density (yellow with slight red) positioned symmetrically on either end of the molecule with a region of low electron density (blue) located in the middle.

In contrast, consider water:

The O—H bonds in water are also polar; oxygen and hydrogen have electronegativities of 3.5 and 2.1, respectively. However, the water molecule is not linear but bent, so the two dipole moments do not sum to zero as they do in carbon dioxide. If we imagine each bond in water as a vector pointing toward oxygen (the more electronegative atom), we see that, because of the angle between the vectors, they do not cancel but sum to an overall vector or a net dipole moment (shown by the dashed arrow):

The electrostatic potential map reveals an electron-rich region at the oxygen end of the molecule. Consequently, water is a polar molecule. Table 10.2 (on page 443) summarizes common geometries and molecular polarity.

*Summarizing the Process to Determine Molecular Shape and Polarity:*

- ▶ **Draw the Lewis structure for the molecule and determine its molecular geometry.**
- ▶ **Determine whether the molecule contains polar bonds.** A bond is polar if the two bonding atoms have sufficiently different electronegativities (see Figure 9.8). If the molecule contains polar bonds, superimpose a vector, pointing toward the more electronegative atom, on each bond. Draw the length of the vector proportional to the electronegativity difference between the bonding atoms.
- ▶ **Determine whether the polar bonds add together to form a net dipole moment.** Sum the vectors corresponding to the polar bonds together. If the vectors sum to zero, the molecule is nonpolar. If the vectors sum to a net vector, the molecule is polar.

## Vector Addition

We determine whether a molecule is polar by summing the vectors associated with the dipole moments of all the polar bonds in the molecule. If the vectors sum to zero, the molecule is nonpolar. If they sum to a net vector, the molecule is polar. In this section, we demonstrate how to add vectors together in one dimension and in two or more dimensions.

### One Dimension

To add two vectors that lie on the same line, assign one direction as positive. Vectors pointing in that direction have positive magnitudes. Consider vectors pointing in the opposite direction to have negative magnitudes. Then sum the vectors (always remembering to include their signs), as shown in Examples 1–3.

### Two or More Dimensions

To add two vectors, draw a parallelogram in which the two vectors form two adjacent sides. Draw the other two sides of the parallelogram parallel to and the same length as the two original vectors. Draw the resultant vector beginning at the origin and extending to the far corner of the parallelogram as shown in Examples 4 and 5.

To add three or more vectors, add two of them together first, and then add the third vector to the result as shown in Examples 6 and 7.

**TABLE 10.2 Common Cases of Adding Dipole Moments to Determine Whether a Molecule Is Polar**

<p style="text-align: center;">Linear</p>  <p style="text-align: center;">Nonpolar</p> <p>The dipole moments of two identical polar bonds pointing in opposite directions cancel. If one or more of the bonds are different from the other(s), the dipoles will not cancel and the molecule will be polar.</p>

**Example 10.5 Determining Whether a Molecule Is Polar**Determine whether  $\text{NH}_3$  is polar.**SOLUTION****Draw the Lewis structure for the molecule and determine its molecular geometry.**

The Lewis structure has three bonding groups and one lone pair about the central atom. Therefore the molecular geometry is trigonal pyramidal.

**Determine whether the molecule contains polar bonds.** Sketch the molecule and superimpose a vector for each polar bond. The relative length of each vector is proportional to the electronegativity difference between the atoms forming each bond. The vectors point in the direction of the more electronegative atom.

The electronegativities of nitrogen and hydrogen are 3.0 and 2.1, respectively. Therefore, the bonds are polar.

**Determine whether the polar bonds add together to form a net dipole moment.** Examine the symmetry of the vectors (representing dipole moments) and determine whether they cancel each other or sum to a net dipole moment.

The three dipole moments sum to a net dipole moment. The molecule is polar.

**FOR PRACTICE 10.5** Determine whether  $\text{CF}_4$  is polar.

Opposite magnetic poles attract one another.

Opposite partial charges on molecules attract one another.

**▲ FIGURE 10.5 Interaction of Polar Molecules** The north pole of one magnet attracts the south pole of another magnet. In an analogous way, the positively charged end of one molecule attracts the negatively charged end of another (although the forces involved are different). As a result of this electrical attraction, polar molecules interact strongly with one another.

Polar and nonpolar molecules have different properties. Water and oil do not mix, for example, because water molecules are polar and the molecules that compose oil are generally nonpolar. Polar molecules interact strongly with other polar molecules because the positive end of one molecule is attracted to the negative end of another, just as the south pole of a magnet is attracted to the north pole of another magnet (Figure 10.5). A mixture of polar and nonpolar molecules is similar to a mixture of small magnetic particles and nonmagnetic ones. The magnetic particles (which are like polar molecules) clump together, excluding the nonmagnetic particles (which are like nonpolar molecules) and separating into distinct regions.

**▲** Oil and water do not mix because water molecules are polar and the molecules that compose oil are nonpolar.

**▲** A mixture of polar and nonpolar molecules is analogous to a mixture of magnetic marbles (opaque) and nonmagnetic marbles (transparent). As with the magnetic marbles, mutual attraction causes polar molecules to clump together, excluding the nonpolar molecules.

## Chemistry IN YOUR DAY How Soap Works

**I**magine eating a greasy cheeseburger with both hands without a napkin. By the end of the meal, grease and oil coat your hands. If you try to wash them with only water, they remain greasy. However, if you add a little soap, the grease washes away. Why? As we just learned, water molecules are polar and the molecules that compose grease and oil are nonpolar. As a result, water and grease do not mix.

The molecules that compose soap, however, have a special structure that allows them to interact strongly with both water and grease. One end of a soap molecule is polar and the other end is nonpolar.

The nonpolar end is a long hydrocarbon chain. Hydrocarbons are always nonpolar because the electronegativity difference between carbon and hydrogen is small and because the tetrahedral arrangement about each carbon atom tends to cancel any small dipole moments of individual bonds. The polar head of a soap molecule—usually, though not always, ionic—strongly attracts water molecules, while the nonpolar tail interacts more strongly with grease and oil molecules (we examine the nature of these interactions in Chapter 11). Thus, soap acts as a sort of molecular liaison, one end interacting with water and the other end interacting with grease. Soap allows water and grease to mix, removing the grease from your hands and washing it down the drain.

### QUESTION

Consider the detergent molecule shown at right. Which end do you think is polar? Which end is nonpolar?

Polar head attracts water.

Nonpolar tail interacts with grease.

## 10.6 Valence Bond Theory: Orbital Overlap as a Chemical Bond

Valence Bond Theory

In the Lewis model, we use dots to represent electrons. We know from quantum-mechanical theory, however, that such a treatment is an oversimplification. More advanced bonding theories treat electrons in a quantum-mechanical manner. These theories are actually extensions of quantum mechanics, applied to molecules. Although a detailed quantitative treatment of these theories is beyond the scope of this book, we introduce them in a *qualitative* manner in the sections that follow. Keep in mind, however, that modern *quantitative* approaches to chemical bonding using these theories accurately predict many of the properties of molecules—such as bond lengths, bond strengths, molecular geometries, and dipole moments—that we discuss in this book.

The simpler of the two more advanced bonding theories is **valence bond theory**. According to valence bond theory, electrons reside in quantum-mechanical orbitals localized on individual atoms. In many cases, these orbitals are simply the standard *s*, *p*, *d*, and *f* atomic orbitals that we learned about in Chapter 7. In other cases, these orbitals are *hybridized atomic orbitals*, a kind of blend or combination of two or more standard atomic orbitals.

When two atoms approach each other, the electrons and nucleus of one atom interact with the electrons and nucleus of the other atom. In valence bond theory, we calculate how these interactions affect the energies of the electrons in the atomic orbitals. If the energy of the system is lowered because of the interactions, then a chemical bond forms. If the energy of the system is raised by the interactions, then a chemical bond does not form.

The interaction energy is usually calculated as a function of the internuclear distance between the two bonding atoms. For example, Figure 10.6 shows the calculated interaction energy between two hydrogen atoms as a function of the distance between them. The *y*-axis of the graph is the potential energy of the interaction between the electron and nucleus of one hydrogen atom and the electron and nucleus of the other hydrogen atom. The *x*-axis is the separation (or internuclear distance) between the two atoms. As we can see from the graph, when the atoms are far apart (right side of the graph, labeled 1), the interaction energy is nearly zero because the two atoms do not interact to any significant extent. As the atoms get closer (labeled 2 and 3 on the graph), the interaction energy becomes negative. The lowering of the interaction energy is a net stabilization that attracts one hydrogen atom to the other. If the atoms get too close

Valence bond theory is an application of a general quantum-mechanical approximation method called *perturbation theory*. In perturbation theory, a complex system (such as a molecule) is viewed as a simpler system (such as two atoms) that is slightly altered or perturbed by some additional force or interaction (such as the interaction between the two atoms).

Interaction Energy of Two Hydrogen Atoms

**FIGURE 10.6** Interaction Energy Diagram for  $\text{H}_2$  The potential energy of two hydrogen atoms is lowest when they are separated by a distance that allows their 1s orbitals a substantial degree of overlap without too much repulsion between their nuclei. This distance, at which the system is most stable, is the bond length of the  $\text{H}_2$  molecule (labeled 3 on this graph).

(labeled 4 on the graph), however, the interaction energy begins to rise, primarily because of the mutual repulsion of the two positively charged nuclei. The most stable point on the curve occurs at the minimum of the interaction energy—this is the equilibrium bond length (labeled 3 on the graph). At this distance, the two atomic  $1s$  orbitals have a significant amount of overlap, and the electrons spend time in the internuclear region where they can interact with both nuclei. The value of the interaction energy at the equilibrium bond distance is the bond energy.

When we apply valence bond theory to a number of atoms and their corresponding molecules, we arrive at the following general observation: *the interaction energy is usually negative (or stabilizing) when the interacting atomic orbitals contain a total of two electrons that can spin-pair (orient with opposing spins).* Most commonly, the two electrons come from two half-filled orbitals, but in some cases, the two electrons come from one filled orbital overlapping with a completely empty orbital (this is called a coordinate covalent bond, and we will cover it in more detail in Chapter 25). In other words, when two atoms with half-filled orbitals approach each other, the half-filled orbitals *overlap*—parts of the orbitals occupy the same space—and the electrons occupying them align with opposite spins. This results in a net energy stabilization that constitutes a covalent chemical bond. The resulting geometry of the molecule emerges from the geometry of the overlapping orbitals.

When completely filled orbitals overlap, the interaction energy is positive (or destabilizing) and no bond forms.

#### Summarizing Valence Bond Theory:

- ▶ The valence electrons of the atoms in a molecule reside in quantum-mechanical atomic orbitals. The orbitals can be the standard  $s$ ,  $p$ ,  $d$ , and  $f$  orbitals, or they may be hybrid combinations of these.
- ▶ A chemical bond results from the overlap of two half-filled orbitals with spin-pairing of the two valence electrons (or less commonly the overlap of a completely filled orbital with an empty orbital).
- ▶ The geometry of the overlapping orbitals determines the shape of the molecule.

We can apply the general concepts of valence bond theory to explain bonding in hydrogen sulfide,  $\text{H}_2\text{S}$ . The valence electron configurations of the atoms in the molecule are as follows:

The hydrogen atoms each have one half-filled orbital, and the sulfur atom has two half-filled orbitals. The half-filled orbitals on each hydrogen atom overlap with the two half-filled orbitals on the sulfur atom, forming two chemical bonds:

To show the spin-pairing of the electrons in the overlapping orbitals, we superimpose a half-arrow for each electron in each half-filled orbital to indicate that, within a bond, the electrons are spin-paired (one half-arrow is pointing up and the other is pointing

down). We also superimpose paired half-arrows in the filled sulfur  $s$  and  $p$  orbitals to represent the lone pair electrons in those orbitals. (Since those orbitals are full, they are not involved in bonding.)

A quantitative calculation of  $\text{H}_2\text{S}$  using valence bond theory yields bond energies, bond lengths, and bond angles. In our qualitative treatment, we simply show how orbital overlap leads to bonding and make a rough sketch of the molecule based on the overlapping orbitals. Notice that, because the overlapping orbitals on the central atom (sulfur) are  $p$  orbitals and because  $p$  orbitals are oriented at  $90^\circ$  to one another, the predicted bond angle is  $90^\circ$ . The actual bond angle in  $\text{H}_2\text{S}$  is  $92^\circ$ . In the case of  $\text{H}_2\text{S}$ , a simple valence bond treatment matches well with the experimentally measured bond angle (in contrast to VSEPR theory, which predicts a bond angle of less than  $109.5^\circ$ ).

**What Is a Chemical Bond? Part I** The answer to the question “What is a chemical bond?” depends on the bonding model. Answer these three questions:

- (a) What is a covalent chemical bond according to the Lewis model?
- (b) What is a covalent chemical bond according to valence bond theory?
- (c) Why are the answers different?

## CONCEPTUAL CONNECTION 10.6

## 10.7 Valence Bond Theory: Hybridization of Atomic Orbitals

Although the overlap of half-filled *standard* atomic orbitals adequately explains the bonding in  $\text{H}_2\text{S}$ , it cannot adequately explain the bonding in many other molecules. For example, suppose we try to explain the bonding between hydrogen and carbon using the same approach. The valence electron configurations of H and C are as follows:

Carbon has only two half-filled orbitals and should therefore form only two bonds with two hydrogen atoms. We would therefore predict that carbon and hydrogen should form a molecule with the formula  $\text{CH}_2$  and with a bond angle of  $90^\circ$  (corresponding to the angle between any two  $p$  orbitals).

However, from experiments, we know that the stable compound formed from carbon and hydrogen is  $\text{CH}_4$  (methane), which has bond angles of  $109.5^\circ$ . The experimental reality is different from our simple prediction in two ways. First, carbon forms bonds to four hydrogen atoms, not two. Second, the bond angles are much larger than the angle between two  $p$  orbitals. Valence bond theory accounts for the bonding in  $\text{CH}_4$  and many other polyatomic molecules by incorporating an additional concept called *orbital hybridization*.

So far, we have assumed that the overlapping orbitals that form chemical bonds are simply the standard  $s$ ,  $p$ , or  $d$  atomic orbitals. Valence bond theory treats the electrons in a molecule as if they occupied these standard atomic orbitals, but this is a major oversimplification. The concept of hybridization in valence bond theory is essentially a step toward recognizing that *the orbitals in a molecule are not necessarily the same as the orbitals in an atom*. **Hybridization** is a mathematical procedure in which the standard atomic orbitals are combined to form new atomic orbitals called **hybrid orbitals** that

**Valence Bond Theory: Hybridization**

Theoretical prediction

Observed reality

In Section 10.8, we examine another theory called *molecular orbital theory*, which treats electrons in a molecule as occupying orbitals that belong to the molecule as a whole.

As we saw in Chapter 9, the word *hybrid* comes from breeding. A *hybrid* is an offspring of two animals or plants of different standard races or breeds. Similarly, a hybrid orbital is a product of mixing two or more standard atomic orbitals.

In a more nuanced treatment, hybridization is not an all-or-nothing process—it can occur to varying degrees that are not always easy to predict. We saw earlier, for example, that sulfur does not hybridize very much in forming  $\text{H}_2\text{S}$ .

correspond more closely to the actual distribution of electrons in chemically bonded atoms. Hybrid orbitals are still localized on individual atoms, but their shapes and energies differ from those of standard atomic orbitals.

Why do we hypothesize that electrons in some molecules occupy hybrid orbitals? In valence bond theory, a chemical bond is the overlap of two orbitals that together contain two electrons. The greater the overlap, the stronger the bond and the lower the energy. In hybrid orbitals, the electron probability density is more concentrated in a single directional lobe, allowing greater overlap with the orbitals of other atoms. Hybrid orbitals *minimize* the energy of the molecule by *maximizing* the orbital overlap in a bond.

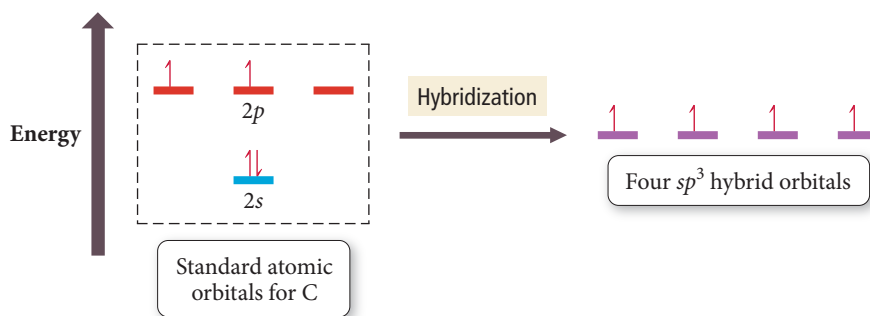

Hybridization, however, is not a free lunch—in most cases it actually costs some energy. So hybridization occurs only to the degree that the energy payback through bond formation is large. In general, therefore, the more bonds that an atom forms, the greater the tendency of its orbitals to hybridize. Central or interior atoms, which form the most bonds, have the greatest tendency to hybridize. Terminal atoms, which form the fewest bonds, have the least tendency to hybridize. *In this book, we focus on the hybridization of interior atoms and assume that all terminal atoms—those bonding to only one other atom—are unhybridized.* Hybridization is particularly important in carbon, which tends to form four bonds in its compounds and therefore always hybridizes.

Although we cannot examine the procedure for obtaining hybrid orbitals in mathematical detail here, we can make the following general statements regarding hybridization:

- ▶ The *number of standard atomic orbitals* added together always equals the *number of hybrid orbitals* formed. The total number of orbitals is conserved.
- ▶ The *particular combination* of standard atomic orbitals added together determines the *shapes and energies* of the hybrid orbitals formed.
- ▶ The *particular type of hybridization that occurs* is the one that yields the *lowest overall energy for the molecule*. Since actual energy calculations are beyond the scope of this book, we use electron geometries as determined by VSEPR theory to predict the type of hybridization.

## $sp^3$ Hybridization

We can account for the tetrahedral geometry in  $\text{CH}_4$  by the hybridization of the one  $2s$  orbital and the three  $2p$  orbitals on the carbon atom. The four new orbitals that result, called  $sp^3$  hybrids, are shown in the following energy diagram:

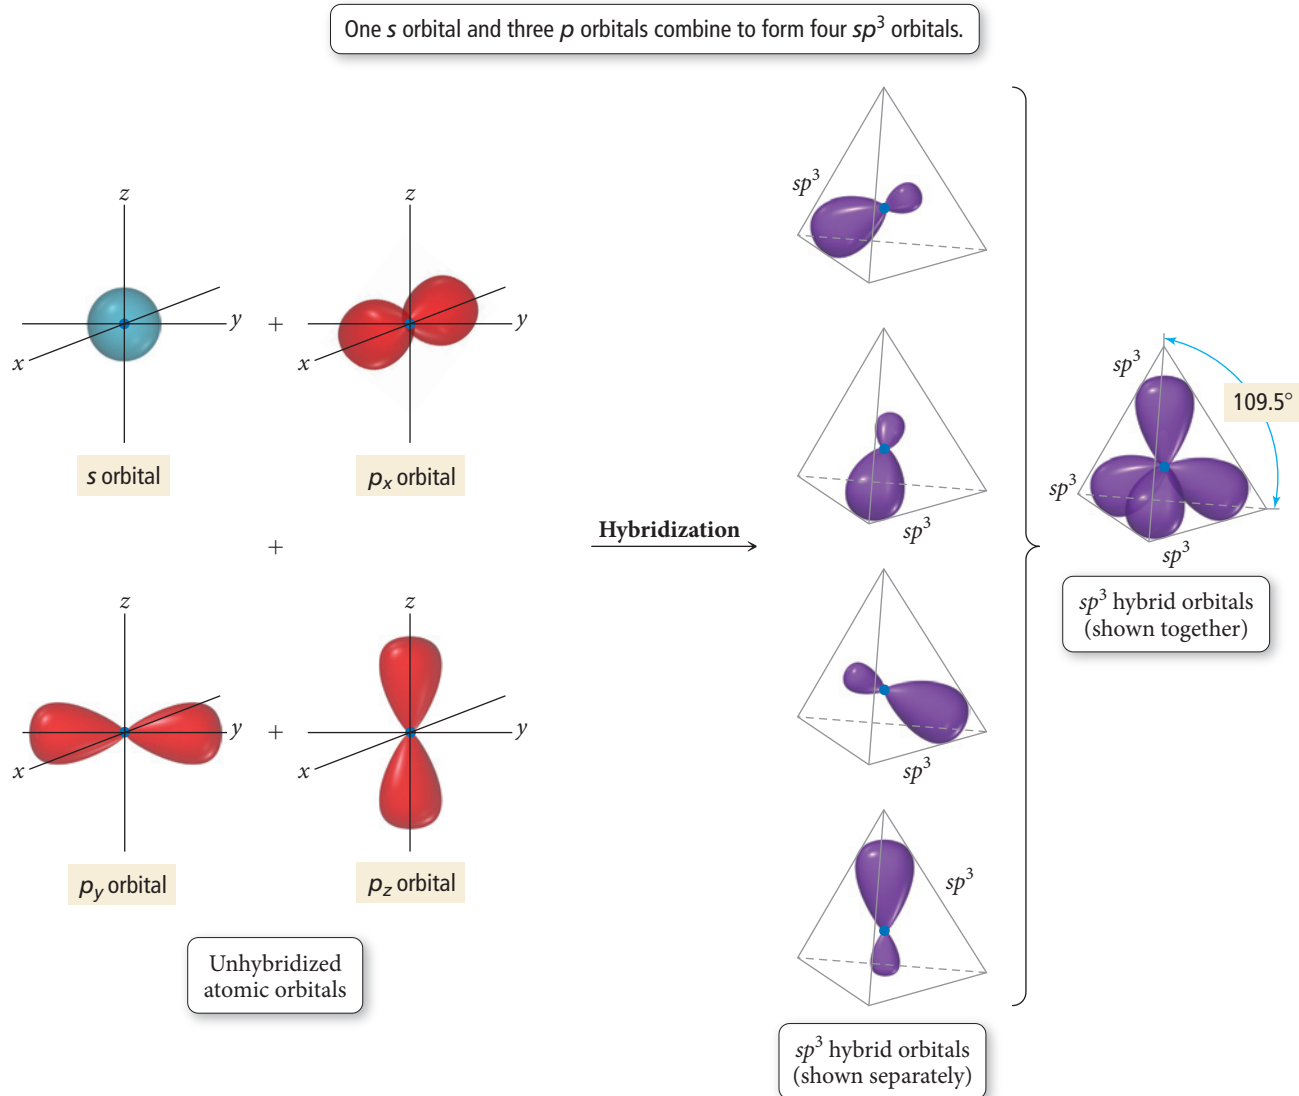

The notation  $sp^3$  indicates that the hybrid orbitals are mixtures of one  $s$  orbital and three  $p$  orbitals. Notice that the hybrid orbitals all have the same energy—they are degenerate. The shapes of the  $sp^3$  hybrid orbitals are shown in Figure 10.7▶. The four hybrid orbitals are arranged in a tetrahedral geometry with  $109.5^\circ$  angles between them.

We can write an orbital diagram for carbon using these hybrid orbitals:

Formation of  $sp^3$  Hybrid Orbitals

**▲ FIGURE 10.7  $sp^3$  Hybridization** One  $s$  orbital and three  $p$  orbitals combine to form four  $sp^3$  hybrid orbitals.

Carbon's four valence electrons occupy the orbitals singly with parallel spins as dictated by Hund's rule. With this electron configuration, carbon has four half-filled orbitals and can form four bonds with four hydrogen atoms:

The geometry of the *overlapping orbitals* (the hybrids) is tetrahedral, with angles of  $109.5^\circ$  between the orbitals, so the *resulting geometry of the molecule* is tetrahedral, with  $109.5^\circ$  bond angles. This agrees with the experimentally measured geometry of  $\text{CH}_4$  and with the predicted VSEPR geometry.

Hybridized orbitals readily form chemical bonds because they tend to maximize overlap with other orbitals. However, if the central atom of a molecule contains lone pairs, hybrid orbitals can also accommodate them. For example, the nitrogen orbitals in ammonia are  $sp^3$  hybrids. Three of the hybrids are involved in bonding with three hydrogen atoms, but the fourth hybrid contains a lone pair. The presence of the lone pair lowers the tendency of nitrogen's orbitals to hybridize. (Remember that the tendency to hybridize increases with the number of bonds formed.) Therefore the bond angle in  $\text{NH}_3$  is  $107^\circ$ , a bit closer to the unhybridized  $p$  orbital bond angle of  $90^\circ$ .

### CONCEPTUAL CONNECTION 10.7

**Number of Hybrid Orbitals Part I** How many  $sp^3$  hybrid orbitals result from the hybridization of  $s$  and  $p$  orbitals?

## $sp^2$ Hybridization and Double Bonds

Hybridization of one  $s$  and two  $p$  orbitals results in three  $sp^2$  hybrids and one leftover unhybridized  $p$  orbital:

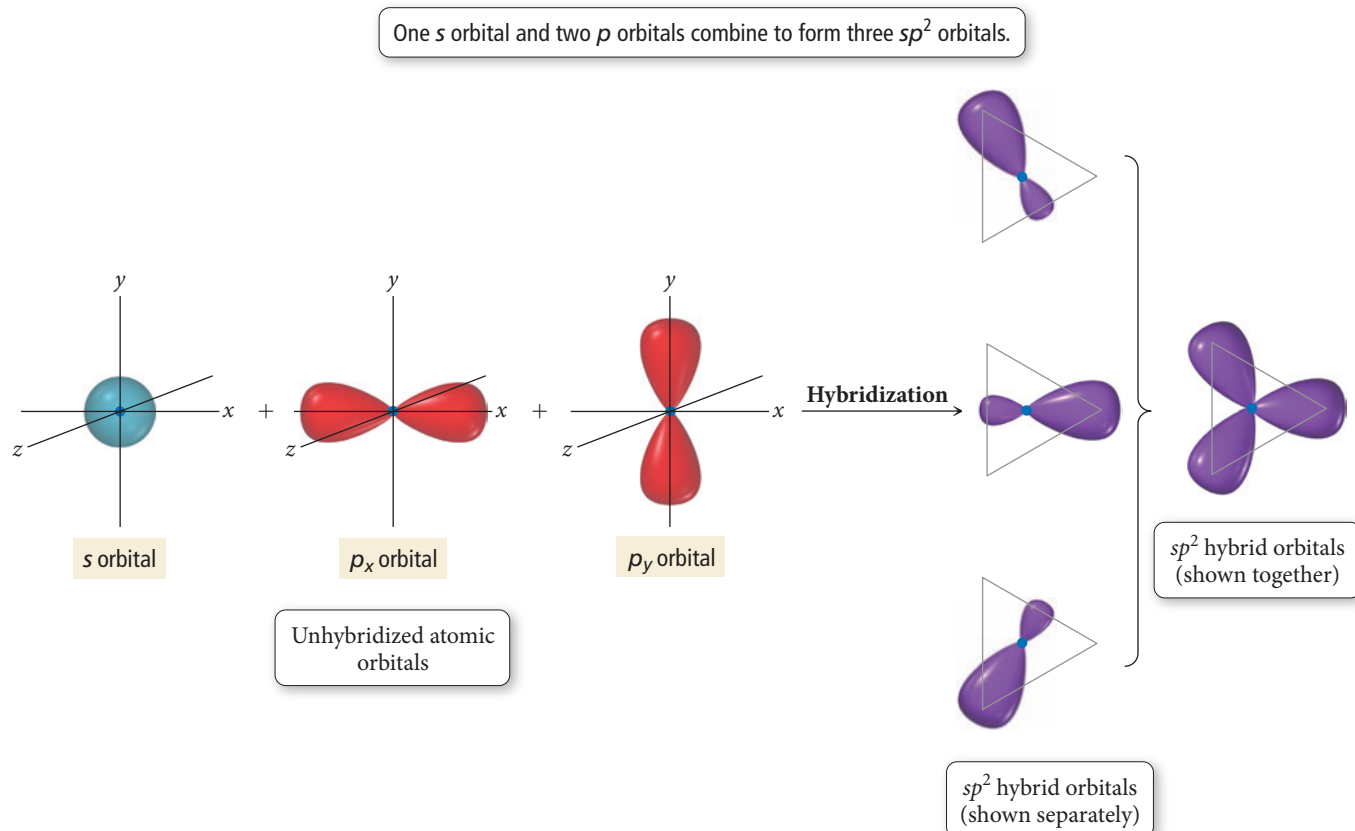

In valence bond theory, the particular hybridization scheme to follow ( $sp^2$  versus  $sp^3$ , for example) for a given molecule is determined computationally, which is beyond the scope of this text. In this book, we determine the particular hybridization scheme from the VSEPR geometry of the molecule, as shown later in this section.

The notation  $sp^2$  indicates that the hybrids are mixtures of one  $s$  orbital and two  $p$  orbitals. Figure 10.8 illustrates the shapes of the  $sp^2$  hybrid orbitals. Notice that the three hybrid orbitals have a trigonal planar geometry with  $120^\circ$  angles between them. The unhybridized  $p$  orbital is perpendicular to the three hybridized orbitals.

As an example of a molecule with  $sp^2$  hybrid orbitals, consider  $\text{H}_2\text{CO}$ . The unhybridized valence electron configurations of each of the atoms are as follows:

Formation of  $sp^2$  Hybrid Orbitals▲ FIGURE 10.8  $sp^2$ 

**Hybridization** One  $s$  orbital and two  $p$  orbitals combine to form three  $sp^2$  hybrid orbitals. One  $p$  orbital (not shown) remains unhybridized.

Carbon is the central atom and the hybridization of its orbitals is  $sp^2$ :

Each of the  $sp^2$  orbitals is half filled. The remaining electron occupies the leftover  $p$  orbital, even though it is slightly higher in energy. We can now see that the carbon atom has four half-filled orbitals and can therefore form four bonds: two with two hydrogen atoms and two (a double bond) with the oxygen atom. We draw the molecule and the overlapping orbitals as follows:

► **FIGURE 10.9** Sigma and Pi

**Bonding** When orbitals overlap side by side, the result is a pi ( $\pi$ ) bond. When orbitals overlap end to end, they form a sigma ( $\sigma$ ) bond. Two atoms can form only one sigma bond. A single bond is a sigma bond, a double bond consists of a sigma bond and a pi bond, and a triple bond consists of a sigma bond and two pi bonds.

Notice the overlap between the half-filled  $p$  orbitals on the carbon and oxygen atoms. When  $p$  orbitals overlap this way (side by side) the resulting bond is a **pi ( $\pi$ ) bond**, and the electron density is above and below the internuclear axis. When orbitals overlap end to end, as is the case in all of the rest of the bonds in the molecule, the resulting bond is a **sigma ( $\sigma$ ) bond** (Figure 10.9▲). Even though we represent the two electrons in a  $\pi$  bond as two half-arrows in the upper lobe, they are actually spread out over both the upper and lower lobes (this is one of the limitations we encounter when we try to represent electrons with arrows). We can label all the bonds in the molecule using a notation that specifies the type of bond ( $\sigma$  or  $\pi$ ) as well as the type of overlapping orbitals. We have included this notation, as well as the Lewis structure of  $\text{H}_2\text{CO}$  for comparison, in the bonding diagram for  $\text{H}_2\text{CO}$ :

Notice the correspondence between valence bond theory and the Lewis model. In both models, the central carbon atom forms four bonds: two single bonds and one double bond. However, valence bond theory gives us more insight into the bonds. The double bond between carbon and oxygen according to valence bond theory consists of two different kinds of bonds—one  $\sigma$  and one  $\pi$ —whereas in the Lewis model the two bonds within the double bond appear identical. *A double bond in the Lewis model always corresponds to one  $\sigma$  and one  $\pi$  bond in valence bond theory.* In general,  $\pi$  bonds are weaker than  $\sigma$  bonds because side-to-side orbital overlap tends to be less efficient than end-to-end orbital overlap. Consequently, the  $\pi$  bond in a double bond is generally easier to break than the  $\sigma$  bond. Valence bond theory, as you can see, gives us more insight into the nature of a double bond than the Lewis model.

One—and only one— $\sigma$  bond forms between any two atoms. Additional bonds must be  $\pi$  bonds.

Valence bond theory shows us the types of orbitals involved in the bonding and their shapes. For example, in  $\text{H}_2\text{CO}$ , the  $sp^2$  hybrid orbitals on the central atom are trigonal planar with  $120^\circ$  angles between them, so the resulting predicted geometry of the molecule is trigonal planar with  $120^\circ$  bond angles. The experimentally measured bond angles in  $\text{H}_2\text{CO}$ , as discussed previously, are  $121.9^\circ$  for the HCO bond and  $116.2^\circ$  for the HCH bond angle, close to the predicted values.

Valence bond theory allows us to see why the rotation about a double bond is severely restricted. Because of the side-by-side overlap of the  $p$  orbitals, the  $\pi$  bond must essentially break for rotation to occur (see Chemistry in Your Day: *The Chemistry of Vision*).

Although rotation about a double bond is highly restricted, rotation about a single bond is relatively unrestricted. Consider, for example, the structures of two chlorinated hydrocarbons, 1,2-dichloroethane and 1,2-dichloroethene:

The hybridization of the carbon atoms in 1,2-dichloroethane is  $sp^3$ , resulting in relatively free rotation about the sigma single bond. Consequently, there is no difference between the following two structures at room temperature because they quickly interconvert:

In contrast, rotation about the double bond (sigma + pi) in 1,2-dichloroethene is restricted; therefore at room temperature, 1,2-dichloroethene exists in two forms:

## Chemistry IN YOUR DAY The Chemistry of Vision

In the human eye, light is detected by a chemical switch involving the breaking and re-forming of a  $\pi$  bond. The back portion of the eye, the retina, is coated with millions of light-sensitive cells called rods and cones. Each of these cells contains proteins that bind a compound called 11-*cis*-retinal, which has the following structure:

11-*cis*-Retinal

When a photon of sufficient energy strikes a rod or cone, it causes the isomerization of 11-*cis*-retinal to all-*trans*-retinal:

all-*trans*-Retinal

The isomerization occurs because visible light contains enough energy to break the  $\pi$  bond between the eleventh and twelfth carbon atom in 11-*cis*-retinal. The  $\sigma$  bond, which is stronger, does not break, allowing the molecule to freely rotate about that bond. The  $\pi$  bond then re-forms with the molecule in the *trans* conformation. The different shape of the resultant all-*trans*-retinal causes conformational changes in the protein to which it is bound. These changes cause an electrical signal to be transmitted to the brain.

### QUESTION

What is the hybridization of the eleventh and twelfth carbon atoms in retinal?

These two forms of 1,2-dichloroethene are different compounds with different properties. We distinguish between them with the designations *cis* (meaning “same side”) and *trans* (meaning “opposite sides”). Compounds such as these, with the same molecular formula but different structures or different spatial arrangement of atoms, are called *isomers*. Nature can—and does—make different compounds out of the same atoms by arranging the atoms in different ways. Isomerism is common throughout chemistry and especially important in organic chemistry, as we will discuss in Chapter 21.

### CONCEPTUAL CONNECTION 10.8

**Single and Double Bonds** In Section 9.10 we learned that double bonds are stronger and shorter than single bonds. For example, a C—C single bond has an average bond energy of 347 kJ/mole, whereas a C=C double bond has an average bond energy of 611 kJ/mole. Use valence bond theory to explain why a double bond is *not* simply twice as strong as a single bond.

### *sp* Hybridization and Triple Bonds

Hybridization of one *s* and one *p* orbital results in two *sp* hybrid orbitals and two leftover unhybridized *p* orbitals:

Figure 10.10 shows the shapes of the  $sp$  hybrid orbitals. Notice that the two  $sp$  hybrid orbitals are arranged in a linear geometry with a  $180^\circ$  angle between them. The unhybridized  $p$  orbitals are oriented in the plane that is perpendicular to the hybridized  $sp$  orbitals.

### Formation of $sp$ Hybrid Orbitals

FIGURE 10.10

**$sp$  Hybridization** One  $s$  orbital and one  $p$  orbital combine to form two  $sp$  hybrid orbitals. Two  $p$  orbitals (not shown) remain unhybridized.

The acetylene molecule,  $\text{HC}\equiv\text{CH}$ , has  $sp$  hybrid orbitals. The four valence electrons of carbon distribute themselves among the two  $sp$  hybrid orbitals and the two  $p$  orbitals:

Each carbon atom then has four half-filled orbitals and can form four bonds: one with a hydrogen atom and three (a triple bond) with the other carbon atom. We draw the molecule and the overlapping orbitals as follows:

Notice that the triple bond between the two carbon atoms consists of two  $\pi$  bonds (overlapping  $p$  orbitals) and one  $\sigma$  bond (overlapping  $sp$  orbitals). The  $sp$  orbitals on the carbon atoms are linear with  $180^\circ$  between them, so the resulting geometry of each carbon on the molecule is linear with  $180^\circ$  bond angles, in agreement with the experimentally measured geometry of  $\text{HC}\equiv\text{CH}$ , and also in agreement with the prediction of VSEPR theory.

## CONCEPTUAL CONNECTION 10.9

**Number of Hybrid Orbitals Part II** How many  $sp$  hybrid orbitals result from the hybridization of  $s$  and  $p$  orbitals?

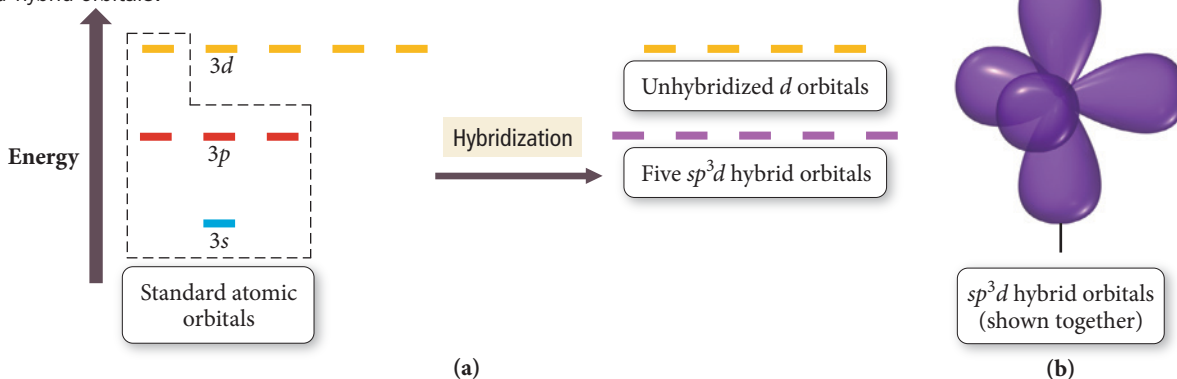

### $sp^3d$ and $sp^3d^2$ Hybridization

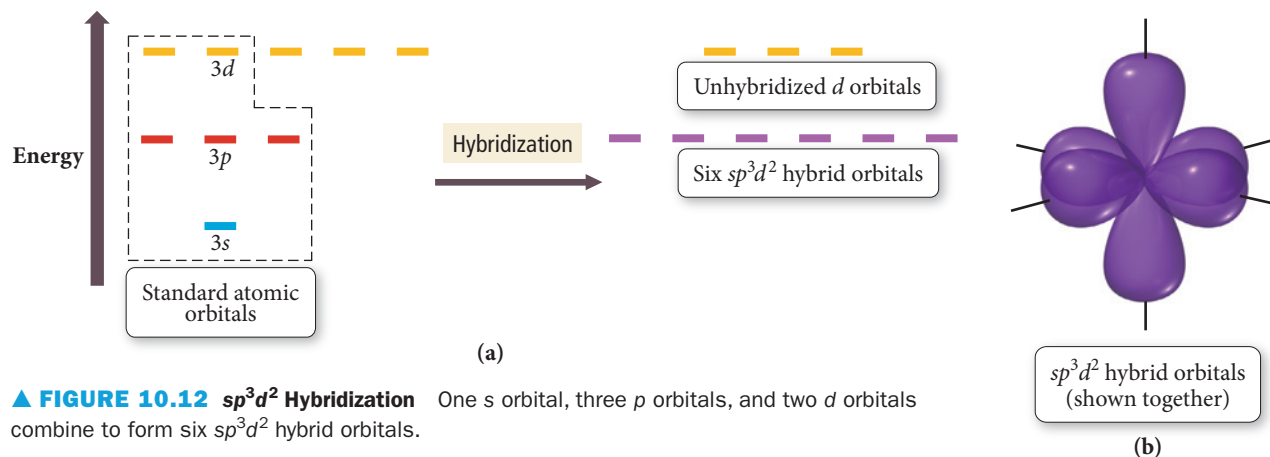

Recall that, according to the Lewis model, elements occurring in the third row of the periodic table (or below) can exhibit expanded octets (see Section 9.9). The equivalent concept in valence bond theory is hybridization involving the  $d$  orbitals. For third-period elements, the  $3d$  orbitals are involved in hybridization because their energies are close to the energies of the  $3s$  and  $3p$  orbitals. The hybridization of one  $s$  orbital, three  $p$  orbitals, and one  $d$  orbital results in  $sp^3d$  hybrid orbitals (Figure 10.11(a)▼). The five  $sp^3d$  hybrid orbitals have a trigonal bipyramidal arrangement (Figure 10.11(b)▼). As an example of  $sp^3d$  hybridization, consider arsenic pentafluoride,  $\text{AsF}_5$ . The arsenic atom bonds to five fluorine atoms by overlap between the  $sp^3d$  hybrid orbitals on arsenic and  $p$  orbitals on the fluorine atoms, as shown here:

▼ **FIGURE 10.11**  $sp^3d$  Hybridization One  $s$  orbital, three  $p$  orbitals, and one  $d$  orbital combine to form five  $sp^3d$  hybrid orbitals.

The  $sp^3d$  orbitals on the arsenic atom are trigonal bipyramidal, so the molecular geometry is trigonal bipyramidal.

The hybridization of one  $s$  orbital, three  $p$  orbitals, and two  $d$  orbitals results in  $sp^3d^2$  hybrid orbitals (Figure 10.12(a)▲). The six  $sp^3d^2$  hybrid orbitals have an octahedral geometry (Figure 10.12(b)▲). As an example of  $sp^3d^2$  hybridization, consider sulfur hexafluoride,  $SF_6$ . The sulfur atom bonds to six fluorine atoms by overlap between the  $sp^3d^2$  hybrid orbitals on sulfur and  $p$  orbitals on the fluorine atoms:

The  $sp^3d^2$  orbitals on the sulfur atom are octahedral, so the molecular geometry is octahedral, again in agreement with VSEPR theory and with the experimentally observed geometry.

## Writing Hybridization and Bonding Schemes

We have now studied examples of the five main types of atomic orbital hybridization. *But how do we know which hybridization scheme best describes the orbitals of a specific atom in a specific molecule?* In computational valence bond theory, the energy of the molecule is calculated using a computer; the degree of hybridization as well as the type of hybridization are varied to find the combination that gives the molecule the lowest overall energy. For our purposes, we can assign a hybridization scheme from the electron geometry—determined using VSEPR theory—of the central atom (or interior atoms) of

TABLE 10.3 Hybridization Scheme from Electron Geometry

Number of Electron Groups	Electron Geometry (from VSEPR Theory)	Hybridization Scheme
2	Linear	$sp$ 
3	Trigonal planar	$sp^2$ 
4	Tetrahedral	$sp^3$ 
5	Trigonal bipyramidal	$sp^3d$ 
6	Octahedral	$sp^3d^2$ 

the molecule. The five VSEPR electron geometries and the corresponding hybridization schemes are shown in Table 10.3. For example, if the electron geometry of the central atom is tetrahedral, then the hybridization is  $sp^3$ , and if the electron geometry is octahedral, then the hybridization is  $sp^3d^2$ , and so on. Although this method of determining the hybridization scheme is not 100% accurate (for example, it predicts that  $\text{H}_2\text{S}$  should be  $sp^3$  when in fact  $\text{H}_2\text{S}$  is largely unhybridized), it is the best we can do without more complex computer-based calculations.

We are now ready to put the Lewis model and valence bond theory together to describe bonding in molecules. In the procedure and examples that follow, you will learn how to write a *hybridization and bonding scheme* for a molecule. This involves drawing the Lewis structure for the molecule, determining its geometry using VSEPR theory, determining the hybridization of the interior atoms, drawing the molecule with its overlapping orbitals, and labeling each bond with the  $\sigma$  and  $\pi$  notation followed by the type of overlapping orbitals. As you can see, this procedure involves virtually everything you have learned about bonding in this chapter and Chapter 9. The procedure for writing a hybridization and bonding scheme is shown in the left column, with two examples of how to apply the procedure in the columns to the right.

## Procedure for...

Hybridization and Bonding Scheme	<b>Example 10.6</b> <b>Hybridization and Bonding Scheme</b> Write a hybridization and bonding scheme for bromine trifluoride, $\text{BrF}_3$ .	<b>Example 10.7</b> <b>Hybridization and Bonding Scheme</b> Write a hybridization and bonding scheme for acetaldehyde, $\text{H}_3\text{C}-\overset{\text{O}}{\parallel}{\text{C}}-\text{H}$
1. Write the Lewis structure for the molecule.	<b>SOLUTION</b> $\text{BrF}_3$ has 28 valence electrons and the following Lewis structure: $\begin{array}{c} \text{:}\ddot{\text{F}}\text{:} \\   \\ \text{:}\ddot{\text{Br}}-\ddot{\text{F}}\text{:} \\   \\ \text{:}\ddot{\text{F}}\text{:} \end{array}$	<b>SOLUTION</b> Acetaldehyde has 18 valence electrons and the following Lewis structure: $\begin{array}{c} \text{H} \quad \text{:O:} \\   \quad \parallel \\ \text{H}-\text{C}-\text{C}-\text{H} \\   \\ \text{H} \end{array}$
2. Use VSEPR theory to predict the electron geometry about the central atom (or interior atoms).	The bromine atom has five electron groups and therefore has a trigonal bipyramidal electron geometry.	The leftmost carbon atom has four electron groups and a tetrahedral electron geometry. The rightmost carbon atom has three electron groups and a trigonal planar geometry.
3. Select the correct hybridization for the central atom (or interior atoms) based on the electron geometry (see Table 10.3).	A trigonal bipyramidal electron geometry corresponds to $sp^3d$ hybridization.	The leftmost carbon atom is $sp^3$ hybridized, and the rightmost carbon atom is $sp^2$ hybridized.
4. Sketch the molecule, beginning with the central atom and its orbitals. Show overlap with the appropriate orbitals on the terminal atoms.		
5. Label all bonds using $\sigma$ or $\pi$ notation followed by the type of overlapping orbitals.	 <p><math>\sigma: \text{Br}(sp^3d) - \text{F}(p)</math></p> <p>Lone pairs in <math>sp^3d</math> orbitals</p>	 <p><math>\sigma: \text{C}(sp^3) - \text{H}(s)</math></p> <p><math>\pi: \text{C}(p) - \text{O}(p)</math></p> <p><math>\sigma: \text{C}(sp^2) - \text{H}(s)</math></p> <p><math>\sigma: \text{C}(sp^3) - \text{C}(sp^2)</math></p> <p><math>\sigma: \text{C}(sp^2) - \text{O}(p)</math></p>
	<b>FOR PRACTICE 10.6</b> Write the hybridization and bonding scheme for $\text{XeF}_4$ .	<b>FOR PRACTICE 10.7</b> Write the hybridization and bonding scheme for $\text{HCN}$ .

**Example 10.8** Hybridization and Bonding Scheme

Use valence bond theory to write a hybridization and bonding scheme for ethene,  $\text{H}_2\text{C}=\text{CH}_2$ .

**SOLUTION**

1. Write the Lewis structure for the molecule.	$\begin{array}{c} \text{H} \quad \text{H} \\   \quad   \\ \text{H}-\text{C}=\text{C}-\text{H} \end{array}$
2. Apply VSEPR theory to predict the electron geometry about the central atom (or interior atoms).	The molecule has two interior atoms. Because each atom has three electron groups (one double bond and two single bonds), the electron geometry about each atom is trigonal planar.
3. Select the correct hybridization for the central atom (or interior atoms) based on the electron geometry (see Table 10.3).	A trigonal planar geometry corresponds to $sp^2$ hybridization.
4. Sketch the molecule, beginning with the central atom and its orbitals. Show overlap with the appropriate orbitals on the terminal atoms.	
5. Label all bonds using $\sigma$ or $\pi$ notation followed by the type of overlapping orbitals.	

**FOR PRACTICE 10.8** Use valence bond theory to write a hybridization and bonding scheme for  $\text{CO}_2$ .

**FOR MORE PRACTICE 10.8** What is the hybridization of the central iodine atom in  $\text{I}_3^-$ ?

## 10.8 Molecular Orbital Theory: Electron Delocalization

Valence bond theory can explain many aspects of chemical bonding—such as the rigidity of a double bond—but it also has limitations. In valence bond theory, we treat electrons as if they reside in the quantum-mechanical orbitals that we calculated *for atoms*. This is a significant oversimplification that we partially compensate for by hybridization. Nevertheless, we can do better.

In Chapter 7, we stated that the mathematical derivation of energies and orbitals for electrons *in atoms* comes from solving the Schrödinger equation for the atom of

interest. For a molecule, we can theoretically do the same thing. The resulting orbitals would be the actual *molecular* orbitals of the molecule as a whole (in contrast to valence bond theory, in which the orbitals are those of individual atoms). As it turns out, however, solving the Schrödinger equation exactly for even the simplest molecules is impossible without making some approximations.

In **molecular orbital (MO) theory**, we do not actually solve the Schrödinger equation for a molecule directly. Instead, we use a trial function, an “educated guess” as to what the solution might be. In other words, rather than mathematically solving the Schrödinger equation, which would give us a mathematical function describing an orbital, we start with a trial mathematical function for the orbital. We then test the trial function to see how well it “works.”

We can understand this process by analogy to solving an algebraic equation. Suppose we want to know  $x$  in the equation  $4x + 5 = 70$  without actually solving the equation. For an easy equation like this one, we might first estimate that  $x = 16$ . We can then determine how well our estimate works by substituting  $x = 16$  into the equation. If the estimate did not work, we could try again until we found the right value of  $x$ . (In this case, we can quickly see that  $x$  must be a little more than 16.)

In molecular orbital theory, the estimating procedure is analogous. However, we need to add one more important concept to get at the heart of molecular orbital theory. In order to determine how well a trial function for an orbital “works” in molecular orbital theory, we calculate its energy. No matter how good our trial function, *we can never do better than nature at minimizing the energy of the orbital*. In other words, we can devise any trial function for an orbital in a molecule and calculate its energy. The energy we calculate for the devised orbital will always be greater than or (at best) equal to the energy of the actual orbital.

How does this help us? The best possible orbital is therefore the one with the minimum energy. In modern molecular orbital theory, computer programs are designed to try many different variations of a guessed orbital and compare the energies of each one. The variation with the lowest energy is the best approximation for the actual molecular orbital.

Molecular orbital theory is a specific application of a more general quantum-mechanical approximation technique called the variational method. In the variational method, the energy of a trial function within the Schrödinger equation is minimized.

We calculate the energy of an estimated orbital by substituting it into the Schrödinger equation and solving for the energy.

## Linear Combination of Atomic Orbitals (LCAOs)

The simplest trial functions that work reasonably well in molecular orbital theory turn out to be linear combinations of atomic orbitals, or LCAOs. An LCAO molecular orbital is a *weighted linear sum*—*analogous to a weighted average*—of the *valence atomic orbitals* of the atoms in the molecule. At first glance, this concept might seem very similar to that of hybridization in valence bond theory. However, in valence bond theory, hybrid orbitals are weighted linear sums of the valence atomic orbitals of a *particular atom*, and the hybrid orbitals remain *localized* on that atom. In molecular orbital theory, the molecular orbitals are weighted linear sums of the valence atomic orbitals of *all the atoms* in a molecule, and many of the molecular orbitals are *delocalized* over the entire molecule.

Consider the  $\text{H}_2$  molecule. One of the molecular orbitals for  $\text{H}_2$  is simply an equally weighted sum of the  $1s$  orbital from one atom and the  $1s$  orbital from the other. We represent this pictorially and energetically as follows:

When molecular orbitals are calculated mathematically, it is actually the *wave functions* corresponding to the orbitals that are combined.

The name of this molecular orbital is  $\sigma_{1s}$ . The  $\sigma$  comes from the shape of the orbital, which looks like a  $\sigma$  bond in valence bond theory, and the  $1s$  comes from its formation by a linear sum of  $1s$  orbitals. The  $\sigma_{1s}$  orbital is lower in energy than either of the two  $1s$  atomic orbitals from which it was formed. For this reason, this orbital is called a **bonding orbital**. When electrons occupy bonding molecular orbitals, the energy of the electrons is lower than it would be if they were occupying atomic orbitals.

We can think of a molecular orbital in a molecule in much the same way that we think about an atomic orbital in an atom. Electrons seek the lowest energy molecular orbital available, but just as an atom has more than one atomic orbital (and some may be empty), a molecule has more than one molecular orbital (and some may be empty). The next molecular orbital of  $H_2$  is approximated by summing the  $1s$  orbital on one hydrogen atom with the *negative* (opposite phase) of the  $1s$  orbital on the other hydrogen atom:

The different phases of the orbitals result in *destructive* interference between them. The resulting molecular orbital therefore has a node between the two atoms. The different colors (red and blue) on either side of the node represent the different phases of the orbital (see Section 7.6). The name of this molecular orbital is  $\sigma_{1s}^*$ . The star indicates that this orbital is an **antibonding orbital**. Electrons in antibonding orbitals have higher energies than they did in their respective atomic orbitals and therefore tend to raise the energy of the system (relative to the unbonded atoms).

In general, when two atomic orbitals are added together to form molecular orbitals, one of the resultant molecular orbitals is lower in energy (the bonding orbital) than the atomic orbitals and the other is higher in energy (the antibonding orbital). Remember that electrons in orbitals behave like waves. The bonding molecular orbital arises out of constructive interference between the overlapping atomic orbitals because both orbitals have the same phase. The antibonding orbital arises out of destructive interference between the overlapping atomic orbitals because *subtracting* one from the other means the two interacting orbitals have opposite phases (Figure 10.13 ▼).

For this reason, the bonding orbital has an increased electron density in the internuclear region, whereas the antibonding orbital has a node in the internuclear region. Bonding orbitals have greater electron density in the internuclear region, thereby lowering their energy compared to the orbitals in nonbonded atoms. Antibonding orbitals have less electron density in the internuclear region, and their energies are generally higher than in the orbitals of nonbonded atoms.

► **FIGURE 10.13 Formation of Bonding and Antibonding Orbitals** Constructive interference between two atomic orbitals gives rise to a molecular orbital that is lower in energy than the atomic orbitals. This is the bonding orbital. Destructive interference between two atomic orbitals gives rise to a molecular orbital that is higher in energy than the atomic orbitals. This is the antibonding orbital.

We put all of this together in the molecular orbital energy diagram for  $\text{H}_2$ :

We can represent the molecular orbital energy diagram with a molecular orbital electron configuration (which is analogous to the electron configurations we wrote for elements in Section 8.3):

In this notation, the  $\sigma_{1s}$  represents the molecular orbital, and the superscript 2 represents the two electrons in the orbital.

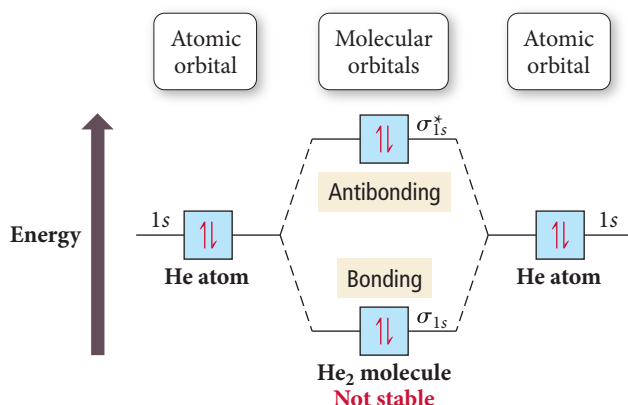

The molecular orbital (MO) energy diagram shows that two hydrogen atoms can lower their overall energy by forming  $\text{H}_2$  because the electrons can move from higher-energy atomic orbitals into the lower-energy  $\sigma_{1s}$  bonding molecular orbital. In molecular orbital theory, we define the **bond order** of a diatomic molecule such as  $\text{H}_2$  as follows:

$$\text{Bond order} = \frac{(\text{number of electrons in bonding MOs}) - (\text{number of electrons in antibonding MOs})}{2}$$

For  $\text{H}_2$ , the bond order is 1:

$$\text{H}_2 \text{ bond order} = \frac{2 - 0}{2} = 1$$

A positive bond order means that there are more electrons in bonding molecular orbitals than in antibonding molecular orbitals. The electrons therefore have lower energy than they did in the orbitals of the isolated atoms, and a chemical bond forms. In general, the higher the bond order, the stronger the bond. A negative or zero bond order indicates that a bond does *not* form between the atoms. For example, consider the MO diagram for  $\text{He}_2$ :

Notice that the two additional electrons must go into the higher-energy antibonding orbital. There is no net stabilization by joining two helium atoms to form a helium molecule, as indicated by the bond order:

$$\text{He}_2 \text{ bond order} = \frac{2 - 2}{2} = 0$$

So according to MO theory,  $\text{He}_2$  should not exist as a stable molecule, and in fact it does not. Another interesting case is the helium-helium ion,  $\text{He}_2^+$ , with the following MO diagram:

The bond order is  $\frac{1}{2}$ , indicating that  $\text{He}_2^+$  should exist, and indeed it does.

**Summarizing LCAO–MO Theory:**

- ▶ We can approximate molecular orbitals (MOs) as a linear combination of atomic orbitals (AOs). The total number of MOs formed from a particular set of AOs always equals the number of AOs in the set.
- ▶ When two AOs combine to form two MOs, one MO is lower in energy (the bonding MO) and the other is higher in energy (the antibonding MO).
- ▶ When assigning the electrons of a molecule to MOs, fill the lowest energy MOs first with a maximum of two spin-paired electrons per orbital.
- ▶ When assigning electrons to two MOs of the same energy, follow Hund's rule—fill the orbitals singly first, with parallel spins, before pairing.
- ▶ The bond order in a diatomic molecule is the number of electrons in bonding MOs minus the number in antibonding MOs divided by two. Stable bonds are associated with a positive bond order (more electrons in bonding MOs than in antibonding MOs).

Notice the power of the molecular orbital approach. Every electron that enters a bonding molecular orbital stabilizes the molecule or polyatomic ion, and every electron that enters an antibonding molecular orbital destabilizes it. The emphasis on electron pairs has been removed. One electron in a bonding molecular orbital stabilizes half as much as two, so a bond order of one-half is nothing mysterious.

### Example 10.9 Bond Order

Use molecular orbital theory to predict the bond order in  $\text{H}_2^-$ . Is the  $\text{H}_2^-$  bond a stronger or weaker bond than the  $\text{H}_2$  bond?

**SOLUTION**

The  $\text{H}_2^-$  ion has three electrons. Assign the three electrons to the molecular orbitals, filling lower-energy orbitals first and proceeding to higher-energy orbitals.

Calculate the bond order by subtracting the number of electrons in antibonding orbitals from the number in bonding orbitals and dividing the result by two.

$$\text{H}_2^- \text{ bond order} = \frac{2 - 1}{2} = +\frac{1}{2}$$

Since the bond order is positive,  $\text{H}_2^-$  should be stable. However, the bond order of  $\text{H}_2^-$  is lower than the bond order of  $\text{H}_2$  (which is 1); therefore, the bond in  $\text{H}_2^-$  is weaker than in  $\text{H}_2$ .

**FOR PRACTICE 10.9** Use molecular orbital theory to predict the bond order in  $\text{H}_2^+$ . Is the  $\text{H}_2^+$  bond a stronger or weaker bond than the  $\text{H}_2$  bond?

## Period Two Homonuclear Diatomic Molecules

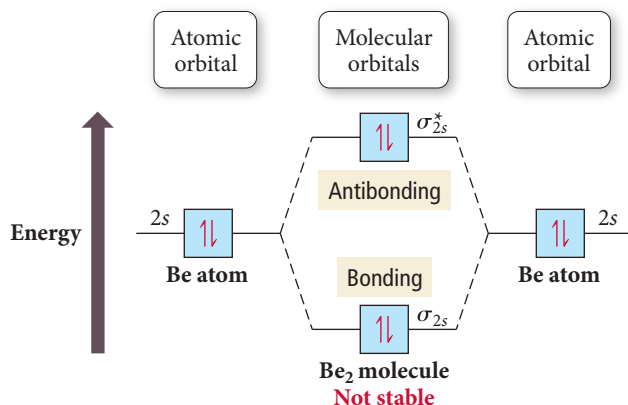

Homonuclear diatomic molecules (molecules made up of two atoms of the same kind) formed from second-period elements have between 2 and 16 valence electrons. To explain bonding in these molecules, we must consider the next set of higher-energy molecular orbitals, which can be approximated by linear combinations of the valence atomic orbitals of the period 2 elements.

We begin with  $\text{Li}_2$ . Even though lithium is normally a metal, we can use MO theory to predict whether or not the  $\text{Li}_2$  molecule should exist in the gas phase. We approximate the molecular orbitals in  $\text{Li}_2$  as linear combinations of the 2s atomic orbitals. The resulting molecular orbitals look much like those of the  $\text{H}_2$  molecule. The MO diagram for  $\text{Li}_2$  therefore looks a lot like the MO diagram for  $\text{H}_2$ :

The core electrons can be ignored (as they are in other models for bonding) because these electrons are held too tightly to individual nuclei to contribute significantly to chemical bonding.

The two valence electrons of  $\text{Li}_2$  occupy a bonding molecular orbital. We would predict that the  $\text{Li}_2$  molecule is stable with a bond order of 1. Experiments confirm this prediction. In contrast, consider the MO diagram for  $\text{Be}_2$ :

The four valence electrons of  $\text{Be}_2$  occupy one bonding MO and one antibonding MO. The bond order is 0 and we predict that  $\text{Be}_2$  should not be stable, which is again consistent with experimental findings.

The next homonuclear molecule composed of second row elements is  $\text{B}_2$ , which has six total valence electrons to accommodate. We can approximate the next higher-energy molecular orbitals for  $\text{B}_2$  and the rest of the period 2 diatomic molecules as linear

combinations of the  $2p$  orbitals taken pairwise. Since the three  $2p$  orbitals orient along three orthogonal axes, we must assign similar axes to the molecule. In this book, we assign the internuclear axis to be the  $x$  direction. Then we represent the LCAO-MOs that result from combining the  $2p_x$  orbitals—the ones that lie along the internuclear axis—from each atom as follows:

The bonding MO in this pair looks something like candy in a wrapper, with increased electron density in the internuclear region due to constructive interference between the two  $2p$  atomic orbitals. It has the characteristic  $\sigma$  shape (it is cylindrically symmetric about the bond axis) and is therefore called the  $\sigma_{2p}$  bonding orbital. The antibonding orbital, called  $\sigma_{2p}^*$ , has a node between the two nuclei (due to destructive interference between the two  $2p$  orbitals) and is higher in energy than either of the  $2p_x$  orbitals.

The LCAO-MOs that result from combining the  $2p_z$  orbitals from each atom are represented as follows:

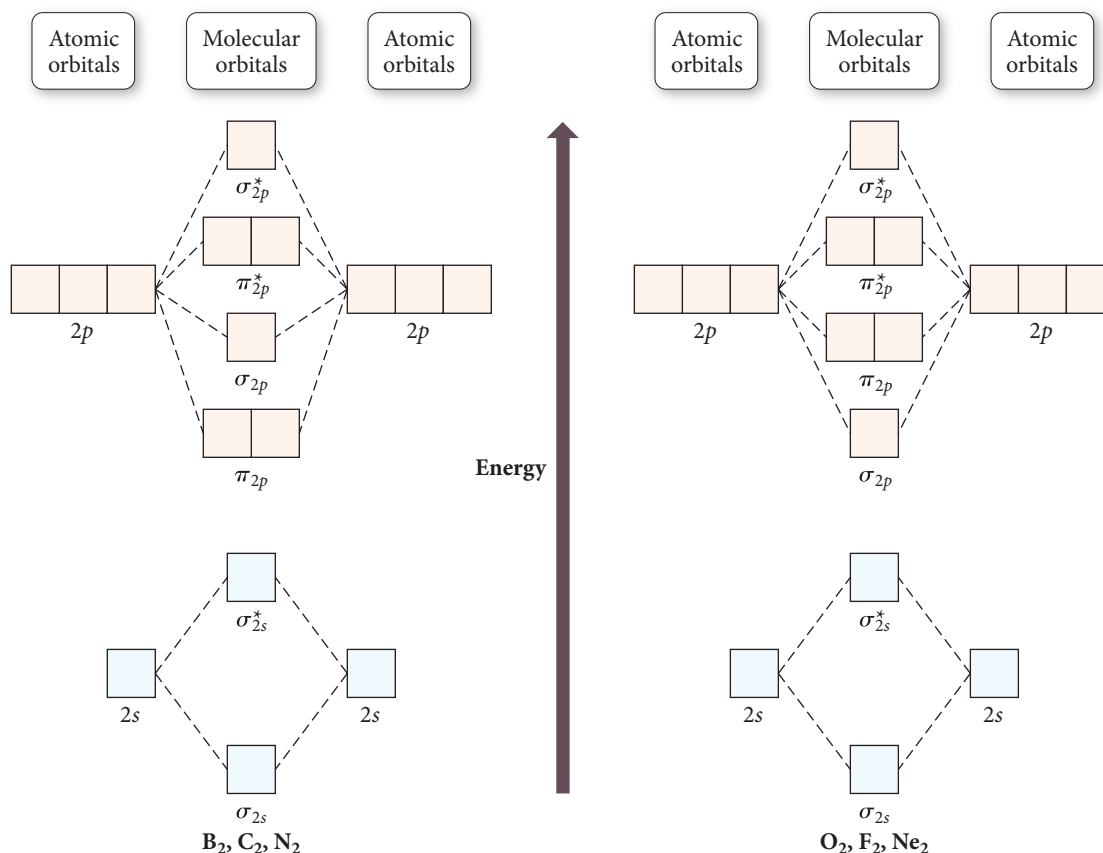

Notice that in this case the  $p$  orbitals are added together in a side-by-side orientation (in contrast to the  $2p_x$  orbitals, which were oriented end to end). The resultant molecular orbitals consequently have a different shape. The electron density in the bonding molecular orbital is above and below the internuclear axis with a nodal plane that includes the internuclear axis. This orbital resembles the electron density distribution of a  $\pi$  bond in valence bond theory. We call this orbital the  $\pi_{2p}$  orbital. The corresponding antibonding orbital has an additional node *between* the nuclei (perpendicular to the internuclear axis) and is called the  $\pi_{2p}^*$  orbital.

The LCAO-MOs that result from combining the  $2p_y$  orbitals from each atom are represented as follows:

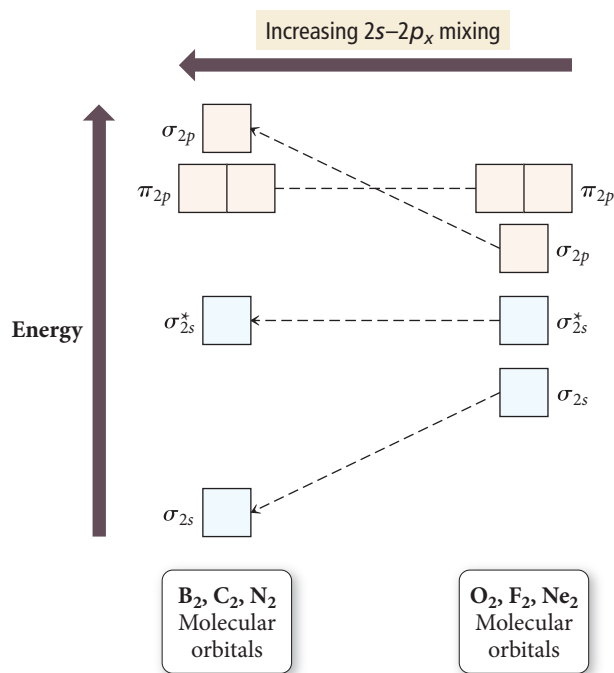

The only difference between the  $2p_y$  and the  $2p_z$  atomic orbitals is a  $90^\circ$  rotation about the internuclear axis. Consequently, the only difference between the resulting MOs is a  $90^\circ$  rotation about the internuclear axis. The energies and the names of the bonding and antibonding MOs obtained from the combination of the  $2p_y$  AOs are identical to those obtained from the combination of the  $2p_z$  AOs.

Before we can draw MO diagrams for  $B_2$  and the other second-period diatomic molecules, we must determine the relative energy ordering of the MOs obtained from the  $2p$  AO combinations. This is not a simple task. The relative ordering of MOs obtained from LCAO-MO theory is usually determined computationally. There is no single order that works for all molecules. For second-period diatomic molecules, computations reveal that the energy ordering for  $B_2$ ,  $C_2$ , and  $N_2$  is slightly different than that for  $O_2$ ,  $F_2$ , and  $Ne_2$  as follows:

▲ Molecular orbital energy diagrams for second-period diatomic molecules show that the energy ordering of the  $\pi_{2p}$  and  $\sigma_{2p}$  molecular orbitals can vary.

**▲ FIGURE 10.14 The Effects of 2s–2p Mixing** The degree of mixing between two orbitals decreases with increasing energy difference between them. Mixing of the 2s and 2p<sub>x</sub> orbitals is therefore greater in B<sub>2</sub>, C<sub>2</sub>, and N<sub>2</sub> than in O<sub>2</sub>, F<sub>2</sub>, and Ne<sub>2</sub> because in B, C, and N the energy levels of the atomic orbitals are more closely spaced than in O, F, and Ne. This mixing produces a change in energy ordering for the  $\pi_{2p}$  and  $\sigma_{2p}$  molecular orbitals.

The difference in energy ordering can only be explained by revisiting our LCAO–MO model. In our simplified treatment, we assumed that the MOs that result from the second-period AOs could be calculated pairwise. In other words, we took the linear combination of a 2s from one atom with the 2s from another, a 2p<sub>x</sub> from one atom with a 2p<sub>x</sub> from the other, and so on. However, in a more comprehensive treatment, the MOs are formed from linear combinations that include all of the AOs that are relatively close to each other in energy and of the correct symmetry. Specifically, in a more detailed treatment, the two 2s orbitals and the two 2p<sub>x</sub> orbitals should all be combined to form a total of four molecular orbitals. The extent to which we include this type of mixing affects the energy levels of the corresponding MOs, as shown in Figure 10.14. The bottom line is that s–p mixing is significant in B<sub>2</sub>, C<sub>2</sub>, and N<sub>2</sub> but not in O<sub>2</sub>, F<sub>2</sub>, and Ne<sub>2</sub>. The result of the mixing is a different energy ordering for some of these diatomic molecules.

Figure 10.15 shows the MO energy diagrams for the rest of the second-period homonuclear diatomic molecules, as well as their bond orders, bond energies, and bond lengths. Notice that as bond order increases, the bond gets stronger (greater bond energy) and shorter (smaller bond length). For B<sub>2</sub>, with six electrons, the bond order is 1. For C<sub>2</sub>, the bond order is 2, and for N<sub>2</sub>, the bond order reaches a maximum with a value of 3. Recall that the Lewis structure for N<sub>2</sub> has a triple bond, so both the Lewis model and molecular orbital theory predict a strong bond for N<sub>2</sub>, which is experimentally observed.

**► FIGURE 10.15 Molecular Orbital Energy Diagrams for Second-Row p-block Homonuclear Diatomic Molecules**

	Large 2s–2p <sub>x</sub> interaction			Small 2s–2p <sub>x</sub> interaction		
	B <sub>2</sub>	C <sub>2</sub>	N <sub>2</sub>	O <sub>2</sub>	F <sub>2</sub>	Ne <sub>2</sub>
$\sigma_{2p}^*$						
$\pi_{2p}^*$						
$\sigma_{2p}$						
$\pi_{2p}$						
$\sigma_{2s}^*$						
$\sigma_{2s}$						
Bond order	1	2	3	2	1	0
Bond energy (kJ/mol)	290	620	946	498	159	—
Bond length (pm)	159	131	110	121	143	—

In  $O_2$ , the two additional electrons occupy antibonding orbitals and the bond order is 2. These two electrons are unpaired—they occupy the  $\pi_{2p}^*$  orbitals *singly with parallel spins*, as indicated by Hund's rule. The presence of unpaired electrons in the molecular orbital diagram of oxygen is significant because oxygen is known from experiment to be *paramagnetic*—it is attracted to a magnetic field (see Section 8.7). The paramagnetism of oxygen can be demonstrated by suspending liquid oxygen between the poles of a magnet. This magnetic property is the direct result of *unpaired electrons*, whose spin and movement around the nucleus (more accurately known as orbital angular momentum) generate tiny magnetic fields. When a paramagnetic substance is placed in an external magnetic field, the magnetic fields of each atom or molecule align with the external field, creating the attraction (much as two magnets attract each other when properly oriented). In contrast, when the electrons in an atom or molecule are all *paired*, the magnetic fields caused by electron spin and orbital angular momentum tend to cancel each other, resulting in diamagnetism. A *diamagnetic* substance is not attracted to a magnetic field (and is, in fact, slightly repelled).

In the Lewis structure of  $O_2$ , as well as in the valence bond model of  $O_2$ , all of the electrons seem to be paired:

▲ Liquid oxygen can be suspended between the poles of a magnet because it is paramagnetic. It contains unpaired electrons (depicted here in the inset) that generate tiny magnetic fields, which align with and interact with the external field.

The s orbital on each oxygen atom contains two electrons, but for clarity neither the s orbitals nor the electrons that occupy them are shown.

In the MO diagram for  $O_2$ , however, we can see the unpaired electrons. Molecular orbital theory is the more powerful theory in that it can account for the paramagnetism of  $O_2$ —it gives us a picture of bonding that more closely corresponds to what we see in experiments. Continuing along the second-row homonuclear diatomic molecules, we see that  $F_2$  has a bond order of 1 and  $Ne_2$  has a bond order of 0, again consistent with experiment since  $F_2$  exists and  $Ne_2$  does not.

### Example 10.10 Molecular Orbital Theory

Draw an MO energy diagram and determine the bond order for the  $N_2^-$  ion. Do you expect the bond in the  $N_2^-$  ion to be stronger or weaker than the bond in the  $N_2$  molecule? Is  $N_2^-$  diamagnetic or paramagnetic?

#### SOLUTION

Write an energy-level diagram for the molecular orbitals in  $N_2^-$ . Use the energy ordering for  $N_2$ .

—Continued on the next page

—Continued

<p>The <math>\text{N}_2^-</math> ion has 11 valence electrons (five for each nitrogen atom plus one for the negative charge). Assign the electrons to the molecular orbitals beginning with the lowest energy orbitals and following Hund's rule.</p>	
<p>Calculate the bond order by subtracting the number of electrons in antibonding orbitals from the number in bonding orbitals and dividing the result by 2.</p>	$\text{N}_2^- \text{ bond order} = \frac{8 - 3}{2} = +2.5$
<p>The bond order is 2.5, which is a lower bond order than in the <math>\text{N}_2</math> molecule (bond order = 3); therefore, the bond is weaker. The MO diagram shows that the <math>\text{N}_2^-</math> ion has one unpaired electron and is therefore paramagnetic.</p>	
<p><b>FOR PRACTICE 10.10</b> Draw an MO energy diagram and determine the bond order for the <math>\text{N}_2^+</math> ion. Do you expect the bond in the <math>\text{N}_2^+</math> ion to be stronger or weaker than the bond in the <math>\text{N}_2</math> molecule? Is <math>\text{N}_2^+</math> diamagnetic or paramagnetic?</p> <p><b>FOR MORE PRACTICE 10.10</b> Apply molecular orbital theory to determine the bond order of <math>\text{Ne}_2</math>.</p>	

## Second-Period Heteronuclear Diatomic Molecules

We can also apply molecular orbital theory to heteronuclear diatomic molecules (two different atoms). For example, we can draw an MO diagram for NO as follows:

A given orbital will have lower energy in a more electronegative atom. For this reason, electronegative atoms have the ability to attract electrons to themselves.

Oxygen is more electronegative than nitrogen, so its atomic orbitals are lower in energy than nitrogen's atomic orbitals. When two atomic orbitals are identical and of equal energy, the weighting of each orbital in forming a molecular orbital is identical. However, when two atomic orbitals are different, the weighting of each orbital in forming

a molecular orbital may be different. More specifically, when a molecular orbital is approximated as a linear combination of atomic orbitals of different energies, the lower-energy atomic orbital makes a greater contribution to the bonding molecular orbital and the higher-energy atomic orbital makes a greater contribution to the antibonding molecular orbital. For example, notice that the  $\sigma_{2s}$  bonding orbital is closer in energy to the oxygen  $2s$  orbital than to the nitrogen  $2s$  orbital. We can also see this unequal weighting in the shape of the resultant molecular orbital, in which the electron density is concentrated on the oxygen atom, as shown in Figure 10.16.

As another example of a heteronuclear diatomic molecule, consider the MO diagram for HF:

Fluorine is so electronegative that all of its atomic orbitals are lower in energy than hydrogen's atomic orbitals. In fact, fluorine's  $2s$  orbital is so low in energy compared to hydrogen's  $1s$  orbital that it does not contribute appreciably to the molecular orbitals. The molecular orbitals in HF are approximated by the linear combination of the fluorine  $2p_x$  orbital and the hydrogen  $1s$  orbital. The other  $2p$  orbitals remain localized on the fluorine and appear in the energy diagram as **nonbonding orbitals**. The electrons in the nonbonding orbitals remain localized on the fluorine atom.

**▲ FIGURE 10.16** Shape of  $\sigma_{2s}$  bonding orbital in NO The molecular orbital shows more electron density at the oxygen end of the molecule because the atomic orbitals of oxygen, the more electronegative element, are lower in energy than those of nitrogen. They therefore contribute more to the bonding molecular orbital.

### Example 10.11 Molecular Orbital Theory Applied to Heteronuclear Diatomic Molecules and Ions

Use molecular orbital theory to determine the bond order of the  $\text{CN}^-$  ion. Is the ion paramagnetic or diamagnetic?

#### SOLUTION

Determine the number of valence electrons in the molecule or ion.

Number of valence electrons  
 $= 4$  (from C) +  $5$  (from N) +  
 $1$  (from negative charge) =  $10$

Write an energy-level diagram using Figure 10.15 as a guide. Fill the orbitals beginning with the lowest energy orbital and progressing upward until all electrons have been assigned to an orbital. Remember to allow no more than two electrons (with paired spins) per orbital and to fill degenerate orbitals with single electrons (with parallel spins) before pairing.

—Continued on the next page

—Continued

Calculate the bond order using the appropriate formula: Bond order = $\frac{(\text{number of } e^- \text{ in bonding MOs}) - (\text{number of } e^- \text{ in antibonding MOs})}{2}$	$\text{CN}^- \text{ bond order} = \frac{8 - 2}{2} = +3$
If the MO diagram has unpaired electrons, the molecule or ion is paramagnetic. If the electrons are all paired, the molecule or ion is diamagnetic.	The MO diagram has no unpaired electrons, so the ion is diamagnetic.
<b>FOR PRACTICE 10.11</b> Apply molecular orbital theory to determine the bond order of NO. (Use the energy ordering of $\text{O}_2$ .) Is the molecule paramagnetic or diamagnetic?	

## Polyatomic Molecules

With the aid of computers, molecular orbital theory can be applied to polyatomic molecules and ions, yielding results that correlate very well with experimental measurements. These applications are beyond the scope of this text. However, the delocalization of electrons over an entire molecule is an important contribution of molecular orbital theory to our basic understanding of chemical bonding. For example, consider the Lewis structure and valence bond diagram of ozone:

In the Lewis model, we use resonance forms to represent the two equivalent bonds. In valence bond theory, it appears that the two oxygen–oxygen bonds should be different. In molecular orbital theory, however, the  $\pi$  molecular orbitals in ozone are formed from a linear combination of the three oxygen  $2p$  orbitals and are delocalized over the entire molecule. The lowest energy  $\pi$  bonding molecular orbital is shown in the left margin.

When we examine ozone in nature, we indeed find two equivalent bonds. A similar situation occurs with benzene ( $\text{C}_6\text{H}_6$ ). In the Lewis model, we represent the structure with two resonance forms:

In molecular orbital theory, the  $\pi$  molecular orbitals in benzene are formed from a linear combination of the six carbon  $2p$  orbitals and are delocalized over the entire molecule. The lowest energy  $\pi$  bonding molecular orbital is shown in the left margin.

Benzene is in fact a highly symmetric molecule with six identical carbon–carbon bonds. The best picture of the  $\pi$  electrons in benzene is one in which the electrons occupy roughly circular-shaped orbitals above and below the plane of the molecule, as depicted in the molecular orbital theory approach.

## CONCEPTUAL CONNECTION 10.11

**What Is a Chemical Bond? Part II** We have learned that the Lewis model portrays a chemical bond as the transfer or sharing of electrons represented as dots. Valence bond theory portrays a chemical bond as the overlap of two half-filled atomic orbitals. What is a chemical bond according to molecular orbital theory?

### Self-Assessment Quiz

- Q1.** Determine the molecular geometry of  $\text{CBr}_4$ .
- linear
  - trigonal planar
  - tetrahedral
  - trigonal pyramidal
- Q2.** Determine the molecular geometry of  $\text{SeF}_4$ .
- tetrahedral
  - trigonal bipyramidal
  - T-shaped
  - seesaw
- Q3.** Predict the relative bond angles in  $\text{BF}_3$  and  $\text{SO}_2$ .
- $\text{BF}_3$  bond angles  $>$   $\text{SO}_2$  bond angle
  - $\text{SO}_2$  bond angle  $>$   $\text{BF}_3$  bond angles
  - $\text{BF}_3$  bond angles  $=$   $\text{SO}_2$  bond angle
  - Relative bond angles cannot be predicted.
- Q4.** Predict the molecular geometry about nitrogen in the molecule  $\text{CH}_3\text{NHCH}_3$ .
- linear
  - trigonal planar
  - trigonal pyramidal
  - bent
- Q5.** Which molecule is polar?
- $\text{SF}_2$
  - $\text{BH}_3$
  - $\text{PF}_5$
  - $\text{CS}_2$
- Q6.** Determine the hybridization about oxygen in  $\text{CH}_3\text{OH}$ .
- $sp$
  - $sp^2$
  - $sp^3$
  - $sp^3d$
- Q7.** Determine the hybridization about carbon in  $\text{H}_2\text{CO}$ .
- $sp$
  - $sp^2$
  - $sp^3$
  - $sp^3d$
- Q8.** According to valence bond theory, which kind of orbitals overlap to form the  $\text{P}-\text{Cl}$  bonds in  $\text{PCl}_5$ ?
- $\text{P}(sp^3) - \text{Cl}(p)$
  - $\text{P}(sp^3d) - \text{Cl}(s)$
  - $\text{P}(sp^3) - \text{Cl}(s)$
  - $\text{P}(sp^3d) - \text{Cl}(p)$
- Q9.** Apply molecular orbital theory to determine the bond order in  $\text{C}_2$ .
- 0
  - 1
  - 2
  - 3
- Q10.** Apply molecular orbital theory to predict which species has the strongest bond.
- $\text{N}_2$
  - $\text{N}_2^-$
  - $\text{N}_2^+$
  - All bonds are equivalent according to molecular orbital theory.
- Q11.** Apply molecular orbital theory to determine which molecule is diamagnetic.
- $\text{CO}$
  - $\text{B}_2$
  - $\text{O}_2$
  - None of the above (all are paramagnetic)
- Q12.** Which hybridization scheme occurs about nitrogen when nitrogen forms a double bond?
- $sp$
  - $sp^2$
  - $sp^3$
  - $sp^3d$
- Q13.** Which molecular geometry results when a central atom has five total electron groups, with three of those being bonding groups and two being lone pairs?
- trigonal bipyramidal
  - seesaw
  - T-shaped
  - bent
- Q14.** Determine the correct molecular geometry (from left to right) about each interior atom in  $\text{CH}_3\text{CH}_2\text{OH}$ .
- 1st C tetrahedral; 2nd C trigonal planar; O linear
  - 1st C trigonal planar; 2nd C bent; O linear
  - 1st C trigonal planar; 2nd C trigonal pyramidal; O bent
  - 1st C tetrahedral; 2nd C tetrahedral; O bent
- Q15.** The central atom in a molecule has a bent molecular geometry. Determine the hybridization of the orbitals in the atom.
- $sp$
  - $sp^2$
  - $sp^3$
  - Hybridization cannot be determined from the information given.

Answers: 1. (c) 2. (d) 3. (a) 4. (c) 5. (a) 6. (c) 7. (b) 8. (d) 9. (c) 10. (a) 11. (a) 12. (b) 13. (c) 14. (d) 15. (d)

## Chapter 10 IN REVIEW

### Key Terms

#### Section 10.2

valence shell electron pair repulsion (VSEPR) theory (428)  
electron groups (428)  
linear geometry (429)  
trigonal planar geometry (429)  
tetrahedral geometry (430)  
trigonal bipyramidal geometry (431)  
octahedral geometry (431)

#### Section 10.3

electron geometry (432)  
molecular geometry (432)  
trigonal pyramidal geometry (432)  
bent geometry (433)  
seesaw geometry (434)  
T-shaped geometry (434)  
square pyramidal geometry (435)  
square planar geometry (435)

#### Section 10.6

valence bond theory (445)

#### Section 10.7

hybridization (447)  
hybrid orbitals (447)

bonding orbital (462)  
antibonding orbital (462)  
bond order (463)  
nonbonding orbitals (472)

### Key Concepts

#### Molecular Shape and VSEPR Theory (10.1–10.4)

- ▶ The properties of molecules are directly related to their shapes. In VSEPR theory, molecular geometries are determined by the repulsions between electron groups on the central atom. An electron group can be a single bond, double bond, triple bond, lone pair, or even a single electron.
- ▶ The five basic molecular shapes are linear (two electron groups), trigonal planar (three electron groups), tetrahedral (four electron groups), trigonal bipyramidal (five electron groups), and octahedral (six electron groups).
- ▶ When lone pairs are present on the central atom, the *electron* geometry is still one of the five basic shapes, but one or more positions are occupied by lone pairs. The *molecular* geometry is therefore different from the electron geometry. Lone pairs are positioned so as to minimize repulsions with other lone pairs and with bonding pairs.

#### Polarity (10.5)

- ▶ The polarity of a polyatomic molecule containing polar bonds depends on its geometry. If the dipole moments of the polar bonds are aligned in such a way that they cancel one another, the molecule is not polar. If they are aligned in such a way as to sum together, the molecule is polar.
- ▶ Highly symmetric molecules tend to be nonpolar, whereas asymmetric molecules containing polar bonds tend to be polar. The polarity of a molecule dramatically affects its properties.

#### Valence Bond Theory (10.6–10.7)

- ▶ In contrast to the Lewis model, in which a covalent chemical bond is the sharing of electrons represented by dots, in valence bond theory a chemical bond is the overlap of half-filled atomic orbitals (or in some cases the overlap between a completely filled orbital

and an empty one).

- ▶ The overlapping orbitals may be the standard atomic orbitals, such as  $1s$  or  $2p$ , or they may be hybridized atomic orbitals, which are mathematical combinations of the standard orbitals on a single atom. The basic hybridized orbitals are  $sp$ ,  $sp^2$ ,  $sp^3$ ,  $sp^3d$ , and  $sp^3d^2$ .
- ▶ The geometry of the molecule is determined by the geometry of the overlapping orbitals.
- ▶ In our treatment of valence bond theory, we use the electron geometry determined by VSEPR theory to determine the correct hybridization scheme.
- ▶ In valence bond theory, we distinguish between two types of bonds,  $\sigma$  (sigma) and  $\pi$  (pi). In a  $\sigma$  bond, the orbital overlap occurs in the region that lies directly between the two bonding atoms. In a  $\pi$  bond, formed from the side-by-side overlap of  $p$  orbitals, the overlap occurs above and below the region that lies directly between the two bonding atoms.
- ▶ Rotation about a  $\sigma$  bond is relatively free, whereas rotation about a  $\pi$  bond is restricted.

#### Molecular Orbital Theory (10.8)

- ▶ The simplest molecular orbitals are linear combinations of atomic orbitals (LCAOs), weighted averages of the atomic orbitals of the different atoms in the molecule.
- ▶ When two atomic orbitals combine to form molecular orbitals, they form one molecular orbital of lower energy (the bonding orbital) and one of higher energy (the antibonding orbital).
- ▶ A set of molecular orbitals fills in much the same way as atomic orbitals.
- ▶ The stability of the molecule and the strength of the bond depend on the number of electrons in bonding orbitals compared to the number in antibonding orbitals.

### Key Equations and Relationships

#### Bond Order of a Diatomic Molecule (10.8)

$$\text{Bond order} = \frac{(\text{number of electrons in bonding MOs}) - (\text{number of electrons in antibonding MOs})}{2}$$

## Key Learning Outcomes

CHAPTER OBJECTIVES	ASSESSMENT
Using VSEPR Theory to Predict the Basic Shapes of Molecules ( <b>10.2</b> )	Example 10.1 For Practice 10.1 Exercises 31–32
Predicting Molecular Geometries Using VSEPR Theory and the Effects of Lone Pairs ( <b>10.4</b> )	Examples 10.2–10.3 For Practice 10.2–10.3 Exercises 35–36
Predicting the Shapes of Larger Molecules ( <b>10.4</b> )	Example 10.4 For Practice 10.4 Exercises 41–42, 45–46
Using Molecular Shape to Determine Polarity of a Molecule ( <b>10.5</b> )	Example 10.5 For Practice 10.5 Exercises 49–52
Writing Hybridization and Bonding Schemes Using Valence Bond Theory ( <b>10.7</b> )	Examples 10.6–10.8 For Practice 10.6–10.8 For More Practice 10.8 Exercises 61–66
Drawing Molecular Orbital Diagrams to Predict Bond Order and Magnetism of a Diatomic Molecule ( <b>10.8</b> )	Examples 10.9–10.11 For Practice 10.9–10.11 For More Practice 10.10 Exercises 71–72, 75–78, 81–82

## EXERCISES

### Review Questions

- Why is molecular geometry important? Cite some examples.
- According to VSEPR theory, what determines the geometry of a molecule?
- Name and sketch the five basic electron geometries, and state the number of electron groups corresponding to each. What constitutes an *electron group*?
- Explain the difference between electron geometry and molecular geometry. Under what circumstances are they not the same?
- Give the correct electron and molecular geometries that correspond to each set of electron groups around the central atom of a molecule.
  - four electron groups overall; three bonding groups and one lone pair
  - four electron groups overall; two bonding groups and two lone pairs
  - five electron groups overall; four bonding groups and one lone pair
  - five electron groups overall; three bonding groups and two lone pairs
  - five electron groups overall; two bonding groups and three lone pairs
  - six electron groups overall; five bonding groups and one lone pair
  - six electron groups overall; four bonding groups and two lone pairs
- How do you apply VSEPR theory to predict the shape of a molecule with more than one interior atom?
- How do you determine whether a molecule is polar? Why is polarity important?
- What is a chemical bond according to valence bond theory?
- In valence bond theory, what determines the geometry of a molecule?
- In valence bond theory, the interaction energy between the electrons and nucleus of one atom with the electrons and nucleus of another atom is usually negative (stabilizing) when \_\_\_\_\_.
- What is hybridization? Why is hybridization necessary in valence bond theory?
- How does hybridization of the atomic orbitals in the central atom of a molecule help lower the overall energy of the molecule?
- How is the *number* of hybrid orbitals related to the number of standard atomic orbitals that are hybridized?
- Sketch each set of hybrid orbitals.
  - $sp$
  - $sp^2$
  - $sp^3$
  - $sp^3d$
  - $sp^3d^2$
- In the Lewis model, the two bonds in a double bond look identical. However, valence bond theory shows that they are not. Describe a double bond according to valence bond theory. Explain why rotation is restricted about a double bond but not about a single bond.
- Name the hybridization scheme that corresponds to each electron geometry.
  - linear
  - trigonal planar
  - tetrahedral
  - trigonal bipyramidal
  - octahedral
- What is a chemical bond according to molecular orbital theory?
- Explain the difference between hybrid atomic orbitals in valence bond theory and LCAO molecular orbitals in molecular orbital theory.
- What is a bonding molecular orbital?
- What is an antibonding molecular orbital?
- What is the role of wave interference in determining whether a molecular orbital is bonding or antibonding?

22. In molecular orbital theory, what is bond order? Why is it important?
23. How is the number of molecular orbitals approximated by a linear combination of atomic orbitals related to the number of atomic orbitals used in the approximation?
24. Sketch each molecular orbital.
- a.  $\sigma_{2s}$       b.  $\sigma_{2s}^*$       c.  $\sigma_{2p}$   
 d.  $\sigma_{2p}^*$       e.  $\pi_{2p}$       f.  $\pi_{2p}^*$
25. Draw an energy diagram for the molecular orbitals of period 2 diatomic molecules. Show the difference in ordering for  $B_2$ ,  $C_2$ , and  $N_2$  compared to  $O_2$ ,  $F_2$ , and  $Ne_2$ .
26. Why does the energy ordering of the molecular orbitals of the period 2 diatomic molecules change in going from  $N_2$  to  $O_2$ ?
27. Explain the difference between a paramagnetic species and a diamagnetic one.
28. When applying molecular orbital theory to heteronuclear diatomic molecules, the atomic orbitals used may be of different energies. If two atomic orbitals of different energies make two molecular orbitals, how are the energies of the molecular orbitals related to the energies of the atomic orbitals? How is the shape of the resultant molecular orbitals related to the shape of the atomic orbitals?
29. In molecular orbital theory, what is a nonbonding orbital?
30. Write a short paragraph describing chemical bonding according to the Lewis model, valence bond theory, and molecular orbital theory. Indicate how the theories differ in their description of a chemical bond and indicate the strengths and weaknesses of each theory. Which theory is correct?

## Problems by Topic

### VSEPR Theory and Molecular Geometry

31. A molecule with the formula  $AB_3$  has a trigonal pyramidal geometry. How many electron groups are on the central atom (A)?
32. A molecule with the formula  $AB_3$  has a trigonal planar geometry. How many electron groups are on the central atom?
33. For each molecular geometry, list the number of total electron groups, the number of bonding groups, and the number of lone pairs on the central atom.

34. For each molecular geometry, list the number of total electron groups, the number of bonding groups, and the number of lone pairs on the central atom.

35. Determine the electron geometry, molecular geometry, and idealized bond angles for each molecule. In which cases do you expect deviations from the idealized bond angle?
- a.  $PF_3$       b.  $SBr_2$       c.  $CHCl_3$       d.  $CS_2$
36. Determine the electron geometry, molecular geometry, and idealized bond angles for each molecule. In which cases do you expect deviations from the idealized bond angle?
- a.  $CF_4$       b.  $NF_3$       c.  $OF_2$       d.  $H_2S$
37. Which species has the smaller bond angle,  $H_3O^+$  or  $H_2O$ ? Explain.
38. Which species has the smaller bond angle,  $ClO_4^-$  or  $ClO_3^-$ ? Explain.
39. Determine the molecular geometry and sketch each molecule or ion using the bond conventions shown in "Representing Molecular Geometries on Paper" in Section 10.4.
- a.  $SF_4$       b.  $ClF_3$       c.  $IF_2^-$       d.  $IBr_4^-$

40. Determine the molecular geometry and sketch each molecule or ion, using the bond conventions shown in "Representing Molecular Geometries on Paper" in Section 10.4.
- a.  $BrF_5$       b.  $SCl_6$       c.  $PF_5$       d.  $IF_4^+$
41. Determine the molecular geometry about each interior atom and sketch each molecule.
- a.  $C_2H_2$  (skeletal structure HCCH)  
 b.  $C_2H_4$  (skeletal structure  $H_2CCH_2$ )  
 c.  $C_2H_6$  (skeletal structure  $H_3CCH_3$ )
42. Determine the molecular geometry about each interior atom and sketch each molecule.
- a.  $N_2$       b.  $N_2H_2$  (skeletal structure HNNH)  
 c.  $N_2H_4$  (skeletal structure  $H_2NNH_2$ )
43. Each ball-and-stick model shows the electron and molecular geometry of a generic molecule. Explain what is wrong with each molecular geometry and provide the correct molecular geometry, given the number of lone pairs and bonding groups on the central atom.

44. Each ball-and-stick model shows the electron and molecular geometry of a generic molecule. Explain what is wrong with each molecular geometry and provide the correct molecular geometry, given the number of lone pairs and bonding groups on the central atom.

45. Determine the geometry about each interior atom in each molecule and sketch the molecule. (Skeletal structure is indicated in parentheses.)
- a.  $CH_3OH$  ( $H_3COH$ )      b.  $CH_3OCH_3$  ( $H_3COCH_3$ )  
 c.  $H_2O_2$  ( $HOOH$ )

46. Determine the geometry about each interior atom in each molecule and sketch the molecule. (Skeletal structure is indicated in parentheses.)
- $\text{CH}_3\text{NH}_2$  ( $\text{H}_3\text{CNH}_2$ )
  - $\text{CH}_3\text{CO}_2\text{CH}_3$  ( $\text{H}_3\text{CCOOCH}_3$  One O atom attached to 2nd C atom; the other O atom is bonded to the 2nd and 3rd C atom)
  - $\text{NH}_2\text{CO}_2\text{H}$  ( $\text{H}_2\text{NCOOH}$  both O atoms attached to C)

### Molecular Shape and Polarity

47. Explain why  $\text{CO}_2$  and  $\text{CCl}_4$  are both nonpolar even though they contain polar bonds.
48.  $\text{CH}_3\text{F}$  is a polar molecule, even though the tetrahedral geometry often leads to nonpolar molecules. Explain.
49. Determine whether each molecule in Exercise 35 is polar or nonpolar.
50. Determine whether each molecule in Exercise 36 is polar or nonpolar.
51. Determine whether each molecule is polar or nonpolar.
- $\text{SCl}_2$
  - $\text{SCl}_4$
  - $\text{BrCl}_5$
52. Determine whether each molecule is polar or nonpolar.
- $\text{SiCl}_4$
  - $\text{CF}_2\text{Cl}_2$
  - $\text{SeF}_6$
  - $\text{IF}_5$

### Valence Bond Theory

53. The valence electron configurations of several atoms are shown here. How many bonds can each atom make without hybridization?
- Be  $2s^2$
  - P  $3s^2 3p^3$
  - F  $2s^2 2p^5$
54. The valence electron configurations of several atoms are shown here. How many bonds can each atom make without hybridization?
- B  $2s^2 2p^1$
  - N  $2s^2 2p^3$
  - O  $2s^2 2p^4$
55. Write orbital diagrams (boxes with arrows in them) to represent the electron configurations—without hybridization—for all the atoms in  $\text{PH}_3$ . Circle the electrons involved in bonding. Draw a three-dimensional sketch of the molecule and show orbital overlap. What bond angle do you expect from the unhybridized orbitals? How well does valence bond theory agree with the experimentally measured bond angle of  $93.3^\circ$ ?
56. Write orbital diagrams (boxes with arrows in them) to represent the electron configurations—without hybridization—for all the atoms in  $\text{SF}_2$ . Circle the electrons involved in bonding. Draw a three-dimensional sketch of the molecule and show orbital overlap. What bond angle do you expect from the unhybridized orbitals? How well does valence bond theory agree with the experimentally measured bond angle of  $98.2^\circ$ ?
57. Write orbital diagrams (boxes with arrows in them) to represent the electron configuration of carbon before and after  $sp^3$  hybridization.
58. Write orbital diagrams (boxes with arrows in them) to represent the electron configurations of carbon before and after  $sp$  hybridization.
59. Which hybridization scheme allows the formation of at least one  $\pi$  bond?
- $sp^3$ ,  $sp^2$ ,  $sp^3d^2$
60. Which hybridization scheme allows the central atom to form more than four bonds?
- $sp^3$ ,  $sp^3d$ ,  $sp^2$
61. Write a hybridization and bonding scheme for each molecule. Sketch the molecule, including overlapping orbitals, and label all bonds using the notation shown in Examples 10.6 and 10.7.
- $\text{CCl}_4$
  - $\text{NH}_3$
  - $\text{OF}_2$
  - $\text{CO}_2$

62. Write a hybridization and bonding scheme for each molecule. Sketch the molecule, including overlapping orbitals, and label all bonds using the notation shown in Examples 10.6 and 10.7.
- $\text{CH}_2\text{Br}_2$
  - $\text{SO}_2$
  - $\text{NF}_3$
  - $\text{BF}_3$
63. Write a hybridization and bonding scheme for each molecule or ion. Sketch the structure, including overlapping orbitals, and label all bonds using the notation shown in Examples 10.6 and 10.7.
- $\text{COCl}_2$  (carbon is the central atom)
  - $\text{BrF}_5$
  - $\text{XeF}_2$
  - $\text{I}_3^-$
64. Write a hybridization and bonding scheme for each molecule or ion. Sketch the structure, including overlapping orbitals, and label all bonds using the notation shown in Examples 10.6 and 10.7.
- $\text{SO}_3^{2-}$
  - $\text{PF}_6^-$
  - $\text{BrF}_3$
  - $\text{HCN}$
65. Write a hybridization and bonding scheme for each molecule that contains more than one interior atom. Indicate the hybridization about each interior atom. Sketch the structure, including overlapping orbitals, and label all bonds using the notation shown in Examples 10.6 and 10.7.
- $\text{N}_2\text{H}_2$  (skeletal structure  $\text{HNNH}$ )
  - $\text{N}_2\text{H}_4$  (skeletal structure  $\text{H}_2\text{NNH}_2$ )
  - $\text{CH}_3\text{NH}_2$  (skeletal structure  $\text{H}_3\text{CNH}_2$ )
66. Write a hybridization and bonding scheme for each molecule that contains more than one interior atom. Indicate the hybridization about each interior atom. Sketch the structure, including overlapping orbitals, and label all bonds using the notation shown in Examples 10.6 and 10.7.
- $\text{C}_2\text{H}_2$  (skeletal structure  $\text{HCCH}$ )
  - $\text{C}_2\text{H}_4$  (skeletal structure  $\text{H}_2\text{CCH}_2$ )
  - $\text{C}_2\text{H}_6$  (skeletal structure  $\text{H}_3\text{CCH}_3$ )
67. Consider the structure of the amino acid alanine. Indicate the hybridization about each interior atom.

68. Consider the structure of the amino acid aspartic acid. Indicate the hybridization about each interior atom.

## Molecular Orbital Theory

69. Sketch the bonding molecular orbital that results from the linear combination of two 1s orbitals. Indicate the region where interference occurs and state the kind of interference (constructive or destructive).
70. Sketch the antibonding molecular orbital that results from the linear combination of two 1s orbitals. Indicate the region where interference occurs and state the kind of interference (constructive or destructive).
71. Draw an MO energy diagram and predict the bond order of  $\text{Be}_2^+$  and  $\text{Be}_2^-$ . Do you expect these molecules to exist in the gas phase?
72. Draw an MO energy diagram and predict the bond order of  $\text{Li}_2^+$  and  $\text{Li}_2^-$ . Do you expect these molecules to exist in the gas phase?
73. Sketch the bonding and antibonding molecular orbitals that result from linear combinations of the  $2p_x$  atomic orbitals in a homonuclear diatomic molecule. (The  $2p_x$  orbitals are those whose lobes are oriented along the bonding axis.)
74. Sketch the bonding and antibonding molecular orbitals that result from linear combinations of the  $2p_z$  atomic orbitals in a homonuclear diatomic molecule. (The  $2p_z$  orbitals are those whose lobes are oriented perpendicular to the bonding axis.) How do these molecular orbitals differ from those obtained from linear combinations of the  $2p_y$  atomic orbitals? (The  $2p_y$  orbitals are also oriented perpendicular to the bonding axis, but also perpendicular to the  $2p_z$  orbitals.)
75. Using the molecular orbital energy ordering for second-row homonuclear diatomic molecules in which the  $\pi_{2p}$  orbitals lie at lower energy than the  $\sigma_{2p}$ , draw MO energy diagrams and predict the bond order in a molecule or ion with each number of total valence electrons. Will the molecule or ion be diamagnetic or paramagnetic?
- a. 4      b. 6      c. 8      d. 9
76. Using the molecular orbital energy ordering for second-row homonuclear diatomic molecules in which the  $\pi_{2p}$  orbitals lie at higher energy than the  $\sigma_{2p}$ , draw MO energy diagrams and predict the bond order in a molecule or ion with each number of total valence electrons. Will the molecule or ion be diamagnetic or paramagnetic?
- a. 10      b. 12      c. 13      d. 14
77. Use molecular orbital theory to predict if each molecule or ion exists in a relatively stable form.
- a.  $\text{H}_2^{2-}$       b.  $\text{Ne}_2$       c.  $\text{He}_2^{2+}$       d.  $\text{F}_2^{2-}$
78. Use molecular orbital theory to predict if each molecule or ion exists in a relatively stable form.
- a.  $\text{C}_2^{2+}$       b.  $\text{Li}_2$       c.  $\text{Be}_2^{2+}$       d.  $\text{Li}_2^{2-}$
79. According to MO theory, which molecule or ion has the highest bond order? Highest bond energy? Shortest bond length?
- $\text{C}_2, \text{C}_2^+, \text{C}_2^-$
80. According to MO theory, which molecule or ion has the highest bond order? Highest bond energy? Shortest bond length?
- $\text{O}_2, \text{O}_2^-, \text{O}_2^{2-}$
81. Draw an MO energy diagram for CO. (Use the energy ordering of  $\text{O}_2$ .) Predict the bond order and make a sketch of the lowest energy bonding molecular orbital.
82. Draw an energy diagram for HCl. Predict the bond order and make a sketch of the lowest energy bonding molecular orbital.

## Cumulative Problems

83. For each compound, draw the Lewis structure, determine the geometry using VSEPR theory, determine whether the molecule is polar, identify the hybridization of all interior atoms, and make a sketch of the molecule, according to valence bond theory, showing orbital overlap.
- a.  $\text{COF}_2$  (carbon is the central atom)  
b.  $\text{S}_2\text{Cl}_2$  (ClSSCl)  
c.  $\text{SF}_4$
84. For each compound, draw the Lewis structure, determine the geometry using VSEPR theory, determine whether the molecule is polar, identify the hybridization of all interior atoms, and make a sketch of the molecule, according to valence bond theory, showing orbital overlap.
- a.  $\text{IF}_5$       b.  $\text{CH}_2\text{CHCH}_3$       c.  $\text{CH}_3\text{SH}$
85. Amino acids are biological compounds that link together to form proteins, the workhorse molecules in living organisms. The skeletal structures of several simple amino acids are shown here. For each skeletal structure, complete the Lewis structure, determine the geometry and hybridization about each interior atom, and make a sketch of the molecule, using the bond conventions of Section 10.4.

86. The genetic code is based on four different bases with the structures shown here. Assign a geometry and hybridization to each interior atom in these four bases.
- a. cytosine      b. adenine      c. thymine      d. guanine

87. The structure of caffeine, present in coffee and many soft drinks, is shown here. How many pi bonds are present in caffeine? How many sigma bonds? Insert the lone pairs in the molecule. What kinds of orbitals do the lone pairs occupy?

88. The structure of acetylsalicylic acid (aspirin) is shown here. How many pi bonds are present in acetylsalicylic acid? How many sigma bonds? What parts of the molecule are free to rotate? What parts are rigid?

89. Most vitamins can be classified as either fat soluble, which results in their tendency to accumulate in the body (so that taking too much can be harmful), or water soluble, which results in their tendency to be quickly eliminated from the body in urine. Examine the structural formulas and space-filling models of these vitamins and determine whether each one is fat soluble (mostly nonpolar) or water soluble (mostly polar).

(a) vitamin C

(b) vitamin A

(c) niacin (vitamin B<sub>3</sub>)

(d) vitamin E

90. Water does not easily remove grease from dishes or hands because grease is nonpolar and water is polar. The addition of soap to water, however, allows the grease to dissolve. Study the structure of sodium stearate (a soap) and describe how it works.

91. Draw a molecular orbital energy diagram for ClF. (Assume that the  $\sigma_p$  orbitals are lower in energy than the  $\pi$  orbitals.) What is the bond order in ClF?
92. Draw Lewis structures and MO diagrams for  $\text{CN}^+$ ,  $\text{CN}$ , and  $\text{CN}^-$ . According to the Lewis model, which species is most stable? According to MO theory, which species is most stable? Do the two theories agree?

93. Bromine can form compounds or ions with any number of fluorine atoms from one to five. Write the formulas of all five of these species, assign a hybridization, and describe their electron and molecular geometry.
94. The compound  $\text{C}_3\text{H}_4$  has two double bonds. Describe its bonding and geometry, using a valence bond approach.
95. Draw the structure of a molecule with the formula  $\text{C}_4\text{H}_6\text{Cl}_2$  that has a dipole moment of 0.
96. Draw the structures of two compounds that have the composition  $\text{CH}_3\text{NO}_2$  and have all three H atoms bonded to the C. Predict which compound has the larger ONO bond angle.
97. How many types of hybrid orbitals do we use to describe each molecule?
- $\text{N}_2\text{O}_5$
  - $\text{C}_2\text{H}_5\text{NO}$  (four C — H bonds and one O — H bond)
  - $\text{BrCN}$  (no formal charges)
98. Indicate which orbitals overlap to form the  $\sigma$  bonds in each molecule.
- $\text{BeBr}_2$
  - $\text{HgCl}_2$
  - $\text{ICN}$

## Challenge Problems

99. In VSEPR theory, which uses the Lewis model to determine molecular geometry, the trend of decreasing bond angles in  $\text{CH}_4$ ,  $\text{NH}_3$ , and  $\text{H}_2\text{O}$  is accounted for by the greater repulsion of lone pair electrons compared to bonding pair electrons. How would this trend be accounted for in valence bond theory?
100. The results of a molecular orbital calculation for  $\text{H}_2\text{O}$  are shown here. Examine each of the orbitals and classify them as bonding, antibonding, or nonbonding. Assign the correct number of electrons to the energy diagram. According to this energy diagram, is  $\text{H}_2\text{O}$  stable? Explain.

101. The results of a molecular orbital calculation for  $\text{NH}_3$  are shown here. Examine each of the orbitals and classify them as bonding, antibonding, or nonbonding. Assign the correct number of electrons to the energy diagram. According to this energy diagram, is  $\text{NH}_3$  stable? Explain.

- 102.** *cis*-2-Butene isomerizes to *trans*-2-butene via the reaction shown here.

- If isomerization requires breaking the  $\pi$  bond, what minimum energy is required for isomerization in J/mol? In J/molecule?
  - If the energy for isomerization came from light, what minimum frequency of light would be required? In what portion of the electromagnetic spectrum does this frequency lie?
- 103.** The species  $\text{NO}_2$ ,  $\text{NO}_2^+$ , and  $\text{NO}_2^-$  in which N is the central atom have very different bond angles. Predict what these bond angles might be with respect to the ideal angles and justify your prediction.
- 104.** The bond angles increase steadily in the series  $\text{PF}_3$ ,  $\text{PCl}_3$ ,  $\text{PBr}_3$ , and  $\text{PI}_3$ . After consulting the data on atomic radii in Chapter 8, provide an explanation for this observation.
- 105.** The ion  $\text{CH}_5^+$  can form under very special high-energy conditions in the vapor phase in a mass spectrometer. Propose a hybridization for the carbon atom and predict the geometry.
- 106.** Neither the VSEPR model nor the hybridization model is able to account for the experimental observation that the  $\text{F}-\text{Ba}-\text{F}$  bond angle in gaseous  $\text{BaF}_2$  is  $108^\circ$  rather than the predicted  $180^\circ$ . Suggest some possible explanations for this observation.
- 107.** Draw the Lewis structure for acetamide ( $\text{CH}_3\text{CONH}_2$ ), an organic compound, and determine the geometry about each interior atom. Experiments show that the geometry about the nitrogen atom in acetamide is nearly planar. What resonance structure can account for the planar geometry about the nitrogen atom?
- 108.** Use VSEPR theory to predict the geometry (including bond angles) about each interior atom of methyl azide ( $\text{CH}_3\text{N}_3$ ), and make a sketch of the molecule. Would you expect the bond angle between the two interior nitrogen atoms to be the same or different? Would you expect the two nitrogen–nitrogen bond lengths to be the same or different?

## Conceptual Problems

- 109.** Which statement best captures the fundamental idea behind VSEPR theory? Explain what is wrong with each of the other statements.
- The angle between two or more bonds is determined primarily by the repulsions between the electrons within those bonds and other (lone pair) electrons on the central atom of a molecule. Each of these electron groups (bonding electrons or lone pair electrons) will lower its potential energy by maximizing its separation from other electron groups, thus determining the geometry of the molecule.
  - The angle between two or more bonds is determined primarily by the repulsions between the electrons within those bonds. Each of these bonding electrons will lower its potential energy by maximizing its separation from other electron groups, thus determining the geometry of the molecule.
  - The geometry of a molecule is determined by the shapes of the overlapping orbitals that form the chemical bonds. Therefore, to determine the geometry of a molecule, you must determine the shapes of the orbitals involved in bonding.
- 110.** Suppose that a molecule has four bonding groups and one lone pair on the central atom. Suppose further that the molecule is confined to two dimensions (this is a purely hypothetical assumption for the sake of understanding the principles behind VSEPR theory). Make a sketch of the molecule and estimate the bond angles.
- 111.** How does each of the three major bonding theories (the Lewis model, valence bond theory, and molecular orbital theory) define a single chemical bond? A double bond? A triple bond? How are these definitions similar? How are they different?
- 112.** The most stable forms of the nonmetals in groups 4A, 5A, and 6A of the second period are molecules with multiple bonds. Beginning with the third period, the most stable forms of the nonmetals of these groups are molecules without multiple bonds. Propose an explanation for this observation based on valence bond theory.

### Active Classroom Learning

## Questions for Group Work

Discuss these questions with the group and record your consensus answer.

- 113.** In complete sentences, describe why someone might expect the bond angles in methane ( $\text{CH}_4$ ) to be  $90^\circ$  even though the bond angles are actually  $109.5^\circ$ .
- 114.** At least two different numbers of electron groups can result in a linear molecule. What are they? What are the numbers of bonding groups and lone pairs in each case? Provide an example of a linear molecule in each case.
- 115.** Have each member of your group select one of the molecules shown below and complete steps a–d. Each member should then present his or her results to the rest of the group, explaining the reasoning used to determine the answers.

- Draw the Lewis dot structure.
  - Determine the molecular geometry and draw it accurately.
  - Indicate the polarity of any polar bonds within the structure.
  - Classify the molecule as polar or nonpolar.
- 116.** How many atomic orbitals form a set of  $sp^3$  hybrid orbitals? A set of  $sp^2$  hybrid orbitals? A set of  $sp$  hybrid orbitals? What is the relationship between these numbers and the number of electron groups around the central atom?
- 117.** Use molecular orbital theory to explain in detail why  $\text{N}_2^+$  and  $\text{N}_2^-$  have similar bond strengths and both are very different from neutral  $\text{N}_2$ .

## Data Interpretation and Analysis

### Using Distances between Atoms to Predict Bond Angles

**118.** The distance between two atoms that are attached to a common central atom is approximately equal to the sum of their “target distance” atomic radii. For example, consider the structures of  $\text{CF}_4$  and  $\text{OCF}_2$  in Figure a. Given that the target distance radius of fluorine when it is bonded to carbon is 108 pm, the target distance between the two fluorine atoms

**▲ FIGURE a** Lewis Structures and Target Distances for  $\text{CF}_4$  and  $\text{OCF}_2$

(represented as dashed lines in the figure) is about 216 pm ( $108 \text{ pm} + 108 \text{ pm}$ ) in both  $\text{CF}_4$  and  $\text{OCF}_2$ . If we know the C—F bond length to be 132.3 pm, we can use trigonometry (Figure b) to determine the F—C—F bond angle in each molecule.

$$\sin \theta = \frac{\text{opposite}}{\text{hypotenuse}} = \frac{108 \text{ pm}}{132.3 \text{ pm}} = 0.816$$

$$\theta = 54.7^\circ$$

$$\theta + \theta = 109.4^\circ$$

**▲ FIGURE b** Using Trigonometry to Determine the F—C—F Bond Angles in  $\text{OCF}_2$

Use the relation  $\sin \theta = \text{opposite/hypotenuse}$  to complete the information in the table:

	C—Cl Bond Length (pm)	Cl—C—Cl Bond Angle ( $^\circ$ )	Cl—Cl target distance (pm)
C—Cl			
$\text{CCl}_4$	177.1		290
$\text{CF}_2\text{Cl}_2$	174.4		290
$\text{CCl}_3\text{F}$	176		290

## Answers to Conceptual Connections

### Electron Groups and Molecular Geometry

**10.1** The geometry of a molecule is determined by how the terminal atoms are arranged around the central atom, which is in turn determined by how the electron groups are arranged around the central atom. The electron groups on the terminal atoms do not affect this arrangement.

### Molecular Geometry

**10.2 (a)** Linear. HCN has two electron groups (the single bond and the triple bond) resulting in a linear geometry.

### Lone Pair Electrons and Molecular Geometry

**10.3 (c)** Positions 1 and 4 would put the greatest distance between the lone pairs and minimize lone pair–lone pair repulsions.

### Molecular Geometry and Electron Group Repulsions

**10.4 (d)** All electron groups on the central atom (or interior atoms, if there is more than one) determine the shape of a molecule according to VSEPR theory.

### The Shape of Larger Molecules

**10.5** The nitrogen atom has four electron groups and one lone pair, as the Lewis structure shown to the right illustrates; therefore, the molecular geometry about the nitrogen atom is trigonal pyramidal.

### What Is a Chemical Bond? Part I

**10.6 (a)** In the Lewis model, a covalent chemical bond is the sharing of electrons (represented by dots). (b) In valence bond theory, a covalent chemical bond is the overlap of half-filled atomic orbitals. (c) The answers are different because the Lewis model and valence bond theory are different models for chemical bonding. They both make useful and often similar predictions, but the assumptions of each model are different, and so are their respective descriptions of a chemical bond.

### Number of Hybrid Orbitals Part I

**10.7** The number of  $sp^3$  hybrid orbitals is 4. You can determine the number of hybrid orbitals by summing the superscripts in the hybridization notation. For  $sp^3$ , you add the implied 1 superscript on the  $s$  to the 3 superscript on the  $p$  and you get  $1 + 3 = 4$ .

### Single and Double Bonds

**10.8** Applying valence bond theory, we see that a double bond is actually composed of two different kinds of bonds, one  $\sigma$

and one  $\pi$ . The orbital overlap in the  $\pi$  bond is side to side between two  $p$  orbitals and consequently different from the end-to-end overlap in a  $\sigma$  bond. Since the bonds are different types, the bond energy of the double bond is not just twice the bond energy of the single bond.

#### Number of Hybrid Orbitals Part II

- 10.9** The number of  $sp$  hybrid orbitals is 2. You can determine the number of hybrid orbitals by summing the superscripts in the hybridization notation. For  $sp$ , you add the implied 1 superscript on the  $s$  to the implied 1 superscript on the  $p$  and you get  $1 + 1 = 2$ .

#### Bond Order

- 10.10** The bond order is 1.5. Remember that bond order is equal to the number of bonding electrons minus the number of antibonding electrons, all divided by two, so you get that the bond order  $= (6 - 3)/2 = 1.5$ .

#### What Is a Chemical Bond? Part II

- 10.11** In MO theory, atoms will join together (or bond) when the electrons in the atoms can lower their energy by occupying the molecular orbitals of the resultant molecule. Unlike the Lewis model or valence bond theory, the chemical “bonds” in MO theory are not localized between atoms, but spread throughout the entire molecule.

# Liquids, Solids, and Intermolecular Forces

Substance 520**

**KEY LEARNING OUTCOMES 524**

**R**ecall from Chapter 1 that matter exists primarily in three states (or phases): solid, liquid, and gas. In Chapter 5, we examined the gas state. In this chapter we turn to the solid and liquid states, known collectively as the *condensed* states. The solid and liquid states are more similar to each other than they are to the gas state. In the gas state, constituent particles—atoms or molecules—are separated by large distances and do not interact with each other very much. In the condensed states, constituent particles are close together and exert moderate to strong attractive forces on one another. Whether a substance is a solid, liquid, or gas at a given temperature depends on the structure of the particles that compose the substance. Remember the theme we have emphasized since Chapter 1 of this book: the properties of matter are determined by the properties of molecules and atoms. In this chapter, we see how the structure of a particular atom or molecule determines the state in which it will exist at a given temperature.

▲ *In the absence of gravity (such as in a space station), a sample of spilled water forms a perfect sphere. This behavior is a direct result of intermolecular forces—attractive forces that exist among the particles that compose matter.*

## 11.1 Water, No Gravity

In the space station there are no spills. When an astronaut squeezes a full water bottle, the water squirts out like it does on Earth, but instead of falling to the floor and forming a puddle, the water molecules stick together to form a floating, oscillating blob. Over time, the blob stops oscillating and forms a nearly perfect sphere. Why?

The reason is the main topic of this chapter: *intermolecular forces*, the attractive forces that exist among the particles that compose matter. The molecules that compose water are attracted to one another, much like a collection of small magnets are attracted to each other. These attractions hold the water together as a liquid (instead of a gas) at

room temperature. These forces also cause samples of water to clump together into a blob, which is clearly seen in the absence of gravity. Over time, irregularities in the shape of the blob smooth out, and the blob becomes a sphere. The sphere is the geometrical shape with the lowest surface area to volume ratio. By forming a sphere, the water molecules maximize their interaction with one another because the sphere results in the minimum number of molecules being at the surface of the liquid, where fewer interactions occur (compared to the interior of the liquid).

Intermolecular forces exist, not only among water molecules, but among all particles that compose matter. You can see the effect of these attractive forces in the image to the left, which shows an astronaut touching a floating blob of water in the absence of gravity. Notice how the water sticks to the astronaut’s finger. The water molecules experience an attractive force to the molecules that compose skin. This attractive force deforms the entire blob of water. *Intermolecular forces exist among all the particles that compose matter.*

Intermolecular forces are responsible for the very existence of condensed states. The state of a sample of matter—solid, liquid, or gas—depends on the magnitude of intermolecular forces among the constituent particles relative to the amount of thermal energy in the sample. Recall from Chapter 6 that the molecules and atoms composing matter are in constant random motion that increases with increasing temperature. The energy associated with this motion is *thermal energy*. When thermal energy is high relative to intermolecular forces, matter tends to be gaseous. When thermal energy is low relative to intermolecular forces, matter tends to be liquid or solid.

11.2 Solids, Liquids, and Gases: A Molecular Comparison

We are all familiar with solids and liquids. Water, gasoline, rubbing alcohol, and nail polish remover are common liquids. Ice, dry ice, and diamond are familiar solids. What makes these states so different?

Differences between States of Matter

To illustrate the differences between the three common states of matter, Table 11.1 lists the density and molar volume of water in its three different states, along with molecular representations of each state. Notice that the densities of the solid and liquid states are

TABLE 11.1 The Three States of Water				
Phase	Temperature (°C)	Density (g/cm <sup>3</sup> , at 1 atm)	Molar Volume	Molecular View
Gas (steam)	100	5.90 × 10 <sup>−4</sup>	30.5 L	
Liquid (water)	20	0.998	18.0 mL	
Solid (ice)	0	0.917	19.6 mL	

much greater than the density of the gas state. Notice also that the solid and liquid states are more similar in density and molar volume to one another than they are to the gas state. The molecular representations show the reason for these differences. The molecules in liquid water and ice are in close contact with one another—essentially touching—whereas those in gaseous water are separated by large distances. The molecular representation of gaseous water in Table 11.1 is actually out of proportion—the water molecules in the figure should be much farther apart for their size. (Only a fraction of a molecule could be included in the figure if it were drawn to scale.) From the molar volumes, we know that 18.0 mL of liquid water (slightly more than a tablespoon) occupies 30.5 L when converted to gas at 100 °C (at atmospheric pressure). The low density of gaseous water is a direct result of this large separation between molecules.

Notice also that, for water, the solid is slightly less dense than the liquid. This is *atypical* behavior. Most solids are slightly denser than their corresponding liquids because the molecules move closer together upon freezing. As we will discuss in Section 11.9, ice is less dense than liquid water because the unique crystal structure of ice results in water molecules moving slightly farther apart upon freezing.

A major difference between liquids and solids is the freedom of movement of the constituent molecules or atoms. Even though the atoms or molecules in a liquid are in close contact, thermal energy partially overcomes the attractions between them, allowing them to move around one another. This is not the case in solids; the atoms or molecules in a solid are virtually locked in their positions, only vibrating back and forth about a fixed point. Table 11.2 summarizes the properties of liquids and solids, as well as the properties of gases for comparison.

**TABLE 11.2** Properties of the States of Matter

State	Density	Shape	Volume	Strength of Intermolecular Forces (Relative to Thermal Energy)
Gas	Low	Indefinite	Indefinite	Weak
Liquid	High	Indefinite	Definite	Moderate
Solid	High	Definite	Definite	Strong

Liquids assume the shape of their containers because the atoms or molecules that compose liquids are free to flow (or move around one another). When we pour water into a flask, the water flows and assumes the shape of the flask (Figure 11.1►). Liquids are not easily compressed because the molecules or atoms that compose them are already in close contact—they cannot be pushed much closer together. The molecules in a gas, by contrast, have a great deal of space between them and are easily forced into a smaller volume by an increase in external pressure (Figure 11.2▼).

**▲ FIGURE 11.2** **Gases Are Compressible** Molecules in a liquid are closely spaced and are not easily compressed. Molecules in a gas have a great deal of space between them, making gases compressible.

**▲ FIGURE 11.1** **Liquids Assume the Shapes of Their Containers** When we pour water into a flask, it assumes the shape of the flask because water molecules are free to flow.

According to some definitions, an amorphous solid is considered a unique state, different from the normal solid state because it lacks any long-range order.

Solids have a definite shape because, in contrast to liquids and gases, the molecules or atoms that compose solids are fixed in place—each molecule or atom in a solid merely vibrates about a fixed point. Like liquids, solids have a definite volume and generally cannot be compressed because the molecules or atoms composing them are already in close contact. Solids may be **crystalline**, in which case the atoms or molecules that compose them are arranged in a well-ordered three-dimensional array, or they may be **amorphous**, in which case the atoms or molecules that compose them have no long-range order (Figure 11.3 ▼).

► **FIGURE 11.3 Crystalline and Amorphous Solids** In a crystalline solid, the arrangement of the particles displays long-range order. In an amorphous solid, the arrangement of the particles has no long-range order.

## Changes between States

We can transform one state of matter to another by changing the temperature, pressure, or both. For example, we can convert solid ice to liquid water by heating, and liquid water to solid ice by cooling. The following diagram shows the three states of matter and the changes in conditions that commonly induce transitions between the states:

We can induce a transition between the liquid and gas state, not only by heating and cooling, but also by changing the pressure. In general, increases in pressure favor the denser state, so increasing the pressure of a gas sample results in a transition to the liquid state.

The most familiar example of this phenomenon occurs in the LP (liquefied petroleum) gas used as a fuel for outdoor grills and lanterns. LP gas is composed primarily of propane, a gas at room temperature and atmospheric pressure. However, it liquefies at pressures exceeding about 2.7 atm. The propane you buy in a tank is under pressure and therefore in the liquid form. When you open the tank, some of the propane escapes as a gas, lowering the pressure in the tank for a brief moment. Immediately, however, some of the liquid propane evaporates, replacing the gas that escaped. Storing gases like propane as liquids is efficient because, in their liquid form, they occupy much less space.

◀ The propane in an LP gas tank is in the liquid state. When you open the tank, some propane vaporizes and escapes as a gas.

**State Changes** This molecular diagram shows a sample of liquid water:

Which of the diagrams below best depicts the vapor emitted from a pot of boiling water?

## CONCEPTUAL CONNECTION 11.1

### 11.3 Intermolecular Forces: The Forces That Hold Condensed States Together

Intermolecular Forces

The structure of the particles that compose a substance determines the strength of the intermolecular forces that hold the substance together, which in turn determines whether the substance is a solid, liquid, or gas at a given temperature. At room temperature, moderate to strong intermolecular forces tend to result in liquids and solids (high melting and boiling points), and weak intermolecular forces tend to result in gases (low melting and boiling points).

Intermolecular forces originate from the interactions among charges, partial charges, and temporary charges on molecules (or atoms and ions), much as bonding forces originate from interactions among charged particles in atoms. Recall from Section 8.3 that according to Coulomb's law, the potential energy ( $E$ ) of two oppositely charged particles (with charges  $q_1$  and  $q_2$ ) decreases (becomes more negative) with increasing magnitude of charge and with decreasing separation ( $r$ ):

$$E = \frac{1}{4\pi\epsilon_0} \frac{q_1 q_2}{r} \quad (\text{When } q_1 \text{ and } q_2 \text{ are opposite in sign, } E \text{ is negative.})$$

Therefore, as we have seen, protons and electrons are attracted to each other because their potential energy decreases as they get closer together. Similarly, molecules with partial or temporary charges are attracted to each other because *their* potential energy decreases as they get closer together. However, intermolecular forces, even the strongest ones, are generally *much weaker* than bonding forces.

The reason for the relative weakness of intermolecular forces compared to bonding forces is also related to Coulomb's law. Bonding forces are the result of large charges (the charges on protons and electrons) interacting at very close distances. Intermolecular forces are the result of smaller charges (as we shall see in the following discussion) interacting at greater distances. For example, consider the interaction between two water molecules in liquid water:

The length of an O—H bond in liquid water is 96 pm; however, the average distance between water molecules in liquid water is about 300 pm. The larger distances between molecules, as well as the smaller charges involved (the partial charges on the hydrogen and oxygen atoms), result in weaker forces. To break the O—H bonds in water, we have to heat the water to thousands of degrees Celsius. However, to completely overcome the intermolecular forces *between* water molecules, we have to heat water only to its boiling point, 100 °C (at sea level).

In this section we examine several different types of intermolecular forces, including dispersion forces, dipole–dipole forces, hydrogen bonding, and ion–dipole forces. The first three of these can potentially occur in all substances; the last one occurs only in mixtures.

## Dispersion Force

The one intermolecular force present between all molecules and atoms is the **dispersion force** (also called the London force). Dispersion forces are the result of fluctuations in the electron distribution within molecules or atoms. Since all atoms and molecules have electrons, they all exhibit dispersion forces. The electrons in an atom or molecule may, *at any one instant*, be unevenly distributed. Imagine a frame-by-frame movie of a helium atom in which each “frame” captures the position of the helium atom’s two electrons:

In any one frame, the electrons may not be symmetrically arranged around the nucleus. In frame 3, for example, helium’s two electrons are on the left side of the helium atom. At that instant, the left side has a slightly negative charge ( $\delta^-$ ). The right side of the atom, which temporarily has no electrons, has a slightly positive charge ( $\delta^+$ ) because of the charge of the nucleus. This fleeting charge separation is called an *instantaneous dipole* or a *temporary dipole*. As shown in Figure 11.4 ▼, an instantaneous dipole on one helium atom induces an instantaneous dipole on its neighboring atoms because the positive end of the instantaneous dipole attracts electrons in the neighboring atoms. The neighboring atoms then attract one another—the positive end of one instantaneous dipole attracting the negative end of another. This attraction is the dispersion force.

► **FIGURE 11.4 Dispersion Interactions** The temporary dipole in one helium atom induces a temporary dipole in its neighbor. The resulting attraction between the positive and negative charges creates the dispersion force.

### Dispersion Force

An instantaneous dipole on any one helium atom induces instantaneous dipoles on neighboring atoms, which then attract one another.

To polarize means to form a dipole moment (see Section 9.6).

The *magnitude* of the dispersion force depends on how easily the electrons in the atom or molecule can move or *polarize* in response to an instantaneous dipole, which in turn depends on the size (or volume) of the electron cloud. A larger electron cloud

results in a greater dispersion force because the electrons are held less tightly by the nucleus and therefore polarize more easily. If all other variables are constant, the dispersion force increases with increasing molar mass because molecules or atoms of higher molar mass generally have more electrons dispersed over a greater volume. For example, consider the boiling points of the noble gases displayed in Table 11.3. As the molar masses and electron cloud volumes of the noble gases increase, the greater dispersion forces result in increasing boiling points (because the atoms are more strongly attracted to one another).

Molar mass alone, however, does not always exactly correlate with the magnitude of the dispersion force. Compare the molar masses and boiling points of *n*-pentane and neopentane:

**TABLE 11.3** Boiling Points of the Noble Gases

Noble Gas		Molar Mass (g/mol)	Boiling Point (K)
He		4.00	4.2
Ne		20.18	27
Ar		39.95	87
Kr		83.80	120
Xe		131.30	165

These molecules have identical molar masses, but *n*-pentane has a higher boiling point than neopentane. Why? Because the two molecules have different shapes. The *n*-pentane molecules are long and can interact with one another along their entire length, as shown in Figure 11.5(a)▼. In contrast, the bulky, round shape of neopentane molecules results in a smaller area of interaction between neighboring molecules, as shown in Figure 11.5(b)▼. The result is a lower boiling point for neopentane.

▲ **FIGURE 11.5 Dispersion Force and Molecular Shape** (a) The straight shape of *n*-pentane molecules allows them to interact with one another along the entire length of the molecules. (b) The nearly spherical shape of neopentane molecules allows for only a small area of interaction. Thus, dispersion forces are weaker in neopentane than in *n*-pentane, resulting in a lower boiling point.

Although we must always consider molecular shape and other factors in predicting the magnitude of dispersion forces, molar mass can act as a guide when comparing dispersion forces within a family of similar elements or compounds as illustrated in Figure 11.6► on the next page.

► **FIGURE 11.6 Boiling Points of the *n*-Alkanes** The boiling points of the *n*-alkanes rise with increasing molar mass and the consequent stronger dispersion forces.

## CONCEPTUAL CONNECTION 11.2

 (a) Cl<sub>2</sub> (b) Br<sub>2</sub> (c) I<sub>2</sub>

## Dipole–Dipole Force

See Section 9.6 and 10.5 to review how to determine if a molecule is polar.

The **dipole–dipole force** exists between all molecules that are polar. Polar molecules have electron-rich regions (which have a partial negative charge) and electron-deficient regions (which have a partial positive charge). For example, consider acetone:

Structural formula

Space-filling model

Electrostatic potential map

The image on the right is an electrostatic potential map of acetone; we first saw these kinds of maps in Sections 9.6 and 10.5. Recall that the red areas indicate electron-rich regions in the molecule and that the blue areas indicate electron-poor regions.

Notice that acetone has an electron-rich region surrounding the oxygen atom (because oxygen is more electronegative than the rest of the molecule) and electron-poorer regions surrounding the carbon and hydrogen atoms. The result is that acetone has a **permanent dipole** that can interact with other acetone molecules as shown in Figure 11.7▼. The positive end of one permanent dipole attracts the negative end of

### Dipole–Dipole Interaction

The positive end of a polar molecule is attracted to the negative end of its neighbor.

Space-filling model

Electrostatic potential map

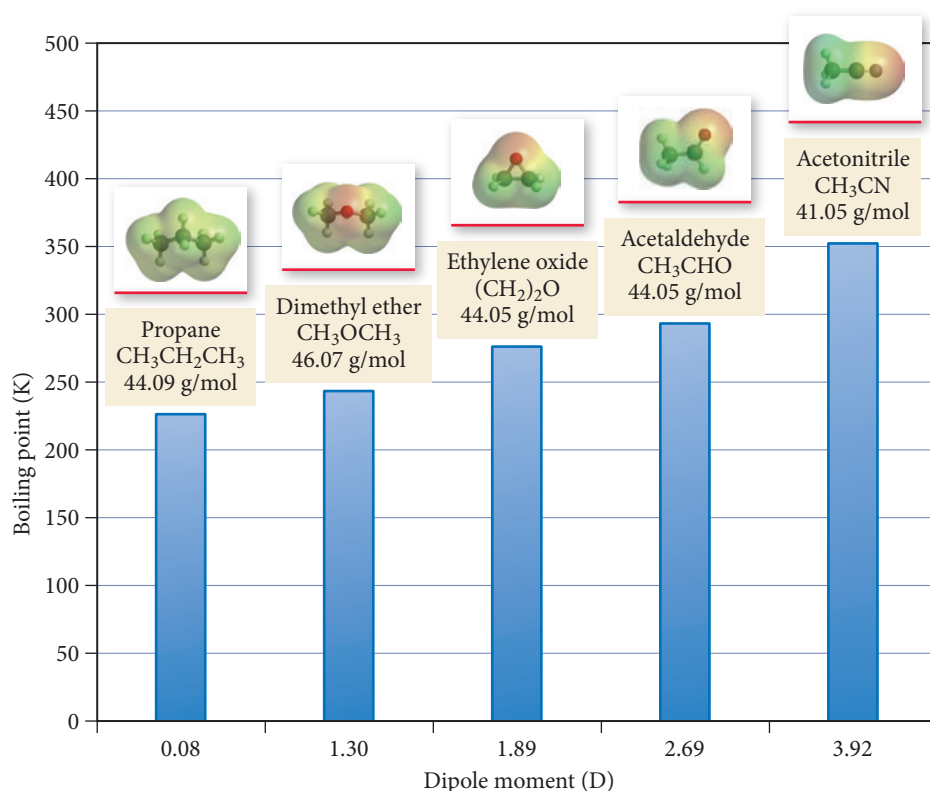

► **FIGURE 11.7 Dipole–Dipole Interaction** Molecules with permanent dipoles, such as acetone, are attracted to one another via dipole–dipole interactions.

another; this attraction is the dipole–dipole force. Polar molecules, therefore, have higher melting and boiling points than nonpolar molecules of similar molar mass.

Remember that all molecules (including polar ones) have dispersion forces. Polar molecules have, *in addition*, dipole–dipole forces. This additional attractive force raises their melting and boiling points relative to nonpolar molecules of similar molar mass. For example, consider formaldehyde and ethane:

Name	Formula	Molar Mass (g/mol)	Structure		bp (°C)	mp (°C)
Formaldehyde	CH <sub>2</sub> O	30.03	$\begin{array}{c} \text{O} \\    \\ \text{H}-\text{C}-\text{H} \end{array}$ 		-19.5	-92
Ethane	C <sub>2</sub> H <sub>6</sub>	30.07	$\begin{array}{cc} \text{H} & \text{H} \\   &   \\ \text{H}-\text{C} & -\text{C}-\text{H} \\   &   \\ \text{H} & \text{H} \end{array}$ 		-88	-172

Formaldehyde is polar, and has a higher melting point and boiling point than nonpolar ethane, even though the two compounds have the same molar mass. Figure 11.8▼ shows the boiling points of a series of molecules with similar molar mass but progressively greater dipole moments. Notice that the boiling points increase with increasing dipole moment.

◀ **FIGURE 11.8 Dipole Moment and Boiling Point** The molecules shown here all have similar molar masses but different dipole moments. The boiling points increase with increasing dipole moment.

The polarity of molecules is also important in determining the **miscibility**—the ability to mix without separating into two states—of liquids. This is especially true for water, which is highly polar. In general, polar liquids tend to be miscible with water, while nonpolar liquids are not. For example, pentane (C<sub>5</sub>H<sub>12</sub>) is nonpolar and does not mix with water (Figure 11.9▶ on the next page). Similarly, water and oil (nonpolar) do not mix. Consequently, oily hands or oily stains on clothes cannot be washed with plain water (see *Chemistry in Your Day: How Soap Works* in Section 10.5).

► **FIGURE 11.9** Polar and Nonpolar

**Substances** Water and pentane do not mix because water molecules are polar and pentane molecules are nonpolar.

**Example 11.1** Dipole–Dipole Forces

Which molecules have dipole–dipole forces?

- (a)  $\text{CO}_2$   
 (b)  $\text{CH}_2\text{Cl}_2$   
 (c)  $\text{CH}_4$

**SOLUTION**

A molecule has dipole–dipole forces if it is polar. To determine if a molecule is polar: (1) *determine if the molecule contains polar bonds* (Section 9.6); and (2) *determine if the polar bonds add together to form a net dipole moment* (Section 10.5).

**(a)**  $\text{CO}_2$ 

- (1) Since the electronegativity of carbon is 2.5 and that of oxygen is 3.5 (see Figure 9.8),  $\text{CO}_2$  has polar bonds.  
 (2) The geometry of  $\text{CO}_2$  is linear. Consequently, the dipoles of the polar bonds cancel, so the molecule is *not polar* and does not have dipole–dipole forces.

**(b)**  $\text{CH}_2\text{Cl}_2$ 

- (1) The electronegativity of C is 2.5, that of H is 2.1, and that of Cl is 3.0. Consequently,  $\text{CH}_2\text{Cl}_2$  has two polar bonds ( $\text{C}-\text{Cl}$ ) and two bonds that are nearly nonpolar ( $\text{C}-\text{H}$ ).  
 (2) The geometry of  $\text{CH}_2\text{Cl}_2$  is tetrahedral. Because the  $\text{C}-\text{Cl}$  bonds and the  $\text{C}-\text{H}$  bonds are different, their dipoles do not cancel but sum to a net dipole moment. The molecule is polar and has dipole–dipole forces.

**(c)**  $\text{CH}_4$ 

- (1) The electronegativity of C is 2.5 and that of hydrogen is 2.1, so the  $\text{C}-\text{H}$  bonds are nearly nonpolar.  
 (2) In addition, since the geometry of the molecule is tetrahedral, any slight polarities that the bonds might have cancel.  $\text{CH}_4$  is therefore nonpolar and does not have dipole–dipole forces.

**FOR PRACTICE 11.1** Which molecules have dipole–dipole forces?

- (a)  $\text{Cl}_4$       (b)  $\text{CH}_3\text{Cl}$       (c)  $\text{HCl}$

**Dipole–Dipole Interaction** An electrostatic potential map for acetonitrile ( $\text{CH}_3\text{CN}$ ), which is polar, is shown here:

From this map, determine the geometry for how two acetonitrile molecules would interact with each other. Draw structural formulas, using the three-dimensional bond notation introduced in Section 10.4, to illustrate the geometry of the interaction.

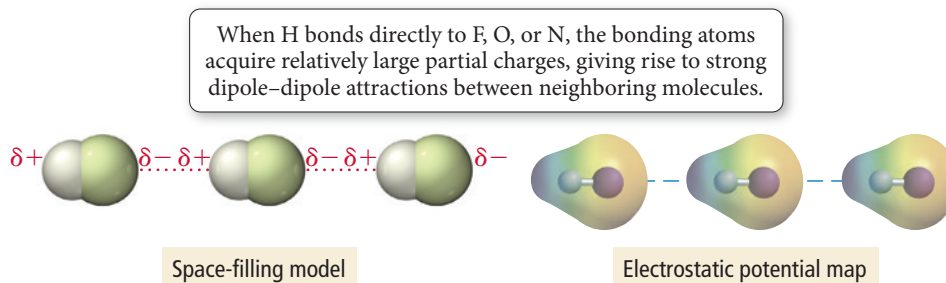

### CONCEPTUAL CONNECTION 11.3

## Hydrogen Bonding

Polar molecules containing hydrogen atoms bonded directly to small electronegative atoms—most importantly fluorine, oxygen, or nitrogen—exhibit an intermolecular force called **hydrogen bonding**.  $\text{HF}$ ,  $\text{NH}_3$ , and  $\text{H}_2\text{O}$ , for example, all exhibit hydrogen bonding. The hydrogen bond is a sort of *super* dipole–dipole force. The large electronegativity difference between hydrogen and any of these electronegative elements causes the hydrogen atom to have a fairly large partial positive charge ( $\delta^+$ ) within the bond, while the F, O, or N atom has a fairly large partial negative charge ( $\delta^-$ ). In addition, since these atoms are all quite small, the H atom on one molecule can approach the F, O, or N atom on an adjacent molecule very closely. The result is a strong attraction between the H atom on one molecule and the F, O, or N on its neighbor—an attraction called a **hydrogen bond**.

For example, in  $\text{HF}$ , the hydrogen atom in one molecule is strongly attracted to the fluorine atom on a neighboring molecule (Figure 11.10▼). The electrostatic potential maps in Figure 11.10 illustrate the large differences in electron density that result in unusually large partial charges.

### Hydrogen Bonding

◀ **FIGURE 11.10** Hydrogen Bonding in  $\text{HF}$  The hydrogen of one  $\text{HF}$  molecule, with its partial positive charge, is attracted to the fluorine of its neighbor, with its partial negative charge. This dipole–dipole interaction is an example of a hydrogen bond.

*Hydrogen bonds should not be confused with chemical bonds.* Chemical bonds occur *between individual atoms within a molecule*, whereas hydrogen bonds—like dispersion forces and dipole–dipole forces—are intermolecular forces that occur *between molecules*. A typical hydrogen bond is only 2–5% as strong as a typical covalent chemical bond. Hydrogen bonds are, however, the strongest of the three *intermolecular* forces we have discussed so far. Substances composed of molecules that form hydrogen bonds have higher melting and boiling points than comparable substances composed of molecules that do not form hydrogen bonds.

For example, consider ethanol and dimethyl ether:

Name	Formula		Molar Mass (g/mol)	Structure	bp (°C)	mp (°C)
Ethanol	$\text{C}_2\text{H}_6\text{O}$		46.07	$\text{CH}_3\text{CH}_2\text{OH}$	78.3	–114.1
Dimethyl ether	$\text{C}_2\text{H}_6\text{O}$		46.07	$\text{CH}_3\text{OCH}_3$	–22.0	–138.5

**▶ FIGURE 11.11 Hydrogen Bonding in Ethanol**

The left side shows the space-filling models, and the right side shows the electrostatic potential maps.

**Hydrogen Bonding in Ethanol**

The partial positive charge on H is strongly attracted to the partial negative charge on O.

**Hydrogen Bonding in Water**

**▲ FIGURE 11.12 Hydrogen Bonding in Water**

Since ethanol contains hydrogen bonded directly to oxygen, ethanol molecules form hydrogen bonds with each other as shown in Figure 11.11▲. The hydrogen that is directly bonded to oxygen in an individual ethanol molecule is strongly attracted to the oxygen on neighboring molecules. This strong attraction (i.e., hydrogen bond) makes the boiling point of ethanol 78.3 °C. Consequently, ethanol is a liquid at room temperature. In contrast, dimethyl ether has an identical molar mass to ethanol but does not exhibit hydrogen bonding because in the dimethyl ether molecule, the oxygen atom is not bonded directly to hydrogen; this results in lower boiling and melting points, and dimethyl ether is a gas at room temperature.

Water is another good example of a molecule with hydrogen bonding (Figure 11.12◀). Figure 11.13▼ plots the boiling points of the simple hydrogen compounds of the group 4A and group 6A elements. In general, boiling points increase with increasing molar mass, as expected based on increasing dispersion forces. However, because of hydrogen bonding, the boiling point of water (100 °C) is much higher than expected based on its molar mass (18.0 g/mol). Without hydrogen bonding, all the water on our planet would be gaseous.

**▲ FIGURE 11.13 Boiling Points of Group 4A and 6A Compounds** Because of hydrogen bonding, the boiling point of water is anomalous compared to the boiling points of other hydrogen-containing compounds.

**Example 11.2** Hydrogen Bonding

One of these compounds is a liquid at room temperature. Which one and why?

Formaldehyde

Fluoromethane

Hydrogen peroxide

**SOLUTION**

The three compounds have similar molar masses:

Formaldehyde            30.03 g/mol

Fluoromethane        34.03 g/mol

Hydrogen peroxide    34.02 g/mol

As a result, the strengths of their dispersion forces are similar. All three compounds are also polar, so they have dipole–dipole forces. Hydrogen peroxide, however, is the only one of these compounds that also contains H bonded directly to F, O, or N. Therefore, it also has hydrogen bonding and is likely to have the highest boiling point of the three. Since the example stated that only one of the compounds was a liquid, it is safe to assume that hydrogen peroxide is the liquid. Note that, although fluoromethane *contains* both H and F, H is not *directly bonded* to F, so fluoromethane does not have hydrogen bonding as an intermolecular force. Similarly, formaldehyde *contains* both H and O, but H is not *directly bonded* to O, so formaldehyde does not exhibit hydrogen bonding either.

**FOR PRACTICE 11.2** Which has the higher boiling point, HF or HCl? Why?

**Ion–Dipole Force**

The **ion–dipole force** occurs when an ionic compound is mixed with a polar compound; it is especially important in aqueous solutions of ionic compounds. For example, when sodium chloride is mixed with water, the sodium and chloride ions interact with water molecules via ion–dipole forces, as shown in Figure 11.14. The positive sodium ions interact with the negative poles of water molecules, while the negative chloride ions interact with the positive poles. Ion–dipole forces are the strongest of the types of intermolecular forces discussed and are responsible for the ability of ionic substances to form solutions with water. We discuss aqueous solutions more thoroughly in Chapter 13.

**Summarizing Intermolecular Forces (as shown in Table 11.4 on the next page):**

- ▶ Dispersion forces are present in all molecules and atoms and generally increase with increasing molar mass. These forces are always weak in small molecules but can be significant in molecules with high molar masses.
- ▶ Dipole–dipole forces are present in polar molecules.
- ▶ Hydrogen bonds, the strongest of the intermolecular forces that can occur in pure substances (second only to ion–dipole forces in general), are present in molecules containing hydrogen bonded directly to fluorine, oxygen, or nitrogen.
- ▶ Ion–dipole forces are present in mixtures of ionic compounds and polar compounds. These forces are very strong and are especially important in aqueous solutions of ionic compounds.

**Ion–Dipole Forces**

The positively charged end of a polar molecule such as  $\text{H}_2\text{O}$  is attracted to negative ions, and the negatively charged end of the molecule is attracted to positive ions.

**▲ FIGURE 11.14 Ion–Dipole Forces** Ion–dipole forces exist between  $\text{Na}^+$  and the negative ends of  $\text{H}_2\text{O}$  molecules and between  $\text{Cl}^-$  and the positive ends of  $\text{H}_2\text{O}$  molecules.

**TABLE 11.4** Types of Intermolecular Forces

Type	Present In	Molecular Perspective	Strength
Dispersion*	All molecules and atoms		0.05–20+ kJ/mol
Dipole–dipole	Polar molecules		3–20+ kJ/mol
Hydrogen bonding	Molecules containing H bonded to F, O, or N		10–40 kJ/mol
Ion–dipole	Mixtures of ionic compounds and polar compounds		30–100+ kJ/mol

\*The dispersion force can become very strong (as strong and even stronger than the others) for molecules of high molar mass.

### CONCEPTUAL CONNECTION 11.4

- (a)  $\text{CH}_3\text{OH}$       (b)  $\text{CO}$       (c)  $\text{N}_2$

## Chemistry AND Medicine

### Hydrogen Bonding in DNA

**D**NA is a long, chainlike molecule that acts as a blueprint for each living organism. Copies of DNA are passed from parent to offspring, which is how we inherit traits from our parents. A DNA molecule is composed of thousands of repeating units called *nucleotides* (Figure 11.15▼). Each nucleotide contains one of four different *organic bases*: adenine, thymine, cytosine, and guanine (abbreviated A, T, C, and G).

The sequence of these bases along DNA encodes the information that determines the nature of the proteins that are made in the body (proteins are the molecules that do most of the work in living organisms). Our proteins in turn determine many of our characteristics, including how we look, what diseases we are at risk of developing, and even our behavior.

◀ **FIGURE 11.15** Nucleotides

The individual units in a DNA polymer are nucleotides. Each nucleotide contains one of four bases: adenine, thymine, cytosine, and guanine (abbreviated A, T, C, and G).

The replicating mechanism of DNA is related to its structure, which was discovered in 1953 by James Watson (1928–) and Francis Crick (1916–2004). DNA consists of two *complementary* strands wrapped around each other in the now famous double helix and linked by hydrogen bonds between the bases on each strand. Each base (A, T, C, and G) has a complementary partner with which it forms hydrogen bonds (Figure 11.16▶): adenine (A) with thymine (T) and cytosine (C) with guanine (G). The hydrogen bonding is so specific that each base will pair only with its complementary partner. When a cell is going to divide, enzymes unzip the DNA molecule across the hydrogen bonds that join its two strands (Figure 11.17▼). Then new bases, complementary to the bases in each strand, are added along each of the original strands, forming hydrogen bonds with their complements. The result is two identical copies of the original DNA.

### QUESTION

*Why would dispersion forces not work as a way to hold the two strands of DNA together? Why would covalent bonds not work?*

▶ **FIGURE 11.16**  
**Complementary Base Pairing via Hydrogen Bonds**

The individual bases in DNA interact with one another via specific hydrogen bonds that form between A and T and between C and G.

◀ **FIGURE 11.17**

**Copying DNA** The two strands of the DNA molecule “unzip” by breaking the hydrogen bonds that join the base pairs. New bases complementary to the bases of each strand are assembled and joined together. The result is two molecules, each identical to the original one.

## 11.4 Intermolecular Forces in Action: Surface Tension, Viscosity, and Capillary Action

The most important manifestation of intermolecular forces is the very existence of liquids and solids. In liquids, we also observe several other manifestations of intermolecular forces, including surface tension, viscosity, and capillary action.

### Surface Tension

A fly fisherman delicately casts a small fishing fly (a metal hook with a few feathers and strings attached to make it look like an insect) onto the surface of a moving stream. The fly floats on the surface of the water—even though the metal composing the hook is

▲ A trout fly can float on water because of surface tension.

▲ **FIGURE 11.18 The Origin of Surface Tension** Molecules at the liquid surface have a higher potential energy than those in the interior. As a result, a liquid tends to minimize its surface area; its surface behaves like a “skin.”

Recall from Section 11.3 that the interactions between molecules lower their potential energy in much the same way that the interaction between protons and electrons lowers their potential energy, in accordance with Coulomb's law.

▲ **FIGURE 11.19 Surface Tension in Action** A paper clip floats on water because of surface tension.

▲ **FIGURE 11.20 Spherical Water Droplets** Tiny water droplets are not distorted much by gravity and form nearly perfect spheres held together by intermolecular forces between water molecules.

denser than water—and attracts trout. Why? The hook floats because of *surface tension*, the tendency of liquids to minimize their surface area.

Figure 11.18▲ depicts the intermolecular forces experienced by a molecule at the surface of the liquid compared to those experienced by a molecule in the interior. Notice that a molecule at the surface has relatively fewer neighbors with which to interact, and it is therefore inherently less stable—it has higher potential energy—than those in the interior. (Remember that attractive interactions with other molecules lower potential energy.) In order to increase the surface area of the liquid, molecules from the interior have to be moved to the surface, and, because molecules at the surface have a higher potential energy than those in the interior, this movement requires energy. Therefore, liquids tend to minimize their surface area. The **surface tension** of a liquid is the energy required to increase the surface area by a unit amount. For example, at room temperature, water has a surface tension of  $72.8 \text{ mJ/m}^2$ —it takes  $72.8 \text{ mJ}$  to increase the surface area of water by one square meter.

Why does surface tension allow the fly fisherman's hook to float on water? The tendency for liquids to minimize their surface area creates a kind of skin at the surface that resists penetration. For the fisherman's hook to sink into the water, the water's surface area must increase slightly—an increase that is resisted by the surface tension. We can observe surface tension by carefully placing a paper clip on the surface of water (Figure 11.19◀). The paper clip, even though it is denser than water, floats on the surface of the water. A slight tap on the clip provides the energy necessary to overcome the surface tension and causes the clip to sink.

Surface tension decreases as intermolecular forces decrease. You can't float a paper clip on benzene, for example, because the dispersion forces among the molecules composing benzene are significantly weaker than the hydrogen bonds among water molecules. The surface tension of benzene is only  $28 \text{ mJ/m}^2$ —just 40% that of water.

Surface tension is also the reason for the behavior of water that we discussed in the chapter-opening section on water and gravity. You can see this behavior on Earth by looking at small water droplets (those not large enough to be distorted by gravity) on a leaf or a spider's web (Figure 11.20◀). Just as larger samples of water form spheres in the space station, so smaller samples form spheres on Earth. Why? In the same way that gravity pulls the matter of a planet or star inward to form a sphere, intermolecular forces among collections of water molecules pull the water into a sphere. As we discussed in Section 11.1, the sphere is the geometrical shape with the smallest ratio of surface area to volume; therefore, the formation of a sphere minimizes the number of molecules at the surface, minimizing the potential energy of the system.

## Viscosity

Another manifestation of intermolecular forces is **viscosity**, the resistance of a liquid to flow. Motor oil, for example, is more viscous than gasoline, and maple syrup is more viscous than water. Viscosity is measured in a unit called the poise (P), defined as  $1 \text{ g/cm} \cdot \text{s}$ . The viscosity of water at room temperature is approximately one centipoise (cP). Viscosity is greater in substances with stronger intermolecular forces because if molecules are more strongly attracted to each other, they do not flow around each other as freely. Viscosity also depends on molecular shape, increasing in longer molecules that can interact over a greater area and possibly become entangled. Table 11.5 lists the viscosity of several hydrocarbons. Notice the increase in viscosity with increasing molar mass (and therefore increasing magnitude of dispersion forces) and with increasing length (and therefore increasing potential for molecular entanglement).

Viscosity also depends on temperature because thermal energy partially overcomes the intermolecular forces, allowing molecules to flow past each other more easily. Table 11.6 lists the viscosity of water as a function of temperature. Nearly all liquids become less viscous as temperature increases.

**TABLE 11.5** Viscosity of Several Hydrocarbons at 20 °C

Hydrocarbon	Molar Mass (g/mol)	Formula	Viscosity (cP)
<i>n</i> -Pentane	72.15	$\text{CH}_3\text{CH}_2\text{CH}_2\text{CH}_2\text{CH}_3$	0.240

## Chemistry IN YOUR DAY Viscosity and Motor Oil

**V**iscosity is an important property of the motor oil you put into your car. The oil must be thick enough to adequately coat engine surfaces to lubricate them, but also thin enough to be pumped easily into all the required engine compartments. Motor oil viscosity is usually reported on the SAE scale (named after the Society of Automotive Engineers). The higher the SAE rating, the more viscous the oil. The thinnest motor oils have SAE ratings of 5 or 10, whereas the thickest have SAE ratings of up to 50.

Before the 1950s, most automobile owners changed the oil in their engine to accommodate seasonal changes in weather—a higher SAE rating was required in the summer months and a lower rating in the winter. Today, the advent of multigrade oils allows car owners in many climates to keep the same oil all year long. Multigrade oils, such as the 10W-40 oil shown at right, contain polymers (long molecules made up of repeating structural units) that coil at low temperatures but unwind at high temperatures. At low temperatures, the coiled polymers—because of their compact shape—do not contribute very much to the oil's viscosity. As the temperature increases, however, the molecules unwind and their long shape results in intermolecular forces and molecular entanglements that prevent the oil's viscosity from decreasing as much as it would normally. The result is an oil whose viscosity is less temperature-dependent than it would be otherwise, allowing the same oil to be used over a wider range of temperatures. The 10W-40 designation indicates that the oil has an SAE rating of 10 at low temperatures and 40 at high temperatures.

## Capillary Action

Medical technicians take advantage of **capillary action**—the ability of a liquid to flow against gravity up a narrow tube—when taking a blood sample. The technician pokes the patient's finger with a pin, squeezes some blood out of the puncture, and

▲ Blood is drawn into a capillary tube by capillary action.

▲ **FIGURE 11.21 Capillary Action** The attraction of water molecules to the glass surface draws the liquid around the edge of the tube up the walls. The water in the rest of the column is pulled along by the attraction of water molecules to one another. As can be seen in this figure, the narrower the tube, the higher the liquid will rise.

then collects the blood with a thin tube. When the tube's tip comes into contact with the blood, the blood is drawn into the tube by capillary action. The same force helps trees and plants draw water from the soil.

Capillary action results from a combination of two forces: the attraction between molecules in a liquid, called *cohesive forces*, and the attraction between these molecules and the surface of the tube, called *adhesive forces*. The adhesive forces cause the liquid to spread out over the surface of the tube, whereas the cohesive forces cause the liquid to stay together. If the adhesive forces are greater than the cohesive forces (as is the case for water in a glass tube), the attraction to the surface draws the liquid up the tube and the cohesive forces pull along those molecules not in direct contact with the tube walls (Figure 11.21 ◀). The water rises up the tube until the force of gravity balances the capillary action—the thinner the tube, the higher the rise. If the adhesive forces are less than the cohesive forces (as is the case for liquid mercury), the liquid does not rise up the tube at all (and in fact drops to a level below the level of the surrounding liquid).

We can see the result of the differences in the relative magnitudes of cohesive and adhesive forces by comparing the meniscus of water to the meniscus of mercury (Figure 11.22 ▶). (The meniscus is the curved shape of a liquid surface within a tube.) The meniscus of water is concave (rounded inward) because the *adhesive forces* are greater than the cohesive forces, causing the edges of the water to creep up the sides of the tube a bit, forming the familiar cupped shape. The meniscus of mercury is convex (rounded outward) because the *cohesive forces*—due to metallic bonding between the atoms—are greater than the adhesive forces. The mercury atoms crowd toward the interior of the liquid to maximize their interactions with each other, resulting in the upward bulge at the center of the surface.

▲ **FIGURE 11.22 Menisci of Water and Mercury** The meniscus of water is concave because water molecules are more strongly attracted to the glass wall than to one another. The meniscus of mercury is convex because mercury atoms are more strongly attracted to one another than to the glass walls.

### KCV Vaporization and Vapor Pressure

▲ **FIGURE 11.23 Vaporization of Water** Some molecules in an open beaker have enough kinetic energy to vaporize from the surface of the liquid.

## 11.5 Vaporization and Vapor Pressure

We now turn our attention to *vaporization*, the process by which thermal energy can overcome intermolecular forces and produce a state change from liquid to gas. We first discuss the process of vaporization itself, then the energetics of vaporization, and finally the concepts of *vapor pressure*, *dynamic equilibrium*, and *critical point*. Vaporization is a common occurrence that we experience every day and even depend on to maintain proper body temperature.

### The Process of Vaporization

Imagine water molecules in a beaker at room temperature and open to the atmosphere (Figure 11.23 ◀). The molecules are in constant motion due to thermal energy. If we could actually see the molecules at the surface, we would witness what theoretical chemist Roald Hoffmann describes as a “wild dance floor” (see the chapter-opening quote) because of all the vibrating, jostling, and molecular movement. *The higher the temperature, the greater the average energy of the collection of molecules.* However, at any one time, some molecules have more thermal energy than the average and some have less.

The distributions of thermal energies for the molecules in a sample of water at two different temperatures are shown in Figure 11.24 ▶. The molecules at the high end of the distribution curve have enough energy to break free from the surface—where

◀ **FIGURE 11.24** **Distribution of Thermal Energy** The thermal energies of the molecules in a liquid are distributed over a range. The peak energy increases with increasing temperature.

molecules are held less tightly than they are in the interior due to fewer neighbor-neighbor interactions—and into the gas state. This transition, from liquid to gas, is known as **vaporization**. Some of the water molecules in the gas state, at the low end of the energy distribution curve for the gaseous molecules, plunge back into the water and are captured by intermolecular forces. This transition, from gas to liquid, is the opposite of vaporization and is called **condensation**.

Although both vaporization and condensation occur in a beaker open to the atmosphere, under normal conditions (such as relatively dry air at room temperature) evaporation takes place at a greater rate because most of the newly evaporated molecules escape into the surrounding atmosphere and never come back. The result is a noticeable decrease in the water level within an open beaker over time (usually several days).

What happens if we increase the temperature of the water within the beaker? Because of the shift in the energy distribution to higher energies (see Figure 11.24), more molecules now have enough energy to break free and evaporate, so vaporization occurs more quickly. What happens if we spill the water on the table or floor? The same amount of water is now spread over a wider area, resulting in more molecules at the surface of the liquid. Since molecules at the surface have the greatest tendency to evaporate—because they are held less tightly—vaporization also occurs more quickly in this case. You probably know from experience that water in a beaker or glass may take many days to evaporate completely, whereas the same amount of water spilled on a table or floor typically evaporates within a few hours (depending on the exact conditions).

What happens if the liquid in the beaker is not water, but some other substance with weaker intermolecular forces, such as acetone (the main component in nail polish remover)? The weaker intermolecular forces allow more molecules to evaporate at a given temperature, increasing the rate of vaporization. We call liquids that vaporize easily **volatile** and those that do not vaporize easily **nonvolatile**. Acetone is more volatile than water. Motor oil is virtually nonvolatile at room temperature.

#### *Summarizing the Process of Vaporization:*

- ▶ The rate of vaporization increases with increasing temperature.
- ▶ The rate of vaporization increases with increasing surface area.
- ▶ The rate of vaporization increases with decreasing strength of intermolecular forces.

## The Energetics of Vaporization

To understand the energetics of vaporization, consider again a beaker of water from the molecular point of view, except now imagine that the beaker is thermally insulated so that heat from the surroundings cannot enter the beaker. What happens to the temperature of the water left in the beaker as molecules evaporate? To answer this question,

See Chapter 6 to review endothermic and exothermic processes.

▲ When we sweat, water evaporates from the skin. Since evaporation is endothermic, the result is a cooling effect.

The normal boiling point of a substance is its boiling point at a pressure of 1 atm, as discussed later in this section.

The sign conventions of  $\Delta H$  were introduced in Chapter 6.

think about the energy distribution curve again (see Figure 11.24). The molecules that leave the beaker are the ones at the high end of the energy curve—the most energetic. If no additional heat enters the beaker, the average energy of the entire collection of molecules decreases—much as the class average on an exam goes down if you eliminate the highest-scoring students. So vaporization is an *endothermic* process; it takes energy to vaporize the molecules in a liquid. Another way to understand the endothermicity of vaporization is to remember that vaporization requires overcoming the intermolecular forces that hold liquids together. Since energy is needed to pull the molecules away from one another, the process is endothermic.

Our bodies use the endothermic nature of vaporization for cooling. When we overheat, we sweat and our skin is covered with liquid water. As this water evaporates, it absorbs heat from the body, cooling the skin. A fan makes us feel cooler because it blows newly vaporized water away from our skin, allowing more sweat to vaporize and causing even more cooling. High humidity, in contrast, slows down the net rate of evaporation, preventing cooling. When the air already contains large amounts of water vapor, the sweat evaporates more slowly, making the body’s cooling system less efficient.

*Condensation*, the opposite of vaporization, is exothermic—heat is released when a gas condenses to a liquid. If you have ever accidentally put your hand above a steaming kettle or opened a bag of microwaved popcorn too soon, you may have experienced a *steam burn*. As the steam condenses to a liquid on your skin, it releases a lot of heat, causing the burn. The condensation of water vapor is also the reason that winter overnight temperatures in coastal regions, which tend to have water vapor in the air, do not get as low as in deserts, which tend to have dry air. As the air temperature in a coastal area drops, water condenses out of the air, releasing heat and preventing the temperature from dropping further. In deserts, the air contains almost no moisture to condense, so the temperature drop is more extreme.

The amount of heat required to vaporize one mole of a liquid to gas is its **heat (or enthalpy) of vaporization ( $\Delta H_{\text{vap}}$ )**. The heat of vaporization of water at its normal boiling point of 100 °C is +40.7 kJ/mol:

The heat of vaporization is always positive because the process is endothermic—energy must be absorbed to vaporize a substance. The heat of vaporization is somewhat temperature dependent. For example, at 25 °C the heat of vaporization of water is +44.0 kJ/mol, slightly more than it is at 100 °C because the water contains less thermal energy at 25 °C. Table 11.7 lists the heats of vaporization of several liquids at their boiling points and at 25 °C.

When a substance condenses from a gas to a liquid, the same amount of heat is involved, but the heat is emitted rather than absorbed:

When one mole of water condenses, it releases 40.7 kJ of heat. The sign of  $\Delta H$  in this case is negative because the process is exothermic.

We can use the heat of vaporization of a liquid to calculate the amount of energy required to vaporize a given mass of the liquid (or the amount of heat given off by the condensation of a given mass of liquid), using concepts similar to those covered in Section 6.6 (stoichiometry of  $\Delta H$ ). The heat of vaporization is like a conversion factor between the number of moles of a liquid and the amount of heat required to vaporize it (or the amount of heat emitted when it condenses), as demonstrated in Example 11.3.

TABLE 11.7 Heats of Vaporization of Several Liquids at Their Boiling Points and at 25 °C				
Liquid	Chemical Formula	Normal Boiling Point (°C)	$\Delta H_{\text{vap}}$ (kJ/mol) at Boiling Point	$\Delta H_{\text{vap}}$ (kJ/mol) at 25 °C
Water	H <sub>2</sub> O	100	40.7	44.0
Rubbing alcohol (isopropyl alcohol)	C <sub>3</sub> H <sub>8</sub> O	82.3	39.9	45.4
Acetone	C <sub>3</sub> H <sub>6</sub> O	56.1	29.1	31.0
Diethyl ether	C <sub>4</sub> H <sub>10</sub> O	34.6	26.5	27.1

**Example 11.3** Using the Heat of Vaporization in Calculations

Calculate the mass of water (in g) that can be vaporized at its boiling point with 155 kJ of heat.

**SORT** You are given a certain amount of heat in kilojoules and asked to find the mass of water that can be vaporized.

**GIVEN:** 155 kJ

**FIND:** g H<sub>2</sub>O

**STRATEGIZE** The heat of vaporization gives the relationship between heat absorbed and moles of water vaporized. Begin with the given amount of heat (in kJ) and convert to moles of water that can be vaporized. Then use the molar mass as a conversion factor to convert from moles of water to mass of water.

**CONCEPTUAL PLAN****RELATIONSHIPS USED**

$$\Delta H_{\text{vap}} = 40.7 \text{ kJ/mol (at } 100^\circ\text{C)}$$

$$18.02 \text{ g H}_2\text{O} = 1 \text{ mol H}_2\text{O}$$

**SOLVE** Follow the conceptual plan to solve the problem.

**SOLUTION**

$$155 \text{ kJ} \times \frac{1 \text{ mol H}_2\text{O}}{40.7 \text{ kJ}} \times \frac{18.02 \text{ g H}_2\text{O}}{1 \text{ mol H}_2\text{O}} = 68.6 \text{ g H}_2\text{O}$$

**FOR PRACTICE 11.3** Calculate the amount of heat (in kJ) required to vaporize 2.58 kg of water at its boiling point.

**FOR MORE PRACTICE 11.3** Suppose that 0.48 g of water at 25 °C condenses on the surface of a 55-g block of aluminum that is initially 25 °C. If the heat released during condensation goes only toward heating the metal, what is the final temperature (in °C) of the metal block? (The specific heat capacity of aluminum is 0.903 J/g °C.)

**Vapor Pressure and Dynamic Equilibrium**

We have already seen that if a container of water is left uncovered at room temperature, the water slowly evaporates away. What happens if the container is sealed? Imagine a sealed evacuated flask—one from which the air has been removed—containing liquid water, as shown in Figure 11.25. Initially, the water molecules evaporate, as

**▲ FIGURE 11.25** Vaporization in a Sealed Flask (a) When water is in a sealed container, water molecules begin to vaporize. (b) As water molecules build up in the gas state, they begin to recondense into the liquid. (c) When the rate of evaporation equals the rate of condensation, dynamic equilibrium is reached.

**▲ FIGURE 11.26 Dynamic Equilibrium** Dynamic equilibrium occurs when the rate of condensation is equal to the rate of evaporation.

they did in the open beaker. But because of the seal, the evaporated molecules cannot escape into the atmosphere. As water molecules enter the gas state, some start condensing back into the liquid. As the concentration (or partial pressure) of gaseous water molecules increases, the rate of condensation also increases. However, as long as the water remains at a constant temperature, the rate of evaporation remains constant. Eventually, the rate of condensation and the rate of vaporization become equal—**dynamic equilibrium** has been reached (Figure 11.26◀). Condensation and vaporization continue at equal rates, and the concentration of water vapor above the liquid is constant.

The pressure of a gas in dynamic equilibrium with its liquid is its **vapor pressure**. The vapor pressure of a particular liquid depends on the intermolecular forces present in the liquid and the temperature. Weak intermolecular forces result in volatile (easily vaporizable) substances with high vapor pressures at a given temperature because the intermolecular forces are easily overcome by thermal energy. Strong intermolecular forces result in nonvolatile substances with low vapor pressures at a given temperature.

A liquid in dynamic equilibrium with its vapor is a balanced system that tends to return to equilibrium if disturbed. For example, consider a sample of *n*-pentane (a component of gasoline) at 25 °C in a cylinder equipped with a moveable piston (Figure 11.27(a)▼). The cylinder contains no other gases except *n*-pentane vapor in dynamic equilibrium with the liquid. Since the vapor pressure of *n*-pentane at 25 °C is 510 mmHg, the pressure in the cylinder is 510 mmHg.

Now, what happens when the piston is moved upward to expand the volume within the cylinder? Initially, the pressure in the cylinder drops below 510 mmHg, in accordance with Boyle's law. Then, however, more liquid vaporizes until equilibrium is reached once again (Figure 11.27(b)▼). If the volume of the cylinder is expanded again, the same thing happens—the pressure initially drops and more *n*-pentane vaporizes to bring the system back into equilibrium. Further expansion causes the same result *as long as some liquid n-pentane remains in the cylinder*.

Conversely, what happens if the piston is lowered, decreasing the volume in the cylinder? Initially, the pressure in the cylinder rises above 510 mmHg, but then some of the gas condenses into liquid until equilibrium is reached again (Figure 11.27(c)▼).

**▲ FIGURE 11.27 Dynamic Equilibrium in *n*-Pentane** (a) Liquid *n*-pentane is in dynamic equilibrium with its vapor. (b) When the volume is increased, the pressure drops and some liquid converts to gas to bring the pressure back up. (c) When the volume is decreased, the pressure increases and some gas converts to liquid to bring the pressure back down.

Boyle's law is discussed in Section 5.3.

We describe the tendency of a system in dynamic equilibrium to return to equilibrium with the following general statement:

**When a system in dynamic equilibrium is disturbed, the system responds so as to minimize the disturbance and return to a state of equilibrium.**

If the pressure above a liquid–vapor system in equilibrium decreases, some of the liquid evaporates, restoring the equilibrium pressure. If the pressure increases, some of the vapor condenses, bringing the pressure back down to the equilibrium pressure. This basic principle—Le Châtelier’s principle—is applicable to any chemical system in equilibrium, as we shall see in Chapter 15.

### CONCEPTUAL CONNECTION 11.5

**Vapor Pressure** What happens to the vapor pressure of a substance when its surface area is increased at constant temperature?

- (a) The vapor pressure increases.
- (b) The vapor pressure remains the same.
- (c) The vapor pressure decreases.

### Temperature Dependence of Vapor Pressure and Boiling Point

When the temperature of a liquid increases, its vapor pressure rises because the higher thermal energy increases the number of molecules that have enough energy to vaporize (see Figure 11.24). Because of the shape of the thermal energy distribution curve, a small change in temperature makes a large difference in the number of molecules that have enough energy to vaporize, which results in a large increase in vapor pressure. For example, the vapor pressure of water at 25 °C is 23.3 torr, while at 60 °C the vapor pressure is 149.4 torr. Figure 11.28 plots the vapor pressure of water and several other liquids as a function of temperature.

The **boiling point** of a liquid is *the temperature at which the liquid’s vapor pressure equals the external pressure*. When a liquid reaches its boiling point, the thermal energy is enough for molecules in the interior of the liquid (not just those at the surface) to break

**▲ FIGURE 11.28** Vapor Pressure of Several Liquids at Different Temperatures At higher temperatures, more molecules have enough thermal energy to escape into the gas state, so vapor pressure increases with increasing temperature.

► **FIGURE 11.29 Boiling** A liquid boils when thermal energy is high enough to cause molecules in the interior of the liquid to become gaseous, forming bubbles that rise to the surface.

Sometimes you see bubbles begin to form in hot water below 100 °C. These bubbles are dissolved air—not gaseous water—leaving the liquid. Dissolved air comes out of water as you heat it because the solubility of a gas in a liquid decreases with increasing temperature (as we will see in Chapter 13).

free of their neighbors and enter the gas state (Figure 11.29▲). The bubbles in boiling water are pockets of gaseous water that form within the liquid water. The bubbles float to the surface and leave as gaseous water or steam.

The **normal boiling point** of a liquid is *the temperature at which its vapor pressure equals 1 atm*. The normal boiling point of pure water is 100 °C. However, at a lower pressure, water boils at a lower temperature. In Denver, Colorado, where the altitude is around 1600 meters (5200 feet) above sea level, for example, the average atmospheric pressure is about 83% of what it is at sea level, and water boils at approximately 94 °C. For this reason, it takes slightly longer to cook food in boiling water in Denver than in San Francisco (which is at sea level). Table 11.8 lists the boiling point of water at several locations of varied altitudes.

TABLE 11.8 Boiling Points of Water at Several Locations of Varied Altitudes			
Location	Elevation (ft)	Approximate Pressure (atm) *	Approximate Boiling Point of Water (°C)
Mount Everest, Tibet (highest mountain peak on Earth)	29,035	0.32	78
Mount McKinley (Denali), Alaska (highest mountain peak in North America)	20,320	0.46	83
Mount Whitney, California (highest mountain peak in 48 contiguous U.S. states)	14,495	0.60	87
Denver, Colorado (mile high city)	5,280	0.83	94
Boston, Massachusetts (sea level)	20	1.0	100

\*The atmospheric pressure in each of these locations is subject to weather conditions and can vary significantly from these values.

▲ **FIGURE 11.30 The Temperature during Boiling** The temperature of water during boiling remains at 100 °C.

Once the boiling point of a liquid is reached, additional heating only causes more rapid boiling; it does not raise the temperature of the liquid above its boiling point, as shown in the *heating curve* in Figure 11.30◀. Therefore, at 1 atm, boiling water always has a temperature of 100 °C. As long as liquid water is present, its temperature cannot rise above its boiling point. After all the water has been converted to steam, the temperature of the steam can continue to rise beyond 100 °C.

**The Clausius–Clapeyron Equation**

Now, let’s return our attention to Figure 11.28. As we can see from the graph, the vapor pressure of a liquid increases with increasing temperature. However, *the relationship is not linear*. In other words, doubling the temperature results in more than doubling the vapor pressure.

The relationship between vapor pressure and temperature is exponential, and we can express it as follows:

$$P_{\text{vap}} = \beta \exp\left(\frac{-\Delta H_{\text{vap}}}{RT}\right) \quad [11.1]$$

In this expression  $P_{\text{vap}}$  is the vapor pressure,  $\beta$  is a constant that depends on the gas,  $\Delta H_{\text{vap}}$  is the heat of vaporization,  $R$  is the gas constant ( $8.314 \text{ J/mol} \cdot \text{K}$ ), and  $T$  is the temperature in kelvins. We can rearrange Equation 11.1 by taking the natural logarithm of both sides:

$$\ln P_{\text{vap}} = \ln \left[ \beta \exp\left(\frac{-\Delta H_{\text{vap}}}{RT}\right) \right] \quad [11.2]$$

Because  $\ln AB = \ln A + \ln B$ , we can rearrange the right side of Equation 11.2:

$$\ln P_{\text{vap}} = \ln \beta + \ln \left[ \exp\left(\frac{-\Delta H_{\text{vap}}}{RT}\right) \right] \quad [11.3]$$

Because  $\ln e^x = x$  (see Appendix IB), we can simplify Equation 11.3:

$$\ln P_{\text{vap}} = \ln \beta + \frac{-\Delta H_{\text{vap}}}{RT} \quad [11.4]$$

A slight additional rearrangement gives the following important result:

$$\ln P_{\text{vap}} = \frac{-\Delta H_{\text{vap}}}{R} \left( \frac{1}{T} \right) + \ln \beta \quad \text{Clausius–Clapeyron equation}$$

$$y = m(x) + b \quad \text{(equation for a line)}$$

Notice the parallel relationship between the **Clausius–Clapeyron equation** and the equation for a straight line. Just as a plot of  $y$  versus  $x$  yields a straight line with slope  $m$  and intercept  $b$ , so a plot of  $\ln P_{\text{vap}}$  (equivalent to  $y$ ) versus  $1/T$  (equivalent to  $x$ ) gives a straight line with slope  $-\Delta H_{\text{vap}}/R$  (equivalent to  $m$ ) and  $y$ -intercept  $\ln \beta$  (equivalent to  $b$ ), as shown in Figure 11.31. The Clausius–Clapeyron equation gives a linear relationship—not between the vapor pressure and the temperature (which have an exponential relationship)—but between the *natural log* of the vapor pressure and the *inverse* of temperature. This is a common technique in the analysis of chemical data. If two variables are not linearly related, it is often convenient to find ways to graph *functions of those variables* that are linearly related.

Using the Clausius–Clapeyron equation in this way ignores the relatively small temperature dependence of  $\Delta H_{\text{vap}}$ .

**FIGURE 11.31 A Clausius–Clapeyron Plot for Diethyl Ether ( $\text{CH}_3\text{CH}_2\text{OCH}_2\text{CH}_3$ )** A plot of the natural log of the vapor pressure versus the inverse of the temperature in K yields a straight line with slope  $-\Delta H_{\text{vap}}/R$ .

The Clausius–Clapeyron equation leads to a convenient way to determine the heat of vaporization in the laboratory. We simply measure the vapor pressure of a liquid as a function of temperature and create a plot of the natural log of the vapor pressure versus the inverse of the temperature. We then determine the slope of the line to find the heat of vaporization, as demonstrated in Example 11.4.

### Example 11.4 Using the Clausius–Clapeyron Equation to Determine Heat of Vaporization from Experimental Measurements of Vapor Pressure

The vapor pressure of dichloromethane is measured as a function of temperature, and the results are tabulated. Determine the heat of vaporization of dichloromethane from the results.

Temperature (K)	Vapor Pressure (torr)
200	0.8
220	4.5
240	21
260	71
280	197
300	391

#### SOLUTION

To find the heat of vaporization, use an Excel spreadsheet or a graphing calculator to plot the natural log of vapor pressure ( $\ln P$ ) as a function of the inverse of the temperature in kelvins ( $1/T$ ). Then fit the points to a line and determine the slope of the line. The slope of the best-fitting line is  $-3773 \text{ K}$ . Since the slope equals  $-\Delta H_{\text{vap}}/R$ , we find the heat of vaporization as follows:

$$\begin{aligned}
 \text{slope} &= -\Delta H_{\text{vap}}/R \\
 \Delta H_{\text{vap}} &= -\text{slope} \times R \\
 &= -(-3773 \text{ K})(8.314 \text{ J/mol} \cdot \text{K}) \\
 &= 3.14 \times 10^4 \text{ J/mol} \\
 &= 31.4 \text{ kJ/mol}
 \end{aligned}$$

**FOR PRACTICE 11.4** The vapor pressure of carbon tetrachloride is measured as a function of the temperature and the results are tabulated. Determine the heat of vaporization of carbon tetrachloride from the results.

Temperature (K)	Vapor Pressure (torr)
255	11.3
265	21.0
275	36.8
285	61.5
295	99.0
300	123.8

The Clausius–Clapeyron equation can also be expressed in a two-point form that we can use with just two measurements of vapor pressure and temperature to determine the heat of vaporization:

$$\ln \frac{P_2}{P_1} = \frac{-\Delta H_{\text{vap}}}{R} \left( \frac{1}{T_2} - \frac{1}{T_1} \right) \quad \text{Clausius–Clapeyron equation (two-point form)}$$

The two-point method is generally inferior to plotting multiple points because fewer data points result in more chance for error.

We can use this form of the equation to predict the vapor pressure of a liquid at any temperature if we know the enthalpy of vaporization and the normal boiling point (or the vapor pressure at some other temperature), as demonstrated in Example 11.5.

**Example 11.5** Using the Two-Point Form of the Clausius–Clapeyron Equation to Predict the Vapor Pressure at a Given Temperature

Methanol has a normal boiling point of 64.6 °C and a heat of vaporization ( $\Delta H_{\text{vap}}$ ) of 35.2 kJ/mol. What is the vapor pressure of methanol at 12.0 °C?

**SORT** You are given the normal boiling point of methanol (the temperature at which the vapor pressure is 760 mmHg) and the heat of vaporization. You are asked to find the vapor pressure at a specified temperature that is also given.

**GIVEN:**  $T_1(^{\circ}\text{C}) = 64.6^{\circ}\text{C}$   
 $P_1 = 760 \text{ torr}$   
 $\Delta H_{\text{vap}} = 35.2 \text{ kJ/mol}$   
 $T_2(^{\circ}\text{C}) = 12.0^{\circ}\text{C}$

**FIND:**  $P_2$

**STRATEGIZE** The conceptual plan is essentially the Clausius–Clapeyron equation, which relates the given and find quantities.

**CONCEPTUAL PLAN**

$$\ln \frac{P_2}{P_1} = \frac{-\Delta H_{\text{vap}}}{R} \left( \frac{1}{T_2} - \frac{1}{T_1} \right)$$

(Clausius–Clapeyron equation, two-point form)

**SOLVE** First, convert  $T_1$  and  $T_2$  from °C to K.

**SOLUTION**

$$\begin{aligned} T_1(\text{K}) &= T_1(^{\circ}\text{C}) + 273.15 \\ &= 64.6 + 273.15 \\ &= 337.8 \text{ K} \\ T_2(\text{K}) &= T_2(^{\circ}\text{C}) + 273.15 \\ &= 12.0 + 273.15 \\ &= 285.2 \text{ K} \end{aligned}$$

Then, substitute the required values into the Clausius–Clapeyron equation and solve for  $P_2$ .

$$\begin{aligned} \ln \frac{P_2}{P_1} &= \frac{-\Delta H_{\text{vap}}}{R} \left( \frac{1}{T_2} - \frac{1}{T_1} \right) \\ \ln \frac{P_2}{P_1} &= \frac{-35.2 \times 10^3 \frac{\text{J}}{\text{mol}}}{8.314 \frac{\text{J}}{\text{mol} \cdot \text{K}}} \left( \frac{1}{285.2 \text{ K}} - \frac{1}{337.8 \text{ K}} \right) \\ &= -2.31 \end{aligned}$$

In order to isolate  $P_2$ , you must take the inverse natural log (or inv ln) of  $\ln(P_2/P_1)$ . Remember that  $\text{inv ln}(\ln x) = x$ .

$$\begin{aligned} \frac{P_2}{P_1} &= e^{-2.31} \\ P_2 &= P_1(e^{-2.31}) \\ &= 760 \text{ torr}(0.0993) \\ &= 75.4 \text{ torr} \end{aligned}$$

**CHECK** The units of the answer are correct. The magnitude of the answer makes sense because vapor pressure should be significantly lower at the lower temperature.

**FOR PRACTICE 11.5** Propane has a normal boiling point of  $-42.0^{\circ}\text{C}$  and a heat of vaporization ( $\Delta H_{\text{vap}}$ ) of 19.04 kJ/mol. What is the vapor pressure of propane at  $25.0^{\circ}\text{C}$ ?

## The Critical Point: The Transition to an Unusual State of Matter

We have considered the vaporization of a liquid in a container open to the atmosphere with and without heating, and the vaporization of a liquid in a *sealed* container without heating. We now examine the vaporization of a liquid in a *sealed* container *during heating*.

Consider liquid *n*-pentane in equilibrium with its vapor in a sealed container initially at  $25^{\circ}\text{C}$ . At this temperature, the vapor pressure of *n*-pentane is 0.67 atm.

What happens if we heat the liquid? As the temperature rises, more *n*-pentane vaporizes and the pressure within the container increases. At 100 °C, the pressure is 5.5 atm, and at 190 °C the pressure is 29 atm. As the temperature and pressure increase, more and more gaseous *n*-pentane is forced into the same amount of space, and the density of the *gas* gets higher and higher. At the same time, the increasing temperature causes the density of the *liquid* to become lower and lower. At 197 °C, the meniscus between the liquid and gaseous *n*-pentane disappears, and the gas and liquid states commingle to form a *supercritical fluid* (Figure 11.32▼). For any substance, the *temperature* at which this transition occurs is the **critical temperature** ( $T_c$ ). The liquid cannot exist (regardless of pressure) above this temperature. The *pressure* at which this transition occurs is the **critical pressure** ( $P_c$ ).

▲ **FIGURE 11.32 Critical Point Transition** As *n*-pentane is heated in a sealed container, it undergoes a transition to a supercritical fluid. At the critical point, the meniscus separating the liquid and gas disappears, and the fluid becomes supercritical—neither a liquid nor a gas.

Researchers are interested in supercritical fluids because of their unique properties. A supercritical fluid has properties of both liquids and gases—it is in some sense intermediate between the two. Supercritical fluids can act as good solvents, selectively dissolving a number of compounds. For example, supercritical carbon dioxide is used as a solvent to extract caffeine from coffee beans. The caffeine dissolves in the supercritical carbon dioxide, but other substances—such as those responsible for the flavor of coffee—do not. Consequently, the caffeine is removed and the flavor of the coffee is not substantially altered. The supercritical carbon dioxide is easily removed from the mixture by simply lowering the pressure below the critical pressure, at which point the carbon dioxide evaporates, leaving no residue.

▲ **FIGURE 11.33 The Sublimation of Ice** The water molecules at the surface of an ice cube can sublime directly into the gas state.

## 11.6 Sublimation and Fusion

In Section 11.5, we examined a beaker of liquid water at room temperature from the molecular viewpoint. Now, let's examine a block of ice at  $-10^{\circ}\text{C}$  from the same molecular perspective, paying close attention to two common processes: sublimation and fusion.

### Sublimation

Even though a block of ice is solid, the water molecules in the ice have thermal energy, which causes each one to vibrate about a fixed point. The motion is much less vigorous than in a liquid, but it is significant nonetheless. As in liquids, at any instant some molecules in the block of ice have more thermal energy than the average and some have less. The molecules with high enough thermal energy can break free from the ice surface—where, as in liquids, molecules are held less tightly than in the interior due to fewer neighbor-neighbor interactions—and go directly into the gas state (Figure 11.33◀). This process is **sublimation**, the transition from solid to gas. Some of the water molecules in the gas state (those at the low end of the energy distribution curve for the gaseous

molecules) collide with the surface of the ice and are captured by the intermolecular forces with other molecules. This process—the opposite of sublimation—is **deposition**, the transition from gas to solid. As is the case with liquids, the pressure of a gas in dynamic equilibrium with its solid is the vapor pressure of the solid.

Although both sublimation and deposition occur on the surface of an ice block open to the atmosphere at  $-10^{\circ}\text{C}$ , sublimation usually occurs at a greater rate than deposition because most of the newly sublimed molecules escape into the surrounding atmosphere and never come back. The result is a noticeable decrease in the size of the ice block over time (even though the temperature is below the melting point).

If you live in a cold climate, you may have noticed the disappearance of ice and snow from the ground even though the temperature remains below  $0^{\circ}\text{C}$ . Similarly, ice cubes left in the freezer for a long time slowly shrink, even though the freezer is always below  $0^{\circ}\text{C}$ . In both cases, the ice is *subliming*, turning directly into water vapor. Ice also sublimates out of frozen foods. You may have noticed, for example, the gradual growth of ice crystals on the *inside* of airtight plastic food-storage bags in a freezer. The ice crystals are composed of water that has sublimed out of the food and redeposited on the surface of the bag or on the surface of the food. For this reason, food that remains frozen for too long becomes dried out. Such dehydration can be avoided to some degree by freezing foods to colder temperatures, a process called deep-freezing. The colder temperature lowers the vapor pressure of ice and preserves the food longer. Freezer burn on meats is another common manifestation of sublimation. When you improperly store meat (for example, in a container that is not airtight) sublimation continues unabated. The result is the dehydration of the surface of the meat, which becomes discolored and loses flavor and texture.

A substance commonly associated with sublimation is solid carbon dioxide or dry ice, which does not melt under atmospheric pressure no matter what the temperature is. However, at  $-78^{\circ}\text{C}$  the  $\text{CO}_2$  molecules have enough energy to leave the surface of the dry ice and become gaseous through sublimation.

▲ Dry ice (solid  $\text{CO}_2$ ) sublimates but does not melt at atmospheric pressure.

## Fusion

Let's return to our ice block and examine what happens at the molecular level as we increase its temperature. The increasing thermal energy causes the water molecules to vibrate faster and faster. At the **melting point** ( $0^{\circ}\text{C}$  for water), the molecules have enough thermal energy to overcome the intermolecular forces that hold the molecules at their stationary points, and the solid turns into a liquid. This process is **melting** or **fusion**, the transition from solid to liquid. The opposite of melting is **freezing**, the transition from liquid to solid. Once the melting point of a solid is reached, additional heating only causes more rapid melting; it does not raise the temperature of the solid above its melting point (Figure 11.34▶). Only after all of the ice has melted will additional heating raise the temperature of the liquid water past  $0^{\circ}\text{C}$ . A mixture of water *and* ice always has a temperature of  $0^{\circ}\text{C}$  (at 1 atm pressure).

▲ **FIGURE 11.34 Temperature during Melting** The temperature of water during melting remains at  $0.0^{\circ}\text{C}$  as long as both solid and liquid water remain.

## Energetics of Melting and Freezing

The most common way to cool a beverage quickly is to drop several ice cubes into it. As the ice melts, the drink cools because melting is endothermic—the melting ice absorbs heat from the liquid. The amount of heat required to melt 1 mol of a solid is the **heat of fusion** ( $\Delta H_{\text{fus}}$ ). The heat of fusion for water is  $6.02 \text{ kJ/mol}$ :

The heat of fusion is positive because melting is endothermic.

Freezing, the opposite of melting, is exothermic—heat is released when a liquid freezes into a solid. For example, as water in the freezer turns into ice, it releases heat, which must be removed by the refrigeration system of the freezer. If the refrigeration system did not remove the heat, the water would not completely freeze into ice. The heat

The term *fusion* is used for melting because if we heat several crystals of a solid, they fuse into a continuous liquid upon melting.

released as the water began to freeze would warm the freezer, preventing further freezing. The change in enthalpy for freezing has the same magnitude as the heat of fusion but the opposite sign:

Different substances have different heats of fusion as listed in Table 11.9.

**TABLE 11.9** Heats of Fusion of Several Substances

Liquid	Chemical Formula	Melting Point (°C)	$\Delta H_{\text{fus}}$ (kJ/mol)
Water	H <sub>2</sub> O	0.00	6.02
Rubbing alcohol (isopropyl alcohol)	C <sub>3</sub> H <sub>8</sub> O	−89.5	5.37
Acetone	C <sub>3</sub> H <sub>6</sub> O	−94.8	5.69
Diethyl ether	C <sub>4</sub> H <sub>10</sub> O	−116.3	7.27

**▲ FIGURE 11.35** Heat of Fusion and Heat of Vaporization Typical heats of fusion are significantly less than heats of vaporization.

In general, the heat of fusion for a substance is significantly less than its heat of vaporization (Figure 11.35). We have already seen that the solid and liquid states are closer to each other in many ways than they are to the gas state. It takes less energy to melt 1 mol of ice into liquid than it does to vaporize 1 mol of liquid water into gas because vaporization requires complete separation of molecules from one another, so the intermolecular forces must be completely overcome. Melting, in contrast, requires that intermolecular forces be only partially overcome, allowing molecules to move around one another while still remaining in contact.

The amount of heat required to sublime one mole of a solid to a gas is its **heat (or enthalpy) of sublimation** ( $\Delta H_{\text{sub}}$ ). Since enthalpy is a state function, the change in enthalpy of any two-step process is simply the sum of the changes in enthalpies of each step. Because the sublimation of a substance is equivalent to its fusion followed by its vaporization, the heat of sublimation is the sum of the heat of fusion and the heat of vaporization. For water, we calculate the heat of sublimation at 0 °C as follows:

$$\begin{aligned}\Delta H_{\text{sub}} &= \Delta H_{\text{fus}} + \Delta H_{\text{vap}} \\ &= 6.01 \text{ kJ/mol} + 40.7 \text{ kJ/mol} \\ &= 46.7 \text{ kJ/mol}\end{aligned}$$

### Heating Curve for Water

## 11.7 Heating Curve for Water

We can combine and build on the concepts from Sections 11.5 and 11.6 by examining the *heating curve* for 1.00 mol of water at 1.00 atm pressure shown in Figure 11.36. The y-axis of the heating curve represents the temperature of the water sample. The x-axis represents the amount of heat added (in kilojoules) during heating. In the diagram, we divide the process into five segments: (1) ice warming; (2) ice melting into liquid water; (3) liquid water warming; (4) liquid water vaporizing into steam; and (5) steam warming.

In two of these segments (2 and 4) the temperature is constant as heat is added because the added heat goes into producing the transition between states, not into increasing the temperature. The two states are in equilibrium during the transition, and the temperature remains constant. The amount of heat required to achieve the state change is given by  $q = n\Delta H$ .

▲ **FIGURE 11.36** Heating Curve for Water

In the other three segments (1, 3, and 5), temperature increases linearly. These segments represent the heating of a single state in which the deposited heat raises the temperature in accordance with the substance's heat capacity ( $q = mC_s \Delta T$ ). We examine each of these segments individually.

### Segment 1

In segment 1, solid ice is warmed from  $-25^\circ\text{C}$  to  $0^\circ\text{C}$ . Since no transition between states occurs here, the amount of heat required to heat the solid ice is given by  $q = mC_s \Delta T$  (see Section 6.4), where  $C_s$  is the specific heat capacity of ice ( $C_{s,\text{ice}} = 2.09 \text{ J/g}\cdot^\circ\text{C}$ ). For 1.00 mol of water (18.0 g), we calculate the amount of heat as follows:

$$\begin{aligned}
 q &= mC_{s,\text{ice}} \Delta T \\
 &= 18.0 \text{ g} \left( 2.09 \frac{\text{J}}{\text{g}\cdot^\circ\text{C}} \right) [0.0^\circ\text{C} - (-25.0^\circ\text{C})] \\
 &= 941 \text{ J} = 0.941 \text{ kJ}
 \end{aligned}$$

So in segment 1, 0.941 kJ of heat is added to the ice, warming it from  $-25^\circ\text{C}$  to  $0^\circ\text{C}$ .

### Segment 2

In segment 2, the added heat does not change the temperature of the ice and water mixture because the heat is absorbed by the transition from solid to liquid. The amount of

heat required to convert the ice to liquid water is given by  $q = n \Delta H_{\text{fus}}$ , where  $n$  is the number of moles of water and  $\Delta H_{\text{fus}}$  is the heat of fusion (see Section 11.6):

$$\begin{aligned} q &= n \Delta H_{\text{fus}} \\ &= 1.00 \text{ mol} \left( \frac{6.02 \text{ kJ}}{\text{mol}} \right) \\ &= 6.02 \text{ kJ} \end{aligned}$$

In segment 2, 6.02 kJ is added to the ice, melting it into liquid water. Notice that the temperature does not change during melting. The liquid and solid coexist at 0 °C as the melting occurs.

### Segment 3

In segment 3, the liquid water warms from 0 °C to 100 °C. Since no transition between states occurs here, the amount of heat required to heat the liquid water is given by  $q = mC_s \Delta T$ , as in segment 1. However, now we must use the heat capacity of liquid water (not ice) for the calculation. For 1.00 mol of water (18.0 g), we calculate the amount of heat as follows:

$$\begin{aligned} q &= mC_{s, \text{liq}} \Delta T \\ &= 18.0 \text{ g} \left( 4.18 \frac{\text{J}}{\text{g} \cdot ^\circ\text{C}} \right) (100.0 ^\circ\text{C} - 0.0 ^\circ\text{C}) \\ &= 7.52 \times 10^3 \text{ J} = 7.52 \text{ kJ} \end{aligned}$$

So in segment 3, 7.52 kJ of heat is added to the liquid water, warming it from 0 °C to 100 °C.

### Segment 4

In segment 4, the water undergoes a second transition between states, this time from liquid to gas. The amount of heat required to convert the liquid to gas is given by  $q = n \Delta H_{\text{vap}}$ , where  $n$  is the number of moles and  $\Delta H_{\text{vap}}$  is the heat of vaporization (see Section 11.5):

$$\begin{aligned} q &= n \Delta H_{\text{vap}} \\ &= 1.00 \text{ mol} \left( \frac{40.7 \text{ kJ}}{\text{mol}} \right) \\ &= 40.7 \text{ kJ} \end{aligned}$$

Thus, in segment 4, 40.7 kJ is added to the water, vaporizing it into steam. Notice that the temperature does not change during boiling. The liquid and gas coexist at 100 °C as the boiling occurs.

### Segment 5

In segment 5, the steam warms from 100 °C to 125 °C. Since no transition between states occurs here, the amount of heat required to heat the steam is given by  $q = mC_s \Delta T$  (as in segments 1 and 3) except that we must use the heat capacity of steam (2.01 J/g · °C):

$$\begin{aligned} q &= mC_{s, \text{steam}} \Delta T \\ &= 18.0 \text{ g} \left( 2.01 \frac{\text{J}}{\text{g} \cdot ^\circ\text{C}} \right) (125.0 ^\circ\text{C} - 100.0 ^\circ\text{C}) \\ &= 905 \text{ J} = 0.905 \text{ kJ} \end{aligned}$$

So in segment 5, 0.905 kJ of heat is added to the steam, warming it from 100 °C to 125 °C.

## CONCEPTUAL CONNECTION 11.6

**Cooling of Water with Ice** You just saw that the heat capacity of ice is  $C_{s, \text{ice}} = 2.09 \text{ J/g} \cdot ^\circ\text{C}$  and that the heat of fusion of ice is  $6.02 \text{ kJ/mol}$ . When a small ice cube at  $-10^\circ\text{C}$  is put into a cup of water at room temperature, which of the following plays a greater role in cooling the liquid water: the warming of the ice from  $-10^\circ\text{C}$  to  $0^\circ\text{C}$ , or the melting of the ice?

## 11.8 Phase Diagrams

Phase Diagrams

Throughout most of this chapter, we have examined how the state of a substance changes in response to changes in temperature and pressure. We can combine both the temperature dependence and pressure dependence of the state of a particular substance in a graph called a *phase diagram*. A **phase diagram** is a map of the state or *phase* of a substance as a function of pressure (on the  $y$ -axis) and temperature (on the  $x$ -axis). In this section of the chapter, we first examine the major features of a phase diagram, then turn to navigating within a phase diagram, and finally examine and compare the phase diagrams of selected substances.

### The Major Features of a Phase Diagram

We can introduce the major features of a phase diagram by examining the phase diagram for water as an example (Figure 11.37). The  $y$ -axis displays the pressure in torr and the  $x$ -axis displays the temperature in degrees Celsius. We categorize the main features of the phase diagram as regions, lines, and points.

Phase Diagram for Water

◀ **FIGURE 11.37** Phase Diagram for Water

### Regions

Each of the three main regions—solid, liquid, and gas—in the phase diagram represents conditions under which that particular state is stable. For example, under any of the temperatures and pressures within the liquid region in the phase diagram of water, the liquid is the stable state. Notice that the point  $25^\circ\text{C}$  and  $760 \text{ torr}$  falls within the liquid region, as we know from everyday experience. In general, low temperature and high pressure favor the solid state, high temperature and low pressure favor the gas state, and intermediate conditions

favor the liquid state. A sample of matter that is not in the state indicated by its phase diagram for a given set of conditions converts to that state when those conditions are imposed. For example, steam that is cooled to room temperature at 1 atm condenses to liquid.

### Lines

Each of the lines (or curves) in the phase diagram represents a set of temperatures and pressures at which the substance is in equilibrium between the two states on either side of the line. In the phase diagram for water shown in Figure 11.37, consider the curved line beginning just beyond 0 °C separating the liquid from the gas. This line is the vaporization curve (also called the vapor pressure curve) for water that we examined in Section 11.5. At any of the temperatures and pressures that fall along this line, the liquid and gas states of water are equally stable and in equilibrium. For example, at 100 °C and 760 torr pressure, water and its vapor are in equilibrium—they are equally stable and coexist. The other two major lines in a phase diagram are the *sublimation curve* (separating the solid and the gas) and the *fusion curve* (separating the solid and the liquid).

### The Triple Point

The **triple point** in a phase diagram represents the unique set of conditions at which the three states are equally stable and in equilibrium. In the phase diagram for water, the triple point occurs at 0.0098 °C and 4.58 torr. Under these unique conditions (and only under these conditions), the solid, liquid, and gas states of water are equally stable and coexist in equilibrium.

### The Critical Point

As we discussed in Section 11.5, at the critical temperature and pressure, the liquid and gas states coalesce into a *supercritical fluid*. The **critical point** in a phase diagram represents the temperature and pressure above which a supercritical fluid exists.

## Navigation within a Phase Diagram

We can represent changes in the temperature or pressure of a sample of water as movement within the phase diagram. For example, suppose we heat a block of ice initially at 1.0 atm and –25 °C. We represent the change in temperature at constant pressure as movement along the line marked A in Figure 11.38. As the temperature rises, we move to the right along the line. At the fusion curve, the temperature stops rising and melting

► **FIGURE 11.38** Navigation on the Phase Diagram for Water

The triple point of a substance such as water can be reproduced anywhere to calibrate a thermometer or pressure gauge with a known temperature and pressure.

occurs until the solid ice is completely converted to liquid water. Crossing the fusion curve requires the complete transition from solid to liquid. Once the ice has completely melted, the temperature of the liquid water can begin to rise until the vaporization curve is reached. At this point, the temperature again stops rising and boiling occurs until all the liquid is converted to gas.

We represent a change in pressure with a vertical line on the phase diagram. For example, suppose we lower the pressure above a sample of water initially at 1.0 atm and 25 °C. We represent the change in pressure at constant temperature as movement along the line marked B in Figure 11.38. As the pressure drops, we move down the line and approach the vaporization curve. At the vaporization curve, the pressure stops dropping and vaporization occurs until the liquid completely converts to vapor. Crossing the vaporization curve requires the complete transition from liquid to gas. Only after the liquid has all vaporized can the pressure continue to drop.

## The Phase Diagrams of Other Substances

Next, let's examine the phase diagrams of iodine and carbon dioxide in Figure 11.39. The phase diagrams are similar to the diagram of water in most of their general features, but some significant differences exist.

**▲ FIGURE 11.39** Phase Diagrams for Other Substances (a) Iodine, (b) Carbon dioxide.

Note that the fusion curves for both carbon dioxide and iodine have a positive slope—as the temperature increases, the pressure also increases—in contrast to the fusion curve for water, which has a negative slope. The behavior of water is atypical. The fusion curve within the phase diagrams for most substances has a positive slope because increasing pressure favors the denser state, which for most substances is the solid state.

For example, suppose we increase the pressure on a sample of iodine from 1 atm to 100 atm at 184 °C, as shown by line A in Figure 11.39(a). Notice that this change crosses the fusion curve, converting the liquid into a solid. In contrast, a pressure increase from 1 atm to 100 atm at –0.1 °C in water causes a state transition from solid to liquid. Unlike most substances, the liquid state of water is actually denser than the solid state.

Both water and iodine have stable solid, liquid, and gaseous states at a pressure of 1 atm. However, notice that carbon dioxide has no stable liquid state at a pressure of 1 atm. If we increase the temperature of a block of solid carbon dioxide (dry ice) at 1 atm, as indicated by line B in Figure 11.39(b), we cross the sublimation curve at –78.5 °C. At this temperature, the solid sublimates to a gas, which is one reason that dry ice is useful (it does not melt into a liquid at atmospheric pressure). Carbon dioxide forms a liquid only above pressures of 5.1 atm.

CONCEPTUAL  
CONNECTION 11.7

**Phase Diagrams** A substance has a triple point at  $-24.5^{\circ}\text{C}$  and 225 mmHg. What is most likely to happen to a solid sample of the substance as it is warmed from  $-35^{\circ}\text{C}$  to  $0^{\circ}\text{C}$  at a pressure of 220 mmHg?

- (a) The solid melts into a liquid.
- (b) The solid sublimates into a gas.
- (c) Nothing (the solid remains solid).

▲ The Mars Curiosity Rover has found evidence that liquid water (which could possibly sustain life) once existed on the surface of Mars.

► **FIGURE 11.40 Boiling Points of Main-Group Hydrides** Water is the only common main-group hydride that is a liquid at room temperature.

## 11.9 Water: An Extraordinary Substance

Water is the most common and important liquid on Earth. It fills our oceans, lakes, and streams. In its solid form, it caps our mountains, and in its gaseous form, it humidifies our air. We drink water, we sweat water, and we excrete bodily wastes dissolved in water. Indeed, the majority of our body mass *is* water. Life is impossible without water, and in most places on Earth where liquid water exists, life exists. Recent evidence for the past existence of water on Mars has fueled hopes of finding life or evidence of past life there. And though it may not be obvious to us (because we take water for granted), this familiar substance has many remarkable properties.

Among liquids, water is unique. It has a low molar mass (18.02 g/mol), yet it is a liquid at room temperature. Other main-group hydrides have higher molar masses but lower boiling points, as shown in Figure 11.40▼. No other substance of similar molar mass (except HF) comes close to being a liquid at room temperature.

We can understand water's high boiling point (in spite of its low molar mass) by examining its molecular structure. The bent geometry of the water molecule and the highly polar nature of the O—H bonds result in a molecule with a significant dipole moment. Water's two O—H bonds (hydrogen directly bonded to oxygen) allow a water molecule to form strong hydrogen bonds with four other water molecules (Figure 11.41◀), resulting in a relatively high boiling point.

Water's high polarity allows it to dissolve many other polar and ionic compounds and even a number of nonpolar gases such as oxygen and carbon dioxide (by inducing a dipole moment in their molecules). Consequently, water is the main solvent within living organisms, transporting nutrients and other important compounds throughout the body. Water is the main solvent in our environment as well, allowing aquatic animals, for example, to survive by breathing dissolved oxygen and allowing aquatic plants to survive by using dissolved carbon dioxide for photosynthesis.

▲ **FIGURE 11.41 Hydrogen Bonding in Water** A water molecule can form four strong hydrogen bonds with four other water molecules.

Recall from Section 6.4 that water has an exceptionally high specific heat capacity, which has a moderating effect on the climate of coastal cities. In some cities, such as San Francisco, for example, the daily fluctuation in temperature can be less than 10 °C. This same moderating effect occurs over the entire planet, two-thirds of which is covered by water. Without water, the daily temperature fluctuations on our planet might be more like those on Mars, where temperatures fluctuate 63 °C (113 °F) between midday and early morning. Imagine awakening to below-freezing temperatures, only to bake at summer desert temperatures in the afternoon! The presence of water on Earth and water's uniquely high specific heat capacity are largely responsible for our planet's much smaller daily fluctuations.

As we have discussed, the way water freezes is also unique. Unlike other substances, which contract upon freezing, water expands upon freezing. Consequently, ice is less dense than liquid water, which is why ice floats. This seemingly trivial property has significant consequences. The frozen layer of ice at the surface of a winter lake insulates the water in the lake from further freezing. If this ice layer sank, it would kill bottom-dwelling aquatic life and possibly allow the lake to freeze solid, eliminating virtually all life in the lake.

The expansion of water upon freezing, however, is one reason that most organisms do not survive freezing. When the water within a cell freezes, it expands and often ruptures the cell, just as water freezing within a pipe bursts the pipe. Many foods, especially those with high water content, do not survive freezing very well either. Have you ever tried, for example, to freeze your own vegetables? If you put lettuce or spinach in the freezer, it will be limp and damaged upon thawing. The frozen-food industry gets around this problem by *flash freezing* vegetables and other foods. In this process, foods are frozen nearly instantaneously, which prevents water molecules from settling into their preferred crystalline structure. Consequently, the water does not expand very much, and the food remains largely undamaged.

▲ When lettuce freezes, the water within its cells expands, rupturing them.

## Chemistry IN THE Environment | Water Pollution

**W**ater quality is critical to human health. Many human diseases—especially in developing nations—are caused by poor water quality. Several kinds of pollutants, including biological and chemical contaminants, can enter water supplies.

◀ Uncontaminated, sanitary water supplies are critical to human health.

Biological contaminants are microorganisms that cause diseases such as hepatitis, cholera, dysentery, and typhoid. They get into drinking water primarily when human or animal waste is dumped into bodies of water. Drinking water in developed nations is usually chemically treated to kill microorganisms. Water containing biological contaminants poses an immediate danger to human health and

should not be consumed. Boiling eliminates most biological contaminants from untreated water.

Chemical contaminants enter drinking water supplies as a result of industrial dumping, pesticide and fertilizer use, and household dumping. These contaminants include organic compounds, such as carbon tetrachloride and dioxin, and inorganic elements and compounds, such as mercury, lead, and nitrates. Because many chemical contaminants are neither volatile nor alive (like biological contaminants are), they are usually not eliminated through boiling.

The U.S. Environmental Protection Agency (EPA), under the Safe Drinking Water Act of 1974 and its amendments, sets standards that specify the maximum contamination level (MCL) of nearly 100 biological and chemical contaminants in water. Water providers that serve more than 25 people must periodically test the water they deliver to their consumers for these contaminants. If levels exceed the standards set by the EPA, the water provider must notify consumers and take appropriate measures to remove the contaminant from the water. According to the EPA, water from providers that serve more than 25 people should be safe to consume over a lifetime. If it is not safe to drink for a short period of time, providers must notify consumers.

### QUESTION

*Why doesn't boiling eliminate nonvolatile contaminants such as lead?*

## Self-Assessment Quiz

**Q1.** Which state of matter is compressible?

- a) gas
- b) liquid
- c) solid
- d) none of the above

**Q2.** Liquid nitrogen boils at 77 K. The image shown below depicts a sample of liquid nitrogen.

Which image best depicts the nitrogen after it has boiled?

**Q3.** Based on the expected intermolecular forces, which halogen has the highest boiling point?

- a)  $F_2$
- b)  $Cl_2$
- c)  $Br_2$
- d)  $I_2$

**Q4.** Which substance experiences dipole–dipole forces?

- a)  $CCl_4$
- b)  $NF_3$
- c)  $CS_2$
- d)  $SO_3$

**Q5.** One of these substances is a liquid at room temperature. Which one?

- a)  $CH_3OH$
- b)  $CF_4$
- c)  $SiH_4$
- d)  $CO_2$

**Q6.** Which property of a liquid increases with increasing temperature?

- a) surface tension
- b) viscosity
- c) vapor pressure
- d) none of the above

**Q7.** Determine the amount of heat (in kJ) required to vaporize 1.55 kg of water at its boiling point. For water,  $\Delta H_{vap} = 40.7 \text{ kJ/mol}$  (at  $100^\circ\text{C}$ ).

- a)  $3.50 \times 10^3 \text{ kJ}$
- b)  $1.14 \times 10^6 \text{ kJ}$
- c) 2.11 kJ
- d) 686 kJ

**Q8.** The vapor pressure of a substance is measured over a range of temperatures. A plot of the natural log of the vapor pressure versus the inverse of the temperature (in Kelvin) produces a straight line with a slope of  $-3.46 \times 10^3 \text{ K}$ . Find the enthalpy of vaporization of the substance.

- a)  $2.40 \times 10^{-3} \text{ kJ/mol}$
- b) 28.8 kJ/mol
- c) 0.416 kJ/mol
- d) 3.22 kJ/mol

**Q9.** Acetic acid has a normal boiling point of  $118^\circ\text{C}$  and a  $\Delta H_{vap}$  of 23.4 kJ/mol. What is the vapor pressure (in mmHg) of acetic acid at  $25^\circ\text{C}$ ?

- a)  $2.92 \times 10^{-39} \text{ mmHg}$
- b)  $7.16 \times 10^3 \text{ mmHg}$
- c) 758 mmHg
- d) 80.6 mmHg

**Q10.** Consider the phase diagram shown here. A sample of the substance in the phase diagram is initially at  $175^\circ\text{C}$  and 925 mmHg. What phase transition occurs when the pressure is decreased to 760 mmHg at constant temperature?

- a) solid to liquid
- b) liquid to gas
- c) solid to gas
- d) liquid to solid

Answers: 1. (a) 2. (d) 3. (d) 4. (b) 5. (a) 6. (c) 7. (a) 8. (b) 9. (d) 10. (b)

## Chapter 11 IN REVIEW

### Key Terms

#### Section 11.2

crystalline (488)  
amorphous (488)

#### Section 11.3

dispersion force (490)  
dipole–dipole force (492)  
permanent dipole (492)  
miscibility (493)  
hydrogen bonding (495)  
hydrogen bond (495)  
ion–dipole force (497)

#### Section 11.4

surface tension (500)  
viscosity (501)  
capillary action (501)

#### Section 11.5

vaporization (503)  
condensation (503)  
volatile (503)  
nonvolatile (503)  
heat (or enthalpy) of vaporization ( $\Delta H_{\text{vap}}$ ) (504)  
dynamic equilibrium (506)  
vapor pressure (506)  
boiling point (507)  
normal boiling point (508)  
Clausius–Clapeyron equation (509)  
critical temperature ( $T_c$ ) (512)  
critical pressure ( $P_c$ ) (512)

#### Section 11.6

sublimation (512)  
deposition (513)  
melting point (513)  
melting (fusion) (513)  
freezing (513)  
heat of fusion ( $\Delta H_{\text{fus}}$ ) (513)  
heat (or enthalpy) of sublimation ( $\Delta H_{\text{sub}}$ ) (514)

#### Section 11.8

phase diagram (517)  
triple point (518)  
critical point (518)

### Key Concepts

#### Solids, Liquids, and Intermolecular Forces

##### (11.1, 11.2, 11.3)

- ▶ The forces that hold molecules or atoms together in a liquid or solid are intermolecular forces. The strength of the intermolecular forces in a substance determines its state.
- ▶ Dispersion forces are present in all elements and compounds; they arise from the fluctuations in electron distribution within atoms and molecules. These are the weakest intermolecular forces, but they are significant in molecules with high molar masses.
- ▶ Dipole–dipole forces, generally stronger than dispersion forces, are present in all polar molecules.
- ▶ Hydrogen bonding occurs in polar molecules that contain hydrogen atoms bonded directly to fluorine, oxygen, or nitrogen. These are among the strongest intermolecular forces.
- ▶ Ion–dipole forces occur when ionic compounds are mixed with polar compounds, and they are especially important in aqueous solutions.

#### Surface Tension, Viscosity, and Capillary Action (11.4)

- ▶ Surface tension results from the tendency of liquids to minimize their surface area in order to maximize the interactions between their constituent particles, thus lowering potential energy. Surface tension causes water droplets to form spheres and allows insects and paper clips to “float” on the surface of water.
- ▶ Viscosity is the resistance of a liquid to flow. Viscosity increases with increasing strength of intermolecular forces and decreases with increasing temperature.

- ▶ Capillary action is the ability of a liquid to flow against gravity up a narrow tube. It is the result of adhesive forces, the attraction between the molecules and the surface of the tube, and cohesive forces, the attraction between the molecules in the liquid.

#### Vaporization and Vapor Pressure (11.5, 11.7)

- ▶ Vaporization, the transition from liquid to gas, occurs when thermal energy overcomes the intermolecular forces present in a liquid. The opposite process is condensation. Vaporization is endothermic and condensation is exothermic.
- ▶ The rate of vaporization increases with increasing temperature, increasing surface area, and decreasing strength of intermolecular forces.
- ▶ The heat of vaporization ( $\Delta H_{\text{vap}}$ ) is the heat required to vaporize one mole of a liquid.
- ▶ In a sealed container, a liquid and its vapor come into dynamic equilibrium, at which point the rate of vaporization equals the rate of condensation. The pressure of a gas that is in dynamic equilibrium with its liquid is its vapor pressure.
- ▶ The vapor pressure of a substance increases with increasing temperature and with decreasing strength of its intermolecular forces.
- ▶ The boiling point of a liquid is the temperature at which its vapor pressure equals the external pressure.
- ▶ The Clausius–Clapeyron equation expresses the relationship between the vapor pressure of a substance and its temperature and can be used to calculate the heat of vaporization from experimental measurements.
- ▶ When a liquid is heated in a sealed container, it eventually forms a supercritical fluid, which has properties intermediate between a liquid and a gas. This occurs at critical temperature and critical pressure.

**Fusion and Sublimation (11.6, 11.7)**

- ▶ Sublimation is the transition from solid to gas. The opposite process is deposition.
- ▶ Fusion, or melting, is the transition from solid to liquid. The opposite process is freezing.
- ▶ The heat of fusion ( $\Delta H_{\text{fus}}$ ) is the amount of heat required to melt one mole of a solid. Fusion is endothermic.
- ▶ The heat of fusion is generally less than the heat of vaporization because intermolecular forces do not have to be completely overcome for melting to occur.

**Phase Diagrams (11.8)**

- ▶ A phase diagram is a map of the states of a substance as a function of its pressure (y-axis) and temperature (x-axis).
- ▶ The regions in a phase diagram represent conditions under which a single stable state (solid, liquid, gas) exists.

- ▶ The lines represent conditions under which two states are in equilibrium.
- ▶ The triple point represents the conditions under which all three states coexist.
- ▶ The critical point is the temperature and pressure above which a supercritical fluid exists.

**The Uniqueness of Water (11.9)**

- ▶ Water is a liquid at room temperature despite its low molar mass. Water forms strong hydrogen bonds, resulting in its high boiling point.
- ▶ The polarity of water enables it to dissolve many polar and ionic compounds and even nonpolar gases.
- ▶ Water expands upon freezing, so ice is less dense than liquid water. Water is critical both to the existence of life and to human health.

**Key Equations and Relationships**

Clausius–Clapeyron Equation: Relationship between Vapor Pressure ( $P_{\text{vap}}$ ), the Heat of Vaporization ( $\Delta H_{\text{vap}}$ ), and Temperature ( $T$ ) (11.5)

$$\ln P_{\text{vap}} = \frac{-\Delta H_{\text{vap}}}{RT} + \ln \beta \quad (\beta \text{ is a constant})$$

$$\ln \frac{P_2}{P_1} = \frac{-\Delta H_{\text{vap}}}{R} \left( \frac{1}{T_2} - \frac{1}{T_1} \right)$$

**Key Learning Outcomes**

CHAPTER OBJECTIVES	ASSESSMENT
Determining Whether a Molecule Has Dipole–Dipole Forces (11.3)	Example 11.1 For Practice 11.1 Exercises 35–46
Determining Whether a Molecule Displays Hydrogen Bonding (11.3)	Example 11.2 For Practice 11.2 Exercises 35–46
Using the Heat of Vaporization in Calculations (11.5)	Example 11.3 For Practice 11.3 For More Practice 11.3 Exercises 57–60
Using the Clausius–Clapeyron Equation (11.5)	Examples 11.4, 11.5 For Practice 11.4, 11.5 Exercises 61–66

**EXERCISES****Review Questions**

1. Explain why water drops are spherical in the absence of gravity.
2. Why are intermolecular forces important?
3. What are the main properties of liquids (in contrast to gases and solids)?
4. What are the main properties of solids (in contrast to liquids and gases)?
5. What is the fundamental difference between an amorphous solid and a crystalline solid?
6. What factors cause transitions between the solid and liquid state? The liquid and gas state?
7. Describe the relationship between the state of a substance, its temperature, and the strength of its intermolecular forces.
8. From what kinds of interactions do intermolecular forces originate?
9. Why are intermolecular forces generally much weaker than bonding forces?
10. What is the dispersion force? What does the magnitude of the dispersion force depend on? How can you predict the magnitude of the dispersion force for closely related elements or compounds?
11. What is the dipole–dipole force? How can you predict the presence of dipole–dipole forces in a compound?

12. How is the polarity of a liquid generally related to its miscibility with water?
13. What is hydrogen bonding? How can you predict the presence of hydrogen bonding in a compound?
14. What is the ion-dipole force? Why is it important?
15. What is surface tension? How does surface tension result from intermolecular forces? How is it related to the strength of intermolecular forces?
16. What is viscosity? How does viscosity depend on intermolecular forces? What other factors affect viscosity?
17. What is capillary action? How does it depend on the relative strengths of adhesive and cohesive forces?
18. Explain what happens in the processes of vaporization and condensation. Why does the rate of vaporization increase with increasing temperature and surface area?
19. Why is vaporization endothermic? Why is condensation exothermic?
20. How is the volatility of a substance related to the intermolecular forces present within the substance?
21. What is the heat of vaporization for a liquid and why is it useful?
22. Explain the process of dynamic equilibrium. How is dynamic equilibrium related to vapor pressure?
23. What happens to a system in dynamic equilibrium when it is disturbed in some way?
24. How is vapor pressure related to temperature? What happens to the vapor pressure of a substance when the temperature is increased? Decreased?
25. Define the terms *boiling point* and *normal boiling point*.
26. What is the Clausius–Clapeyron equation and why is it important?
27. Explain what happens to a substance when it is heated in a closed container to its critical temperature.
28. What is sublimation? Give a common example of sublimation.
29. What is fusion? Is fusion exothermic or endothermic? Why?
30. What is the heat of fusion and why is it important?
31. Examine the heating curve for water in Section 11.7 (Figure 11.36). Explain why the curve has two segments in which heat is added to the water but the temperature does not rise.
32. Examine the heating curve for water in Section 11.7 (Figure 11.36). Explain the significance of the slopes of each of the three rising segments. Why are the slopes different?
33. What is a phase diagram? Draw a generic phase diagram and label its important features. What is the significance of crossing a line in a phase diagram?
34. How do the properties of water differ from those of most other substances?

## Problems by Topic

### Intermolecular Forces

35. Determine the kinds of intermolecular forces that are present in each element or compound.
  - a.  $\text{N}_2$
  - b.  $\text{NH}_3$
  - c.  $\text{CO}$
  - d.  $\text{CCl}_4$
36. Determine the kinds of intermolecular forces that are present in each element or compound.
  - a.  $\text{Kr}$
  - b.  $\text{NCl}_3$
  - c.  $\text{SiH}_4$
  - d.  $\text{HF}$
37. Determine the kinds of intermolecular forces that are present in each element or compound.
  - a.  $\text{HCl}$
  - b.  $\text{H}_2\text{O}$
  - c.  $\text{Br}_2$
  - d.  $\text{He}$
38. Determine the kinds of intermolecular forces that are present in each element or compound.
  - a.  $\text{PH}_3$
  - b.  $\text{HBr}$
  - c.  $\text{CH}_3\text{OH}$
  - d.  $\text{I}_2$
39. Arrange these compounds in order of increasing boiling point. Explain your reasoning.
  - a.  $\text{CH}_4$
  - b.  $\text{CH}_3\text{CH}_3$
  - c.  $\text{CH}_3\text{CH}_2\text{Cl}$
  - d.  $\text{CH}_3\text{CH}_2\text{OH}$
40. Arrange these compounds in order of increasing boiling point. Explain your reasoning.
  - a.  $\text{H}_2\text{S}$
  - b.  $\text{H}_2\text{Se}$
  - c.  $\text{H}_2\text{O}$
41. In each pair of compounds, pick the one with the higher boiling point. Explain your reasoning.
  - a.  $\text{CH}_3\text{OH}$  or  $\text{CH}_3\text{SH}$
  - b.  $\text{CH}_3\text{OCH}_3$  or  $\text{CH}_3\text{CH}_2\text{OH}$
  - c.  $\text{CH}_4$  or  $\text{CH}_3\text{CH}_3$
42. In each pair of compounds, pick the one with the higher boiling point. Explain your reasoning.
  - a.  $\text{NH}_3$  or  $\text{CH}_4$
  - b.  $\text{CS}_2$  or  $\text{CO}_2$
  - c.  $\text{CO}_2$  or  $\text{NO}_2$
43. In each pair of compounds, pick the one with the higher vapor pressure at a given temperature. Explain your reasoning.
  - a.  $\text{Br}_2$  or  $\text{I}_2$
  - b.  $\text{H}_2\text{S}$  or  $\text{H}_2\text{O}$
  - c.  $\text{NH}_3$  or  $\text{PH}_3$
44. In each pair of compounds, pick the one with the higher vapor pressure at a given temperature. Explain your reasoning.
  - a.  $\text{CH}_4$  or  $\text{CH}_3\text{Cl}$
  - b.  $\text{CH}_3\text{CH}_2\text{CH}_2\text{OH}$  or  $\text{CH}_3\text{OH}$
  - c.  $\text{CH}_3\text{OH}$  or  $\text{H}_2\text{CO}$
45. Determine whether each pair of compounds forms a homogeneous solution when combined. For those that form homogeneous solutions, indicate the type of forces that are involved.
  - a.  $\text{CCl}_4$  and  $\text{H}_2\text{O}$
  - b.  $\text{KCl}$  and  $\text{H}_2\text{O}$
  - c.  $\text{Br}_2$  and  $\text{CCl}_4$
  - d.  $\text{CH}_3\text{CH}_2\text{OH}$  and  $\text{H}_2\text{O}$
46. Determine whether each pair of compounds forms a homogeneous solution when combined. For those that form homogeneous solutions, indicate the type of forces that are involved.
  - a.  $\text{CH}_3\text{CH}_2\text{CH}_2\text{CH}_2\text{CH}_3$  and  $\text{CH}_3\text{CH}_2\text{CH}_2\text{CH}_2\text{CH}_2\text{CH}_3$
  - b.  $\text{CBr}_4$  and  $\text{H}_2\text{O}$
  - c.  $\text{LiNO}_3$  and  $\text{H}_2\text{O}$
  - d.  $\text{CH}_3\text{OH}$  and  $\text{CH}_3\text{CH}_2\text{CH}_2\text{CH}_2\text{CH}_3$

## Surface Tension, Viscosity, and Capillary Action

47. Which compound would you expect to have greater surface tension: acetone  $[(\text{CH}_3)_2\text{CO}]$  or water  $(\text{H}_2\text{O})$ ? Explain.
48. Water (a) “wets” some surfaces and beads up on others. Mercury (b), in contrast, beads up on almost all surfaces. Explain this difference.

49. The structures of two isomers of heptane are shown. Which of these two compounds would you expect to have the greater viscosity?

50. Explain why the viscosity of multigrade motor oils is less temperature-dependent than that of single-grade motor oils.
51. Water in a glass tube that contains grease or oil residue displays a flat meniscus (left), whereas water in a clean glass tube displays a concave meniscus (right). Explain this observation.

52. When a thin glass tube is put into water, the water rises 1.4 cm. When the same tube is put into hexane, the hexane rises only 0.4 cm. Explain.

## Vaporization and Vapor Pressure

53. Which evaporates more quickly: 55 mL of water in a beaker with a diameter of 4.5 cm or 55 mL of water in a dish with a

diameter of 12 cm? Is the vapor pressure of the water different in the two containers? Explain.

54. Which evaporates more quickly: 55 mL of water  $(\text{H}_2\text{O})$  in a beaker or 55 mL of acetone  $[(\text{CH}_3)_2\text{CO}]$  in an identical beaker under identical conditions? Is the vapor pressure of the two substances different? Explain.
55. Spilling room-temperature water over your skin on a hot day cools you down. Spilling room-temperature vegetable oil over your skin on a hot day does not. Explain the difference.
56. Why is the heat of vaporization of water greater at room temperature than it is at its boiling point?
57. The human body obtains 915 kJ of energy from a candy bar. If this energy were used to vaporize water at  $100.0^\circ\text{C}$ , how much water (in liters) could be vaporized? (Assume the density of water is  $1.00\text{ g/mL}$ .)
58. A  $100.0\text{-mL}$  sample of water is heated to its boiling point. How much heat (in kJ) is required to vaporize it? (Assume a density of  $1.00\text{ g/mL}$ .)
59. Suppose that  $0.95\text{ g}$  of water condenses on a  $75.0\text{-g}$  block of iron that is initially at  $22^\circ\text{C}$ . If the heat released during condensation goes only to warming the iron block, what is the final temperature (in  $^\circ\text{C}$ ) of the iron block? (Assume a constant enthalpy of vaporization for water of  $44.0\text{ kJ/mol}$ .)
60. Suppose that  $1.15\text{ g}$  of rubbing alcohol  $(\text{C}_3\text{H}_8\text{O})$  evaporates from a  $65.0\text{-g}$  aluminum block. If the aluminum block is initially at  $25^\circ\text{C}$ , what is the final temperature of the block after the evaporation of the alcohol? Assume that the heat required for the vaporization of the alcohol comes only from the aluminum block and that the alcohol vaporizes at  $25^\circ\text{C}$ .
61. This table displays the vapor pressure of ammonia at several different temperatures. Use the data to determine the heat of vaporization and normal boiling point of ammonia.

Temperature (K)	Pressure (torr)
200	65.3
210	134.3
220	255.7
230	456.0
235	597.0

62. This table displays the vapor pressure of nitrogen at several different temperatures. Use the data to determine the heat of vaporization and normal boiling point of nitrogen.

Temperature (K)	Pressure (torr)
65	130.5
70	289.5
75	570.8
80	1028
85	1718

63. Ethanol has a heat of vaporization of  $38.56\text{ kJ/mol}$  and a normal boiling point of  $78.4^\circ\text{C}$ . What is the vapor pressure of ethanol at  $15^\circ\text{C}$ ?
64. Benzene has a heat of vaporization of  $30.72\text{ kJ/mol}$  and a normal boiling point of  $80.1^\circ\text{C}$ . At what temperature does benzene boil when the external pressure is  $445\text{ torr}$ ?

65. Carbon disulfide has a vapor pressure of 363 torr at 25 °C and a normal boiling point of 46.3 °C. Find  $\Delta H_{\text{vap}}$  for carbon disulfide.
66. Methylamine has a vapor pressure of 344 torr at -25 °C and a boiling point of -6.4 °C. Find  $\Delta H_{\text{vap}}$  for methylamine.

### Sublimation and Fusion

67. How much energy is released when 65.8 g of water freezes?
68. Calculate the amount of heat required to completely sublime 50.0 g of solid dry ice ( $\text{CO}_2$ ) at its sublimation temperature. The heat of sublimation for carbon dioxide is 32.3 kJ/mol.
69. An 8.5-g ice cube is placed into 255 g of water. Calculate the temperature change in the water upon the complete melting of the ice. Assume that all of the energy required to melt the ice comes from the water.
70. How much ice (in grams) would have to melt to lower the temperature of 352 mL of water from 25 °C to 5 °C? (Assume the density of water is 1.0 g/mL.)
71. How much heat (in kJ) is required to warm 10.0 g of ice, initially at -10.0 °C, to steam at 110.0 °C? The heat capacity of ice is 2.09 J/g · °C, and that of steam is 2.01 J/g · °C.
72. How much heat (in kJ) is evolved in converting 1.00 mol of steam at 145 °C to ice at -50 °C? The heat capacity of steam is 2.01 J/g · °C, and that of ice is 2.09 J/g · °C.

### Phase Diagrams

73. Consider the phase diagram shown here. Identify the states present at points *a* through *g*.

74. Consider the phase diagram for iodine shown here.
- What is the normal boiling point for iodine?
  - What is the melting point for iodine at 1 atm?
  - What state is present at room temperature and normal atmospheric pressure?
  - What state is present at 186 °C and 1.0 atm?

75. Nitrogen has a normal boiling point of 77.3 K and a melting point (at 1 atm) of 63.1 K. Its critical temperature is 126.2 K and its critical pressure is  $2.55 \times 10^4$  torr. It has a triple point at 63.1 K and 94.0 torr. Sketch the phase diagram for nitrogen. Does nitrogen have a stable liquid state at 1 atm?
76. Argon has a normal boiling point of 87.2 K and a melting point (at 1 atm) of 84.1 K. Its critical temperature is 150.8 K and its critical pressure is 48.3 atm. It has a triple point at 83.7 K and 0.68 atm. Sketch the phase diagram for argon. Which has the greater density, solid argon or liquid argon?
77. The phase diagram for sulfur is shown here. The rhombic and monoclinic states are two solid states with different structures.
- Below what pressure does solid sulfur sublime?
  - Which of the two solid states of sulfur is more dense?

78. The high-pressure phase diagram of ice is shown here. Notice that, under high pressure, ice can exist in several different solid forms. What three forms of ice are present at the triple point marked O? How does the density of ice II compare to ice I (the familiar form of ice)? Would ice III sink or float in liquid water?

### The Uniqueness of Water

79. Water has a high boiling point given its relatively low molar mass. Why?
80. Water is a good solvent for many substances. What is the molecular basis for this property, and why is it significant?
81. Explain the role of water in moderating Earth's climate.
82. How is the density of solid water compared to that of liquid water atypical among substances? Why is this significant?

## Cumulative Problems

83. Explain the observed trend in the melting points of the hydrogen halides.

HI	−50.8 °C
HBr	−88.5 °C
HCl	−114.8 °C
HF	−83.1 °C

84. Explain the observed trend in the boiling points of these compounds.

H <sub>2</sub> Te	−2 °C
H <sub>2</sub> Se	−41.5 °C
H <sub>2</sub> S	−60.7 °C
H <sub>2</sub> O	100 °C

85. The vapor pressure of water at 25 °C is 23.76 torr. If 1.25 g of water is enclosed in a 1.5-L container, will any liquid be present? If so, what mass of liquid?
86. The vapor pressure of CCl<sub>3</sub>F at 300 K is 856 torr. If 11.5 g of CCl<sub>3</sub>F is enclosed in a 1.0-L container, will any liquid be present? If so, what mass of liquid?
87. Examine the phase diagram for iodine shown in Figure 11.39(a). What state transitions occur as we uniformly increase the pressure on a gaseous sample of iodine from 0.010 atm at 185 °C to 100 atm at 185 °C? Make a graph, analogous to the heating curve for water shown in Figure 11.36. Plot pressure versus time during the pressure increase.
88. Carbon tetrachloride displays a triple point at 249.0 K and a melting point (at 1 atm) of 250.3 K. Which state of carbon tetrachloride is more dense, the solid or the liquid? Explain.
89. Four ice cubes at exactly 0 °C with a total mass of 53.5 g are combined with 115 g of water at 75 °C in an insulated container. If no heat is lost to the surroundings, what is the final temperature of the mixture?
90. A sample of steam with a mass of 0.552 g and at a temperature of 100 °C condenses into an insulated container holding 4.25 g of water at 5.0 °C. Assuming that no heat is lost to the surroundings, what is the final temperature of the mixture?
91. Draw a heating curve (such as the one in Figure 11.36) for 1 mole of methanol beginning at 170 K and ending at 350 K. Assume that the values given here are constant over the relevant temperature ranges.

Melting point	176 K
Boiling point	338 K
$\Delta H_{\text{fus}}$	2.2 kJ/mol
$\Delta H_{\text{vap}}$	35.2 kJ/mol
$C_{\text{s,solid}}$	105 J/mol · K
$C_{\text{s,liquid}}$	81.3 J/mol · K
$C_{\text{s,gas}}$	48 J/mol · K

92. Draw a heating curve (such as the one in Figure 11.36) for 1 mol of benzene beginning at 0 °C and ending at 100 °C. Assume that the values given here are constant over the relevant temperature ranges.

Melting point	5.4 °C
Boiling point	80.1 °C
$\Delta H_{\text{fus}}$	9.9 kJ/mol
$\Delta H_{\text{vap}}$	30.7 kJ/mol
$C_{\text{s,solid}}$	118 J/mol · K
$C_{\text{s,liquid}}$	135 J/mol · K
$C_{\text{s,gas}}$	104 J/mol · K

93. Air conditioners not only cool air, but dry it as well. A room in a home measures 6.0 m × 10.0 m × 2.2 m. If the outdoor temperature is 30 °C and the partial pressure of water in the air is 85% of the vapor pressure of water at this temperature, what mass of water must be removed from the air each time the volume of air in the room is cycled through the air conditioner? (Assume that all of the water must be removed from the air.) The vapor pressure for water at 30 °C is 31.8 torr.
94. A sealed flask contains 0.55 g of water at 28 °C. The vapor pressure of water at this temperature is 28.35 mmHg. What is the minimum volume of the flask in order that no liquid water be present in the flask?
95. Based on the phase diagram of CO<sub>2</sub> shown in Figure 11.39(b), describe the state changes that occur when the temperature of CO<sub>2</sub> is increased from 190 K to 350 K at a constant pressure of (a) 1 atm, (b) 5.1 atm, (c) 10 atm, (d) 100 atm.
96. Consider a planet where the pressure of the atmosphere at sea level is 2500 mmHg. Does water behave in a way that can sustain life on the planet?

## Challenge Problems

97. Liquid nitrogen can be used as a cryogenic substance to obtain low temperatures. Under atmospheric pressure, liquid nitrogen boils at 77 K, allowing low temperatures to be reached. However, if the nitrogen is placed in a sealed, insulated container connected to a vacuum pump, even lower temperatures can be reached. Why? If the vacuum pump has sufficient capacity and is left on for an extended period of time, the liquid nitrogen will start to freeze. Explain.

98. Given that the heat of fusion of water is −6.02 kJ/mol, the heat capacity of H<sub>2</sub>O(l) is 75.2 J/mol · K, and the heat capacity of H<sub>2</sub>O(s) is 37.7 J/mol · K, calculate the heat of fusion of water at −10 °C.
99. The heat of combustion of CH<sub>4</sub> is 890.4 kJ/mol, and the heat capacity of H<sub>2</sub>O is 75.2 J/mol · K. Find the volume of methane measured at 298 K and 1.00 atm required to convert 1.00 L of water at 298 K to water vapor at 373 K.

- 100.** Two liquids, A and B, have vapor pressures at a given temperature of 24 mmHg and 36 mmHg, respectively. We prepare solutions of A and B at a given temperature and measure the total pressures above the solutions. We obtain this data:

Solution	Amt A (mol)	Amt B (mol)	P (mmHg)
1	1	1	30
2	2	1	28
3	1	2	32
4	1	3	33

Predict the total pressure above a solution of 5 mol A and 1 mol B.

## Conceptual Problems

- 103.** The following image is an electrostatic potential map for ethylene oxide,  $(\text{CH}_2)_2\text{O}$ , a polar molecule. Use the electrostatic potential map to predict the geometry for how one ethylene oxide molecule interacts with another. Draw structural formulas, using the 3D bond notation introduced in Section 10.4, to show the geometry of the interaction.

- 104.** One prediction of global warming is the melting of global ice, which may result in coastal flooding. A criticism of this prediction is that the melting of icebergs does not increase ocean levels any more than the melting of ice in a glass of water increases the level of liquid in the glass. Is this a valid criticism? Does the melting of an ice cube in a cup of water raise the level of the liquid in the cup? Why or why not? In response to this criticism, scientists have asserted that they are not worried about melting icebergs, but rather the melting of ice sheets that sit on the continent of Antarctica. Would the melting of this ice increase ocean levels? Why or why not?
- 105.** The rate of vaporization depends on the surface area of the liquid. However, the vapor pressure of a liquid does not depend on the surface area. Explain.
- 106.** Substance A has a smaller heat of vaporization than substance B. Which of the two substances will undergo a larger change in vapor pressure for a given change in temperature?

- 101.** Three 1.0-L flasks, maintained at 308 K, are connected to each other with stopcocks. Initially, the stopcocks are closed. One of the flasks contains 1.0 atm of  $\text{N}_2$ ; the second, 2.0 g of  $\text{H}_2\text{O}$ ; and the third, 0.50 g of ethanol,  $\text{C}_2\text{H}_5\text{O}$ . The vapor pressure of  $\text{H}_2\text{O}$  at 308 K is 42 mmHg and that of ethanol is 102 mmHg. The stopcocks are then opened and the contents mix freely. What is the pressure?
- 102.** Butane ( $\text{C}_4\text{H}_{10}$ ) has a heat of vaporization of 22.44 kJ/mol and a normal boiling point of  $-0.4^\circ\text{C}$ . A 250-mL sealed flask contains 0.55 g of butane at  $-22^\circ\text{C}$ . How much butane is present as a liquid? If the butane is warmed to  $25^\circ\text{C}$ , how much is present as a liquid?

- 107.** The density of a substance is greater in its solid state than in its liquid state. If the triple point in the phase diagram of the substance is below 1.0 atm, which will necessarily be at a lower temperature, the triple point or the normal melting point?
- 108.** A substance has a heat of vaporization of  $\Delta H_{\text{vap}}$  and a heat of fusion of  $\Delta H_{\text{fus}}$ . Express the heat of sublimation in terms of  $\Delta H_{\text{vap}}$  and  $\Delta H_{\text{fus}}$ .
- 109.** Examine the heating curve for water in Section 11.7 (Figure 11.36). If heat is added to the water at a constant rate, which of the three segments in which temperature is rising will have the least steep slope? Why?
- 110.** A root cellar is an underground chamber used to store fruits, vegetables, and even meats. In extreme cold, farmers put large vats of water into the root cellar to prevent the fruits and vegetables from freezing. Explain why this works.
- 111.** Suggest an explanation for the observation that the heat of fusion of a substance is always smaller than its heat of vaporization.
- 112.** Refer to Figure 11.36 to answer each question.
- A sample of steam begins on the line segment labeled 5 on the graph. Is heat absorbed or released in moving from the line segment labeled 5 to the line segment labeled 3? What is the sign of  $q$  for this change?
  - In moving from left to right along the line segment labeled 2 on the graph, heat is absorbed, but the temperature remains constant. Where does the heat go?
  - How would the graph change if it were for another substance (other than water)?

## Active Classroom Learning

## Questions for Group Work

Discuss these questions with the group and record your consensus answer.

- 113.** The boiling points of three compounds are tabulated here.

	Molar Mass	Boiling Point
2-hexanone	100.16	128 $^\circ\text{C}$
heptane	100.20	98 $^\circ\text{C}$
1-hexanol	102.17	156 $^\circ\text{C}$

Answer the following questions without looking up the structures for these molecules: Which compound experiences hydrogen bonding? Which compound is polar but is unable to experience hydrogen bonding? Which is neither polar nor capable of hydrogen bonding? Explain your answers.

**114.** The vapor pressure for pure water and pure acetone is measured as a function of temperature. In each case, a graph of the log of the vapor pressure versus  $1/T$  is found to be a straight line. The slope of the line for water is  $-4895\text{ K}$  and the slope of the line for acetone is  $-3765\text{ K}$ . Determine  $\Delta H_{\text{vap}}$  for each substance. Account for the difference by discussing the molecular structure of the two molecules.

**115.** Based on the heating curve for water, does it take more energy to melt a mole of water or to boil a mole of water? Does it take more energy to warm the solid, the liquid, or the gas by  $10^\circ\text{C}$ ? Explain your answers clearly.

**116.** Sketch the phase diagram for carbon dioxide. If you have carbon dioxide at  $1.0\text{ atm}$  and  $25^\circ\text{C}$ , could you make it a liquid by cooling it down? How could you make it a liquid at  $25^\circ\text{C}$ ? If you increase the pressure of carbon dioxide that is at body temperature ( $37^\circ\text{C}$ ), will it ever liquefy?

## Data Interpretation and Analysis

### Intermolecular Forces of Group 6A Hydrides

**117.** Students in a chemistry laboratory course are investigating the following question: “How do the molar mass and structure influence the boiling point of the group 6A hydrides?” The students review Figure a, which is a graph of the boiling point versus molar mass of the group 6A hydrides.

**▲ FIGURE a** Boiling Point and Molar Mass of Group 6A Hydrides

The molar mass, boiling points, dipole moments, and polarizability of some group 6A compounds are listed in Table a. (Polarizability is the ability of an atom's or a molecule's outer electron cloud to be distorted from its normal shape by an electric field. The units of polarizability are in  $\text{\AA}^3 = 10^{-24}\text{ cm}^3$ .)

Compound	Molar Mass	<i>n</i> -Boiling Point ( $^\circ\text{C}$ )	Dipole Moment (D)	Polarizability ( $\times 10^{-24}\text{ cm}^3$ )
H <sub>2</sub> O	18.01	100	1.85	1.45
H <sub>2</sub> S	34.08	-60	1.10	3.81
H <sub>2</sub> Se	80.98	-42.2	0.41	4.71
H <sub>2</sub> Te	129.6	-2.2	0.22	5.01

**TABLE a** Relationship among Boiling Points, Dipole Moments, and Polarizability of Some Binary Hydrides

Use the information provided in the figure and the table to answer the following questions:

- Does molar mass correlate with the trend in boiling points for the group 6A hydrides?
- Which intermolecular force correlates with dipole moment?
- Which intermolecular force correlates with polarizability?
- Which is the predominant intermolecular force responsible for the boiling-point trend of H<sub>2</sub>S, H<sub>2</sub>Se and H<sub>2</sub>Te. Justify your answer using the information presented in Table a.
- Is your answer to part d in agreement with the information presented in Table 11.4? Explain.
- Explain which intermolecular force is primarily responsible for the unusually high boiling point of water. Use the data presented in Table a to justify your answer. Compare the strengths of intermolecular forces of attraction present in a sample of liquid water to the strengths of intermolecular forces of attraction present in liquid samples of H<sub>2</sub>S, H<sub>2</sub>Se, and H<sub>2</sub>Te.
- Starting with a diagram of six H<sub>2</sub>O molecules in the liquid state, draw a diagram showing what happens at the molecular level when water boils (a change from the liquid phase to the gas phase).

## Answers to Conceptual Connections

### State Changes

**11.1 (a)** When water boils, it simply changes state from liquid to gas. Water molecules do not decompose during boiling.

### Dispersion Forces

**11.2 (c)**  $I_2$  has the highest boiling point because it has the highest molar mass. Since the halogens are all similar in other ways, we expect  $I_2$  to have the greatest dispersion forces and therefore the highest boiling point (and in fact it does).

### Dipole–Dipole Interaction

### Intermolecular Forces and Boiling Point

**11.4 (a)**  $CH_3OH$ . The compounds all have similar molar masses, so the dispersion forces are similar in all three.  $CO$  is polar, but because  $CH_3OH$  contains H directly bonded to O, it has hydrogen bonding, resulting in the highest boiling point.

### Vapor Pressure

**11.5 (b)** Although the *rate of vaporization* increases with increasing surface area, the *vapor pressure* of a liquid is independent of surface area. An increase in surface area increases both the rate of vaporization and the rate of condensation—the effects exactly cancel and the vapor pressure does not change.

### Cooling of Water with Ice

**11.6** The warming of the ice from  $-10\text{ }^\circ\text{C}$  to  $0\text{ }^\circ\text{C}$  absorbs only  $20.9\text{ J/g}$  of ice. The melting of the ice, however, absorbs about  $334\text{ J/g}$  of ice. (You can obtain this value by dividing the heat of fusion of water by its molar mass.) Therefore, the melting of the ice produces a larger temperature decrease in the water than does the warming of the ice.

### Phase Diagrams

**11.7 (b)** The solid will sublime into a gas. Since the pressure is below the triple point, the liquid state is not stable.

# Solids and Modern Materials

Should we not suppose that in the formation of a crystal, the particles are not only established in rows and columns set in regular figures, but also by means of some polar property have turned identical sides in identical directions?

KEY LEARNING OUTCOMES 562

In this chapter, we focus on the solid state of matter. We first examine the structures of solids, keeping in mind that these structures determine the properties of solids. For example, the repeating hexagonal pattern of water molecules in crystalline ice determines the hexagonal shape of a snowflake, and the repeating cubic pattern of sodium and chloride ions in sodium chloride determines the cubic shape of salt grains. We then turn our attention to the study and development of solids with unique and useful properties, a field known as *materials science*. The ceramics that compose your coffee cups, the semiconductors in your electronic devices, and the plastics that are most likely all around you even at this moment are materials developed to have specific properties that serve specific purposes. In this chapter, we take a brief look at each of these kinds of materials.

▲ Graphene is the thinnest material known—it is only one atom thick.

## 12.1 Friday Night Experiments: The Discovery of Graphene

In 2010, Andre Geim (1958–) and Konstantin Novoselov (1974–) were awarded the Nobel Prize in Physics for the discovery of a new material—**graphene**. Graphene is the thinnest known material (only one atom thick); it is also the strongest. It conducts heat and electricity, it is transparent, and it is completely impermeable to all substances, including helium. Although its many possible applications are yet to be realized, graphene may one day be used to make faster computers, foldable touchscreens, ultrathin light panels,

and super-strong plastics to construct satellites, airplanes, ships, and cars. And how did these scientists discover this wonder material? Through *Friday night experiments*.

Most successful modern scientists work in a narrow field of study, chipping away at a problem about which they have become experts. Andre Geim also worked this way—but not all of the time. Geim often ventured into what he calls *lateral ideas*, which were explorations into fields far from his immediate area of expertise. Over a 15-year period, he explored about two dozen such ideas. These explorations became known as *Friday night experiments* (even though they took much longer than just one night). Most of Geim's Friday night experiments were complete failures, but some succeeded. For example, in one Friday night experiment, Geim was able to suspend an entire frog in a magnetic field. In another, he developed a new kind of tape based on mimicking the toes of a gecko. However, his most successful Friday night experiment was the discovery of graphene.

In 2002, Geim assigned his brand-new graduate student a Friday night experiment as a way to give the student time to get acquainted with the laboratory. His assignment was to make films of graphite “as thin as possible.” The graduate student tackled the task by attempting to polish a tablet of graphite down to almost nothingness. In spite of his best efforts, the thinnest sheet he could attain by this method was still pretty thick (about  $10\ \mu\text{m}$ ).

In a breakthrough moment, a colleague brought Geim a piece of scotch tape that had been adhered to a graphite surface and then removed. The tape had remnants of graphite stuck to it. When Geim examined the graphite flakes under a microscope, he realized that these flakes were much thinner than those his graduate student was able to produce through polishing. In fact, some of the flakes were just one layer thick! Over the next several months, Geim and his colleagues were able to isolate these flakes and measure some of their properties. In 2004, Geim and his colleagues published their results—the discovery of atomically thin carbon—in *Nature*. In 2010, Geim and his closest collaborator on the project, Konstantin Novoselov, were awarded the Nobel Prize in Physics for “ground-breaking experiments regarding the two-dimensional material graphene.”

Graphene has been right under our noses for some time. Every time you write with a pencil, layers of graphite flake onto the paper, leaving the familiar gray trail. That trail undoubtedly also contains flakes of graphene—too small to see. Geim and Novoselov were able to see what others had missed and as a result, discovered a new wonder material. These kinds of discoveries often have huge impacts on society—although it may take decades to realize and refine their applications.

In this chapter, we look into the world of solids and materials and see how they permanently changed societies, just as graphene may someday change our present society. For example, the discovery of cement led to a revolution in building, the discovery of porcelain led to a revolution in dishware, and the discovery of semiconducting materials made possible the computer and Internet revolution which is still unfolding today. The development of new materials continues to be an active and growing area of research. We begin by examining a technique to determine the structure of solids.

▲ The hexagonal shape of a snowflake derives from the hexagonal arrangement of water molecules in crystalline ice.

## 12.2 X-Ray Crystallography

In Section 11.2, we discussed the differences between solids, liquids, and gases. Recall that solids can be *crystalline* (composed of atoms or molecules arranged in structures with long-range order) or *amorphous* (composed of atoms or molecules with no long-range order). If you have ever visited the mineral section of a natural history museum and seen crystals with smooth faces and well-defined angles, or if you have carefully observed the hexagonal shapes of snowflakes, you have witnessed some of the effects of the underlying long-range order in crystalline solids. The beautiful geometric shapes that are visible on the macroscopic scale are the result of specific structural patterns on the molecular and atomic scales. But how do we study these patterns? How do we look into the atomic and molecular world to determine the arrangement of the atoms and measure the distances between them? In this section, we examine **X-ray diffraction**, a powerful laboratory technique that enables us to do exactly that.

In Section 7.2 we saw that electromagnetic waves (light waves) interact with each other in a characteristic way called *interference*: they can cancel each other out or reinforce each other, depending on the alignment of their crests and troughs. *Constructive interference* occurs when two waves interact with their crests and troughs in alignment. *Destructive interference* occurs when two waves interact with the crests of one aligning with the troughs of the other. Recall also that when light encounters two slits separated by a distance comparable to the wavelength of the light, constructive and destructive interference produces a characteristic *interference pattern*, consisting of alternating bright and dark lines.

Atomic planes within crystals are separated by about  $10^2$  pm. As a result, light of similar wavelength (which happens to fall in the X-ray region of the electromagnetic spectrum) forms interference patterns or *diffraction patterns* when it interacts with those atoms. The exact pattern of diffraction reveals the spacing between planes of atoms.

Consider two planes of atoms within a crystalline lattice separated by a distance  $d$ , as illustrated in Figure 12.1. If two rays of light with wavelength  $\lambda$  that are initially in phase (that is, the crests of one wave are aligned with the crests of the other) diffract from the two planes, the diffracted rays may interfere with each other constructively or destructively, depending on the difference between the path lengths traveled by each ray. If the difference between the two path lengths ( $2a$ ) is an integral number ( $n$ ) of wavelengths, then the interference is constructive:

$$n\lambda = 2a \quad (\text{criterion for constructive interference}) \quad [12.1]$$

**FIGURE 12.1 Diffraction from a Crystal** When X-rays strike parallel planes of atoms in a crystal, constructive interference occurs if the difference in path length between beams reflected from adjacent planes is an integral number of wavelengths.

Using trigonometry, we can determine that constructive interference occurs when the angle of reflection ( $\theta$ ) is related to the distance  $a$  and the separation between layers ( $d$ ) by the following relation:

$$\sin \theta = \frac{a}{d} \quad [12.2]$$

Rearranging, we get:

$$a = d \sin \theta \quad [12.3]$$

By substituting Equation 12.3 into Equation 12.1, we arrive at the following important relationship:

$$n\lambda = 2d \sin \theta \quad \text{Bragg's law}$$

This equation is *Bragg's law*. For a given wavelength of light incident on atoms arranged in layers, we can measure the angle that produces constructive interference (which appears as a bright spot on the X-ray diffraction pattern) and then calculate  $d$ , the distance between the atomic layers:

$$d = \frac{n\lambda}{2 \sin \theta} \quad [12.4]$$

**► FIGURE 12.2 X-Ray Diffraction Analysis**

In X-ray crystallography, an X-ray beam is passed through a sample, which is rotated to allow diffraction from different crystalline planes. The resulting patterns, representing constructive interference from various planes, are analyzed to determine crystalline structure.

In a modern X-ray diffractometer (Figure 12.2▲), a computer collects and analyzes the diffraction pattern from a crystal. By rotating the crystal and collecting the resulting diffraction patterns at different angles, the distances between various crystalline planes can be measured, eventually yielding the entire crystalline structure. This process is **X-ray crystallography**.

Researchers use X-ray crystallography to determine not only the structures of simple atomic lattices, but also the structures of proteins, DNA, and other biologically important molecules. For example, the famous X-ray diffraction photograph shown in the margin, obtained by Rosalind Franklin (1920–1958) and Maurice Wilkins (1916–2004), helped Watson and Crick determine the double-helical structure of DNA. Recall from Section 9.1 that researchers also used X-ray diffraction to determine the structure of HIV protease, a protein critical to the reproduction of HIV and the development of AIDS. Knowledge of that structure was then employed to design drug molecules to inhibit the action of HIV protease and halt the advance of the disease.

**Example 12.1 Using Bragg's Law**

When an X-ray beam of  $\lambda = 154 \text{ pm}$  is incident on the surface of an iron crystal, it produces a maximum diffraction at an angle of  $\theta = 32.6^\circ$ . Assuming  $n = 1$ , calculate the separation between layers of iron atoms in the crystal.

**SOLUTION**

To solve this problem, use Bragg's law in the form given by Equation 12.4. The distance,  $d$ , is the separation between layers in the crystal.

$$\begin{aligned} d &= \frac{n\lambda}{2 \sin \theta} \\ &= \frac{154 \text{ pm}}{2 \sin(32.6^\circ)} \\ &= 143 \text{ pm} \end{aligned}$$

**FOR PRACTICE 12.1** The spacing between layers of molybdenum atoms is 157 pm. Calculate the angle at which 154-pm X-rays produce a maximum reflection for  $n = 1$ .

## 12.3 Unit Cells and Basic Structures

Unit Cells: Simple Cubic,  
Body-Centered Cubic, and  
Face-Centered Cubic

X-ray crystallography allows us to determine the regular arrangements of atoms within a crystalline solid. This arrangement is called the **crystalline lattice**. The crystalline lattice of any solid is nature's way of aggregating the particles to minimize their energy. We represent the crystalline lattice with a small collection of atoms, ions, or molecules called the **unit cell**. When the unit cell is repeated over and over—like the tiles of a floor or the pattern in a wallpaper design, but in three dimensions—the entire lattice is reproduced. For example, consider the two-dimensional crystalline lattice shown here:

The unit cell for this lattice is the dark-colored square. Each circle represents an atom, ion, or molecule. Repeating the pattern in the square throughout the two-dimensional space generates the entire lattice.

### Cubic Unit Cells

Many different unit cells exist, and we often classify unit cells by their symmetry. Figure 12.3▼ shows the different fundamental types of unit cells. In this book, we focus primarily on *cubic unit cells* (although we look at one hexagonal unit cell). Cubic unit cells are characterized by equal edge lengths and  $90^\circ$  angles at their corners. Figure 12.4► on the next page lists three cubic unit cells—simple cubic, body-centered cubic, and face-centered cubic—along with some of their basic characteristics. The two colors in the images in this table make it easier to visualize the different positions of the atoms; the colors *do not* represent different *kinds* of atoms. For these unit cells, *each atom in any one structure is identical to the other atoms in that structure*.

▲ **FIGURE 12.3** The Seven Fundamental Types of Unit Cells In this book, we focus on cubic unit cells.

Cubic Cell Name	Atoms per Unit Cell	Structure	Coordination Number	Edge Length in terms of $r$	Packing Efficiency (fraction of volume occupied)
Simple Cubic	1		6	$2r$	52%
Body-Centered Cubic	2		8	$\frac{4r}{\sqrt{3}}$	68%
Face-Centered Cubic	4		12	$2\sqrt{2}r$	74%

Simple cubic

▲ In the simple cubic lattice, the atoms touch along each edge so that the edge length is  $2r$ .

▲ **FIGURE 12.4 Cubic Crystalline Lattices** The different colors used for the atoms in this figure are for clarity only. All atoms within each structure are identical. Unit cells, such as the cubic ones shown here, are customarily portrayed with “whole” atoms, even though only a part of the whole atom may actually be in the unit cell.

The **simple cubic** unit cell (Figure 12.5▼) consists of a cube with one atom at each corner. As we can see in the figure at the left, the atoms touch along each edge of the cube, so the edge length is twice the radius of the atoms ( $l = 2r$ ).

Even though it may seem like the unit cell contains eight atoms, it actually contains only one as close examination of Figure 12.5 makes evident. Each corner atom is shared by eight other unit cells. In other words, any one unit cell actually contains only one-eighth of each of the eight atoms at its corners, for a total of only one atom per unit cell.

Simple Cubic Unit Cell

Coordination number = 6

Atoms per unit cell =  $\frac{1}{8} \times 8 = 1$

▲ **FIGURE 12.5 Simple Cubic Unit Cell**

A characteristic feature of any unit cell is the **coordination number**, the number of atoms with which each atom is in *direct contact*. The coordination number is the number of atoms with which a particular atom can strongly interact. The simple cubic unit cell has a coordination number of 6; any one atom touches only six others, as you can see in Figure 12.5. A quantity closely related to the coordination number is the **packing efficiency**, the percentage of the volume of the unit cell occupied by the spheres. The higher the coordination number is, the greater the packing efficiency is. The simple cubic unit cell has a packing efficiency of 52%—it contains a lot of empty space.

### Example 12.2 Calculating the Packing Efficiency of a Unit Cell

Calculate the packing efficiency of the simple cubic unit cell.

#### SOLUTION

The packing efficiency is defined as the ratio of the volume of the unit cell occupied by atoms to the volume of the unit cell itself all multiplied by 100%.

$$\text{Packing Efficiency} = \frac{V_{\text{atom}}}{V_{\text{unit cell}}} \times 100\%$$

First, determine the volume occupied by atoms. Each unit cell contains one atom, so the volume of the unit cell occupied by atoms is simply the volume of one atom.

$$V_{\text{atom}} = \frac{4}{3}\pi r^3$$

Next, calculate the volume of the cube in terms of the radius of the atom. The volume of a cube is its edge length cubed, and the edge length of the simple cubic unit cell is  $2r$ .

$$\begin{aligned} V_{\text{unit cell}} &= l^3 \\ &= (2r)^3 \\ &= 8r^3 \end{aligned}$$

Calculate the packing efficiency by dividing the volume of the atom by the volume of the unit cell and multiplying by 100%.

$$\begin{aligned} \text{Packing Efficiency} &= \frac{V_{\text{atom}}}{V_{\text{unit cell}}} \times 100\% \\ &= \frac{\frac{4}{3}\pi r^3}{8r^3} \times 100\% \\ &= \frac{\frac{4}{3}\pi r^{\cancel{3}}}{8r^{\cancel{3}}} \times 100\% \\ &= \frac{4}{24}\pi \times 100\% = 52.36\% \end{aligned}$$

**FOR PRACTICE 12.2** Calculate the packing efficiency of the two-dimensional lattice shown here:

The **body-centered cubic** unit cell (Figure 12.6, on the next page) consists of a cube with one atom at each corner and one atom (of the same kind) in the very center of the cube. Note that in the body-centered unit cell, the atoms *do not* touch along each edge of the cube, but instead touch along the diagonal line that runs from one corner,

## Body-Centered Cubic Unit Cell

Coordination number = 8

 Atoms per unit cell =  
 $\left(\frac{1}{8} \times 8\right) + 1 = 2$ 

**▲ FIGURE 12.6 Body-Centered Cubic Crystal Structure** The different colors used for the atoms in this figure are for clarity only. All atoms within the structure are identical.

through the middle of the cube, to the opposite corner. The edge length in terms of the atomic radius is therefore  $l = 4r/\sqrt{3}$  as shown here:

Body-centered cubic

$$\begin{aligned}
 c^2 &= b^2 + l^2 & b^2 &= l^2 + l^2 \\
 (4r)^2 &= 2l^2 + l^2 & b^2 &= 2l^2 \\
 (4r)^2 &= 3l^2 \\
 l^2 &= \frac{(4r)^2}{3} \\
 l &= \frac{4r}{\sqrt{3}}
 \end{aligned}$$

► In the body-centered cubic lattice, the atoms touch only along the cube diagonal. The edge length is  $4r/\sqrt{3}$ .

The body-centered unit cell contains two atoms per unit cell because the center atom is not shared with any other neighboring cells. The coordination number of the body-centered cubic unit cell is 8, which we can see by examining the atom in the very center of the cube, which touches eight atoms at the corners. The packing efficiency for the body-centered unit cell is 68%, significantly higher than for the simple cubic unit cell. Each atom in this structure strongly interacts with more atoms than each atom in the simple cubic unit cell.

### Example 12.3 Relating Unit Cell Volume, Edge Length, and Atomic Radius

A body-centered cubic unit cell has a volume of  $4.32 \times 10^{-23} \text{ cm}^3$ . Find the radius of the atom in pm.

**SORT** You are given the volume of a unit cell and asked to find the radius of the atom.

**STRATEGIZE** Use the given volume to find the edge length of the unit cell.

Then use the edge length to determine the radius of the atom.

**GIVEN:**  $V = 4.32 \times 10^{-23} \text{ cm}^3$

**FIND:**  $r$  (in pm)

**CONCEPTUAL PLAN**

	<b>RELATIONSHIPS USED:</b> $V = l^3$ (Volume of a cube) $l = \frac{4r}{\sqrt{3}}$ (Edge length of body-centered cubic unit cell)
<b>SOLVE</b> Solve the equation for the volume of a cube for $l$ and substitute in the given value for $V$ to find $l$ .  Solve the equation for the edge length of a body-centered cubic unit cell for $r$ and substitute in the value of $l$ (from the previous step) to find $r$ .  Convert $r$ from cm to m and then to pm.	<b>SOLUTION</b> $V = l^3$ $l = \sqrt[3]{V} = \sqrt[3]{4.32 \times 10^{-23} \text{ cm}^3} = 3.5088 \times 10^{-8} \text{ cm}$ $l = \frac{4r}{\sqrt{3}}$ $r = \frac{\sqrt{3}l}{4} = \frac{\sqrt{3}(3.5088 \times 10^{-8} \text{ cm})}{4} = 1.5193 \times 10^{-8} \text{ cm}$ $1.5193 \times 10^{-8} \text{ cm} \times \frac{0.01 \text{ m}}{1 \text{ cm}} \times \frac{1 \text{ pm}}{10^{-12} \text{ m}} = 152 \text{ pm}$
<b>CHECK</b> The units of the answer (pm) are correct. The magnitude is reasonable because atomic radii range roughly from 50 to 200 pm.	
<b>FOR PRACTICE 12.3</b> An atom has radius of 138 pm and crystallizes in the body-centered cubic unit cell. What is the volume of the unit cell in $\text{cm}^3$ ?	

The **face-centered cubic** unit cell (Figure 12.7▼) is a cube with one atom at each corner and one atom (of the same kind) in the center of each cube face. Note that in the face-centered unit cell (like the body-centered unit cell), the atoms *do not* touch along each edge of the cube. Instead, the atoms touch *along the face diagonal*. The edge length in terms of the atomic radius is therefore  $l = 2\sqrt{2}r$ , as shown here.

► In the face-centered cubic lattice, the atoms touch along a face diagonal. The edge length is  $2\sqrt{2}r$ .

$$\begin{aligned}
 b^2 &= l^2 + l^2 = 2l^2 \\
 (4r)^2 &= 2l^2 \\
 l^2 &= \frac{(4r)^2}{2} \\
 l &= \frac{4r}{\sqrt{2}} \\
 &= 2\sqrt{2}r
 \end{aligned}$$

Face-centered cubic
