Coordination number = 12

$$\text{Atoms/unit} = \left(\frac{1}{8} \times 8\right) + \left(\frac{1}{2} \times 6\right) = 4$$

▲ **FIGURE 12.7 Face-Centered Cubic Crystal Structure**  
 The different colors used on the atoms in this figure are for clarity only. All atoms within the structure are identical.

The face-centered unit cell contains four atoms per unit cell because the center atoms on each of the six faces are shared between two unit cells. There are  $\frac{1}{2} \times 6 = 3$  face-centered atoms plus  $\frac{1}{8} \times 8 = 1$  corner atom, for a total of four atoms per unit cell. The coordination number of the face-centered cubic unit cell is 12, and its packing efficiency is 74%. In this structure, any one atom strongly interacts with more atoms than the atoms in either the simple cubic unit cell or the body-centered cubic unit cell.

### Example 12.4 Relating Density to Crystal Structure

Aluminum crystallizes with a face-centered cubic unit cell. The radius of an aluminum atom is 143 pm. Calculate the density of solid crystalline aluminum in  $\text{g/cm}^3$ .

**SORT** You are given the radius of an aluminum atom and its crystal structure. You are asked to find the density of solid aluminum.

**GIVEN:**  $r = 143 \text{ pm}$ , face-centered cubic

**FIND:**  $d$

**STRATEGIZE** The conceptual plan is based on the definition of density.

Since the unit cell has the physical properties of the entire crystal, you can find the mass and volume of the unit cell and use these to calculate its density.

**CONCEPTUAL PLAN**

$$d = m/V$$

$m$  = mass of unit cell

= number of atoms in unit cell  $\times$  mass of each atom

$V$  = volume of unit cell

= (edge length)<sup>3</sup>

**SOLVE** Begin by finding the mass of the unit cell. Determine the mass of an aluminum atom from its molar mass. Because the face-centered cubic unit cell contains four atoms per unit cell, multiply the mass of aluminum by 4 to get the mass of a unit cell.

**SOLUTION**

$$\begin{aligned} m(\text{Al atom}) &= 26.98 \frac{\text{g}}{\text{mol}} \times \frac{1 \text{ mol}}{6.022 \times 10^{23} \text{ atoms}} \\ &= 4.480 \times 10^{-23} \text{ g/atom} \end{aligned}$$

$$\begin{aligned} m(\text{unit cell}) &= 4 \text{ atoms}(4.480 \times 10^{-23} \text{ g/atom}) \\ &= 1.792 \times 10^{-22} \text{ g} \end{aligned}$$

Next, calculate the edge length ( $l$ ) of the unit cell (in m) from the atomic radius of aluminum. For the face-centered cubic structure,  $l = 2\sqrt{2}r$ .

$$\begin{aligned} l &= 2\sqrt{2}r \\ &= 2\sqrt{2}(143 \text{ pm}) \\ &= 2\sqrt{2}(143 \times 10^{-12} \text{ m}) \\ &= 4.045 \times 10^{-10} \text{ m} \end{aligned}$$

Calculate the volume of the unit cell (in  $\text{cm}^3$ ) by converting the edge length to cm and cubing the edge length. (Use centimeters because you want to report the density in units of  $\text{g/cm}^3$ .)

$$\begin{aligned} V &= l^3 \\ &= \left( 4.045 \times 10^{-10} \text{ m} \times \frac{1 \text{ cm}}{10^{-2} \text{ m}} \right)^3 \\ &= 6.618 \times 10^{-23} \text{ cm}^3 \end{aligned}$$

Finally, calculate the density by dividing the mass of the unit cell by the volume of the unit cell.

$$\begin{aligned} d &= \frac{m}{V} = \frac{1.792 \times 10^{-22} \text{ g}}{6.618 \times 10^{-23} \text{ cm}^3} \\ &= 2.71 \text{ g/cm}^3 \end{aligned}$$

**CHECK** The units of the answer are correct. The magnitude of the answer is reasonable because the density is greater than  $1 \text{ g/cm}^3$  (as you would expect for metals), but still not too high (because aluminum is a low-density metal).

**FOR PRACTICE 12.4** Chromium crystallizes with a body-centered cubic unit cell. The radius of a chromium atom is 125 pm. Calculate the density of solid crystalline chromium in  $\text{g/cm}^3$ .

## Closest-Packed Structures

Another way to envision crystal structures, especially useful for metals, in which bonds are not usually directional, is to think of the atoms as stacking in layers, much as fruit is stacked at the grocery store. For example, we can envision the simple cubic structure as one layer of atoms arranged in a square pattern, with the next layer stacking directly over the first, so that the atoms in one layer align exactly on top of the atoms in the layer beneath it, as shown here:

As we saw previously, this crystal structure has a great deal of empty space—only 52% of the volume is occupied by the spheres, and the coordination number is 6.

More space-efficient packing can be achieved by aligning neighboring rows of atoms in a pattern, with one row offset from the next by one-half a sphere, as shown here:

In this way, the atoms pack more closely to each other in any one layer. We can further increase the packing efficiency by placing the next layer *not directly on top of the first*, but again offset so that any one atom actually sits in the indentation formed by three atoms in the layer beneath it, as shown here:

This kind of packing leads to two different crystal structures called *closest-packed structures*, both of which have a packing efficiency of 74% and a coordination number of 12. In the first of these two closest-packed structures—called **hexagonal closest packing**—the third layer of atoms aligns exactly on top of the first, as shown here:

Hexagonal closest packing

### Hexagonal Closest Packing

**FIGURE 12.8** Hexagonal Closest-Packing Crystal Structure The unit cell is outlined in bold.

The pattern from one layer to the next is ABAB, with the third layer aligning exactly above the first. Notice that the central atom in layer B of this structure is touching six atoms in its own layer, three atoms in the layer above it, and three atoms in the layer below, for a coordination number of 12. The unit cell for this crystal structure is not a cubic unit cell, but a hexagonal one, shown in Figure 12.8◀.

In the second of the two closest-packed structures—called **cubic closest packing**—the third layer of atoms is offset from the first, as shown here:

The pattern from one layer to the next is ABCABC, with every fourth layer aligning with the first. Although not simple to visualize, the unit cell for cubic closest packing is the face-centered cubic unit cell, shown in Figure 12.9▶. The cubic closest-packed structure is identical to the face-centered cubic unit cell structure.

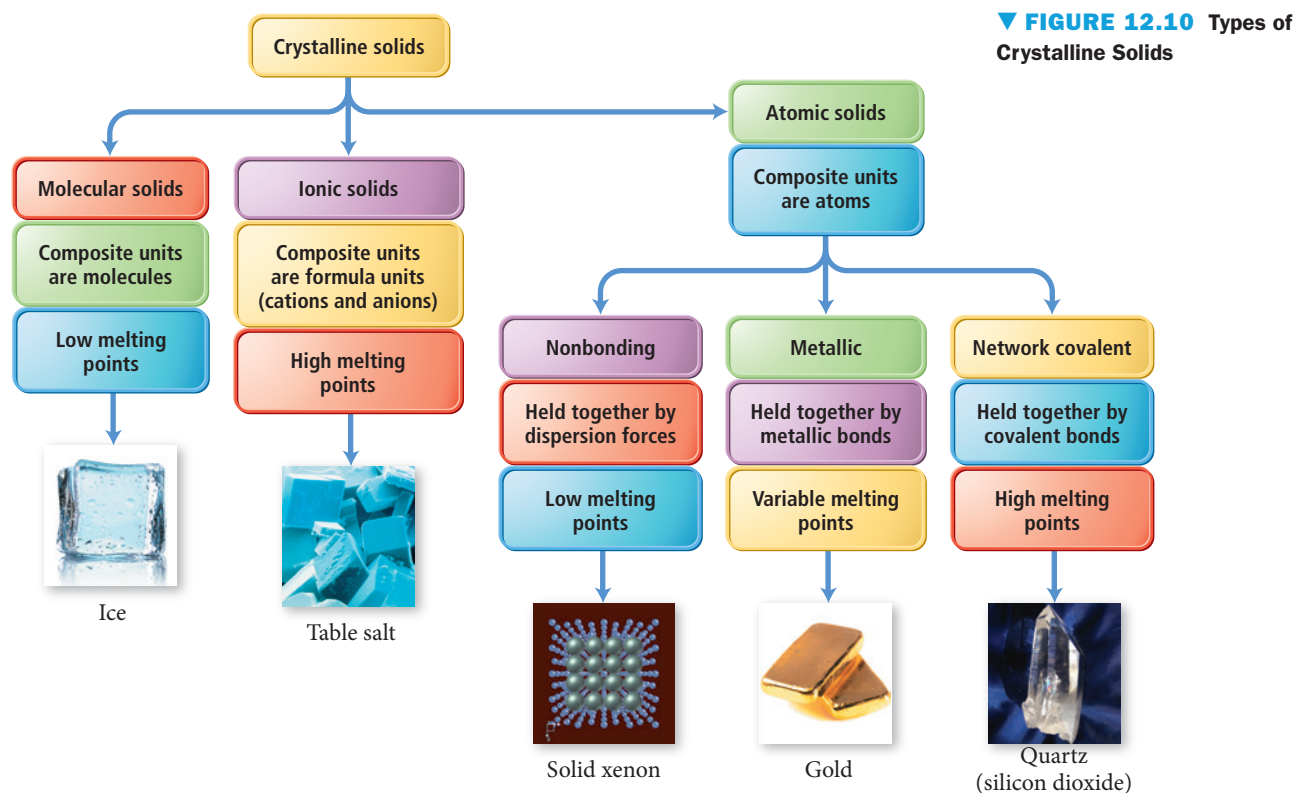

### Cubic Closest Packed = Face-Centered Cubic

**FIGURE 12.9** Cubic Closest-Packing Crystal Structure The unit cell of the cubic closest-packed structure is a face-centered cubic.

## 12.4 The Fundamental Types of Crystalline Solids

We examined some of the basic *structures* of crystalline solids in Section 12.3. In this section, we turn to the different *types* of crystalline solids. We can classify crystalline solids into three categories—molecular, ionic, and atomic—based on the individual particles that compose the solid. Atomic solids can themselves be classified into three categories—nonbonded, metallic, and network covalent—depending on the types of interactions between atoms within the solid. Figure 12.10▶ shows the different categories of crystalline solids.

## Molecular Solids

**Molecular solids** are solids in which the composite particles are *molecules*. The unit cells in a crystalline molecular solid are therefore occupied by molecules. Ice (solid  $\text{H}_2\text{O}$ ) and dry ice (solid  $\text{CO}_2$ ) are examples of molecular solids. Molecular solids are held together by the kinds of intermolecular forces—dispersion forces, dipole–dipole forces, and hydrogen bonding—discussed in Chapter 11. Although molecular solids as a whole tend to have low to moderately low melting points, their specific properties depend on the types of intermolecular forces between the molecules as well as the structure of the molecule and the crystal structure of the solid. For example, benzene and toluene have similar molar masses and similar intermolecular forces (dispersion forces):

Compound	Structure	Molar Mass	Type of Intermolecular Force	Melting Point of Solid
Benzene ( $\text{C}_6\text{H}_6$ )		78.11 g/mol	Dispersion	5.5 °C
Toluene ( $\text{C}_7\text{H}_8$ )		92.14 g/mol	Dispersion	−95.5 °C

Polymorphism can exist in any crystalline material, not just molecular solids.

However, the extra  $\text{—CH}_3$  group on toluene prevents the molecules from packing as efficiently in the crystal as they do in benzene. The result is that, even though toluene has a higher molar mass than benzene, it has a much lower melting point.

Some molecular solids crystallize in different structures called **polymorphs**. The different crystal structures can have different properties, including different melting points and solubilities (see *Chemistry in Your Day: Chocolate, An Edible Material*). Polymorphism is important in pharmaceuticals because different forms of a drug can have different physiological activities. For example, ritonavir was among the first drugs found to be effective in treating HIV and AIDS. When it was first discovered and approved for use, only one polymorph was known. However, soon after its widespread use, a second polymorph was discovered. This second polymorph was more stable, less water-soluble, and much less physiologically active. Even worse, small amounts of this second polymorph in a sample could convert the active polymorph into the less active one. The drug manufacturer had to halt production of ritonavir until researchers solved the problem by switching from a capsule form to a refrigerated gelcap form and later to a stable tablet form.

Chemistry IN YOUR DAY | Chocolate, An Edible Material

Chocolate is an edible and delicious material designed to please your senses. Good chocolate has a smooth and shiny surface, snaps when you break it, and melts in your mouth, releasing its delicious combination of flavors and texture. Like all materials, chocolate's properties depend on its structure. The main structural ingredient in chocolate is cocoa butter, a triglyceride. We examine triglycerides more carefully in Chapter 22, but for now, just know that triglycerides are long organic molecules, which means that chocolate is a crystalline molecular solid. Many crystalline molecular solids only have one crystalline structure; however, some (including cocoa butter) have several possible crystalline structures called polymorphs, each with different properties. Cocoa butter has six possible polymorphs, often called Types I–VI, as shown in Table 12.1. For reference, body temperature is 37 °C.

The most desirable crystalline form of cocoa butter in chocolate is Type V. Types I and II are soft and crumbly and show noticeable blooming. *Blooming* is the white residue that forms on the outside of chocolate. If you have ever let a chocolate bar melt and then re-solidify, you have probably noticed this undesirable residue. Types III and IV are firmer, but they don't have a sharp snap when you break or bite into them. Type V is firm, displays a sharp snap, has a smooth and shiny surface, and tends to melt in your mouth rather than your hand. For this reason, chocolatiers aim for this

▲ The white residue on the surface of the chocolate bon bon on the left is called bloom. The chocolate bon bon on the right has a smooth, shiny surface, characteristic of Type V cocoa butter.

crystal structure. However, this structure is not easy to achieve. If you simply melt chocolate and let it re-solidify, you get a mix of Types I–V with all of their undesirable qualities. Chocolatiers “temper” their chocolate in their quest for primarily Type V characteristics. (Continued on next page.)

TABLE 12.1 Crystalline Forms of Cocoa Butter			
Crystalline Structure Type (Polymorph)	Melting Point (°C)	Description	Increasing Density and Stability
I	17.3	Soft, crumbly, noticeable blooming, melts in the hand.	
II	23.3	Soft, crumbly, noticeable blooming, melts in the hand.	
III	25.5	Firm, poor snap, some blooming, melts in the hand.	
IV	27.3	Firm, poor snap, some blooming, melts in the hand.	
V	33.8	Firm, good snap, smooth and shiny surface, melts in the mouth, most desirable.	
VI	36.3	Hard, some blooming, cannot be formed from melt, takes several months to form.	

Tempering chocolate requires a specific and carefully controlled heating and cooling sequence (Figure 12.11 ▼). First chocolatiers heat the chocolate to melt it. Then they allow it to cool slowly. The slow cooling favors the formation of Type V crystals; however, the other types form as well. The final step is to reheat the chocolate to a temperature just below the melting point of the Type V crystals. This step melts all of the Type I–IV

crystals, leaving only the Type V crystals to act as “seed crystals.”\* A seed crystal is a crystal upon which more of the crystal can grow. Seed crystals have the effect of imposing their own structure on the growing crystalline solid. When the properly tempered chocolate cools, the Type V seed crystals cause the majority of the chocolate to crystallize in the Type V structure, resulting in silky smooth, melt-in-your-mouth, chocolate.

► **FIGURE 12.11 Chocolate Tempering** In order to temper chocolate, chocolate makers heat it carefully. After the tempering sequence is completed, the chocolate can be poured into molds or used as coatings. When the tempered chocolate cools, it is primarily Type V and has a shiny smooth surface.

\*Sometimes solid bits of tempered chocolate are added at this point to act as additional seed crystals.

## Ionic Solids

The composite particles of **ionic solids** are ions. Table salt ( $\text{NaCl}$ ) and calcium fluoride ( $\text{CaF}_2$ ) are examples of ionic solids. The forces holding ionic solids together are strong coulombic forces (or ionic bonds), and because these forces are much stronger than intermolecular forces, ionic solids tend to have much higher melting points than molecular solids. For example, sodium chloride melts at  $801^\circ\text{C}$ , while carbon disulfide ( $\text{CS}_2$ )—a molecular solid with a higher molar mass—melts at  $-110^\circ\text{C}$ . We examine the structure of ionic solids in more detail in Section 12.5.

## Atomic Solids

In **atomic solids** the composite particles are individual atoms. Solid xenon ( $\text{Xe}$ ), iron ( $\text{Fe}$ ), and silicon dioxide ( $\text{SiO}_2$ ) are examples of atomic solids. We classify atomic solids into three categories—*nonbonding atomic solids*, *metallic atomic solids*, and *network covalent atomic solids*—with each type held together by a different kind of force.

### Nonbonding Atomic Solids

**Nonbonding atomic solids** are held together by relatively weak dispersion forces. In order to maximize these interactions, nonbonding atomic solids form closest-packed structures, maximizing their coordination numbers and minimizing the distance between composite units. Nonbonding atomic solids have very low melting points that increase uniformly with molar mass. The only nonbonding atomic solids are noble gases in their solid form. Argon, for example, has a melting point of  $-189^\circ\text{C}$ , and xenon has a melting point of  $-112^\circ\text{C}$ .

### Metallic Atomic Solids

**Metallic atomic solids**, such as iron or gold, are held together by *metallic bonds*, which in the simplest model are represented by the interaction of metal cations with the sea of electrons that surrounds them, as described in Section 9.11 (Figure 12.12 ►).

Because metallic bonds are not directional, many metals tend to form closest-packed crystal structures. For example, nickel crystallizes in the cubic closest-packed structure and zinc crystallizes in the hexagonal closest-packed structure (Figure 12.13 ►, on the next page). Metallic bonds have varying strengths. Some metals, such as mercury,

► **FIGURE 12.12 The Electron Sea Model** In the electron sea model for metals, the metal cations exist in a “sea” of electrons.

► **FIGURE 12.13 Closest-Packed Crystal Structures in Metals** Nickel crystallizes in the cubic closest-packed structure. Zinc crystallizes in the hexagonal closest-packed structure.

have melting points below room temperature, whereas other metals, such as iron, have relatively high melting points (iron melts at 1538 °C).

### Network Covalent Solids

Covalent bonds hold together **network covalent atomic solids**, such as diamond, graphite, and silicon dioxide. The crystal structures of these solids are more restricted by the geometrical constraints of the covalent bonds (which tend to be more directional than intermolecular forces, ionic bonds, or metallic bonds) so they *do not* tend to form closest-packed structures. Network covalent atomic solids have very high melting points because the crystalline solid is held together by covalent bonds. We examine some examples of this class of solids in Section 12.6.

### Example 12.5 Classifying Crystalline Solids

Classify each crystalline solid as molecular, ionic, or atomic.

- (a) Au(s)      (b) CH<sub>3</sub>CH<sub>2</sub>OH(s)      (c) CaF<sub>2</sub>(s)

#### SOLUTION

- (a) Gold (Au) is a metal and is therefore an atomic solid.  
 (b) Ethanol (CH<sub>3</sub>CH<sub>2</sub>OH) is a molecular compound. Solid ethanol is therefore a molecular solid.  
 (c) Calcium fluoride (CaF<sub>2</sub>) is an ionic compound, so it is an ionic solid.

**FOR PRACTICE 12.5** What type of atomic solid is Au(s)?

## CONCEPTUAL CONNECTION 12.2

**Crystalline Solid Types and Melting Points** Which solid would you expect to have the highest melting point?

- (a) MgO(s)      (b) I<sub>2</sub>(s)      (c) Kr(s)

## 12.5 The Structures of Ionic Solids

Many ionic solids have crystalline structures that are closely related to the unit cells that we examined in Section 12.3. However, because ionic compounds necessarily contain both cations and anions, their structures must accommodate the two different types of ions. In an ionic solid, the cations and anions attract one another. The coordination number of the unit cell represents the number of close cation–anion interactions. Because these

interactions lower potential energy, the crystal structure of a particular ionic compound is the structure that maximizes the coordination number while accommodating both charge neutrality (each unit cell must be charge neutral) and the different sizes of the cations and anions that compose the particular compound. In general, the more similar the radii of the cation and the anion, the higher the coordination number.

Cesium chloride (CsCl) is a good example of an ionic compound with cations and anions of similar size ( $\text{Cs}^+$  radius = 167 pm;  $\text{Cl}^-$  radius = 181 pm). In the cesium chloride structure, the chloride ions occupy the lattice sites of a simple cubic cell and one cesium ion lies in the very center of the cell, as shown in Figure 12.14. (Note that in this and subsequent figures of ionic crystal structures, the different colored spheres represent different ions.) The coordination number for cesium chloride is 8, meaning that each cesium ion is in direct contact with eight chloride ions (and vice versa). The cesium chloride unit cell contains one chloride anion ( $8 \times 1/8 = 1$ ) and one cesium cation for a ratio of Cs to Cl of 1:1, as the formula for the compound indicates. (Note that complete chloride ions are shown in Figure 12.14, even though only 1/8 of each ion is in the unit cell.) Calcium sulfide (CaS) has the same structure as cesium chloride.

Sodium chloride is an example of an ionic compound with different ion sizes:  $\text{Na}^+$  (radius = 97 pm) and  $\text{Cl}^-$  (radius = 181 pm). The crystal structure must accommodate the disproportionate sizes. If ion size were the only consideration, the larger chloride anion could theoretically fit many of the smaller sodium cations around it, but charge neutrality requires that each sodium cation be surrounded by an equal number of chloride anions. Therefore, the coordination number is limited by the number of chloride anions that can fit around the relatively small sodium cation. The structure that minimizes the energy is shown in Figure 12.15 and has a coordination number of 6 (each chloride anion is surrounded by six sodium cations and vice versa). We can visualize this structure, called the *rock salt* structure, as chloride anions occupying the lattice sites of a face-centered cubic structure with the smaller sodium cations occupying the holes between the anions. (Alternatively, we can visualize this structure as the *sodium cations* occupying the lattice sites of a face-centered cubic structure with the *larger chloride anions* occupying the spaces between the cations.) Each unit cell contains four chloride anions [ $(8 \times 1/8) + (6 \times 1/2) = 4$ ] and four sodium cations [ $(12 \times 1/4) + 1 = 4$ ], resulting in a ratio of 1:1, as the formula of the compound specifies. Other compounds exhibiting the sodium chloride structure include LiF, KCl, KBr, AgCl, MgO, and CaO.

When there is a greater disproportion between the sizes of the cations and anions in a compound, a coordination number of even 6 is physically impossible. For example, in ZnS ( $\text{Zn}^{2+}$  radius = 74 pm;  $\text{S}^{2-}$  radius = 184 pm) the crystal structure, shown in Figure 12.16, has a coordination number of only 4. We can visualize this structure, called the *zinc blende* structure, as sulfide anions occupying the lattice sites of a face-centered cubic structure with the smaller zinc cations occupying four of the eight tetrahedral holes located directly beneath each corner atom. A tetrahedral hole is the empty space that lies in the center of a tetrahedral arrangement of four atoms, as shown in the figure below. Each unit cell contains four sulfide anions [ $(8 \times 1/8) + (6 \times 1/2) = 4$ ] and four zinc cations (each of the four zinc cations is completely contained within the unit cell), resulting in a ratio of 1:1, just as the formula of the compound indicates. Other compounds that exhibit the zinc blende structure include CuCl, AgI, and CdS.

◀ A tetrahedral hole

When the ratio of cations to anions is not 1:1, the crystal structure must accommodate the unequal number of cations and anions. Many compounds that contain a cation-to-anion ratio of 1:2 adopt the *fluorite* ( $\text{CaF}_2$ ) structure shown in Figure 12.17, on the next page. We can visualize this structure as calcium cations occupying the lattice sites of

Cesium chloride (CsCl)

a face-centered cubic structure with the larger fluoride anions occupying all eight of the tetrahedral holes located directly beneath each corner atom. Each unit cell contains four calcium cations [ $(8 \times \frac{1}{8}) + (6 \times \frac{1}{2}) = 4$ ] and eight fluoride anions (each of the eight fluoride anions is completely contained within the unit cell), resulting in a cation to anion ratio of 1:2, just as in the formula of the compound. Other compounds exhibiting the fluorite structure include  $\text{PbF}_2$ ,  $\text{SrF}_2$ , and  $\text{BaCl}_2$ . Compounds with a cation-to-anion ratio of 2:1 often exhibit the *antifluorite structure*, in which the anions occupy the lattice sites of a face-centered cubic structure and the cations occupy the tetrahedral holes beneath each corner atom.

### CONCEPTUAL CONNECTION 12.3

**Ionic Crystalline Solid Unit Cells** Which compound is most likely to crystallize in the zinc blende structure?

- (a)  $\text{RbCl}$  ( $\text{Rb}^+$  radius = 148 pm;  $\text{Cl}^-$  radius = 181 pm)
- (b)  $\text{MgCl}_2$  ( $\text{Mg}^{2+}$  radius = 65 pm;  $\text{Cl}^-$  radius = 181 pm)
- (c)  $\text{CuI}$  ( $\text{Cu}^+$  radius = 96 pm;  $\text{I}^-$  radius = 216 pm)

## 12.6 Network Covalent Atomic Solids: Carbon and Silicates

As we saw in Section 12.4, network covalent atomic solids are composed of atoms held together by covalent bonds. Because the covalent bonds have to be broken for the solid to melt, network covalent atomic solids have some of the highest melting points of all substances. In this section, we examine two different families of network covalent atomic solids: carbon and silicates.

(a) Graphite

(b) Diamond

▲ **FIGURE 12.18 Network Covalent Atomic Solids** (a) In graphite, carbon atoms are arranged in sheets. Within each sheet, the atoms are covalently bonded to one another by a network of sigma and pi bonds. Neighboring sheets are held together by dispersion forces. (b) In diamond, each carbon atom forms four covalent bonds to four other carbon atoms in a tetrahedral geometry.

### Carbon

Elemental carbon exists in several different forms (or allotropes) including graphene, which we discussed in Section 12.1. Two well-known naturally occurring crystalline forms of carbon are **graphite** and **diamond**. Graphite's structure, shown in Figure 12.18a, consists of flat sheets of carbon atoms covalently bonded together as interconnected hexagonal rings. The bond length between carbon atoms *within a sheet* is 142 pm. However, the forces *between* sheets are much different. There are no covalent bonds between sheets, only relatively weak dispersion forces, and the separation between sheets is 341 pm. Consequently, the sheets slide past each other relatively easily, which explains the slippery feel of graphite and its extensive use as a lubricant. The electrons in the extended pi bonding network within a sheet make graphite a good electrical conductor in the direction of the plane of the sheets. Because of its relative stability and electrical properties, graphite is used for electrodes in electrochemical applications and for heating elements in furnaces.

The density of graphite is  $2.2 \text{ g/cm}^3$ . Under high pressure, the carbon atoms in graphite rearrange to form diamond, which has a higher density of  $3.5 \text{ g/cm}^3$ .

Diamond forms naturally when carbon is exposed to high pressures deep underground. Through movements in Earth's crust, diamond rises toward the surface. Most diamond is found in Africa, mainly in the Congo region and in South Africa. The first synthetic diamonds were produced in the 1940s, using pressures of 50,000 atm and a temperature of 1600 °C. The unit cell for diamond is shown here:

▲ Diamond Unit Cell

▲ Zinc Blende Unit Cell

You can imagine the unit cell for diamond as a face-centered cubic structure with an additional carbon atom in half of the eight tetrahedral holes located directly beneath each corner atom. Notice the similarity between the diamond unit cell and the zinc blende unit cell that we discussed in Section 12.5. Notice also that each carbon atom is covalently bonded to four other carbon atoms at the corners of a tetrahedron. This structure extends throughout the entire crystal, so that a diamond crystal can be thought of as a giant molecule, held together by these covalent bonds.

Because covalent bonds are very strong, diamond has a very high melting point (it is estimated to melt at about 3800 °C). The electrons in diamond are confined to the covalent bonds and are not free to flow. Therefore, diamond does not conduct electricity. Diamond is very hard and is an excellent conductor of heat. Consequently, the largest use of diamonds is for abrasives and cutting tools. Small diamonds are used at the cutting edge of tools, making the edges much harder and giving them a longer life. Natural diamonds are valued as gems for their brilliance and relative inertness.

**Phase Changes and Pressure** Why do high pressures favor the formation of diamond from graphite?

## CONCEPTUAL CONNECTION 12.4

In the 1980s, researchers discovered a new form of carbon when they aimed a powerful laser at a graphite surface. This new form of carbon occurs as soccer-ball-shaped clusters of 60 carbon atoms ( $C_{60}$ ). The atoms form five- and six-membered carbon rings wrapped into a 20-sided icosahedral structure (Figure 12.19 ▼). The compound was named *buckminsterfullerene*, honoring R. Buckminster Fuller (1895–1983), a twentieth-century engineer and architect who advocated the construction of buildings using a structurally strong geodesic dome shape that he patented.

$C_{60}$

◀ **FIGURE 12.19**  $C_{60}$  and a Geodesic Dome The  $C_{60}$  structure resembles Buckminster Fuller's geodesic dome.

Researchers have since identified carbon clusters similar to  $C_{60}$  containing from 36 to over 100 carbon atoms. As a class, these carbon clusters are called **fullerenes** and nicknamed *buckyballs*. At room temperature, fullerenes are black solids similar to graphite—the individual clusters are held to one another by dispersion forces. Fullerenes are somewhat soluble in nonpolar solvents, and the different fullerenes form solutions of different colors.

Researchers have also synthesized long carbon structures called **nanotubes**, which consist of sheets of interconnected  $C_6$  rings that assume the shape of a cylinder (like a roll of chicken wire). The first nanotubes discovered consisted of tubes with double walls of  $C_6$  rings with closed ends. The ends of the tubes can be opened when they are heated under the proper conditions. Today, two general types of nanotubes can be produced: (1) *single-walled nanotubes (SWNT)* that have one layer of interconnected  $C_6$  rings forming the walls and (2) *multiwalled nanotubes (MWNT)* that have concentric layers of interconnected  $C_6$  rings forming the walls. In addition, researchers have been able to form *nanoribbons* by slicing open nanotubes. As we discussed in Section 12.1, carbon can also form graphene, long, extended sheets of carbon atoms just one atom thick. These carbon structures are all shown in Figure 12.20 ▼.

(a) Single-walled nanotube (SWNT)

(b) Multiwalled nanotube (MWNT)

(c) Graphene nanoribbon

(d) Graphene sheet

► **FIGURE 12.20 Carbon Structures** include: (a) a single-walled nanotube; (b) a multiwalled nanotube; (c) a graphene nanoribbon; (d) a graphene sheet.

Nanotubes are 100 times stronger than steel and only 1/16 as dense. Consequently, we use carbon nanotubes commercially for lightweight applications that require strength, such as golf clubs and bicycle frames. When the nanotubes are lined up parallel to one another, a bundle of the tubes forms a “wire” with very low electrical resistance. These tiny wires raise the possibility of making incredibly small electronic devices.

## Silicates

The **silicates** (extended arrays of silicon and oxygen) are the most common network covalent solids. Geologists estimate that 90% of Earth’s crust is composed of silicates. Silicon and oxygen form a network covalent structure in which a silicon atom bonds to four oxygen atoms, assuming a tetrahedral shape with the silicon atom in the middle and the four oxygen atoms at the corners of the tetrahedron (Figure 12.21▶).

In this structure, the silicon atom bonds to each oxygen atom with a single covalent sigma bond. In contrast to carbon, which often bonds to oxygen with a double bond (one sigma and one pi bond), silicon typically forms only a single bond with oxygen because the silicon atom is too large to allow substantial overlap between the *p*-orbitals on the two atoms. The silicon atom in this structure, by bonding to four oxygen atoms, obtains a complete octet. However, each oxygen atom is one electron short of an octet. Therefore, each O atom forms a second covalent bond to a different Si atom, resulting in the three-dimensional structure of **quartz**. Quartz has a formula unit of  $\text{SiO}_2$  and is generally called **silica**. In silica, each Si atom is in a tetrahedron surrounded by four O atoms, and each O atom acts as a bridge connecting the corners of two tetrahedrons (Figure 12.22▶). See Section 23.3 for a more extended discussion of silicate structures.

▲ **FIGURE 12.21**  $\text{SiO}_4$

**Tetrahedron** In an  $\text{SiO}_4$  tetrahedron, silicon occupies the center of the tetrahedron, and one oxygen atom occupies each corner.

**Quartz** In the quartz structure, each Si atom is in a tetrahedron surrounded by four O atoms, and each O atom is a bridge connecting the corners of two tetrahedrons.

## 12.7 Ceramics, Cement, and Glass

The silicate structures we examined in Section 12.6 are common in ceramics, cement, and glass. These substances are used in buildings, electrical devices, pottery, and kitchenware. If you look around wherever you are sitting at this moment, you are likely to see examples of these materials. In this section of the chapter, we examine each of these amazing classes of materials individually.

### Ceramics

**Ceramics** are traditionally defined as inorganic nonmetallic solids that are prepared from powders usually mixed with water, formed into the desired shape and then heated. Ceramics are extensively used to make bricks, tiles, pottery, dishware, and insulating elements in electrical devices. They display a range of properties but are usually hard, strong, nonconductive, and brittle. The word “ceramics” originates from the Greek *keramikos*. *Keramikos* is an area of Athens that was the potters’ quarter of the city, and the Greeks were among the first accomplished potters. However, pottery itself predates recorded history. The oldest known example is the Venus of Dolni, a figurine that dates to 29,000–25,000 BCE. Ceramics can be categorized into three types: silicate, oxide, and nonoxide.

### Silicate Ceramics

Many ceramics are composed of aluminosilicates, a class of minerals in which some of the silicon atoms in the silicate structure are replaced by aluminum (see Section 23.3). The weathering of naturally occurring aluminosilicates produces **clays**, which are essentially powdered forms of the minerals mixed with water. When heated, reactions occur that transform the clay into the ceramic substance.

For example, the clay kaolinite,  $\text{Al}_2\text{Si}_2\text{O}_5(\text{OH})_4$ , undergoes irreversible chemical and structural changes when heated (or fired) above 1500 °C. These changes transform the clay into a white ceramic solid containing an extended network of Si-O and Al-O tetrahedra. Kaolinite is the most important component of porcelain, a ceramic substance that

▲ The Venus of Dolni, the oldest known ceramic object, dates to 29,000–25,000 BCE. It was discovered in 1925 in the Czech Republic.

▲ Ceramic electrical insulator

▲ Aluminum oxide crucible, a container in which substances can be subjected to high temperatures.

originated in China during the Han dynasty about 2000 years ago. Chinese porcelain was superior to previous ceramics and became highly valued and prized for its beauty and durability, especially when formed into cups for drinking tea. The Chinese profitably exported their porcelain wares to the Middle East and the West and kept their recipe for making it a secret for hundreds of years. The term *china* today still refers to the fine plates, saucers, and cups made from porcelain and related ceramic materials. Silicate ceramics also find extensive use as insulators in electrical applications.

### Oxide Ceramics

Among the most common oxide ceramics are  $\text{Al}_2\text{O}_3$  and  $\text{MgO}$ . These materials demonstrate the advantages and disadvantages of ceramic materials compared to metals.  $\text{Al}_2\text{O}_3$  melts at  $2072^\circ\text{C}$ , compared to aluminum metal, which melts at  $660^\circ\text{C}$ .  $\text{MgO}$  melts at an even higher temperature ( $2852^\circ\text{C}$ ). Both are physically and chemically stable at high temperatures. The high melting point and chemical stability make  $\text{Al}_2\text{O}_3$  and  $\text{MgO}$  outstanding *refractory materials*—materials that can be used in high-temperature applications.

For example, aluminum oxide and magnesium oxide are used in industrial furnaces, high-speed cutting tools, crucibles, heating elements, and fire proofing. Engineers have long desired to take advantage of the high-temperature stability of ceramics to make ceramic engines. A ceramic engine can run at a higher temperature, which makes it more efficient and would require less cooling. However, certain less desirable characteristics of ceramics have made that pursuit difficult. Ceramic materials tend to be brittle and subject to thermal shock (they can crack upon fast changes in temperature). Metals can bend and stretch under stress, but ceramics break. Even though ceramics have found some limited use as components of engines, a completely ceramic mass-produced engine remains elusive.

### Nonoxide Ceramics

The nonoxide ceramics include substances such as  $\text{Si}_3\text{N}_4$ , BN, and SiC. Silicon nitride is a network covalent solid with a structure similar to silica; the silicon atoms sit in the center of nitrogen tetrahedra that are linked. Silicon nitride is used extensively in engine parts and nonmetallic ball bearings. Boron nitride is isoelectronic with  $\text{C}_2$  (BN and  $\text{C}_2$  have the same number of valence electrons) and forms structures similar to carbon. For example, BN can form layered sheets (similar to graphite), which are covalently bound within the sheets but with only dispersion forces between the sheets. As a result, this form of BN makes a good high-temperature lubricant. Another form of boron nitride has the diamond structure, which results in a hard, strong substance similar to diamond. This form of boron nitride is used as an abrasive and to make cutting tools. Boron nitride can even form nanotubes similar to those formed by carbon. Silicon carbide also has a diamond structure, but in silicon carbide, half of the carbon atoms are replaced by silicon atoms. It too finds applications as an abrasive, and it is also used as a refractory material and an additive to steel.

### Cement

Cement was first discovered by the Romans, who used lime, volcanic ash, and clay to make a pourable slurry that hardened into a rocklike substance. The Romans used cement to construct the 43.3-m-diameter dome of the Pantheon, a 2000-year-old edifice. This dome remains the largest unreinforced concrete dome in existence.

The majority of the cement used today is Portland cement. **Portland cement** is a powdered mixture consisting mostly of limestone ( $\text{CaCO}_3$ ) and silica ( $\text{SiO}_2$ ), with smaller amounts of alumina ( $\text{Al}_2\text{O}_3$ ), iron(III) oxide ( $\text{Fe}_2\text{O}_3$ ), and gypsum ( $\text{CaSO}_4 \cdot 2\text{H}_2\text{O}$ ). The powdered mixture reacts with water in a number of complex reactions that produce a final rocklike substance. Unlike clays, which lose water upon setting, Portland cement reacts *with* water as it hardens. The hardening process involves the formation of Si-O-Si bridges that produce fibrous structures. These structures bond strongly to each other (and most other substances). The original Portland cement was patented in 1824 by an English bricklayer named Joseph Aspidin (1788–1855). The hardened cement resembles a prestigious building stone from the Isle of Portland in Southwest England and derives its name from this resemblance.

▲ The Roman Pantheon, still a popular tourist attraction, sits in the center of the ancient heart of Rome.

Portland cement is combined with sand and pebbles to make **concrete**, the most widely used building material in the world. Concrete dramatically revolutionized construction. Before concrete, buildings were made exclusively by arranging the materials piece by piece. With the development of concrete, buildings could literally be poured into place. Concrete is used extensively to make foundations, walls, buildings, bridges, aqueducts, roads, and dams. About half of all the structures humans construct are made of concrete.

## Glass

Silica melts when heated above 1500 °C. After melting, if cooled quickly, silica does not crystallize back into the quartz structure. Instead, the Si atoms and O atoms form a randomly ordered amorphous structure called a **glass**. Silicate glass is transparent, impervious to water, and an outstanding material for making windows and drinking vessels. The Egyptians and Greeks likely made glass objects; however, the Romans in the first century BCE were the first to extensively develop glass making. They discovered that adding sodium carbonate to silica dramatically lowers its melting point, allowing glass to form at much lower temperatures. In addition, they developed glass-blowing, which involves melting glass and then using a tube to blow the glass into spherical shapes.

When  $\text{SiO}_2$  is made into a glass, the result is called **vitreous silica** or **fused silica**. This type of glass is hard, resists high temperatures, has a low thermal expansion, and is transparent to both visible light and ultraviolet light. Vitreous silica (because of the high temperatures required to produce it) is too expensive for most common applications. The most common modern glass is **soda-lime glass**, which is also referred to as *window glass*. Soda-lime glass is about 70%  $\text{SiO}_2$ ; the balance is mostly  $\text{Na}_2\text{O}$  and  $\text{CaO}$ . This type of glass is transparent to visible light (not ultraviolet) and has a high thermal expansion, but it is less expensive to make and form into desired shapes than vitreous silica.

One disadvantage of soda-lime glass is its tendency to crack under thermal shock. Adding boric oxide ( $\text{B}_2\text{O}_3$ ) to the glass mixture instead of  $\text{CaO}$  produces **borosilicate glass** (also known as **Pyrex®**), which expands less when heated. As a result, vessels made of Pyrex® can withstand heating and cooling cycles that would shatter soda-lime glass. The beakers, flasks, and other glassware found in most chemistry labs are made of borosilicate glass.

**Leaded glass** (often called *crystal*, even though it is not a crystal) results when  $\text{PbO}$  is mixed with  $\text{SiO}_2$  and a couple of other minor components. This type of glass has a higher index of refraction (it bends light more than ordinary glass), which results in glassware with a more brilliant appearance than soda-lime glass. It also makes a ringing sound when tapped, which is a common test to distinguish lead crystal from ordinary glass. Recent concerns about the toxicity of lead in leaded glass have led to the development of lead-free alternatives (often called lead-free crystal) for stemware and drinking glasses, which has properties similar to those of leaded glass, but without the negative health risks.

▲ Glass blowing involves blowing air into a hot piece of glass to form spherical shapes.

▲ Leaded glass has a higher index of refraction than ordinary glass, making it appear more brilliant.

The amount of lead that leaches into a drink from leaded glass over a short period of time is likely inconsequential. However, storing drinks in leaded glass for long periods of time can lead to elevated lead levels in the liquid.

## 12.8 Semiconductors and Band Theory

Recall that in Section 12.4 we discussed a model for bonding in metals called the *electron sea model*, which we first introduced and explained in Section 9.11. We now turn to a model for bonding in solids that is both more sophisticated and more broadly applicable—it applies to both metallic solids and covalent solids. The model is **band theory**, and it grows out of molecular orbital theory, first discussed in Section 10.8.

### Molecular Orbitals and Energy Bands

Recall that according to molecular orbital theory, the atomic orbitals of the atoms combine within a molecule to form molecular orbitals. These molecular orbitals are not localized on individual atoms but *delocalized over the entire molecule*. Similarly, in band theory, the atomic orbitals of the atoms within a solid crystal combine to form orbitals that are not localized on individual atoms, but delocalized over the entire *crystal*. In some sense, the crystal is like a very large molecule, and its valence electrons occupy the molecular orbitals formed from the atomic orbitals of each atom in the crystal.

▲ **FIGURE 12.23** **Energy Levels of Molecular Orbitals in Lithium Molecules** When many Li atoms are present, the energy levels of the molecular orbitals are so closely spaced that they fuse to form a band. Half of the orbitals are bonding orbitals and contain valence electrons; the other half are antibonding orbitals and are empty.

Consider a series of molecules constructed from individual lithium atoms. The energy levels of the atomic orbitals and resulting molecular orbitals for Li, Li<sub>2</sub>, Li<sub>3</sub>, Li<sub>4</sub>, and Li<sub>N</sub> (where *N* is a large number on the order of 10<sup>23</sup>) are shown in Figure 12.23◀. The lithium atom has a single electron in a single 2s atomic orbital. The Li<sub>2</sub> molecule contains two electrons and two molecular orbitals. The electrons occupy the lower-energy bonding orbital—the higher-energy, or antibonding, molecular orbital is empty. The Li<sub>4</sub> molecule contains four electrons and four molecular orbitals. The electrons occupy the two bonding molecular orbitals—the two antibonding orbitals are completely empty.

The Li<sub>N</sub> molecule contains *N* electrons and *N* molecular orbitals. However, because there are so many molecular orbitals, the energy spacings between them are infinitesimally small; they are no longer discrete energy levels, but rather they form a *band* of energy levels. One half of the orbitals in the band (*N*/2) are bonding molecular orbitals, and (at 0 K) these orbitals contain the *N* valence electrons; this band is called the **valence band**. The other *N*/2 molecular orbitals are antibonding and (at 0 K) are completely empty; this band is called the **conduction band**. If the atoms composing a solid have *p* orbitals available, then the same process leads to another set of bands at higher energies.

In lithium metal, the highest occupied molecular orbital lies in the middle of a band of orbitals, and the energy difference between it and the next higher-energy orbital is infinitesimally small. Therefore, above 0 K, electrons can easily make the transition from the valence band to the conduction band. Because electrons in the conduction band are mobile, lithium, like all metals, is a good electrical conductor. Mobile electrons in the conduction band are also responsible for the thermal conductivity of metals. When a metal is heated, electrons are excited to higher-energy molecular orbitals. These electrons quickly transport the thermal energy throughout the crystal lattice.

In metals, the valence band and conduction band are energetically continuous—the energy difference between the top of the valence band and the bottom of the conduction band is infinitesimally small. In semiconductors and insulators, however, an energy gap, called the **band gap**, exists between the valence band and conduction band as shown in Figure 12.24▶. Band gaps are usually specified in units of electron volts abbreviated as eV (1 eV = 1.602 × 10<sup>-19</sup>J). In insulators, the band gap is large, and electrons are not promoted into the conduction band at ordinary temperatures, resulting in no electrical conductivity. In semiconductors, the band gap is smaller. As a result, the conductivity of semiconductors increases with increasing temperature because heat allows a greater number of electrons to be thermally promoted into the conduction band.

Recall from Section 2.7 that a semiconductor is a substance of intermediate (and highly temperature-dependent) electrical conductivity.

▶ **FIGURE 12.24** **Band Gap** In a conductor, there is no energy gap between the valence band and the conduction band. In semiconductors there is a small energy gap, and in insulators there is a large energy gap.

The Group 4A elements exhibit a range of band gaps as shown in Table 12.2.

**TABLE 12.2** Band Gap of Group 4A Elements

Group 4A Element	Atomic Radius (pm)	Band Gap	Classification
Carbon (diamond)	77	5.5 eV	Insulator
Silicon	118	1.11 eV	Semiconductor
Germanium	122	0.67 eV	Semiconductor
Tin	140	0.08 eV	Metal
Lead	180	none	Metal

Notice that the band gap decreases as you move down the column of elements. Why? We know from our discussion of periodic properties (see Section 8.6) that atomic radius increases as we move down a column in the periodic table. The increasing radius reduces the overlap between orbitals on neighboring atoms, which in turn reduces the energy difference between the antibonding orbitals (the conduction band) and the bonding orbitals (the valence band). This results in a decreasing band gap as you move down the column of elements.

## Doping: Controlling the Conductivity of Semiconductors

Doped semiconductors contain minute amounts of impurities that result in additional electrons in the conduction band or electron “holes” in the valence band. For example, silicon is a group 4A semiconductor. Its valence electrons just fill its valence band. The band gap in silicon is large enough that only a few electrons are promoted into the conduction band at room temperature; therefore, silicon is a poor electrical conductor. However, silicon can be doped with phosphorus, a group 5A element with five valence electrons, to increase its conductivity. The phosphorus atoms are incorporated into the silicon crystal structure, and each phosphorous atom brings with it one additional electron. Since the valence band is completely full, the additional electrons must go into the conduction band. These electrons are then mobile and can conduct electrical current. This type of semiconductor is an **n-type semiconductor** because the charge carriers are *negatively* charged electrons in the conduction band.

Silicon can also be doped with a group 3A element, such as gallium, which has only three valence electrons. When gallium is incorporated into the silicon crystal structure, gallium atoms trap some of the electrons in silicon’s valence band, resulting in electron “holes,” or empty molecular orbitals, in the valence band. The presence of holes also allows for the movement of electrical current because electrons in the valence band can move between holes. In this way, the holes move in the opposite direction as the electrons. This type of semiconductor is a **p-type semiconductor** because each hole acts as a *positive* charge.

At the heart of most modern electronic devices are silicon chips containing millions of **p-n junctions**, tiny spots that are p-type on one side and n-type on the other. These junctions can serve a number of functions, including acting as **diodes** (circuit elements that allow the flow of electrical current in only one direction) or *amplifiers* (elements that amplify a small electrical current into a larger one).

**Semiconductor Type** Which element would you dope into germanium to create a p-type semiconductor?

- (a) indium                      (b) tin                      (c) arsenic

CONCEPTUAL  
CONNECTION 12.5

## 12.9 Polymers and Plastics

**Polymers** are long, chainlike molecules composed of repeating units called **monomers**. In Chapter 22, we discuss natural polymers such as starches, proteins, and DNA, which play important roles in living organisms. In this section, we learn about synthetic polymers, which we encounter daily in plastic products such as PVC tubing, styrofoam coffee cups, nylon rope, and plexiglass windows. Polymeric materials are common in our everyday lives, found in everything from computers to toys to packaging materials. Most polymers are durable, partly because of the length of their molecules. In general, the longer a molecule, the greater the intermolecular forces between molecules and the higher the melting point and boiling point of the substance. Since breaking or tearing a polymeric material involves either overcoming the intermolecular forces between chains or actually breaking the covalent bonds between monomers, polymers tend to be durable materials.

One of the simplest synthetic polymers is polyethylene. The polyethylene monomer is ethene (also called ethylene):

Ethene monomers react with each other, breaking the double bond between carbons and bonding together to form a long polymer chain:

► **FIGURE 12.25 Polyethylene**  
Plastic milk bottles are made from polyethylene.

Polyethylene is an **addition polymer**, a polymer in which the monomers link together without the elimination of any atoms. Polyethylene is the plastic that is used for milk jugs, juice containers, and garbage bags. The properties of polyethylene depend on the exact structure of the ethylene chain and the resulting structure of the material. Although polymers are generally amorphous, they can have regions of crystallinity. For polyethylene, the degree of crystallinity depends in part on the degree of branching in the chain. High-density polyethylene (HDPE), for example, has little branching, so that the chains can align closer to one another, resulting in high crystallinity, high density, and good strength and heat resistance. Common plastic milk jugs are made of HDPE (Figure 12.25◀). Low-density polyethylene (LDPE), in contrast, has more highly branched chains. This branching prevents the chains from interacting as efficiently, resulting in lower crystallinity, density, and strength and heat resistance. Many common plastic bags are made of LDPE.

Substituted polyethylenes make up an entire class of polymers (Table 12.3). For example, polyvinyl chloride (PVC)—the plastic used to make certain kinds of pipes and plumbing fixtures—is composed of monomers in which a chlorine atom has been substituted for one of the hydrogen atoms in ethene (Figure 12.26▶). These monomers, which are shown here, react to form PVC:

► **FIGURE 12.26 Polyvinyl Chloride**  
Polyvinyl chloride is used for many plastic plumbing supplies, such as pipes and connectors.

Some polymers—called *copolymers*—consist of two different kinds of monomers. For example, the monomers that compose nylon 6,6 are hexamethylenediamine and adipic acid. These two monomers add together via a condensation reaction as follows:

Dimer

**TABLE 12.3** Polymers of Commercial Importance

Polymer	Structure	Uses
<b>Addition Polymers</b>		
Polyethylene	$-(\text{CH}_2-\text{CH}_2)_n-$	Films, packaging, bottles
Polypropylene	$\left[ \begin{array}{c} \text{CH}_2-\text{CH}_2 \\   \\ \text{CH}_3 \end{array} \right]_n$	Kitchenware, fibers, appliances
Polystyrene	$\left[ \begin{array}{c} \text{CH}_2-\text{CH} \\   \\ \text{C}_6\text{H}_5 \end{array} \right]_n$	Packaging, disposable food containers, insulation
Polyvinyl chloride	$\left[ \begin{array}{c} \text{CH}_2-\text{CH} \\   \\ \text{Cl} \end{array} \right]_n$	Pipe fittings, clear film for meat packaging
<b>Condensation Polymers</b>		
Polyurethane	$\left[ \begin{array}{c} \text{C}-\text{NH}-\text{R}-\text{NH}-\text{C}-\text{O}-\text{R}'-\text{O} \\    \qquad \qquad \qquad    \\ \text{O} \qquad \qquad \qquad \text{O} \end{array} \right]_n$ R, R' = $-\text{CH}_2-\text{CH}_2-$ (for example)	"Foam" furniture stuffing, spray-on insulation, automotive parts, footwear, water-protective coatings
Polyethylene terephthalate (a polyester)	$\left[ \text{O}-\text{CH}_2-\text{CH}_2-\text{O}-\text{C}(=\text{O})-\text{C}_6\text{H}_4-\text{C}(=\text{O}) \right]_n$	Tire cord, magnetic tape, apparel, soda bottles
Nylon 6,6	$\left[ \text{NH}-(\text{CH}_2)_6-\text{NH}-\text{C}(=\text{O})-(\text{CH}_2)_4-\text{C}(=\text{O}) \right]_n$	Home furnishings, apparel, carpet fibers, fish line, polymer blends

The product that forms between the reaction of two monomers is a **dimer**. The polymer (nylon 6,6) forms as the dimer continues to add more monomers. Polymers that eliminate an atom or a small group of atoms during polymerization are **condensation polymers**. Nylon 6,6 and other similar nylons are drawn into fibers and used to make consumer products such as panty hose, carpet fibers, and fishing line (see *Chemistry in Your Day: Kevlar*).

## Chemistry IN YOUR DAY | Kevlar

In 1965, Stephanie Kwolek, working for DuPont to develop new polymer fibers, noticed an odd cloudy product from a polymerization reaction. Some researchers might have rejected the product, but Kwolek insisted on examining its properties more carefully. The results were astonishing—when the polymer was spun into a fiber, it was stronger than any fiber known before. Kwolek had discovered Kevlar, a material that is pound for pound five times stronger than steel.

Kevlar is a condensation polymer featuring aromatic rings and amide linkages:

The polymeric chains within Kevlar crystallize in a parallel arrangement (like dry spaghetti noodles in a box), with strong cross-linking between neighboring chains resulting from hydrogen bonding. The hydrogen bonding occurs between the  $\text{N}-\text{H}$  groups on one chain and the  $\text{C}=\text{O}$  groups on neighboring chains:

This structure is responsible for Kevlar's high strength and its other properties, including fire resistance and chemical resistance (for example, resistance to acids).

Today, DuPont sells hundreds of millions of dollars worth of Kevlar every year. Kevlar is particularly well known for its use in bulletproof vests. This application of Kwolek's discovery has saved thousands of lives. In addition, Kevlar is used to make helmets, radial tires, brake pads, racing sails, suspension bridge cables, skis, and high-performance hiking and camping gear.

▲ Kevlar is used to make bulletproof vests.

## Self-Assessment Quiz

**Q1.** An X-ray beam of  $\lambda = 154 \text{ pm}$  is incident on the surface of an unknown metallic crystal. It produces a maximum diffraction at an angle of  $\theta = 29.1^\circ$ . Assuming  $n = 1$ ,

calculate the separation between layers of metal atoms in the crystal.

- a) 316 pm                      b) 105 pm  
c) 154 pm                      d) 158 pm

**Q2.** How many atoms are in the body-centered cubic unit cell?

- a) 1                      b) 2                      c) 4                      d) 5

- Q3.** What is the coordination number of an atom in a face-centered unit cell?  
a) 4                      b) 6                      c) 8                      d) 12
- Q4.** What is the packing efficiency of the face-centered cubic unit cell?  
a) 52%                      b) 68%                      c) 74%                      d) 88%
- Q5.** What is the edge length of a body-centered cubic unit cell made up of atoms that each has a radius of 168 pm?  
a) 388 pm                      b) 336 pm                      c) 475 pm                      d) 84 pm
- Q6.** Rhodium crystallizes in a face-centered cubic unit cell. The radius of a rhodium atom is 135 pm. Determine the density of rhodium in g/cm<sup>3</sup>.  
a) 3.07 g/cm<sup>3</sup>                      b) 12.4 g/cm<sup>3</sup>  
c) 278 g/cm<sup>3</sup>                      d) 0.337 g/cm<sup>3</sup>
- Q7.** Which type of solid is dry ice (solid carbon dioxide)?  
a) ionic                      b) molecular  
c) atomic                      d) none of the above
- Q8.** Which solid has the highest melting point?  
a) CS<sub>2</sub>(s)                      b) CaF<sub>2</sub>(s)  
c) C<sub>8</sub>H<sub>18</sub>(s)                      d) Ar(s)
- Q9.** Which material is a common oxide ceramic?  
a) N<sub>2</sub>O                      b) Al<sub>2</sub>O<sub>3</sub>                      c) Fe<sub>2</sub>O<sub>3</sub>                      d) CuO
- Q10.** What is the main component of glass?  
a) Al<sub>2</sub>O<sub>3</sub>                      b) SiO<sub>2</sub>                      c) CaF<sub>2</sub>                      d) SiC
- Q11.** Which substance has the greatest band gap?  
a) silicon                      b) germanium  
c) lead                      d) gold
- Q12.** Which element produces a p-type semiconductor when doped into silicon?  
a) Ge                      b) As  
c) Ga                      d) Sb
- Q13.** Which monomer produces the addition polymer shown here?
- $$\begin{array}{ccccccc} \cdots & \text{CH} & - & \text{CH}_2 & - & \text{CH} & - & \text{CH}_2 & - & \text{CH} & \cdots \\ & | & & & & | & & & & | & \\ & \text{F} & & & & \text{F} & & & & \text{F} & \end{array}$$
- (a) H<sub>2</sub>C=CH<sub>2</sub>  
(b)  $\begin{array}{c} \text{HC}=\text{CH}_2 \\ | \\ \text{F} \end{array}$   
(c)  $\begin{array}{c} \text{HC}=\text{CH} \\ | \quad | \\ \text{F} \quad \text{F} \end{array}$

## Key Concepts

### Crystalline Structures (12.2–12.4)

- ▶ X-ray crystallography uses the diffraction pattern of X-rays to determine the crystal structure of solids.
- ▶ The crystal lattice is represented by a unit cell, a structure that reproduces the entire lattice when repeated in all three dimensions.
- ▶ Three basic cubic unit cells are the simple cubic, the body-centered cubic, and the face-centered cubic.
- ▶ Some crystal lattices can also be depicted as closest-packed structures, including the hexagonal closest-packing structure (not cubic) and the cubic closest-packing structure (which has a face-centered cubic unit cell).
- ▶ The basic types of crystal solids are molecular, ionic, and atomic solids. We divide atomic solids into three different types: non-bonded, metallic, and network covalent.

### Ionic Solids (12.5)

- ▶ Unit cells in the structures of ionic solids are charge neutral. The unit cells must also accommodate the difference in size between the anion and cation.
- ▶ Common unit cells for ionic compounds include the sodium chloride unit cell, the zinc blende unit cell, and the calcium fluoride unit cell.

### Network Covalent Atomic Solids (12.6)

- ▶ Network covalent solids are composed of extended arrays of atoms held together by covalent bonds.
- ▶ Common network covalent solids include diamond, graphite, graphene, and silica.

### Ceramics, Cement, and Glass (12.7)

- ▶ Ceramics are inorganic nonmetallic solids that are prepared from powders typically mixed with water, formed into the desired

shape, and then heated. Ceramics are usually hard, strong, nonconductive, and brittle.

- ▶ Cement is a powdered mixture consisting mostly of limestone ( $\text{CaCO}_3$ ) and silica ( $\text{SiO}_2$ ), with smaller amounts of other substances. When cement is mixed with water, it reacts to form a hard, stone-like substance.
- ▶ Glass is primarily amorphous  $\text{SiO}_2$  or silica. Silicate glass is transparent, impervious to water, and an outstanding material for making windows and drinking vessels.

### Semiconductors and Band Theory (12.8)

- ▶ Band theory is a model for bonding in solids in which the atomic orbitals of the atoms are combined and delocalized over the entire crystal solid. In band theory, solids form energy bands that are occupied by electrons.
- ▶ In metals, the valence band (composed of bonding molecular orbitals) is continuous with the conduction band (composed of antibonding molecular orbitals).
- ▶ Semiconductors have a small energy gap—called the band gap—between the valence band and the conduction band.
- ▶ Semiconductors can be doped with small amounts of impurities to modify their conductivity.

### Polymers and Plastics (12.9)

- ▶ Polymers are long, chainlike molecules that consist of repeating units called monomers. They can be natural or synthetic.
- ▶ Polyethylene is an addition polymer, a polymer formed without the elimination of any atoms.
- ▶ Condensation polymers, such as nylon, are formed by the elimination of small groups of atoms.

## Key Equations and Relationships

Bragg's Law: Relationship between Light Wavelength ( $\lambda$ ), Angle of Reflection ( $\theta$ ), and Distance ( $d$ ) between the Atomic Layers (12.2)

$$n\lambda = 2d \sin \theta \quad (n = \text{integer})$$

## Key Learning Outcomes

### CHAPTER OBJECTIVES

Using Bragg's Law in X-Ray Diffraction Calculations (12.2)

### ASSESSMENT

Example 12.1 For Practice 12.1 Exercises 27, 28

Calculating the Packing Efficiency of a Unit Cell (12.3)	Example 12.2	For Practice 12.2	Exercises 31, 32	
Relating Unit Cell Volume, Edge Length, and Atomic Radius (12.3)	Example 12.3	For Practice 12.3	Exercises 33–36	
Relating Density to Crystal Structure (12.3)		Example 12.4	For Practice 12.4	Exercises 37, 38
Classifying Crystalline Solids (12.4)		Example 12.5	For Practice 12.5	Exercises 49, 50

## EXERCISES

### Review Questions

1. What is graphene? Why is graphene unique?
2. Explain the basic principles involved in X-ray crystallography. Include Bragg's law in your explanation.
3. What is a crystalline lattice? How is the lattice represented with the unit cell?
4. Make a drawing of each unit cell: simple cubic, body-centered cubic, and face-centered cubic.
5. For each of the cubic cells in the previous problem, give the coordination number, edge length in terms of  $r$ , and number of atoms per unit cell.
6. What is the difference between hexagonal closest packing and cubic closest packing? What are the unit cells for each of these structures?
7. What are the three basic types of solids and the composite units of each? What types of forces hold each type of solid together?
8. What are the three categories of atomic solids?
9. What kinds of forces hold each of the three basic categories of atomic solids together?
10. What is a polymorph?
11. In an ionic compound, how are the relative sizes of the cation and anion related to the coordination number of the crystal structure?
12. Show how the cesium chloride, sodium chloride, and zinc blende unit cells each contain a cation-to-anion ratio of 1:1.
13. Show how the fluorite structure accommodates a cation-to-anion ratio of 1:2.
14. Name and describe the different allotropes of carbon.
15. What are silicates? What is quartz?
16. What is the definition of a *ceramic*? What are the three categories of ceramics?
17. List the major and minor components of Portland cement. What is the difference between the hardening process of Portland cement and the hardening process of clays?
18. How is concrete made from Portland cement? What advantage does concrete have for building compared to the construction methods that predated the development of concrete?
19. Describe what happens on the molecular level when silica is heated and then cooled to make glass.
20. Describe the difference between vitreous silica and soda-lime glass. What are some advantages and disadvantages of each of these types of glass?
21. In band theory of bonding for solids, what is a *band*? What is the difference between the *valence band* and the *conduction band*?
22. In band theory of bonding for solids, what is a band gap? How does the band gap differ in metals, semiconductors, and insulators?
23. Explain how doping can increase the conductivity of a semiconductor. What is the difference between an n-type semiconductor and a p-type semiconductor?
24. What is the trend in the size of the band gap as you move down the column of the group 4A elements?
25. What is a polymer? What is the difference between a polymer and a copolymer?
26. How do an addition polymer and a condensation polymer differ from each other?

### Problems by Topic

#### Types of Solids and Their Structures

27. An X-ray beam with  $\lambda = 154 \text{ pm}$  incident on the surface of a crystal produced a maximum reflection at an angle of  $\theta = 28.3^\circ$ . Assuming  $n = 1$ , calculate the separation between layers of atoms in the crystal.
28. An X-ray beam of unknown wavelength is diffracted from a NaCl surface. If the interplanar distance in the crystal is  $286 \text{ pm}$ , and the angle of maximum reflection is found to be  $7.23^\circ$ , what is the wavelength of the X-ray beam? (Assume  $n = 1$ .)

29. Determine the number of atoms per unit cell for each metal.

(a) Polonium

(b) Tungsten

(c) Nickel

30. Determine the coordination number for each structure.

(a) Gold

(b) Ruthenium

(c) Chromium

31. Calculate the packing efficiency of the body-centered cubic unit cell. Show your work.

32. Calculate the packing efficiency of the face-centered cubic unit cell. Show your work.

33. Platinum crystallizes with the face-centered cubic unit cell. The radius of a platinum atom is 139 pm. Calculate the edge length of the unit cell and the density of platinum in  $\text{g}/\text{cm}^3$ .

34. Molybdenum crystallizes with the body-centered unit cell. The radius of a molybdenum atom is 136 pm. Calculate the edge length of the unit cell and the density of molybdenum.

35. Rhodium has a density of  $12.41 \text{ g}/\text{cm}^3$  and crystallizes with the face-centered cubic unit cell. Calculate the radius of a rhodium atom.

36. Barium has a density of  $3.59 \text{ g}/\text{cm}^3$  and crystallizes with the body-centered cubic unit cell. Calculate the radius of a barium atom.

37. Polonium crystallizes with a simple cubic structure. It has a density of  $9.3 \text{ g}/\text{cm}^3$ , a radius of 167 pm, and a molar mass of 209 g/mol. Use these data to calculate Avogadro's number (the number of atoms in one mole).

38. Palladium crystallizes with a face-centered cubic structure. It has a density of  $12.0 \text{ g}/\text{cm}^3$ , a radius of 138 pm, and a molar mass of 106.42 g/mol. Use these data to calculate Avogadro's number.

39. Identify each solid as molecular, ionic, or atomic.

- Ar(s)
- $\text{H}_2\text{O}(s)$
- $\text{K}_2\text{O}(s)$
- Fe(s)

40. Identify each solid as molecular, ionic, or atomic.

- $\text{CaCl}_2(s)$
- $\text{CO}_2(s)$
- Ni(s)
- $\text{I}_2(s)$

41. Which solid has the highest melting point? Why?

Ar(s),  $\text{CCl}_4(s)$ , LiCl(s),  $\text{CH}_3\text{OH}(s)$

42. Which solid has the highest melting point? Why?

C(s, diamond), Kr(s), NaCl(s),  $\text{H}_2\text{O}(s)$

43. Which solid in each pair has the higher melting point and why?

- $\text{TiO}_2(s)$  or  $\text{HOOH}(s)$
- $\text{CCl}_4(s)$  or  $\text{SiCl}_4(s)$
- Kr(s) or Xe(s)
- NaCl(s) or CaO(s)

44. Which solid in each pair has the higher melting point and why?

- Fe(s) or  $\text{CCl}_4(s)$
- KCl(s) or HCl(s)
- Ti(s) or Ne(s)
- $\text{H}_2\text{O}(s)$  or  $\text{H}_2\text{S}(s)$

45. An oxide of titanium crystallizes with the unit cell shown here (titanium = gray; oxygen = red). What is the formula of the oxide?

46. An oxide of rhenium crystallizes with the unit cell shown here (rhenium=gray; oxygen=red). What is the formula of the oxide?

47. The unit cells for cesium chloride and barium chloride are shown here. Show that the ratio of cations to anions in each unit cell corresponds to the ratio of cations to anions in the formula of each compound.

48. The unit cells for lithium oxide and silver iodide are shown here. Show that the ratio of cations to anions in each unit cell corresponds to the ratio of cations to anions in the formula of each compound.

49. Identify the structure of each of the two unit cells shown in Problem 47 as the rock salt structure, zinc blende structure, fluorite structure, antifluorite structure, or none of these.
50. Identify the structure of each of the two unit cells shown in Problem 48 as the rock salt structure, zinc blende structure, fluorite structure, antifluorite structure, or none of these.
51. Consider the rock salt structure in Figure 12.15. What type of structure would result if all the anions were somehow removed, leaving only cations?
52. Consider the zinc blende structure in Figure 12.16. What type of structure would result if the remaining tetrahedral sites in the unit cell were also filled with cations?

### Ceramics, Cement, and Glass

53. Classify each of the following as a component of a silicate ceramic, an oxide ceramic, or a nonoxide ceramic.
- a.  $B_4C$                       b.  $Mg_2SiO_4$                       c.  $MoSi_2$

54. Classify each of the following as a component of a silicate ceramic, an oxide ceramic, or a nonoxide ceramic.
- a.  $TiB_2$   
b.  $ZrO_2$   
c.  $NaAlSi_3O_8$
55. What are the name and formula of the compound commonly used in the manufacture of glass to reduce its tendency to crack or shatter under thermal shock?
56. What are the name and formula of the compound commonly used in the manufacture of glass to increase the index of refraction?
57. One of the key components in the manufacture of Portland cement is  $Ca_3SiO_5$ , a compound that is obtained by firing the reactants in a kiln at 1400–1500 °C. Assign an oxidation state to each element in this compound.
58. Replacement of aluminum ions in kaolinite with magnesium ions yields a compound with the formula  $Mg_3Si_2O_5(OH)_4$ . Assign an oxidation state to each element in this compound.

### Semiconductors and Band Theory

59. Which solid would you expect to have little or no band gap?
- a.  $Zn(s)$   
b.  $Si(s)$   
c.  $As(s)$
60. Which solid would you expect to have the largest band gap?
- a.  $As(s)$   
b.  $Sb(s)$   
c.  $Bi(s)$
61. How many molecular orbitals are present in the conduction band of a lithium crystal with a mass of 11.2 g?
62. How many molecular orbitals are present in the valence band of a sodium crystal with a mass of 5.45 g?
63. A substance has a band gap of 6.9 eV at 273 K. Is this substance best classified as an insulator, a semiconductor, or a metal?
64. A substance has a band gap of 0.85 eV at 273 K. Is this substance best classified as an insulator, a semiconductor, or a metal?
65. Indicate if each solid forms an n-type or a p-type semiconductor.
- a. germanium doped with gallium  
b. silicon doped with arsenic
66. Indicate if each solid forms an n-type or a p-type semiconductor.
- a. silicon doped with gallium  
b. germanium doped with antimony
67. Does a photon of red light with a frequency of  $4.29 \times 10^{14}$  Hz have sufficient energy to promote an electron from the valence band to the conduction band in a sample of silicon (the band gap in silicon is 1.11 eV)?
68. Which wavelength of light (in nm) is emitted if an electron moves from the conduction band to the valence band in a sample of diamond (diamond has a band gap of 5.5 eV)?

### Polymers

69. Teflon is an addition polymer formed from the monomer shown here. Draw the structure of the polymer.

70. Saran, the polymer used to make saran wrap, is an addition polymer formed from two monomers—vinylidene chloride and vinyl chloride. Draw the structure of the polymer. (Hint: The monomers alternate.)

71. One kind of polyester is a condensation copolymer formed from terephthalic acid and ethylene glycol. Draw the structure of the dimer. [Hint: Water (circled) is eliminated when the bond between the monomers forms.]

72. Nomex, a condensation copolymer used by firefighters because of its flame-resistant properties, forms from isophthalic acid and *m*-aminoaniline. Draw the structure of the dimer. (Hint: Water is eliminated when the bond between the monomers forms.)

73. Polyacetylene is an addition polymer with the structure shown here. Draw the structure of the monomer.

74. Polyacrylonitrile (PAN) is an addition polymer with the structure shown here. Draw the structure of the monomer.

75. The polycarbonate Lexan is a condensation polymer and has the structure shown here

Assuming this polymer was formed from the monomer shown here plus another monomer, provide a possible structure for the other monomer that would be required to form LEXAN.

76. Consider the condensation polymer with the structure shown here:

Assuming this polymer was formed from the monomer shown below plus another monomer, provide the structure of the other monomer that would be required to form this polymer.

## Cumulative Problems

77. Silver iodide crystallizes in the zinc blende structure. The separation between nearest-neighbor cations and anions is approximately 325 pm, and the melting point is 558 °C. Cesium chloride, by contrast, crystallizes in the structure shown in Figure 12.14. Even though the separation between nearest-neighbor cations and anions is greater (348 pm), the melting point of cesium chloride is higher (645 °C). Explain.
78. Copper iodide crystallizes in the zinc blende structure. The separation between nearest neighbor cations and anions is approximately 311 pm, and the melting point is 606 °C. Potassium chloride, by contrast, crystallizes in the rock salt structure. Even though the separation between nearest-neighbor cations and anions is greater (319 pm), the melting point of potassium chloride is higher (776 °C). Explain.

79. Consider the face-centered cubic structure shown here:

- What is the length of the line (labeled *c*) that runs diagonally across one of the faces of the cube in terms of *r* (the atomic radius)?
- Use the answer to part a and the Pythagorean theorem to derive the expression for the edge length (*l*) in terms of *r*.

80. Consider the body-centered cubic structure shown here:

- What is the length of the line (labeled  $c$ ) that runs from one corner of the cube diagonally through the center of the cube to the other corner in terms of  $r$  (the atomic radius)?
  - Use the Pythagorean theorem to derive an expression for the length of the line (labeled  $b$ ) that runs diagonally across one of the faces of the cube in terms of the edge length ( $l$ ).
  - Use the answer to parts a and b along with the Pythagorean theorem to derive the expression for the edge length ( $l$ ) in terms of  $r$ .
- The volume of a unit cell of diamond is  $0.0454 \text{ nm}^3$ , and the density of diamond is  $3.52 \text{ g/cm}^3$ . Find the number of carbon atoms in a unit cell of diamond.
  - The density of an unknown metal is  $12.3 \text{ g/cm}^3$ , and its atomic radius is  $0.134 \text{ nm}$ . It has a face-centered cubic lattice. Find the atomic mass of this metal.
  - An unknown metal is found to have a density of  $7.8748 \text{ g/cm}^3$  and to crystallize in a body-centered cubic lattice. The edge of the unit cell is  $0.28664 \text{ nm}$ . Calculate the atomic mass of the metal.
  - When spheres of radius  $r$  are packed in a body-centered cubic arrangement, they occupy 68.0% of the available volume.

Use the fraction of occupied volume to calculate the value of  $a$ , the length of the edge of the cube, in terms of  $r$ .

- Potassium chloride crystallizes in the rock salt structure. Estimate the density of potassium chloride using the ionic radii provided in Chapter 8.
- Calculate the fraction of empty space in cubic closest packing to five significant figures.
- A tetrahedral site in a closest-packed lattice is formed by four spheres at the corners of a regular tetrahedron. This is equivalent to placing the spheres at alternate corners of a cube. In such a closest-packed arrangement the spheres are in contact, and if the spheres have a radius  $r$ , the diagonal of the face of the cube is  $2r$ . The tetrahedral hole is inside the middle of the cube. Find the length of the body diagonal of this cube and then find the radius of the tetrahedral hole.
- X-ray diffractometers often use metals that have had their core electrons excited as a source of X-rays. Consider the  $2p \rightarrow 1s$  transition for copper, which is called the  $K\alpha$  transition. Calculate the wavelength of X-rays (in  $\text{\AA}$ ) given off by the  $K\alpha$  transition if the energy given off by a mole of copper atoms is  $7.77 \times 10^5 \text{ kJ}$ . ( $1 \text{ \AA} = 10^{-10} \text{ m}$ )
- Why is it necessary to use the  $K\alpha$  transition ( $2p \rightarrow 1s$ ) in copper (see Problem 88) to generate X-rays? Why not use, for example, the  $4s \rightarrow 3p$  transition?
- In certain cases where X-ray diffraction is unsuitable for determining the structure of a crystal, *neutron diffraction* can be used. Instead of X-rays, a beam of neutrons is used to analyze the sample. Calculate the velocity of a beam of neutrons with a wavelength of  $2.00 \text{ \AA}$ .

## Challenge Problems

- The structure of the addition polymer polypropylene is shown in Table 12.3.
  - Draw the structure of the monomer.
  - Show how an alternate version of the polypropylene polymer (with a different arrangement) could be formed from the monomer you found in part a.
- Perovskite is a compound with a cubic unit cell and has a strontium atom at the center of the cell, titanium atoms at the corners of the unit cell, and oxygen atoms at the centers of each face of the unit cell.
  - What is the formula of perovskite?
  - What is the coordination number of strontium in the perovskite structure?
  - If the edge length of the unit cell is  $3.905 \text{ \AA}$ , calculate the density of perovskite in  $\text{g/cm}^3$ .
- A compound with the formula  $\text{Rb}_3\text{C}_{60}$  has been shown to demonstrate superconductivity below  $30.0 \text{ K}$ . Given that the  $\text{C}_{60}$  molecules have a face-centered cubic arrangement, which of the tetrahedral and octahedral sites are occupied by Rb atoms?
- Despite Dalton's laws, it is now known that many ionic compounds do not always contain atoms in small integer ratios. For example, a sample of iron(II) oxide may, in fact, contain a significant amount of  $\text{Fe}^{3+}$  in addition to  $\text{Fe}^{2+}$ . This is an example of a *nonstoichiometric* compound. A sample of iron(II) oxide is found to be 75.65% iron by mass. Determine the percentage of  $\text{Fe}^{3+}$  ions in the sample.

## Conceptual Problems

- During the glass manufacturing process, the liquid must be cooled relatively quickly to form the glass. Why?
- Why are X-rays used for crystallography? Why not use some other, more accessible type of electromagnetic radiation such as ultraviolet light?
- Compare the crystal structure of diamond (C) and zinc blende (ZnS). What are the key similarities and differences between the two structures?
- In X-ray crystallography, a small amount of oil is often used to mount the crystal sample on a glass fiber. Explain why neither the oil nor the glass fiber interferes with the diffraction pattern of the crystal.
- Which is not likely to lead to an increase in electrical conductivity?
  - Increasing the temperature of a semiconductor
  - Choosing a semiconductor with a smaller band gap
  - Doping the semiconductor
  - All of the above would likely lead to an increase in electrical conductivity.

## Questions for Group Work

Discuss these questions with the group and record your consensus answer.

100. Have each group member select one of the cubic crystalline lattices. Learn everything you can about your lattice and present it to the group.
101. Using group members to play the role of atoms or molecules, demonstrate the main structural features of the following categories of crystalline solids: molecular solid, ionic solid, nonbonded solid, metallic solid, network covalent solid. Clearly identify what you represent and how you are representing various interactions between particles (e.g., covalent bond, ionic bond, etc.).
102. Make a list of questions you would need to ask in order to classify a solid into one of the categories of crystalline solids (molecular solid, ionic solid, nonbonded solid, metallic solid, and network covalent solid). Determine a good order to ask them. (You may

need a branching decision tree.) Once you have agreed on a good set of questions, have each group member choose a substance from the chapter and then have the other group members ask the questions in turn until the correct classification is reached. You may agree to edit your questions if you discover ways to improve them when you are using your decision tree.

103. Have each group member select and study a material from the section on ceramics, cement, and glass. Take turns describing your material to the group, and see if they can identify the type of material based on your description (without consulting the text).
104. Describe how a common object or toy (e.g., a train, building blocks, or beads on a string) could represent the structure of a polymer. Describe how the following terms would be represented using your model: monomer, dimer, addition polymer, condensation polymer, branching.

## Data Interpretation and Analysis

### Magnesium Niobium Hydride as a Source of Hydrogen Fuel

105. The use of hydrogen as a fuel to power cars and trucks is an active research area. One challenge is storing the hydrogen, which is problematic because the steel fuel tanks are heavy and the hydrogen gas can explode in a crash.

Some metals have the ability to absorb hydrogen gas to form metal hydrides. For example, niobium and magnesium each react with hydrogen gas to form niobium hydride and magnesium hydride, respectively:

Metal hydrides make it possible to store a large amount of hydrogen in a small space. Once each of these reactions occurs, the hydrogen is stored in the solid metal hydride. After a metal hydride is formed, the process can be reversed.

Not all elements form hydrides. Table a lists some elements that form hydrides and some that do not.

Figure a shows the relationship of the reaction enthalpies as a function of hydrogen content for several hydrides.

▲ FIGURE a Hydrogen Content versus Reaction Enthalpy for Several Hydrides (at Room Temperature)

Recently, a research group synthesized magnesium niobium hydride ( $\text{Mg}_{(0.75)}\text{Nb}_{(0.25)}\text{H}_2$ ). The hydrogen absorption measurements of magnesium niobium hydride yielded an enthalpy of hydride formation of  $-53 \text{ kJ/mol H}_2$ .

Use the information provided in the figure and table to answer the following questions:

- a. Identify a pattern for which elements form hydrides and which elements do not. (Hint: There are some exceptions to the pattern, but think about how you would name ionic compounds containing these metals.)
- b. Refer to your knowledge about the size of atoms to offer an explanation why the research group decided to use two metals (magnesium and niobium) to form a complex hydride capable of storing hydrogen.
- c. Calculate the mass percentage of hydrogen in magnesium niobium hydride ( $\text{Mg}_{(0.75)}\text{Nb}_{(0.25)}\text{H}_2$ ).

#### Elements that Form Hydrides

Li				
Na	Mg			
K	Ca	Sc	Ti	V
Rb	Sr			

#### Elements that do not Form Hydrides

Cr	Fe	Co	Cu	Zn
Mo	Ru	Rh	Ag	Cd

TABLE a Some Elements That Form Hydrides and Some That Do Not.

- d. Does the hydrogen content and reaction enthalpy for magnesium niobium hydride fall in the efficient zone according to Figure a? Explain your answer.
- e. Would the metal hydrides discussed in this problem need to be heated or cooled to release hydrogen?

## Answers to Conceptual Connections

### Cubic Structures

**12.1** The face-centered cubic structure has four atoms per unit cell.

### Crystalline Solid Types and Melting Points

**12.2 (a)** MgO, an ionic compound, has the highest melting point because the solid is held together by ionic bonds. I<sub>2</sub> is a molecular compound with only dispersion forces, and Kr is a non-bonding atomic solid with only dispersion forces. As a result, these two substances have much lower melting points.

### Ionic Crystalline Solid Unit Cells

**12.3 (c)** The zinc blende structure occurs in ionic compounds with a one-to-one cation-to-anion ratio in which the cation is much smaller than the anion.

### Phase Changes and Pressure

**12.4** An increase in pressure favors the denser phase, in this case diamond.

### Semiconductor Type

**12.5 (a)** Since indium has three valence electrons and germanium has four, the presence of indium would introduce holes into the valence band, resulting in a p-type semiconductor.

# Solutions

One molecule of nonsaline substance (held in the solvent) dissolved in 100 molecules of any volatile liquid decreases the vapor pressure of this liquid by a nearly constant fraction, nearly 0.0105.

—FRANÇOIS-MARIE RAOULT (1830–1901)

**13.1** Thirsty Solutions: Why You Shouldn't Drink Seawater 571

**13.2** Types of Solutions and Solubility 573

**13.3** Energetics of Solution Formation 577

**13.4** Solution Equilibrium and Factors Affecting Solubility 581

**13.5** Expressing Solution Concentration 585

**13.6** Colligative Properties: Vapor Pressure Lowering, Freezing Point Depression, Boiling Point Elevation, and Osmotic Pressure 593

**13.7** Colligative Properties of Strong Electrolyte Solutions 605

**13.8** Colloids 608

**KEY LEARNING OUTCOMES** 613

**W**e learned in Chapter 1 that most of the matter we encounter is in the form of mixtures. In this chapter, we focus on homogeneous mixtures, known as solutions. Solutions are mixtures in which atoms and molecules intermingle on the molecular and atomic scale. Common examples of solutions include ocean water, gasoline, and air. Why do solutions form? How are their properties different from the properties of the pure substances that compose them? As you read this chapter, keep in mind the large number of solutions that surround you at every moment, including those that exist within your own body.

▲ Drinking seawater causes dehydration because seawater draws water out of body tissues.

### 13.1 Thirsty Solutions: Why You Shouldn't Drink Seawater

In the popular novel *Life of Pi* by Yann Martel, the main character (whose name is Pi) is stranded on a lifeboat with a Bengal tiger in the middle of the Pacific Ocean for 227 days. Pi survives in part by rigging a solar still to distill seawater for drinking. However, in the first three days of his predicament (before he rigs the still) he becomes severely dehydrated from lack of water. He is surrounded by seawater, but drinking *that* water would only have made his condition worse. Why? Seawater actually draws water *out of the body* as it passes through the stomach and intestines, resulting in diarrhea and further dehydration. We can think of seawater as a *thirsty solution*—one that draws more water to itself. Consequently, seawater should never be consumed as drinking water.

In some cases, the concepts of solute and solvent are not useful. For example, a homogeneous mixture of water and ethanol can contain equal amounts of both components, and neither component can then be identified as the solvent.

► **FIGURE 13.1 A Typical Solution** In seawater, sodium chloride is the primary solute. Water is the solvent.

Seawater is a **solution**, a homogeneous mixture of two or more substances or components as shown in Figure 13.1▼. The majority component in a solution is typically called the **solvent**, and the minority component is called the **solute**. In seawater, water is the solvent, and sodium chloride is the primary solute. Solutions form in part because of the intermolecular forces we discussed in Chapter 11. In most solutions, the particles of the solute interact with the particles of the solvent through intermolecular forces.

The reason that seawater draws water to itself is related to nature's tendency toward spontaneous mixing, which we discuss in more detail later in this chapter and in Chapter 18. For now, we simply observe that unless the mixing process is highly unfavorable energetically, substances tend to combine into uniform mixtures, not separate into pure substances. For example, suppose pure water and a sodium chloride solution are in separate compartments with a removable barrier between them, as shown in Figure 13.2(a)▼. If we remove the barrier, the two liquids spontaneously mix, eventually forming a more dilute sodium chloride solution of uniform concentration, as shown in Figure 13.2(b)▼. The tendency toward mixing results in a uniform concentration of the final solution.

Seawater is a *thirsty* solution because of this tendency toward mixing. As seawater moves through the intestine, it flows past cells that line the digestive tract. These cells consist of largely fluid interiors surrounded by membranes. Cellular fluids themselves contain dissolved ions, including sodium and chloride, but the fluids in the cells are more dilute than seawater. Nature's tendency toward mixing (which tends to produce solutions of uniform concentration), together with the selective permeability of the cell

### Spontaneous Mixing

When the barrier is removed, spontaneous mixing occurs, producing a solution of uniform concentration.

▲ **FIGURE 13.2 The Tendency to Mix** (a) A barrier separates pure water and a sodium chloride solution. (b) When the barrier is removed, the two liquids spontaneously mix, producing a single solution of uniform concentration.

membranes (which allows water to flow in and out, but restricts the flow of dissolved solids), cause a *flow of solvent out of the body's cells into the seawater*. In this way, the two solutions become more similar in concentration (as though they had mixed). The solution in the intestine becomes somewhat more dilute than it was, and the solution in the cells becomes somewhat more concentrated. The accumulation of extra fluid in the intestines causes diarrhea, and the decreased fluid in the cells causes dehydration. If Pi had drunk the seawater instead of constructing the solar still, neither he nor his companion, the large Bengal tiger, would have survived their ordeal.

Seawater is a more concentrated solution than the fluids in body cells. As a result, when seawater flows through the digestive tract, it draws water out of the surrounding tissues.

## 13.2 Types of Solutions and Solubility

A solution may be composed of a solid and a liquid (such as the salt and water that are the primary components of seawater), but it may also be composed of a gas and a liquid, two different liquids, or other combinations (see Table 13.1). In **aqueous solutions**, water is the solvent, and a solid, liquid, or gas is the solute. For example, sugar water and salt water are both aqueous solutions. Similarly, ethyl alcohol—the alcohol in alcoholic beverages—readily mixes with water to form a solution, and carbon dioxide dissolves in water to form the aqueous solution that we know as club soda.

Club soda is a solution of carbon dioxide and water.

**TABLE 13.1** Common Types of Solutions

Solution Phase	Solute Phase	Solvent Phase	Example
Gaseous solution	Gas	Gas	Air (mainly oxygen and nitrogen)
Liquid solution	Gas	Liquid	Club soda (CO <sub>2</sub> and water)
	Liquid	Liquid	Vodka (ethanol and water)
	Solid	Liquid	Seawater (salt and water)
Solid solution	Solid	Solid	Brass (copper and zinc) and other alloys

You probably know from experience that a particular solvent, such as water, does not dissolve all possible solutes. For example, you cannot clean your greasy hands with water alone because the water does not dissolve the grease. However, another solvent, such as paint thinner, can easily dissolve the grease. The grease is *insoluble* in water but *soluble* in the paint thinner. The **solubility** of a substance is the amount of the substance that will dissolve in a given amount of solvent. The solubility of sodium chloride in water at 25 °C is 36 g NaCl per 100 g water, whereas the solubility of grease in water is nearly zero. The solubility of one substance in another depends both on the tendency toward mixing that we discussed in Section 13.1 and on the types of intermolecular forces that we discussed in Chapter 11.

The general solubilities of a number of ionic compounds are described by the solubility rules in Section 4.5.

**▲ FIGURE 13.3** Spontaneous Mixing of Two Ideal Gases (a) A barrier separates neon and argon. (b) When the barrier is removed, the two gases spontaneously mix to form a uniform solution.

The potential energy of the gas particles does not change upon mixing because the gas is ideal; the particles do not exert any attractive or repulsive forces on each other, so mixing does not change their potential energy.

## Nature's Tendency toward Mixing: Entropy

So far in this book, we have seen that many physical systems tend toward lower *potential energy*. For example, two particles with opposite charges (such as a proton and an electron or a cation and an anion) move toward each other because their potential energy decreases as their separation decreases according to Coulomb's law. The formation of a solution, however, *does not necessarily* lower the potential energy of its constituent particles. The clearest example of this phenomenon is the formation of a homogeneous mixture (a *solution*) of two ideal gases. Suppose that we enclose neon and argon in a container with a removable barrier between them, as shown in Figure 13.3(a)◀. As soon as we remove the barrier, the neon and argon mix together to form a solution, as shown in Figure 13.3(b)◀. *Why?*

At low pressures and moderate temperatures, both neon and argon behave as ideal gases—they do not interact with each other in any way (that is, there are no significant intermolecular forces between their constituent particles). When the barrier is removed, the two gases mix, but their potential energy remains unchanged. In other words, *we cannot think of the mixing of two ideal gases as lowering their potential energy*. Rather, the tendency to mix is related to a concept called *entropy*.

**Entropy** is a measure of *energy randomization* or *energy dispersal* in a system. Recall that a gas at any temperature above 0 K has kinetic energy due to the motion of its atoms. When neon and argon are confined to their individual compartments, their kinetic energies are also confined to those compartments. When the barrier between the compartments is removed, each gas—along with its kinetic energy—becomes *spread out* or *dispersed* over a larger volume. Thus, the mixture of the two gases has greater energy dispersal, or greater *entropy*, than the separated components.

*The pervasive tendency for energy to spread out, or disperse, whenever it is not restrained from doing so* is the reason that two ideal gases mix. Another common example of the tendency toward energy dispersal is the transfer of thermal energy from hot to cold. If we heat one end of an iron rod, the thermal energy deposited at the end of the rod will spontaneously spread along the entire length of the rod. In contrast to the mixing of two ideal gases—where the kinetic energy of the particles becomes dispersed over a larger volume because the particles themselves become dispersed—the thermal energy in the rod, initially concentrated in relatively fewer particles, becomes dispersed by being distributed over a larger number of particles. The tendency for energy to disperse is why thermal energy flows from the hot end of the rod to the cold one, and not the other way around. Imagine a metal rod that became spontaneously hotter on one end and ice cold on the other—this does not happen because energy does not spontaneously concentrate itself. In Chapter 18, we will see that the dispersal of energy is actually the fundamental criterion that ultimately determines the spontaneity of any process.

## The Effect of Intermolecular Forces

We have just seen that, in the absence of intermolecular forces, two substances spontaneously mix to form a homogeneous solution. We know from Chapter 11, however, that solids and liquids exhibit a number of different types of intermolecular forces including dispersion forces, dipole–dipole forces, hydrogen bonding, and ion–dipole forces (Figure 13.4▶). These forces may promote the formation of a solution or prevent it, depending on the nature of the forces in the particular combination of solute and solvent.

Intermolecular forces exist between (a) the solvent and solute particles, (b) the solvent particles themselves, and (c) the solute particles themselves, as shown in Figure 13.5▶.

<i>Solvent–solute interactions:</i>	The interactions between a solvent particle and a solute particle.
<i>Solvent–solvent interactions:</i>	The interactions between a solvent particle and another solvent particle.
<i>Solute–solute interactions:</i>	The interactions between a solute particle and another solute particle.

## Intermolecular Forces

These forces may contribute to or oppose the formation of a solution.

**▲ FIGURE 13.4** Intermolecular Forces Involved in Solutions

As Table 13.2 indicates, a solution always forms if the solvent–solute interactions are comparable to, or stronger than, the solvent–solvent interactions and the solute–solute interactions. For example, consider mixing the hydrocarbons pentane ( $\text{C}_5\text{H}_{12}$ ) and heptane ( $\text{C}_7\text{H}_{16}$ ). The intermolecular forces present *within* both pentane and heptane are dispersion forces. Similarly, the intermolecular forces present *between* heptane and pentane are also dispersion forces. All three interactions are of similar magnitude, so the two substances are soluble in each other in all proportions—they are said to be **miscible**. The formation of the solution is driven by the tendency toward mixing, or toward greater entropy, that we just discussed.

**TABLE 13.2** Relative Interactions and Solution Formation

Solvent–solute interactions	>	Solvent–solvent and solute–solute interactions	Solution forms
Solvent–solute interactions	=	Solvent–solvent and solute–solute interactions	Solution forms
Solvent–solute interactions	<	Solvent–solvent and solute–solute interactions	Solution may or may not form, depending on relative disparity

If solvent–solute interactions are weaker than solvent–solvent and solute–solute interactions—in other words, if solvent molecules and solute molecules each interact more strongly with molecules of their own kind than with molecules of the other kind—then a solution may still form, depending on the relative disparities between the interactions. If the disparity is small, the tendency to mix results in the formation of a solution even though the process is energetically uphill. If the disparity is large, however, a solution does not form. For example, consider mixing hexane and water. The water molecules have strong hydrogen-bonding attractions to each other but cannot form hydrogen bonds with hexane. The energy required to pull water molecules away

### Solution Interactions

**◀ FIGURE 13.5** Forces in a Solution The relative strengths of these three interactions determine whether a solution forms.

**TABLE 13.3** Common Laboratory Solvents

Common Polar Solvents	Common Nonpolar Solvents
Water (H <sub>2</sub> O)	Hexane (C <sub>6</sub> H <sub>14</sub> )
Acetone (CH <sub>3</sub> COCH <sub>3</sub> )	Diethyl ether (CH <sub>3</sub> CH <sub>2</sub> OCH <sub>2</sub> CH <sub>3</sub> )*
Methanol (CH <sub>3</sub> OH)	Toluene (C <sub>7</sub> H <sub>8</sub> )
Ethanol (CH <sub>3</sub> CH <sub>2</sub> OH)	Carbon tetrachloride (CCl <sub>4</sub> )

\*Diethyl ether has a small dipole moment and can be considered intermediate between polar and nonpolar.

from one another is too great, and too little energy is returned when the water molecules interact with hexane molecules. As a result, a solution does not form when we mix hexane and water. Although the tendency to mix is strong, it cannot overcome the large energy disparity between the powerful solvent-solvent interactions and the weak solvent-solute interactions.

In general, we can use the rule of thumb that *like dissolves like* when predicting the formation of solutions. Similar kinds of solvents dissolve similar kinds of solutes. Polar solvents, such as water, tend to dissolve many polar or ionic solutes, and nonpolar solvents, such as hexane, tend to dissolve many nonpolar solutes. Table 13.3 lists some common polar and nonpolar laboratory solvents.

### Example 13.1 Solubility

Vitamins are often categorized as either fat-soluble or water-soluble. Water-soluble vitamins, on one hand, dissolve in body fluids and are easily eliminated in the urine, so there is little danger of overconsumption. Fat-soluble vitamins, on the other hand, can accumulate in the body's fatty deposits. Overconsumption of a fat-soluble vitamin can be dangerous to your health. Examine the structure of the vitamins shown here and classify each as either fat-soluble or water-soluble.

#### (a) Vitamin C

#### (c) Vitamin A

#### (b) Vitamin K<sub>3</sub>

#### (d) Vitamin B<sub>5</sub>

#### SOLUTION

- (a) The four —OH bonds in vitamin C make it highly polar and allow it to hydrogen-bond with water. Vitamin C is water-soluble.

- (b) The C—C bonds in vitamin K<sub>3</sub> are nonpolar and the C—H bonds are nearly so. The C=O bonds are polar, but the bond dipoles oppose and largely cancel each other, so the molecule is dominated by the nonpolar bonds. Vitamin K<sub>3</sub> is fat-soluble.

- (c) The C—C bonds in vitamin A are nonpolar and the C—H bonds are nearly so. The one polar —OH bond may increase its water solubility slightly, but overall vitamin A is nonpolar and therefore fat-soluble.

- (d) The three —OH bonds and one —NH bond in vitamin B<sub>5</sub> make it highly polar and allow it to hydrogen-bond with water. Vitamin B<sub>5</sub> is water-soluble.

**FOR PRACTICE 13.1** Determine whether each compound is soluble in hexane.

- (a) water (H<sub>2</sub>O)                      (b) propane (CH<sub>3</sub>CH<sub>2</sub>CH<sub>3</sub>)  
(c) ammonia (NH<sub>3</sub>)                  (d) hydrogen chloride (HCl)

**Solubility** Consider the table listing the solubilities of several alcohols in water and in hexane. Explain the observed trend in terms of intermolecular forces.

### CONCEPTUAL CONNECTION 13.1

Alcohol	Space-Filling Model	Solubility in H <sub>2</sub> O (mol alcohol/100 g H <sub>2</sub> O)	Solubility in Hexane (C <sub>6</sub> H <sub>14</sub> ) (mol alcohol/100 g C <sub>6</sub> H <sub>14</sub> )
Methanol (CH <sub>3</sub> OH)		Miscible	0.12
Ethanol (CH <sub>3</sub> CH <sub>2</sub> OH)		Miscible	Miscible
Propanol (CH <sub>3</sub> CH <sub>2</sub> CH <sub>2</sub> OH)		Miscible	Miscible
Butanol (CH <sub>3</sub> CH <sub>2</sub> CH <sub>2</sub> CH <sub>2</sub> OH)		0.11	Miscible
Pentanol (CH <sub>3</sub> CH <sub>2</sub> CH <sub>2</sub> CH <sub>2</sub> CH <sub>2</sub> OH)		0.030	Miscible

## 13.3 Energetics of Solution Formation

In Chapter 6, we examined the energy changes associated with chemical reactions. Similar energy changes can occur when a solution forms, depending on the magnitude of the interactions between the solute and solvent particles. For example, when we dissolve

sodium hydroxide in water, heat is evolved—the solution process is *exothermic*. In contrast, when we dissolve ammonium nitrate ( $\text{NH}_4\text{NO}_3$ ) in water, heat is absorbed—this solution process is *endothermic*. Other solutions, such as sodium chloride in water, barely absorb or evolve heat upon formation. What causes these different behaviors?

## Energy Changes in Solution Formation

We can understand the energy changes associated with solution formation by envisioning the process as occurring in three steps, each with an associated change in enthalpy:

1. Separating the solute into its constituent particles.

This step is always endothermic (positive  $\Delta H$ ) because energy is required to overcome the forces that hold the solute particles together.

2. Separating the solvent particles from each other to make room for the solute particles.

This step is also endothermic because energy is required to overcome the intermolecular forces among the solvent particles.

3. Mixing the solute particles with the solvent particles.

This step is exothermic because energy is released as the solute particles interact (through intermolecular forces) with the solvent particles.

According to Hess's law, the overall enthalpy change upon solution formation, called the **enthalpy of solution** ( $\Delta H_{\text{soln}}$ ), is the sum of the changes in enthalpy for each step:

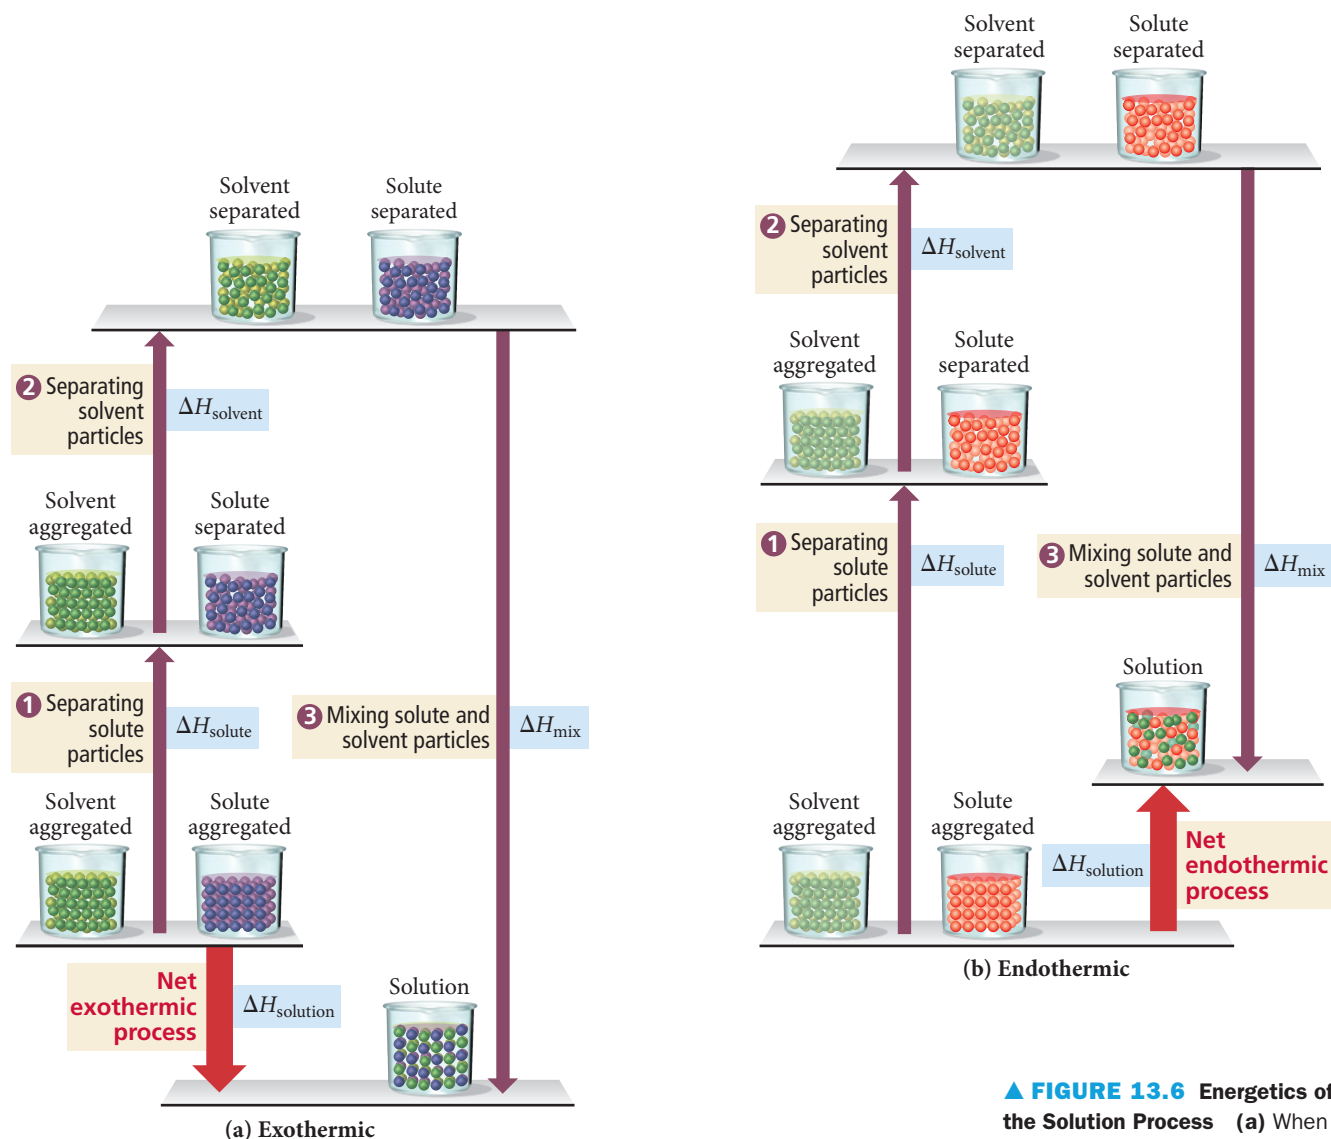

$$\Delta H_{\text{soln}} = \underset{\text{endothermic (+)}}{\Delta H_{\text{solute}}} + \underset{\text{endothermic (+)}}{\Delta H_{\text{solvent}}} + \underset{\text{exothermic (-)}}{\Delta H_{\text{mix}}}$$

Since the first two terms are endothermic (positive  $\Delta H$ ) and the third term is exothermic (negative  $\Delta H$ ), the overall sign of  $\Delta H_{\text{soln}}$  depends on the magnitudes of the individual terms, as shown in Figure 13.6.

1. If the sum of the endothermic terms is approximately equal in magnitude to the exothermic term, then  $\Delta H_{\text{soln}}$  is about zero. The increasing entropy upon mixing drives the formation of a solution while the overall energy of the system remains nearly constant.
2. If the sum of the endothermic terms is smaller in magnitude than the exothermic term, then  $\Delta H_{\text{soln}}$  is negative and the solution process is exothermic. In this case, both the tendency toward lower energy and the tendency toward greater entropy drive the formation of a solution.
3. If the sum of the endothermic terms is greater in magnitude than the exothermic term, then  $\Delta H_{\text{soln}}$  is positive and the solution process is endothermic. In this case, as long as  $\Delta H_{\text{soln}}$  is not too large, the tendency toward greater entropy still drives the formation of a solution. If, on the other hand,  $\Delta H_{\text{soln}}$  is too large, a solution does not form.

## Energetics of Solution Formation

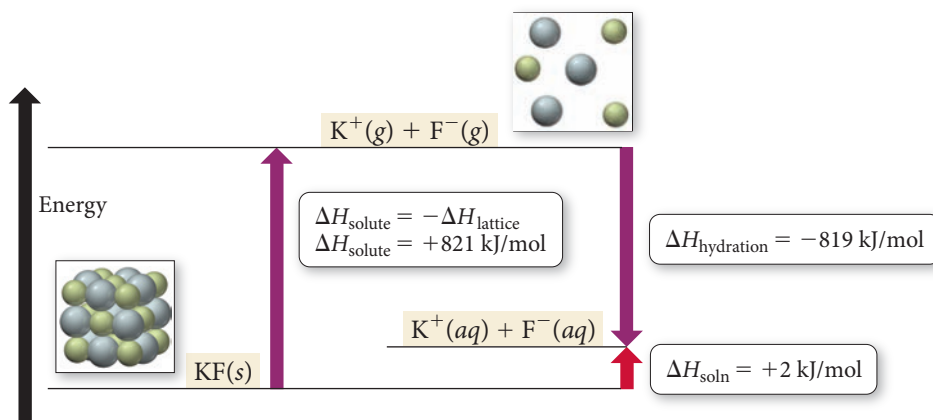

**▲ FIGURE 13.6 Energetics of the Solution Process** (a) When  $\Delta H_{\text{mix}}$  is greater in magnitude than the sum of  $\Delta H_{\text{solute}}$  and  $\Delta H_{\text{solvent}}$ , the heat of solution is negative (exothermic). (b) When  $\Delta H_{\text{mix}}$  is smaller in magnitude than the sum of  $\Delta H_{\text{solute}}$  and  $\Delta H_{\text{solvent}}$ , the heat of solution is positive (endothermic).

## Aqueous Solutions and Heats of Hydration

Many common solutions, such as the seawater mentioned in Section 13.1, contain an ionic compound dissolved in water. In these aqueous solutions,  $\Delta H_{\text{solvent}}$  and  $\Delta H_{\text{mix}}$  can be combined into a single term called the **heat of hydration** ( $\Delta H_{\text{hydration}}$ ) (Figure 13.7 ▼).

## Heat of Hydration

**◀ FIGURE 13.7 Heat of Hydration and Heat of Solution** The heat of hydration is the heat emitted when 1 mol of gaseous solute ions is dissolved in water. The sum of the negative of the lattice energy (which is  $\Delta H_{\text{solute}}$ ) and the heat of hydration is the heat of solution.

► **FIGURE 13.8** Ion–Dipole

**Interactions** Ion–dipole interactions such as those between potassium ions, fluoride ions, and water molecules cause the heat of hydration to be largely negative (exothermic).

The heat of hydration is the enthalpy change that occurs when 1 mol of the gaseous solute ions is dissolved in water. Because the ion–dipole interactions that occur between a dissolved ion and the surrounding water molecules (Figure 13.8▲) are much stronger than the hydrogen bonds in water,  $\Delta H_{\text{hydration}}$  is always largely negative (exothermic) for ionic compounds. Using the heat of hydration, we can write the enthalpy of solution as a sum of just two terms, one endothermic and one exothermic:

$$\begin{aligned}\Delta H_{\text{soln}} &= \Delta H_{\text{solute}} + \underbrace{\Delta H_{\text{solvent}} + \Delta H_{\text{mix}}}_{\Delta H_{\text{hydration}}} \\ \Delta H_{\text{soln}} &= \underbrace{\Delta H_{\text{solute}}}_{\text{endothermic (positive)}} + \underbrace{\Delta H_{\text{hydration}}}_{\text{exothermic (negative)}}\end{aligned}$$

For ionic compounds,  $\Delta H_{\text{solute}}$ , the energy required to separate the solute into its constituent particles, is the negative of the solute's lattice energy ( $\Delta H_{\text{solute}} = -\Delta H_{\text{lattice}}$ ), discussed in Section 9.4. For ionic aqueous solutions, then, the overall enthalpy of solution depends on the relative magnitudes of  $\Delta H_{\text{solute}}$  and  $\Delta H_{\text{hydration}}$ , with three possible scenarios (in each case we refer to the *magnitude (absolute value)* of  $\Delta H$ ):

1.  $|\Delta H_{\text{solute}}| < |\Delta H_{\text{hydration}}|$ . The amount of energy required to separate the solute into its constituent ions is less than the energy given off when the ions are hydrated.  $\Delta H_{\text{soln}}$  is therefore negative, and the solution process is exothermic. Solutes with negative enthalpies of solution include lithium bromide and potassium hydroxide. When these solutes dissolve in water, the resulting solutions feel warm to the touch:

2.  $|\Delta H_{\text{solute}}| > |\Delta H_{\text{hydration}}|$ . The amount of energy required to separate the solute into its constituent ions is greater than the energy given off when the ions are hydrated.  $\Delta H_{\text{soln}}$  is therefore positive, and the solution process is endothermic (if a solution forms at all). Solutes that form aqueous solutions with positive enthalpies of solution include ammonium nitrate and silver nitrate. When these solutes dissolve in water, the resulting solutions feel cool to the touch:

3.  $|\Delta H_{\text{solute}}| \approx |\Delta H_{\text{hydration}}|$ . The amount of energy required to separate the solute into its constituent ions is roughly equal to the energy given off when the ions are hydrated.  $\Delta H_{\text{soln}}$  is therefore approximately zero, and the solution process is

neither appreciably exothermic nor appreciably endothermic. Solutes with enthalpies of solution near zero include sodium chloride and sodium fluoride. When these solutes dissolve in water, the resulting solutions do not undergo a noticeable change in temperature:

**Energetics of Aqueous Solution Formation** The enthalpy of solution for cesium fluoride is  $-36.8 \text{ kJ/mol}$ . What can you conclude about the relative magnitudes of  $\Delta H_{\text{solute}}$  and  $\Delta H_{\text{hydration}}$ ?

## CONCEPTUAL CONNECTION 13.2

### 13.4 Solution Equilibrium and Factors Affecting Solubility

**Solution Equilibrium and the Factors Affecting Solubility**

The dissolution of a solute in a solvent is an equilibrium process similar to the equilibrium process associated with a phase change (discussed in Chapter 11). Imagine, from a molecular viewpoint, the dissolution of a solid solute such as sodium chloride in a liquid solvent such as water (Figure 13.9▼). Initially, water molecules rapidly solvate sodium cations and chloride anions, resulting in a noticeable decrease in the amount of solid sodium chloride in the water. Over time, however, the concentration of dissolved

#### Solution Equilibrium

NaCl(s)	$\text{NaCl(s)} \longrightarrow \text{Na}^+(\text{aq}) + \text{Cl}^-(\text{aq})$	$\text{NaCl(s)} \rightleftharpoons \text{Na}^+(\text{aq}) + \text{Cl}^-(\text{aq})$
When sodium chloride is first added to water, sodium and chloride ions begin to dissolve into the water.	As the solution becomes more concentrated, some of the sodium and chloride ions can begin to recrystallize as solid sodium chloride.	When the rate of dissolution equals the rate of recrystallization, dynamic equilibrium has been reached.
 <p>(a) Initial</p>	 <p>(b) Dissolving</p>	 <p>(c) Dynamic equilibrium</p>
	Rate of dissolution > Rate of recrystallization	Rate of dissolution = Rate of recrystallization

**▲ FIGURE 13.9 Dissolution of NaCl** (a) When sodium chloride is first added to water, sodium and chloride ions dissolve into the water. (b) As the solution becomes more concentrated, some of the sodium and chloride ions recrystallize as solid sodium chloride. (c) When the rate of dissolution equals the rate of recrystallization, dynamic equilibrium is reached.

► **FIGURE 13.10** **Precipitation from a Supersaturated Solution** When a small piece of solid sodium acetate is added to a supersaturated sodium acetate solution, the excess solid precipitates out of the solution.

sodium chloride in the solution increases. This dissolved sodium chloride then begins to recrystallize as solid sodium chloride. Initially the rate of dissolution far exceeds the rate of recrystallization, but as the concentration of dissolved sodium chloride increases, the rate of recrystallization also increases. Eventually, the rates of dissolution and recrystallization become equal—**dynamic equilibrium** has been reached.

A solution in which the dissolved solute is in dynamic equilibrium with the solid (undissolved) solute is a **saturated solution**. *If you add additional solute to a saturated solution, it will not dissolve.* A solution containing less than the equilibrium amount of solute is an **unsaturated solution**. *If you add additional solute to an unsaturated solution, it will dissolve.*

Under certain circumstances, a **supersaturated solution**—one containing more than the equilibrium amount of solute—may form. Supersaturated solutions are unstable and the excess solute normally precipitates out of the solution. However, in some cases, if left undisturbed, a supersaturated solution can exist for an extended period of time. For example, in a common classroom demonstration, a tiny piece of solid sodium acetate is added to a supersaturated solution of sodium acetate. This triggers the precipitation of the solute, which crystallizes out of solution in a dramatic and often beautiful way (Figure 13.10▲).

## The Temperature Dependence of the Solubility of Solids

The solubility of solids in water can be highly dependent on temperature. Have you ever noticed how much more sugar you can dissolve in hot tea than in cold tea? Although exceptions exist, *the solubility of most solids in water increases with increasing temperature*, as shown in Figure 13.11▼. For example, the solubility of potassium nitrate ( $\text{KNO}_3$ ) at

In the case of sugar dissolving in water, the higher temperature increases both *how fast* the sugar dissolves and *how much* sugar dissolves.

► **FIGURE 13.11** **Solubility and Temperature** The solubility of most solids increases with increasing temperature.

room temperature is about 37 g  $\text{KNO}_3$  per 100 g of water. At 50 °C, the solubility rises to 88 g  $\text{KNO}_3$  per 100 g of water.

A common way to purify a solid is a technique called **recrystallization**. In this technique, enough solid is added to water (or some other solvent) to create a saturated solution at an elevated temperature. As the solution cools, it becomes supersaturated and the excess solid precipitates out of solution. If the solution cools slowly, the solid forms crystals as it comes out of solution. The crystalline structure tends to reject impurities, resulting in a purer solid.

You can use the temperature dependence of the solubility of solids to make rock candy. Prepare a saturated sucrose (table sugar) solution at an elevated temperature, and allow a string or stick to dangle into the solution for several days. As the solution cools and the solvent evaporates, the solution becomes supersaturated and sugar crystals grow on the string or stick. After several days, beautiful edible crystals or “rocks” of sugar cover the string.

▲ Rock candy is formed by the recrystallization of sugar.

## Factors Affecting the Solubility of Gases in Water

Solutions of gases dissolved in water are common. Club soda, for example, is a solution of carbon dioxide and water, and most liquids exposed to air contain dissolved gases from air. Fish and other aquatic animals depend on the oxygen dissolved in lake or ocean water for life, and our blood contains dissolved nitrogen, oxygen, and carbon dioxide. Even tap water contains dissolved gases. The solubility of a gas in a liquid is affected by both temperature and pressure.

### The Effect of Temperature

You can observe the effect of temperature on the solubility of a gas in water by heating ordinary tap water on a stove. Before the water reaches its boiling point, small bubbles develop in the water. These bubbles are the dissolved air (mostly nitrogen and oxygen) coming out of solution. (Once the water boils, the bubbling becomes more vigorous—these larger bubbles are composed of water vapor.) The dissolved air comes out of the heated solution because—unlike solids, whose solubility generally increases with increasing temperature—the *solubility of gases in water decreases with increasing temperature*.

The inverse relationship between gas solubility and temperature is the reason that warm soda pop bubbles more than cold soda pop when you open it and warm beer goes flat faster than cold beer. More carbon dioxide comes out of these solutions at room temperature than at a lower temperature because the gas is less soluble at room temperature. The decreasing solubility of gases with increasing temperature is also the reason that fish don't bite much in a warm lake. The warm temperature results in a lower oxygen concentration. With lower oxygen levels, the fish become lethargic and do not strike as aggressively at the lure or bait you cast their way.

Cold soda pop

Warm soda pop

▲ Warm soda pop bubbles more than cold soda pop because carbon dioxide is less soluble in the warm solution.

**Solubility and Temperature** A solution is saturated in both nitrogen gas and potassium bromide at 75 °C. When the solution is cooled to room temperature, what is most likely to happen?

- (a) Some nitrogen gas bubbles out of solution.
- (b) Some potassium bromide precipitates out of solution.
- (c) Some nitrogen gas bubbles out of solution, *and* some potassium bromide precipitates out of solution.
- (d) Nothing happens.

### The Effect of Pressure

The solubility of gases also depends on pressure. The higher the pressure of a gas above a liquid, the more soluble the gas is in the liquid. In a sealed can of soda pop, for example, the carbon dioxide is maintained in solution by a high pressure of carbon dioxide within the can. When the can is opened, this pressure is released and the solubility of carbon dioxide decreases, resulting in bubbling (Figure 13.12►, on the next page).

## CONCEPTUAL CONNECTION 13.3

► FIGURE 13.12 Soda Fizz

The bubbling that occurs when a can of soda is opened results from the reduced pressure of carbon dioxide over the liquid. At lower pressure, the carbon dioxide is less soluble and bubbles out of solution.

The increased solubility of a gas in a liquid can be understood by considering cylinders containing water and carbon dioxide gas:

**TABLE 13.4** Henry's Law Constants for Several Gases in Water at 25 °C

Gas	$k_H$ (M/atm)
O <sub>2</sub>	$1.3 \times 10^{-3}$
N <sub>2</sub>	$6.1 \times 10^{-4}$
CO <sub>2</sub>	$3.4 \times 10^{-2}$
NH <sub>3</sub>	$5.8 \times 10^1$
He	$3.7 \times 10^{-4}$

The first cylinder represents an equilibrium between gaseous and dissolved carbon dioxide—the rate of carbon dioxide molecules entering solution exactly equals the rate of molecules leaving the solution. Now imagine decreasing the volume, as we have done in the second cylinder. The pressure of carbon dioxide increases, causing the rate of molecules entering the solution to rise. The number of molecules in solution increases until equilibrium is established again, as shown in the third cylinder. However, the amount of carbon dioxide in solution in the third cylinder is greater.

We quantify the solubility of gases with increasing pressure with **Henry's law**:

$$S_{\text{gas}} = k_H P_{\text{gas}}$$

where  $S_{\text{gas}}$  is the solubility of the gas (usually in M),  $k_H$  is a constant of proportionality (called the *Henry's law constant*) that depends on the specific solute and solvent and also on temperature, and  $P_{\text{gas}}$  is the partial pressure of the gas (usually in atm). The equation shows that the solubility of a gas in a liquid is directly proportional to the pressure of the gas above the liquid. Table 13.4 lists the Henry's law constants for several common gases.

## CONCEPTUAL CONNECTION 13.4

**Henry's Law** Examine the Henry's law constants in Table 13.4. Why is the constant for ammonia larger than the others?

### Example 13.2 Henry's Law

What pressure of carbon dioxide is required to keep the carbon dioxide concentration in a bottle of club soda at 0.12 M at 25 °C?

**SORT** You are given the desired solubility of carbon dioxide and asked to find the pressure required to achieve this solubility.

**GIVEN:**  $S_{\text{CO}_2} = 0.12 \text{ M}$

**FIND:**  $P_{\text{CO}_2}$

**STRATEGIZE** Use Henry's law to find the required pressure from the solubility. You will need the Henry's law constant for carbon dioxide, which is listed in Table 13.4.

#### CONCEPTUAL PLAN

#### RELATIONSHIPS USED

$S_{\text{gas}} = k_{\text{H}} P_{\text{gas}}$  (Henry's law)

$k_{\text{H,CO}_2} = 3.4 \times 10^{-2} \text{ M/atm}$  (from Table 13.4)

**SOLVE** Solve the Henry's law equation for  $P_{\text{CO}_2}$  and substitute the other quantities to calculate it.

#### SOLUTION

$$S_{\text{CO}_2} = k_{\text{H,CO}_2} P_{\text{CO}_2}$$

$$\begin{aligned} P_{\text{CO}_2} &= \frac{S_{\text{CO}_2}}{k_{\text{H,CO}_2}} \\ &= \frac{0.12 \text{ M}}{3.4 \times 10^{-2} \frac{\text{M}}{\text{atm}}} \\ &= 3.5 \text{ atm} \end{aligned}$$

**CHECK** The answer is in the correct units and seems reasonable. A small answer (for example, less than 1 atm) would be suspect because you know that the soda is under a pressure greater than atmospheric pressure when you open it. A very large answer (for example, over 100 atm) would be suspect because an ordinary can or bottle probably could not sustain such high pressures without bursting.

**FOR PRACTICE 13.2** Determine the solubility of oxygen in water at 25 °C exposed to air at 1.0 atm. Assume a partial pressure for oxygen of 0.21 atm.

## 13.5 Expressing Solution Concentration

As we have seen, the amount of solute in a solution is an important property of the solution. For example, the amount of sodium chloride in a solution determines whether or not the solution will cause dehydration if consumed. A **dilute solution** contains small quantities of solute relative to the amount of solvent. Drinking a dilute sodium chloride solution does not cause dehydration. A **concentrated solution** contains large quantities of solute relative to the amount of solvent. Drinking a concentrated sodium chloride solution does cause dehydration. Common ways of reporting solution concentration include molarity, molality, parts by mass, parts by volume, mole fraction,

**Solution Concentration: Molarity, Molality, Parts by Mass and Volume, Mole Fraction**

## Chemistry IN THE Environment

### Lake Nyos

Most people living near Lake Nyos in the West African country of Cameroon began August 22, 1986, like any other day. Unfortunately, their day ended in tragedy. On that evening, a large cloud of carbon dioxide gas burped up from the depths of Lake Nyos, killing over 1700 people and about 3000 cattle. Two years before, a similar tragedy had occurred in Lake Monoun, just 60 miles away, killing 37 people. Today, scientists have taken steps to prevent these lakes from accumulating the carbon dioxide that caused the disasters.

◀ Lake Nyos, in Cameroon, has a deceptively peaceful appearance; in the summer of 1986, more than 1700 people died around its shores.

Lake Nyos is a water-filled volcanic crater. Some 50 miles beneath the surface of the lake, molten volcanic rock (magma) produces carbon dioxide gas that seeps into the

◀ A plumbing system slowly vents carbon dioxide from Lake Nyos.

lake. The carbon dioxide forms a solution with the lake water. The high pressure at the bottom of the deep lake allows the solution to become highly concentrated in carbon dioxide. The 1986 disaster occurred because over time—either because of the high concentration itself or because of some other natural trigger such as a landslide or small earthquake—some gaseous carbon dioxide escaped. The rising bubbles disrupted the stratified layers of lake water, causing water at the bottom of the lake to rise to a region of lower pressure. The drop in pressure decreased the solubility of the carbon dioxide, so more carbon dioxide bubbles formed. This in turn caused more churning and still more carbon dioxide release. The result was a massive cloud of carbon dioxide gas that escaped from the lake. Since carbon dioxide is heavier than air, the carbon dioxide traveled down the sides of the volcano and into the nearby valley, displacing air and asphyxiating many of the local residents.

In an effort to keep these events from recurring, scientists have constructed a piping system that slowly vents carbon dioxide from the lake bottom, preventing the buildup that led to the tragedy.

### QUESTION

Suppose that the water pressure at the bottom of Lake Nyos is 25 atm. What is the solubility of carbon dioxide at that depth?

and mole percent, as summarized in Table 13.5. We have seen two of these units before: molarity in Section 4.4, and mole fraction in Section 5.6. In the following section, we review the terms we have already covered and introduce the new ones.

### Molarity

The **molarity (M)** of a solution is the amount of solute (in moles) divided by the volume of solution (in liters):

$$\text{Molarity (M)} = \frac{\text{amount solute (in mol)}}{\text{volume solution (in L)}}$$

**TABLE 13.5** Solution Concentration Terms

Unit	Definition	Units
Molarity (M)	$\frac{\text{amount solute (in mol)}}{\text{volume solution (in L)}}$	$\frac{\text{mol}}{\text{L}}$
Molality ( <i>m</i> )	$\frac{\text{amount solute (in mol)}}{\text{mass solvent (in kg)}}$	$\frac{\text{mol}}{\text{kg}}$
Mole fraction ( $\chi$ )	$\frac{\text{amount solute (in mol)}}{\text{total amount of solute and solvent (in mol)}}$	None
Mole percent (mol %)	$\frac{\text{amount solute (in mol)}}{\text{total amount of solute and solvent (in mol)}} \times 100\%$	%
Parts by mass	$\frac{\text{mass solute}}{\text{mass solution}} \times \text{multiplication factor}$	
Percent by mass (%)	Multiplication factor = 100	%
Parts per million by mass (ppm)	Multiplication factor = $10^6$	ppm
Parts per billion by mass (ppb)	Multiplication factor = $10^9$	ppb
Parts by volume (% , ppm, ppb)	$\frac{\text{volume solute}}{\text{volume solution}} \times \text{multiplication factor}^*$	

\*Multiplication factors for parts by volume are identical to those for parts by mass.

Note that molarity is moles of solute per liter of *solution*, not per liter of solvent. To make a solution of a specified molarity, we usually put the solute into a flask and then add water (or another solvent) to the desired volume of solution, as shown in Figure 13.13. Molarity is a convenient unit to use when making, diluting, and transferring solutions because it specifies the amount of solute per unit of solution.

**▲ FIGURE 13.13** Preparing a Solution of Known Concentration To make a 1 M NaCl solution, we add 1 mol of the solid to a flask and dilute with water to make 1 L of solution.

Molarity depends on volume, and because volume varies with temperature, molarity also varies with temperature. For example, a 1 M aqueous solution at room temperature is slightly less than 1 M at an elevated temperature because the volume of the solution is greater at the elevated temperature.

## Molality

A concentration unit that is independent of temperature is **molality (*m*)**, the amount of solute (in moles) divided by the mass of solvent (in kilograms):

$$\text{Molality } (m) = \frac{\text{amount solute (in mol)}}{\text{mass solvent (in kg)}}$$

Notice that molality is defined with respect to kilograms *solvent*, not kilograms solution. Molality is particularly useful when we need to compare concentrations over a range of different temperatures.

Molality is abbreviated with a lowercase italic *m*, and molarity is abbreviated with a capital M.

### CONCEPTUAL CONNECTION 13.5

**Molality** If you combine 25.0 g of a solute that has a mass of 25.0 g/mol with 100.0 g of a solvent, what is the molality of the resulting solution?

## Parts by Mass and Parts by Volume

It is often convenient to report a concentration as a ratio of masses. A **parts by mass** concentration is the ratio of the mass of the solute to the mass of the solution, all multiplied by a multiplication factor:

$$\frac{\text{Mass solute}}{\text{Mass solution}} \times \text{multiplication factor}$$

The concentration of the solution determines the best parts by mass unit (and therefore the multiplication factor) to use. For example, for **percent by mass** the multiplication factor is 100:

$$\text{Percent by mass} = \frac{\text{mass solute}}{\text{mass solution}} \times 100\%$$

*Percent* means *per hundred*; a solution with a concentration of 14% by mass contains 14 g of solute per 100 g of solution.

For more dilute solutions, we might use **parts per million (ppm)**, which has a multiplication factor of  $10^6$ , or **parts per billion (ppb)**, which has a multiplication factor of  $10^9$ .

$$\text{ppm} = \frac{\text{mass solute}}{\text{mass solution}} \times 10^6$$

$$\text{ppb} = \frac{\text{mass solute}}{\text{mass solution}} \times 10^9$$

A solution with a concentration of 15 ppm by mass, for example, contains 15 g of solute per  $10^6$  g of solution.

Sometimes, we report concentrations as a ratio of volumes, especially for solutions in which both the solute and solvent are liquids. A **parts by volume** concentration is usually the ratio of the volume of the solute to the volume of the solution, all multiplied by a multiplication factor:

$$\frac{\text{Volume solute}}{\text{Volume solution}} \times \text{multiplication factor}$$

The multiplication factors are identical to those just described for parts by mass concentrations. For example, a 22% ethanol solution by volume contains 22 mL of ethanol for every 100 mL of solution.

## Using Parts by Mass (or Parts by Volume) in Calculations

We can use the parts by mass (or parts by volume) concentration of a solution as a conversion factor between mass (or volume) of the solute and mass (or volume) of the

For dilute aqueous solutions near room temperature, the units of ppm are equivalent to milligrams solute/per liter of solution. This is because the density of a dilute aqueous solution near room temperature is 1.0 g/mL, so that 1 L has a mass of 1000 g.

solution. For example, for a solution containing 3.5% sodium chloride by mass, we write the following conversion factor:

$$\frac{3.5 \text{ g NaCl}}{100 \text{ g solution}} \quad \text{converts} \quad \boxed{\text{g solution}} \longrightarrow \boxed{\text{g NaCl}}$$

This conversion factor converts from grams solution to grams NaCl. To convert the other way, we invert the conversion factor:

$$\frac{100 \text{ g solution}}{3.5 \text{ g NaCl}} \quad \text{converts} \quad \boxed{\text{g NaCl}} \longrightarrow \boxed{\text{g solution}}$$

### Example 13.3 Using Parts by Mass in Calculations

What volume (in mL) of a soft drink that is 10.5% sucrose ( $\text{C}_{12}\text{H}_{22}\text{O}_{11}$ ) by mass contains 78.5 g of sucrose? (The density of the solution is 1.04 g/mL.)

**SORT** You are given a mass of sucrose and the concentration and density of a sucrose solution, and you are asked to find the volume of solution containing the given mass.

**STRATEGIZE** Begin with the mass of sucrose in grams. Use the mass percent concentration of the solution (written as a ratio, as shown under Relationships Used) to find the number of grams of solution containing this quantity of sucrose. Then use the density of the solution to convert grams to milliliters of solution.

**SOLVE** Begin with 78.5 g  $\text{C}_{12}\text{H}_{22}\text{O}_{11}$  and multiply by the conversion factors to arrive at the volume of solution.

**CHECK** The units of the answer are correct. The magnitude seems correct because the solution is approximately 10% sucrose by mass. Since the density of the solution is approximately 1 g/mL, the volume containing 78.5 g sucrose should be roughly 10 times larger, as calculated ( $719 \approx 10 \times 78.5$ ).

**FOR PRACTICE 13.3** What mass of sucrose ( $\text{C}_{12}\text{H}_{22}\text{O}_{11}$ ), in g, is contained in 355 mL (12 ounces) of a soft drink that is 11.5% sucrose by mass? (Assume a density of 1.04 g/mL.)

**FOR MORE PRACTICE 13.3** A water sample is found to contain the pollutant chlorobenzene with a concentration of 15 ppb (by mass). What volume of this water contains  $5.00 \times 10^2$  mg of chlorobenzene? (Assume a density of 1.00 g/mL.)

**GIVEN:** 78.5 g  $\text{C}_{12}\text{H}_{22}\text{O}_{11}$   
10.5%  $\text{C}_{12}\text{H}_{22}\text{O}_{11}$  by mass  
density = 1.04 g/mL

**FIND:** mL

#### CONCEPTUAL PLAN

#### RELATIONSHIPS USED

$\frac{10.5 \text{ g C}_{12}\text{H}_{22}\text{O}_{11}}{100 \text{ g soln}}$  (percent by mass written as ratio)

$\frac{1.04 \text{ g}}{1 \text{ mL}}$  (given density of the solution)

#### SOLUTION

$$78.5 \text{ g C}_{12}\text{H}_{22}\text{O}_{11} \times \frac{100 \text{ g soln}}{10.5 \text{ g C}_{12}\text{H}_{22}\text{O}_{11}} \times \frac{1 \text{ mL}}{1.04 \text{ g}} = 719 \text{ mL soln}$$

## Mole Fraction and Mole Percent

For some applications, especially those in which the ratio of solute to solvent can vary widely, the most useful way to express concentration is the amount of solute (in moles) divided by the total amount of solute and solvent (in moles). This ratio is the **mole fraction** ( $\chi_{\text{solute}}$ ):

$$\chi_{\text{solute}} = \frac{\text{amount solute (in mol)}}{\text{total amount of solute and solvent (in mol)}} = \frac{n_{\text{solute}}}{n_{\text{solute}} + n_{\text{solvent}}}$$

The mole fraction can also be defined for the solvent:

$$\chi_{\text{solvent}} = \frac{n_{\text{solvent}}}{n_{\text{solute}} + n_{\text{solvent}}}$$

Also in common use is the **mole percent (mol %)**, which is simply the mole fraction  $\times 100$  percent:

$$\text{mol \%} = \chi_{\text{solute}} \times 100\%$$

Chemistry IN THE Environment

The Dirty Dozen

A number of potentially harmful chemicals—such as DDT, dioxin, and polychlorinated biphenyls (PCBs)—can make their way into water sources from industrial dumping, atmospheric emissions, agricultural use, and household dumping. Since crops, livestock, and fish consume water, they too can accumulate these chemicals. Human consumption of food or water contaminated with harmful chemicals can lead to a number of diseases and adverse health effects such as increased cancer risk, liver damage, and central nervous system damage. Governments around the world have joined forces to ban the production of a number of these kinds of chemicals—called persistent organic pollutants or POPs. The original treaty named the Stockholm Convention on Persistent Organic Pollutants was signed in 2001. It targeted 12 such substances referred to as the “dirty dozen” (Table 13.6).

TABLE 13.6 The Dirty Dozen	
1. Aldrin—insecticide	7. Furan—industrial by-product
2. Chlordane—insecticide	8. Heptachlor—insecticide
3. DDT—insecticide	9. Hexachlorobenzene—fungicide, industrial by-product
4. Dieldrin—insecticide	10. Mirex—insecticide, fire retardant
5. Dioxin—industrial by-product	11. Polychlorinated biphenyls (PCBs)—electrical insulators
6. Eldrin—insecticide	12. Toxaphene—insecticide

▲ Potentially harmful chemicals make their way into water sources in many ways.

One problem common to all of these chemicals is their persistence in the environment. These compounds are fairly stable and do not break down under normal environmental conditions. Once they get into the environment, they stay there for a long time. A second problem with these chemicals

is their contribution to a process called *bioamplification*. Because they are nonpolar, these chemicals are stored and concentrated in the fatty tissues of the organisms that consume them. As larger organisms eat smaller ones, they consume more of the stored chemicals. The result is an increase in the concentrations of these chemicals as they move up the food chain.

◀ The bald eagle was nearly driven to extinction by human use of DDT. Bald eagles eat fish, which became contaminated due to bioamplification. The DDT consumed with the fish caused the eagle’s egg shells to become fragile. The DDT ban has allowed the bald eagle population to recover.

For example, the use of DDT nearly drove the bald eagle (whose egg shells were greatly weakened by eating fish contaminated with DDT) to extinction. In 1963, the population dwindled to less than 500 nesting pairs. Fortunately, nearly all intentional production of DDT (and the other chemicals on this list) has been banned. The bald eagle population has recovered to an estimated 10,000 nesting pairs. The recovery has been so strong that the bald eagle has been removed from both the endangered and threatened species lists.

In the United States, the presence of these contaminants in water supplies is monitored by the Environmental Protection Agency (EPA). The EPA has set limits, called maximum contaminant levels (MCLs), for each of these contaminants in food and drinking water. Table 13.7 lists some MCLs for selected compounds in water supplies. Notice the units that the EPA uses to express the concentration of the contaminants, mg/L. This unit is a conversion factor between liters of water consumed and the mass (in mg) of the pollutant. According to the EPA, as long as the contaminant concentrations are below these levels, the water is safe to drink.

TABLE 13.7 EPA Maximum Contaminant Level (MCL) for Several “Dirty Dozen” Chemicals	
Chlordane	0.002 mg/L
Dioxin	0.00000003 mg/L
Heptachlor	0.0004 mg/L
Hexachlorobenzene	0.001 mg/L

**QUESTION**

Calculate how much of each chemical in Table 13.7 at the MCL is present in 715 L of water, the approximate amount of water consumed by an adult in one year.

**Example 13.4** Calculating Concentrations

A solution is prepared by dissolving 17.2 g of ethylene glycol ( $\text{C}_2\text{H}_6\text{O}_2$ ) in 0.500 kg of water. The final volume of the solution is 515 mL. Calculate the concentration of the solution in each unit.

- (a) molarity
- (b) molality
- (c) percent by mass
- (d) mole fraction
- (e) mole percent

**SOLUTION**

<p>(a) To calculate molarity, first find the amount of ethylene glycol in moles from the mass and molar mass. Then divide the amount in moles by the volume of the solution in liters.</p>	$\text{mol C}_2\text{H}_6\text{O}_2 = 17.2 \text{ g C}_2\text{H}_6\text{O}_2 \times \frac{1 \text{ mol C}_2\text{H}_6\text{O}_2}{62.07 \text{ g C}_2\text{H}_6\text{O}_2} = 0.2771 \text{ mol C}_2\text{H}_6\text{O}_2$ $\text{Molarity (M)} = \frac{\text{amount solute (in mol)}}{\text{volume solution (in L)}}$ $= \frac{0.2771 \text{ mol C}_2\text{H}_6\text{O}_2}{0.515 \text{ L solution}}$ $= 0.538 \text{ M}$
<p>(b) To calculate molality, use the amount of ethylene glycol in moles from part (a), and divide by the mass of the water in kilograms.</p>	$\text{Molality (m)} = \frac{\text{amount solute (in mol)}}{\text{mass solvent (in kg)}}$ $= \frac{0.2771 \text{ mol C}_2\text{H}_6\text{O}_2}{0.500 \text{ kg H}_2\text{O}}$ $= 0.554 \text{ m}$
<p>(c) To calculate percent by mass, divide the mass of the solute by the sum of the masses of the solute and solvent and multiply the ratio by 100%.</p>	$\text{Percent by mass} = \frac{\text{mass solute}}{\text{mass solution}} \times 100\%$ $= \frac{17.2 \text{ g}}{17.2 \text{ g} + 5.00 \times 10^2 \text{ g}} \times 100\%$ $= 3.33\%$
<p>(d) To calculate mole fraction, first determine the amount of water in moles from the mass of water and its molar mass. Then divide the amount of ethylene glycol in moles (from part (a)) by the total number of moles.</p>	$\text{mol H}_2\text{O} = 5.00 \times 10^2 \text{ g H}_2\text{O} \times \frac{1 \text{ mol H}_2\text{O}}{18.02 \text{ g H}_2\text{O}}$ $= 27.75 \text{ mol H}_2\text{O}$ $\chi_{\text{solute}} = \frac{n_{\text{solute}}}{n_{\text{solute}} + n_{\text{solvent}}}$ $= \frac{0.2771 \text{ mol}}{0.2771 \text{ mol} + 27.75 \text{ mol}}$ $= 9.89 \times 10^{-3}$
<p>(e) To calculate mole percent, multiply the mole fraction by 100%.</p>	$\text{mol \%} = \chi_{\text{solute}} \times 100\%$ $= 0.989\%$

**FOR PRACTICE 13.4** A solution is prepared by dissolving 50.4 g sucrose ( $\text{C}_{12}\text{H}_{22}\text{O}_{11}$ ) in 0.332 kg of water. The final volume of the solution is 355 mL. Calculate the concentration of the solution in each unit.

- (a) molarity
- (b) molality
- (c) percent by mass
- (d) mole fraction
- (e) mole percent

**Example 13.5** Converting between Concentration Units

What is the molarity of a 6.56% by mass glucose ( $\text{C}_6\text{H}_{12}\text{O}_6$ ) solution? (The density of the solution is 1.03 g/mL.)

**SORT** You are given the concentration of a glucose solution in percent by mass and the density of the solution. Find the concentration of the solution in molarity.

**GIVEN:** 6.56%  $\text{C}_6\text{H}_{12}\text{O}_6$   
density = 1.03 g/mL

**FIND:** M

**STRATEGIZE** Begin with the mass percent concentration of the solution written as a ratio, and separate the numerator from the denominator. Convert the numerator from g  $\text{C}_6\text{H}_{12}\text{O}_6$  to mol  $\text{C}_6\text{H}_{12}\text{O}_6$ . Convert the denominator from g soln to mL of solution and then to L solution. Divide the numerator (now in mol) by the denominator (now in L) to obtain molarity.

**CONCEPTUAL PLAN****RELATIONSHIPS USED**

$$\frac{6.56 \text{ g C}_6\text{H}_{12}\text{O}_6}{100 \text{ g soln}} \text{ (percent by mass written as ratio)}$$

$$\frac{1 \text{ mol}}{180.16 \text{ g C}_6\text{H}_{12}\text{O}_6} \text{ (from molar mass of glucose)}$$

$$\frac{1 \text{ mL}}{1.03 \text{ g}} \text{ (from given density of the solution)}$$

**SOLVE** Begin with the numerator (6.56 g  $\text{C}_6\text{H}_{12}\text{O}_6$ ) and use the molar mass to convert to mol  $\text{C}_6\text{H}_{12}\text{O}_6$ .

Convert the denominator (100 g solution) into mL of solution (using the density) and then to L of solution.

Finally, divide mol  $\text{C}_6\text{H}_{12}\text{O}_6$  by L solution to arrive at molarity.

**SOLUTION**

$$6.56 \text{ g C}_6\text{H}_{12}\text{O}_6 \times \frac{1 \text{ mol C}_6\text{H}_{12}\text{O}_6}{180.16 \text{ g C}_6\text{H}_{12}\text{O}_6} = 0.036412 \text{ mol C}_6\text{H}_{12}\text{O}_6$$

$$100 \text{ g soln} \times \frac{1 \text{ mL}}{1.03 \text{ g}} \times \frac{10^{-3} \text{ L}}{\text{mL}} = 0.097087 \text{ L soln}$$

$$\frac{0.036412 \text{ mol C}_6\text{H}_{12}\text{O}_6}{0.097087 \text{ L soln}} = 0.375 \text{ M C}_6\text{H}_{12}\text{O}_6$$

**CHECK** The units of the answer are correct. The magnitude seems correct. Very high molarities (especially above 25 M) should immediately appear suspect. One liter of water contains about 55 moles of water molecules, so molarities higher than 55 M are physically impossible.

**FOR PRACTICE 13.5** What is the molarity of a 10.5% by mass glucose ( $\text{C}_6\text{H}_{12}\text{O}_6$ ) solution? (The density of the solution is 1.03 g/mL.)

**FOR MORE PRACTICE 13.5** What is the molality of a 10.5% by mass glucose ( $\text{C}_6\text{H}_{12}\text{O}_6$ ) solution? (The density of the solution is 1.03 g/mL.)

## 13.6 Colligative Properties: Vapor Pressure Lowering, Freezing Point Depression, Boiling Point Elevation, and Osmotic Pressure

Have you ever wondered why you add salt to the ice in an ice-cream maker? Or why salt is scattered on icy roads in cold climates? Salt lowers the temperature at which a saltwater solution freezes. A salt and water solution remains liquid even below 0 °C. When salt is added to ice in the ice-cream maker, an ice/water/salt mixture forms that can reach a temperature of about −10 °C, at which point the cream freezes. On the winter road, the salt allows the ice to melt when the ambient temperature is below freezing.

The depression of the freezing point of water by salt is an example of a **colligative property**, a property that depends on the number of particles dissolved in solution, not on the type of particle. In this section, we examine four colligative properties: vapor pressure lowering, freezing point depression, boiling point elevation, and osmotic pressure.

Since these properties depend on the *number* of dissolved particles, nonelectrolytes are treated slightly differently than electrolytes when determining colligative properties. When 1 mol of a nonelectrolyte dissolves in water, it forms 1 mol of dissolved particles. When 1 mol of an electrolyte dissolves in water, however, it normally forms more than 1 mol of dissolved particles (as shown in Figure 13.14▶). For example, when 1 mol of NaCl dissolves in water, it forms 1 mol of dissolved  $\text{Na}^+$  ions and 1 mol of dissolved  $\text{Cl}^-$  ions. Therefore, the resulting solution has 2 mol of dissolved particles. The colligative properties of electrolyte solutions reflect this higher concentration of dissolved particles. In this section we examine colligative properties of nonelectrolyte solutions; we expand the concept to include electrolyte solutions in Section 13.7.

### Colligative Properties

▲ In winter, salt is often applied to roads so that the ice will melt at lower temperatures.

◀ **FIGURE 13.14** When sodium chloride is dissolved in water, each mole of NaCl produces 2 mol of particles: 1 mol of  $\text{Na}^+$  cations and 1 mol of  $\text{Cl}^-$  anions.

### Vapor Pressure Lowering

Recall from Section 11.5 that the vapor pressure of a liquid is the pressure of the gas above the liquid when the two are in dynamic equilibrium (that is, when the rate of vaporization equals the rate of condensation). How does a nonvolatile nonelectrolyte solute affect the vapor pressure of the liquid into which it dissolves? The basic answer to this question is that *the vapor pressure of the solution is lower than the vapor pressure of the pure solvent*. We can understand why this happens in two different ways.

The simplest explanation for why the vapor pressure of a solution is lower than that of the pure solvent is related to the concept of dynamic equilibrium itself. Consider the following representation of a liquid in dynamic equilibrium with its vapor. Here the rate of vaporization is equal to the rate of condensation:

When a nonvolatile solute is added, however, the solute particles (shown in red) interfere with the ability of the solvent particles (blue) to vaporize. The rate of vaporization is thus diminished compared to that of the pure solvent:

Rate of vaporization  
reduced by solute

The change in the rate of vaporization creates an imbalance in the rates; the rate of condensation is now *greater* than the rate of vaporization. The net effect is that some of the molecules that were in the gas state condense into the liquid state. As they condense, the reduced number of molecules in the gas state causes the rate of condensation to decrease. Eventually the two rates become equal again, but only after the concentration of solvent molecules in the gas state has decreased:

Equilibrium reestablished  
but with fewer molecules  
in gas phase

The result is a lower vapor pressure for the solution compared to the pure solvent.

A more fundamental explanation of why the vapor pressure of a solution is lower than that of the pure solvent is related to the tendency toward mixing (toward greater entropy) that we discussed in Sections 13.1 and 13.2. Recall that a concentrated solution is a *thirsty* solution—it has the ability to draw solvent to itself. We can see a dramatic demonstration of this tendency by placing a concentrated solution of a nonvolatile solute

and a beaker of the pure solvent in a sealed container. Over time, the level of the pure solvent will drop, and the level of the solution will rise as molecules vaporize out of the pure solvent and condense into the solution.

Notice the similarity between this process and the dehydration caused by drinking seawater. In both cases, a concentrated solution has the ability to draw solvent to itself. The reason is nature's tendency to mix. If a pure solvent and concentrated solution are combined in a beaker, they naturally form a mixture in which the concentrated solution becomes less concentrated than it was initially. Similarly, if a pure solvent and concentrated solution are combined in a sealed container—even though they are in separate beakers—the two mix so that the concentrated solution becomes less concentrated.

The net transfer of solvent from the beaker containing pure solvent to the one containing the solution shows that the vapor pressure of the solution is lower than that of the pure solvent. As solvent molecules vaporize, the vapor pressure in the sealed container rises. Before dynamic equilibrium can be attained, however, the pressure exceeds the vapor pressure of the solution, causing molecules to condense into the solution (the beaker on the right). Therefore, molecules constantly vaporize from the pure solvent, but the solvent's vapor pressure is never reached because molecules are constantly condensing into the solution. The result is a continuous transfer of solvent molecules from the pure solvent to the solution.

We can quantify the vapor pressure of a solution with **Raoult's law**:

$$P_{\text{solution}} = \chi_{\text{solvent}} P_{\text{solvent}}^{\circ}$$

In this equation,  $P_{\text{solution}}$  is the vapor pressure of the solution,  $\chi_{\text{solvent}}$  is the mole fraction of the solvent, and  $P_{\text{solvent}}^{\circ}$  is the vapor pressure of the pure solvent at the same temperature. For example, suppose a water sample at 25 °C contains 0.900 mol of water and 0.100 mol of a nonvolatile solute such as sucrose. The pure water has a vapor pressure of 23.8 torr. We calculate the vapor pressure of the solution by substituting into Raoult's law:

$$\begin{aligned} P_{\text{solution}} &= \chi_{\text{H}_2\text{O}} P_{\text{H}_2\text{O}}^{\circ} \\ &= 0.900(23.8 \text{ torr}) \\ &= 21.4 \text{ torr} \end{aligned}$$

Notice that the vapor pressure of the solution is directly proportional to the amount of the solvent in the solution. Since the solvent particles compose 90% of all of the particles in the solution, the vapor pressure of the solution is 90% of the vapor pressure of the pure solvent.

To arrive at an equation that shows how much the vapor pressure is lowered by a solute, we define the **vapor pressure lowering ( $\Delta P$ )** as the difference in vapor pressure between the pure solvent and the solution:

$$\Delta P = P_{\text{solvent}}^{\circ} - P_{\text{solution}}$$

Then, for a two-component solution, we can substitute  $\chi_{\text{solvent}} = 1 - \chi_{\text{solute}}$  into Raoult's law:

$$\begin{aligned} P_{\text{solution}} &= \chi_{\text{solvent}} P_{\text{solvent}}^{\circ} \\ P_{\text{solution}} &= (1 - \chi_{\text{solute}}) P_{\text{solvent}}^{\circ} \\ P_{\text{solvent}}^{\circ} - P_{\text{solution}} &= \chi_{\text{solute}} P_{\text{solvent}}^{\circ} \\ \Delta P &= \chi_{\text{solute}} P_{\text{solvent}}^{\circ} \end{aligned}$$

This last equation indicates that the lowering of the vapor pressure is directly proportional to the mole fraction of the solute.

**Example 13.6** Calculating the Vapor Pressure of a Solution Containing a Nonelectrolyte and Nonvolatile Solute

Calculate the vapor pressure at 25 °C of a solution containing 99.5 g sucrose ( $\text{C}_{12}\text{H}_{22}\text{O}_{11}$ ) and 300.0 mL water. The vapor pressure of pure water at 25 °C is 23.8 torr. Assume the density of water is 1.00 g/mL.

**SORT** You are given the mass of sucrose and volume of water in a solution. You are also given the vapor pressure and density of pure water and asked to find the vapor pressure of the solution.

**GIVEN:** 99.5 g  $\text{C}_{12}\text{H}_{22}\text{O}_{11}$   
 300.0 mL  $\text{H}_2\text{O}$   
 $P_{\text{H}_2\text{O}}^\circ = 23.8$  torr at 25 °C  
 $d_{\text{H}_2\text{O}} = 1.00$  g/mL

**FIND:**  $P_{\text{solution}}$

**STRATEGIZE** Raoult's law relates the vapor pressure of a solution to the mole fraction of the solvent and the vapor pressure of the pure solvent. Begin by calculating the amount in moles of sucrose and water.

Calculate the mole fraction of the solvent from the calculated amounts of solute and solvent.

Then use Raoult's law to calculate the vapor pressure of the solution.

**CONCEPTUAL PLAN**

**SOLVE** Calculate the number of moles of each solution component.

Use the number of moles of each component to calculate the mole fraction of the solvent ( $\text{H}_2\text{O}$ ).

Use the mole fraction of water and the vapor pressure of pure water to calculate the vapor pressure of the solution.

**SOLUTION**

$$99.5 \text{ g C}_{12}\text{H}_{22}\text{O}_{11} \times \frac{1 \text{ mol C}_{12}\text{H}_{22}\text{O}_{11}}{342.30 \text{ g C}_{12}\text{H}_{22}\text{O}_{11}} = 0.2907 \text{ mol C}_{12}\text{H}_{22}\text{O}_{11}$$

$$300.0 \text{ mL H}_2\text{O} \times \frac{1.00 \text{ g}}{1 \text{ mL}} \times \frac{1 \text{ mol H}_2\text{O}}{18.02 \text{ g H}_2\text{O}} = 16.65 \text{ mol H}_2\text{O}$$

$$\begin{aligned} \chi_{\text{H}_2\text{O}} &= \frac{n_{\text{H}_2\text{O}}}{n_{\text{C}_{12}\text{H}_{22}\text{O}_{11}} + n_{\text{H}_2\text{O}}} \\ &= \frac{16.65 \text{ mol}}{0.2907 \text{ mol} + 16.65 \text{ mol}} \\ &= 0.9828 \end{aligned}$$

$$\begin{aligned} P_{\text{solution}} &= \chi_{\text{H}_2\text{O}} P_{\text{H}_2\text{O}}^\circ \\ &= 0.9828 (23.8 \text{ torr}) \\ &= 23.4 \text{ torr} \end{aligned}$$

**CHECK** The units of the answer are correct. The magnitude of the answer seems right because the calculated vapor pressure of the solution is just below that of the pure liquid, as you would expect for a solution with a large mole fraction of solvent.

**FOR PRACTICE 13.6** Calculate the vapor pressure at 25 °C of a solution containing 55.3 g ethylene glycol ( $\text{HOCH}_2\text{CH}_2\text{OH}$ ) and 285.2 g water. The vapor pressure of pure water at 25 °C is 23.8 torr.

**FOR MORE PRACTICE 13.6** A solution containing ethylene glycol and water has a vapor pressure of 7.88 torr at 10 °C. Pure water has a vapor pressure of 9.21 torr at 10 °C. What is the mole fraction of ethylene glycol in the solution?

## Vapor Pressures of Solutions Containing a Volatile (Nonelectrolyte) Solute

Some solutions contain not only a volatile solvent, but also a volatile *solute*. In this case, *both* the solvent and the solute contribute to the overall vapor pressure of the solution. A solution like this may be an **ideal solution** (in which case its behavior follows Raoult's law at all concentrations for both the solvent and the solute), or it may be nonideal (in which case it does not follow Raoult's law).

An ideal solution is similar in concept to an ideal gas. Just as an ideal gas follows the ideal gas law exactly, so an ideal solution follows Raoult's law exactly. In an ideal solution, the solute-solvent interactions are similar in magnitude to the solute-solute and solvent-solvent interactions. In this type of solution, the solute simply dilutes the solvent and ideal behavior is observed. The vapor pressure of each solution component is described by Raoult's law throughout the entire composition range of the solution. For a two-component solution containing liquids A and B, we write:

$$P_A = \chi_A P_A^\circ$$

$$P_B = \chi_B P_B^\circ$$

The total pressure above such a solution is the sum of the partial pressures of the components:

$$P_{\text{tot}} = P_A + P_B$$

Figure 13.15(a) is a plot of vapor pressure versus solution composition for an ideal two-component solution.

In a nonideal solution, the solute-solvent interactions are either stronger or weaker than the solvent-solvent interactions. If the solute-solvent interactions are stronger, then the solute tends to prevent the solvent from vaporizing as readily as it would otherwise. If the solution is sufficiently dilute, then the effect will be small and Raoult's law works as an approximation. However, if the solution is not dilute, the effect will be significant and the vapor pressure of the solution will be *less than* that predicted by Raoult's law, as shown in Figure 13.15(b).

If, however, the solute-solvent interactions are weaker than solvent-solvent interactions, then the solute tends to allow more vaporization than would occur with just the solvent. If the solution is not dilute, the effect will be significant and the vapor pressure of the solution will be *greater than* predicted by Raoult's law, as shown in Figure 13.15(c).

Over a complete range of composition of a solution, it no longer makes sense to designate a solvent and solute, so we simply label the two components A and B.

### Deviations from Raoult's Law

**▲ FIGURE 13.15 Behavior of Ideal and Nonideal Solutions** (a) An ideal solution follows Raoult's law for both components. (b) A solution with particularly strong solute-solvent interactions displays negative deviations from Raoult's law. (c) A solution with particularly weak solute-solvent interactions displays positive deviations from Raoult's law. (The dashed lines in parts b and c represent ideal behavior.)

**Example 13.7** Calculating the Vapor Pressure of a Two-Component Solution

A solution contains 3.95 g of carbon disulfide ( $\text{CS}_2$ ) and 2.43 g of acetone ( $\text{CH}_3\text{COCH}_3$ ). At  $35^\circ\text{C}$  the vapor pressures of pure carbon disulfide and pure acetone are 515 torr and 332 torr, respectively. Assuming ideal behavior, calculate the vapor pressures of each component and the total vapor pressure above the solution. The experimentally measured total vapor pressure of the solution at  $35^\circ\text{C}$  is 645 torr. Is the solution ideal? If not, what can you say about the relative strength of carbon disulfide–acetone interactions compared to the acetone–acetone and carbon disulfide–carbon disulfide interactions?

**SORT** You are given the masses and vapor pressures of carbon disulfide and acetone and are asked to find the vapor pressures of each component in the mixture and the total pressure assuming ideal behavior.

**GIVEN:** 3.95 g  $\text{CS}_2$

2.43 g  $\text{CH}_3\text{COCH}_3$

$P_{\text{CS}_2}^\circ = 515 \text{ torr (at } 35^\circ\text{C)}$

$P_{\text{CH}_3\text{COCH}_3}^\circ = 332 \text{ torr (at } 35^\circ\text{C)}$

$P_{\text{tot}}(\text{exp}) = 645 \text{ torr (at } 35^\circ\text{C)}$

**FIND:**  $P_{\text{CS}_2}$ ,  $P_{\text{CH}_3\text{COCH}_3}$ ,  $P_{\text{tot}}(\text{ideal})$

**STRATEGIZE** This problem requires that you use Raoult's law to calculate the partial pressures of each component. In order to use Raoult's law, first calculate the mole fractions of the two components. Convert the masses of each component to moles and then use the definition of mole fraction to calculate the mole fraction of carbon disulfide. You can then find the mole fraction of acetone because the mole fractions of the two components add up to 1.

**CONCEPTUAL PLAN**

Use the mole fraction of each component along with Raoult's law to calculate the partial pressure of each component. The total pressure is the sum of the partial pressures.

$$P_{\text{CS}_2} = \chi_{\text{CS}_2} P_{\text{CS}_2}^\circ$$

$$P_{\text{CH}_3\text{COCH}_3} = \chi_{\text{CH}_3\text{COCH}_3} P_{\text{CH}_3\text{COCH}_3}^\circ$$

$$P_{\text{tot}} = P_{\text{CS}_2} + P_{\text{CH}_3\text{COCH}_3}$$

**RELATIONSHIPS USED**

$$\chi_A = \frac{n_A}{n_A + n_B} \text{ (mole fraction definition)}$$

$$P_A = \chi_A P_A^\circ \text{ (Raoult's law)}$$

**SOLVE** Begin by converting the mass of each component to the amounts in moles.

**SOLUTION**

$$3.95 \text{ g } \text{CS}_2 \times \frac{1 \text{ mol } \text{CS}_2}{76.15 \text{ g } \text{CS}_2} = 0.05187 \text{ mol } \text{CS}_2$$

$$2.43 \text{ g } \text{CH}_3\text{COCH}_3 \times \frac{1 \text{ mol } \text{CH}_3\text{COCH}_3}{58.08 \text{ g } \text{CH}_3\text{COCH}_3} = 0.04184 \text{ mol } \text{CH}_3\text{COCH}_3$$

Then calculate the mole fraction of carbon disulfide.	$\chi_{\text{CS}_2} = \frac{n_{\text{CS}_2}}{n_{\text{CS}_2} + n_{\text{CH}_3\text{COCH}_3}}$ $= \frac{0.05187 \text{ mol}}{0.05187 \text{ mol} + 0.04184 \text{ mol}}$ $= 0.5535$
Calculate the mole fraction of acetone by subtracting the mole fraction of carbon disulfide from 1.	$\chi_{\text{CH}_3\text{COCH}_3} = 1 - 0.5535$ $= 0.4465$
Calculate the partial pressures of carbon disulfide and acetone by using Raoult's law and the given values of the vapor pressures of the pure substances.	$P_{\text{CS}_2} = \chi_{\text{CS}_2} P_{\text{CS}_2}^\circ$ $= 0.5535 (515 \text{ torr})$ $= 285 \text{ torr}$ $P_{\text{CH}_3\text{COCH}_3} = \chi_{\text{CH}_3\text{COCH}_3} P_{\text{CH}_3\text{COCH}_3}^\circ$ $= 0.4465 (332 \text{ torr})$ $= 148 \text{ torr}$
Calculate the total pressure by summing the partial pressures.	$P_{\text{tot}}(\text{ideal}) = 285 \text{ torr} + 148 \text{ torr}$ $= 433 \text{ torr}$
Lastly, compare the calculated total pressure for the ideal case to the experimentally measured total pressure. Since the experimentally measured pressure is greater than the calculated pressure, we can conclude that the interactions between the two components are weaker than the interactions between the components themselves.	$P_{\text{tot}}(\text{exp}) = 645 \text{ torr}$ $P_{\text{tot}}(\text{exp}) > P_{\text{tot}}(\text{ideal})$ <p>The solution is not ideal and shows positive deviations from Raoult's law. Therefore, carbon disulfide–acetone interactions must be weaker than acetone–acetone and carbon disulfide–carbon disulfide interactions.</p>
<b>CHECK</b> The units of the answer (torr) are correct. The magnitude seems reasonable given the partial pressures of the pure substances.	
<p><b>FOR PRACTICE 13.7</b> A solution of benzene (<math>\text{C}_6\text{H}_6</math>) and toluene (<math>\text{C}_7\text{H}_8</math>) is 25.0% benzene by mass. At 25 °C the vapor pressures of pure benzene and pure toluene are 94.2 torr and 28.4 torr, respectively. Assuming ideal behavior, calculate the following:</p> <p>(a) The vapor pressure of each of the solution components in the mixture.</p> <p>(b) The total pressure above the solution.</p> <p>(c) The composition of the vapor in mass percent.</p> <p>Why is the composition of the vapor different from the composition of the solution?</p>	

**Raoult's Law** A solution contains equal amounts (in moles) of liquid components A and B. The vapor pressure of pure A is 100 mmHg and that of pure B is 200 mmHg. The experimentally measured vapor pressure of the solution is 120 mmHg. What are the relative strengths of the solute–solute, solute–solvent, and solvent–solvent interactions in this solution?

### CONCEPTUAL CONNECTION 13.6

## Freezing Point Depression and Boiling Point Elevation

Vapor pressure lowering occurs at all temperatures. We can see the effect of vapor pressure lowering over a range of temperatures by comparing the phase diagrams for a pure solvent and for a solution containing a nonvolatile solute:

► A nonvolatile solute lowers the vapor pressure of a solution, resulting in a lower freezing point and an elevated boiling point.

Notice that the vapor pressure for the solution is shifted downward compared to that of the pure solvent. Consequently, the vapor pressure curve intersects the solid–gas curve at a lower temperature. The net effect is that the solution has a *lower melting point* and a *higher boiling point* than the pure solvent. These effects are called **freezing point depression** and **boiling point elevation**, respectively, both of which are colligative properties (like vapor pressure lowering).

The freezing point of a solution containing a nonvolatile solute is lower than the freezing point of the pure solvent. For example, antifreeze, used to prevent the freezing of engine blocks in cold climates, is an aqueous solution of ethylene glycol ( $\text{C}_2\text{H}_6\text{O}_2$ ). The more concentrated the solution, the lower the freezing point becomes.

The amount that the freezing point decreases is given by the following equation:

$$\Delta T_f = m \times K_f$$

where

- $\Delta T_f$  is the change in temperature of the freezing point in Celsius degrees (relative to the freezing point of the pure solvent), usually reported as a positive number;
- $m$  is the molality of the solution in moles solute per kilogram solvent; and
- $K_f$  is the freezing point depression constant for the solvent.

For water,

$$K_f = 1.86^\circ\text{C}/m$$

When an aqueous solution containing a dissolved solid solute freezes slowly, the ice that forms does not normally contain much of the solute. For example, when ice forms in ocean water, the ice is not salt water, but freshwater. As the ice forms, the crystal structure of the ice tends to exclude the solute particles. You can verify this yourself by partially freezing a saltwater solution in the freezer. Take out the newly formed ice, rinse it several times, and taste it. Compare its taste to the taste of the original solution. The ice is much less salty.

▲ Antifreeze is an aqueous solution of ethylene glycol. The solution has a lower freezing point and higher boiling point than pure water.

**TABLE 13.8** Freezing Point Depression and Boiling Point Elevation Constants for Several Liquid Solvents

Solvent	Normal Freezing Point (°C)	$K_f$ (°C/m)	Normal Boiling Point (°C)	$K_b$ (°C/m)
Benzene (C <sub>6</sub> H <sub>6</sub> )	5.5	5.12	80.1	2.53
Carbon tetrachloride (CCl <sub>4</sub> )	−22.9	29.9	76.7	5.03
Chloroform (CHCl <sub>3</sub> )	−63.5	4.70	61.2	3.63
Ethanol (C <sub>2</sub> H <sub>5</sub> OH)	−114.1	1.99	78.3	1.22
Diethyl ether (C <sub>4</sub> H <sub>10</sub> O)	−116.3	1.79	34.6	2.02
Water (H <sub>2</sub> O)	0.00	1.86	100.0	0.512

Table 13.8 provides freezing point depression and boiling point elevation constants for several liquids. Calculating the freezing point of a solution involves substituting into the freezing point depression equation as Example 13.8 demonstrates.

### Example 13.8 Freezing Point Depression

Calculate the freezing point of a 1.7 *m* aqueous ethylene glycol solution.

**SORT** You are given the molality of a solution and asked to find its freezing point.

**GIVEN:** 1.7 *m* solution

**FIND:** freezing point (from  $\Delta T_f$ )

**STRATEGIZE** To solve this problem, use the freezing point depression equation.

**CONCEPTUAL PLAN**

**SOLVE** Substitute into the equation to calculate  $\Delta T_f$ . The actual freezing point is the freezing point of pure water (0.00 °C) −  $\Delta T_f$ .

**SOLUTION**

$$\begin{aligned}
 \Delta T_f &= m \times K_f \\
 &= 1.7 \cancel{m} \times 1.86 \text{ } ^\circ\text{C}/\cancel{m} \\
 &= 3.2 \text{ } ^\circ\text{C} \\
 \text{Freezing point} &= 0.00 \text{ } ^\circ\text{C} - 3.2 \text{ } ^\circ\text{C} \\
 &= -3.2 \text{ } ^\circ\text{C}
 \end{aligned}$$

**CHECK** The units of the answer are correct. The magnitude seems about right. The expected range for freezing points of an aqueous solution is anywhere from −10 °C to just below 0 °C. Any answers out of this range would be suspect.

**FOR PRACTICE 13.8** Calculate the freezing point of a 2.6 *m* aqueous sucrose solution.

The boiling point of a solution containing a nonvolatile solute is higher than the boiling point of the pure solvent. In automobiles, antifreeze not only prevents the freezing of water within engine blocks in cold climates, it also prevents the boiling of water within engine blocks in hot climates. The amount that boiling points rise in solutions is given by the equation:

$$\Delta T_b = m \times K_b$$

where

- $\Delta T_b$  is the change in temperature of the boiling point in Celsius degrees (relative to the boiling point of the pure solvent);
- $m$  is the molality of the solution in moles solute per kilogram solvent; and
- $K_b$  is the boiling point elevation constant for the solvent.

For water,

$$K_b = 0.512^\circ\text{C}/m$$

Calculating the boiling point of a solution involves substituting into the boiling point elevation equation, as Example 13.9 demonstrates.

## CONCEPTUAL CONNECTION 13.7

**Boiling Point Elevation** Solution A is a 1.0 M solution with a nonionic solute and water as the solvent. Solution B is a 1.0 M solution with the same nonionic solute and ethanol as the solvent. Which solution has the greater increase in its boiling point (relative to the pure solvent)?

### Example 13.9 Boiling Point Elevation

What mass of ethylene glycol ( $\text{C}_2\text{H}_6\text{O}_2$ ), in grams, must be added to 1.0 kg of water to produce a solution that boils at  $105.0^\circ\text{C}$ ?

**SORT** You are given the desired boiling point of an ethylene glycol solution containing 1.0 kg of water and asked to find the mass of ethylene glycol you need to add to raise the boiling point.

**GIVEN:**  $\Delta T_b = 5.0^\circ\text{C}$ , 1.0 kg  $\text{H}_2\text{O}$

**FIND:** g  $\text{C}_2\text{H}_6\text{O}_2$

**STRATEGIZE** To solve this problem, use the boiling point elevation equation to calculate the desired molality of the solution from  $\Delta T_b$ .

#### CONCEPTUAL PLAN

Then use that molality to determine how many moles of ethylene glycol are needed per kilogram of water. Finally, calculate the molar mass of ethylene glycol and use it to convert from moles of ethylene glycol to mass of ethylene glycol.

**RELATIONSHIPS USED**  $\text{C}_2\text{H}_6\text{O}_2$  molar mass = 62.07 g/mol  
 $\Delta T_b = m \times K_b$  (boiling point elevation)

**SOLVE** Begin by solving the boiling point elevation equation for molality and substituting the required quantities to calculate  $m$ .

#### SOLUTION

$$\begin{aligned}
 \Delta T_b &= m \times K_b \\
 m &= \frac{\Delta T_b}{K_b} = \frac{5.0^\circ\text{C}}{0.512^\circ\text{C}/m} \\
 &= 9.77\,m \\
 1.0\,\text{kg H}_2\text{O} &\times \frac{9.77\,\text{mol C}_2\text{H}_6\text{O}_2}{\text{kg H}_2\text{O}} \times \frac{62.07\,\text{g C}_2\text{H}_6\text{O}_2}{1\,\text{mol C}_2\text{H}_6\text{O}_2} = 6.1 \times 10^2\,\text{g C}_2\text{H}_6\text{O}_2
 \end{aligned}$$

**CHECK** The units of the answer are correct. The magnitude might seem a little high initially, but the boiling point elevation constant is so small that a lot of solute is required to raise the boiling point by a small amount.

**FOR PRACTICE 13.9** Calculate the boiling point of a 3.60  $m$  aqueous sucrose solution.

## Chemistry IN YOUR DAY Antifreeze in Frogs

**W**ood frogs (*Rana sylvatica*) look like most other frogs. They are a few inches long and have characteristic greenish-brown skin. However, wood frogs survive cold winters in a remarkable way—they partially freeze. In its partially frozen state, a wood frog has no heartbeat, no blood circulation, no breathing, and no brain activity. Within 1–2 hours of thawing, however, these vital functions return and the frog hops off to find food. How does the wood frog do this?

Most cold-blooded animals cannot survive freezing temperatures because the water within their cells freezes. As we learned in Section 11.9, when water freezes, it expands, irreversibly damaging cells. When the wood frog hibernates for the winter, however, it produces large amounts of glucose that is secreted into its bloodstream and fills the interior of its cells. When the temperature drops below freezing, extracellular body fluids, such as those in the frog's abdominal cavity, freeze solid. Fluids within cells, however, remain liquid because the high glucose concentration lowers their freezing point. In other words, the concentrated glucose solution within the frog's cells acts as antifreeze, preventing the water within the cells from freezing and allowing the frog to survive.

### QUESTION

The wood frog can survive at body temperatures as low as  $-8.0^{\circ}\text{C}$ . Calculate the molality of a glucose solution ( $\text{C}_6\text{H}_{12}\text{O}_6$ ) required to lower the freezing point of water to  $-8.0^{\circ}\text{C}$ .

▲ The wood frog survives winter by partially freezing. It protects its cells by flooding them with glucose, which acts as an antifreeze.

## Osmotic Pressure

The process by which seawater causes dehydration (discussed in Section 13.1) is *osmosis*.

**Osmosis** is the flow of solvent from a solution of lower solute concentration to one of higher solute concentration. Concentrated solutions draw solvent from more dilute solutions because of nature's tendency to mix.

Figure 13.16 illustrates an osmosis cell. The left side of the cell contains a concentrated saltwater solution and the right side of the cell contains pure water. A **semipermeable membrane**—a membrane that selectively allows some substances to pass through but not

### Osmosis and Osmotic Pressure

▲ **FIGURE 13.16 An Osmosis Cell** In an osmosis cell, water flows from the pure-water side of the cell through the semipermeable membrane to the saltwater side.

others—separates the two halves of the cell. Water flows by osmosis from the pure-water side of the cell through the semipermeable membrane and into the saltwater side. Over time, the water level on the left side of the cell rises, while the water level on the right side of the cell falls. If external pressure is applied to the water in the left side, this process can be opposed and even reversed. The pressure required to stop the osmotic flow, called the **osmotic pressure**, is given by the following equation:

$$\Pi = MRT$$

where  $M$  is the molarity of the solution,  $T$  is the temperature (in Kelvin), and  $R$  is the ideal gas constant ( $0.08206 \text{ L} \cdot \text{atm}/\text{mol} \cdot \text{K}$ ).

### Example 13.10 Osmotic Pressure

The osmotic pressure of a solution containing 5.87 mg of an unknown protein per 10.0 mL of solution is 2.45 torr at 25 °C. Find the molar mass of the unknown protein.

**SORT** You are told that a solution of an unknown protein contains 5.87 mg of the protein per 10.0 mL of solution. You are also given the osmotic pressure of the solution at a particular temperature and asked to find the molar mass of the unknown protein.

**GIVEN:** 5.87 mg protein  
10.0 mL solution  
 $\Pi = 2.45 \text{ torr}$   
 $T = 25 \text{ }^{\circ}\text{C}$

**FIND:** molar mass of protein (g/mol)

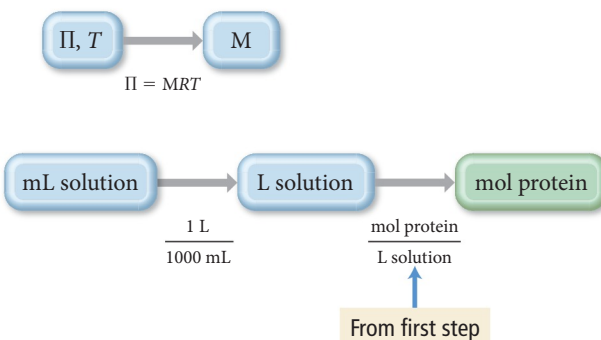

#### STRATEGIZE

Step 1: Use the given osmotic pressure and temperature to find the molarity of the protein solution.

Step 2: Use the molarity calculated in step 1 to find the number of moles of protein in 10 mL of solution.

Step 3: Finally, use the number of moles of the protein calculated in step 2 and the given mass of the protein in 10.0 mL of solution to find the molar mass.

#### CONCEPTUAL PLAN

$$\text{Molar mass} = \frac{\text{mass protein}}{\text{moles protein}}$$

**RELATIONSHIPS USED**  $\Pi = MRT$  (osmotic pressure equation)

**SOLVE** Step 1: Begin by solving the osmotic pressure equation for molarity and substituting in the required quantities in the correct units to calculate  $M$ .

#### SOLUTION

$$\Pi = MRT$$

$$M = \frac{\Pi}{RT} = \frac{2.45 \text{ torr} \times \frac{1 \text{ atm}}{760 \text{ torr}}}{0.08206 \frac{\text{L} \cdot \text{atm}}{\text{mol} \cdot \text{K}} (298 \text{ K})}$$

$$= 1.318 \times 10^{-4} \text{ M}$$

Step 2: Begin with the given volume, convert to liters, then use the molarity to find the number of moles of protein.

$$10.0 \text{ mL} \times \frac{1 \text{ L}}{1000 \text{ mL}} \times \frac{1.318 \times 10^{-4} \text{ mol}}{\text{L}} = 1.318 \times 10^{-6} \text{ mol}$$

Step 3: Use the given mass and the number of moles from step 2 to calculate the molar mass of the protein.

$$\text{Molar mass} = \frac{\text{mass protein}}{\text{moles protein}}$$

$$= \frac{5.87 \times 10^{-3} \text{ g}}{1.318 \times 10^{-6} \text{ mol}} = 4.45 \times 10^3 \text{ g/mol}$$

**CHECK** The units of the answer are correct. The magnitude might seem a little high initially, but proteins are large molecules and therefore have high molar masses.

**FOR PRACTICE 13.10** Calculate the osmotic pressure (in atm) of a solution containing 1.50 g ethylene glycol ( $\text{C}_2\text{H}_6\text{O}_2$ ) in 50.0 mL of solution at 25 °C.

## 13.7 Colligative Properties of Strong Electrolyte Solutions

At the beginning of Section 13.6, we saw that colligative properties depend on the number of dissolved particles and that we must therefore treat electrolytes slightly differently than nonelectrolytes when determining colligative properties. For example, the freezing point depression of a 0.10 *m* sucrose solution is  $\Delta T_f = 0.186$  °C. However, the freezing point depression of a 0.10 *m* sodium chloride solution is nearly twice this large. Why? Because 1 mol of sodium chloride dissociates into nearly 2 mol of ions in solution. The ratio of moles of particles in solution to moles of formula units dissolved is called the **van't Hoff factor (*i*)**:

$$i = \frac{\text{moles of particles in solution}}{\text{moles of formula units dissolved}}$$

Since 1 mol of NaCl produces 2 mol of particles in solution, we expect the van't Hoff factor for NaCl to be exactly 2. In reality, this expected factor only occurs in very dilute solutions. For example, the van't Hoff factor for a 0.10 *m* NaCl solution is 1.87, and for a 0.010 *m* NaCl solution the van't Hoff factor is 1.94. The van't Hoff factor approaches the expected value at infinite dilution (as the concentration approaches zero). Table 13.9 lists the actual and expected van't Hoff factors for a number of solutes.

The reason that van't Hoff factors do not exactly equal expected values is that some ions effectively pair in solution. We expect the dissociation of an ionic compound to be complete in solution. In reality, however, the dissociation is not complete—at any moment, some cations pair with anions (Figure 13.17▶), slightly reducing the number of particles in solution.

To calculate freezing point depression, boiling point elevation, and osmotic pressure of ionic solutions, we use the van't Hoff factor in each equation as follows:

$$\Delta T_f = im \times K_f \text{ (freezing point depression)}$$

$$\Delta T_b = im \times K_b \text{ (boiling point elevation)}$$

$$\Pi = iMRT \text{ (osmotic pressure)}$$

**TABLE 13.9** Van't Hoff Factors at 0.05 *m* Concentration in Aqueous Solution

Solute	<i>i</i> Expected	<i>i</i> Measured
Nonelectrolyte	1	1
NaCl	2	1.9
MgSO <sub>4</sub>	2	1.3
MgCl <sub>2</sub>	3	2.7
K <sub>2</sub> SO <sub>4</sub>	3	2.6
FeCl <sub>3</sub>	4	3.4

◀ **FIGURE 13.17** Ion Pairing  
Hydrated anions and cations may get close enough together to effectively pair, lowering the concentration of particles below what would be expected.

**Colligative Properties** Which solution has the highest boiling point?

- (a) 0.50 M  $\text{C}_{12}\text{H}_{22}\text{O}_{11}$
- (b) 0.50 M NaCl
- (c) 0.50 M  $\text{MgCl}_2$

CONCEPTUAL  
**CONNECTION 13.8**

**Example 13.11** Van't Hoff Factor and Freezing Point Depression

The freezing point of an aqueous 0.050 *m* CaCl<sub>2</sub> solution is  $-0.27^{\circ}\text{C}$ . What is the van't Hoff factor (*i*) for CaCl<sub>2</sub> at this concentration? How does it compare to the expected value of *i*?

**SORT** You are given the molality of a solution and its freezing point. You are asked to find the value of *i*, the van't Hoff factor, and compare it to the expected value.

**GIVEN:** 0.050 *m* CaCl<sub>2</sub> solution,  
 $\Delta T_f = 0.27^{\circ}\text{C}$

**FIND:** *i*

**STRATEGIZE** To solve this problem, use the freezing point depression equation including the van't Hoff factor.

**CONCEPTUAL PLAN**

$$\Delta T_f = im \times K_f$$

**SOLVE** Solve the freezing point depression equation for *i*, substituting in the given quantities to calculate its value.

**SOLUTION**

$$\Delta T_f = im \times K_f$$

The expected value of *i* for CaCl<sub>2</sub> is 3 because calcium chloride forms 3 mol of ions for each mole of calcium chloride that dissolves. Because of ion pairing, the experimental value is slightly less than 3.

$$\begin{aligned} i &= \frac{\Delta T_f}{m \times K_f} \\ &= \frac{0.27^{\circ}\text{C}}{0.050\text{ }m \times \frac{1.86^{\circ}\text{C}}{m}} \\ &= 2.9 \end{aligned}$$

**CHECK** The answer has no units, as expected since *i* is a ratio. The magnitude is about right since it is close to the value you would expect upon complete dissociation of CaCl<sub>2</sub>.

**FOR PRACTICE 13.11** Calculate the freezing point of an aqueous 0.10 *m* FeCl<sub>3</sub> solution using a van't Hoff factor of 3.2.

**Strong Electrolytes and Vapor Pressure**

Just as the freezing point depression of a solution containing an electrolyte solute is greater than that of a solution containing the same concentration of a nonelectrolyte solute, so the vapor pressure lowering is greater (for the same reasons). The vapor pressure for a sodium chloride solution, for example, is lowered about twice as much as it is for a nonelectrolyte solution of the same concentration. To calculate the vapor pressure of a solution containing an ionic solute, we need to account for the dissociation of the solute when we calculate the mole fraction of the solvent, as we demonstrate in Example 13.12.

**Example 13.12** Calculating the Vapor Pressure of a Solution Containing an Ionic Solute

A solution contains 0.102 mol Ca(NO<sub>3</sub>)<sub>2</sub> and 0.927 mol H<sub>2</sub>O. Calculate the vapor pressure of the solution at 55  $^{\circ}\text{C}$ . The vapor pressure of pure water at 55  $^{\circ}\text{C}$  is 118.1 torr. (Assume that the solute completely dissociates.)

**SORT** You are given the number of moles of each component of a solution and asked to find the vapor pressure of the solution. You are also given the vapor pressure of pure water at the appropriate temperature.

**GIVEN:** 0.102 mol Ca(NO<sub>3</sub>)<sub>2</sub>

0.927 mol H<sub>2</sub>O

$P_{\text{H}_2\text{O}}^{\circ} = 118.1\text{ torr (at } 55^{\circ}\text{C)}$

**FIND:**  $P_{\text{solution}}$

**STRATEGIZE** To solve this problem, use Raoult's law as you did in Example 13.6. Calculate  $\chi_{\text{solvent}}$  from the given amounts of solute and solvent.

**CONCEPTUAL PLAN**

**SOLVE** The key to this problem is to understand the dissociation of calcium nitrate. Write the equation showing the dissociation.

Since 1 mol of calcium nitrate dissociates into 3 mol of dissolved particles, multiply the number of moles of calcium nitrate by 3 when calculating the mole fraction.

Use the mole fraction of water and the vapor pressure of pure water to calculate the vapor pressure of the solution.

**SOLUTION**

$$\begin{aligned}\chi_{\text{H}_2\text{O}} &= \frac{n_{\text{H}_2\text{O}}}{3 \times n_{\text{Ca}(\text{NO}_3)_2} + n_{\text{H}_2\text{O}}} \\ &= \frac{0.927 \text{ mol}}{3(0.102) \text{ mol} + 0.927 \text{ mol}} \\ &= 0.7518\end{aligned}$$

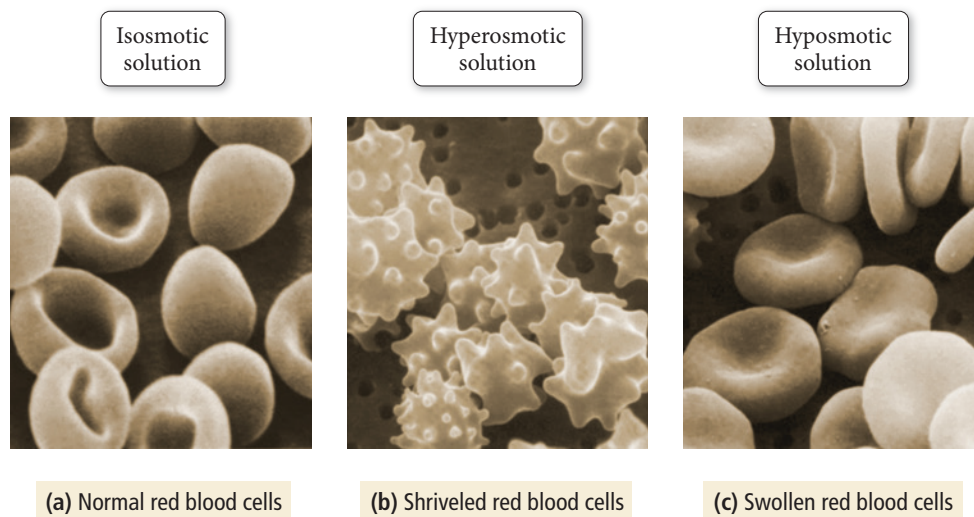

$$\begin{aligned}P_{\text{solution}} &= \chi_{\text{H}_2\text{O}} P_{\text{H}_2\text{O}}^{\circ} \\ &= 0.7518 (118.1 \text{ torr}) \\ &= 88.8 \text{ torr}\end{aligned}$$

**CHECK** The units of the answer are correct. The magnitude also seems right because the calculated vapor pressure of the solution is significantly less than that of the pure solvent, as you would expect for a solution with a significant amount of solute.

**FOR PRACTICE 13.12** A solution contains 0.115 mol  $\text{H}_2\text{O}$  and an unknown number of moles of sodium chloride. The vapor pressure of the solution at  $30^\circ\text{C}$  is 25.7 torr. The vapor pressure of pure water at  $30^\circ\text{C}$  is 31.8 torr. Calculate the number of moles of sodium chloride in the solution.

## Colligative Properties and Medical Solutions

Doctors and other health care workers often administer solutions to patients. The osmotic pressure of these solutions is controlled for the desired effect on the patient. Solutions having osmotic pressures greater than those of body fluids are called *hyperosmotic*. These solutions take water out of cells and tissues. When a human cell is placed in a hyperosmotic solution, it tends to shrivel as it loses water to the surrounding solution (Figure 13.18(b)▼). Solutions having osmotic pressures less than those of body fluids are called *hyposmotic*. These solutions pump water into cells. When a human cell is placed in a hyposmotic solution—such as pure water, for example—water enters the cell, sometimes causing it to burst (Figure 13.18(c)▼).

▲ **FIGURE 13.18 Red Blood Cells and Osmosis** (a) In an isosmotic solution, red blood cells have the normal shape shown here. In a hyperosmotic solution (b), they lose water and shrivel. In a hyposmotic solution (c), they swell up and may burst as water flows into the cell.

Intravenous solutions—those that are administered directly into a patient's veins—must have osmotic pressures equal to those of body fluids. These solutions are called *isosmotic* (or *isotonic*). When a patient is given an IV in a hospital, the majority of the fluid is usually an isosmotic saline solution—a solution containing 0.9 g NaCl per 100 mL of solution. In medicine and in other health-related fields, solution concentrations are often reported in units that indicate the mass of the solute per given volume of solution. Also common is *percent mass to volume*—which is the mass of the solute in grams divided by the volume of the solution in milliliters times 100%. In these units, the concentration of an isotonic saline solution is 0.9% mass/volume.

► Fluids used for intravenous transfusion must be isosmotic with bodily fluids—that is, they must have the same osmotic pressure as body fluids.

## 13.8 Colloids

When you mix water and soap together, the resulting mixture has a distinctive haze (Figure 13.19◀). Soapy water is hazy because soap and water form a *colloidal dispersion* rather than a true solution. A **colloidal dispersion**, or more simply a **colloid**, is a mixture in which a dispersed substance (which is solute-like) is finely divided in a dispersing medium (which is solvent-like). Examples of colloids including fog, smoke, whipped cream, and milk are listed in Table 13.10.

Whether or not a mixture is a colloid is determined by the size of the particles it contains. If the particles are small (for example, individual small molecules), then the mixture is a solution. If the particles have a diameter greater than  $1\ \mu\text{m}$  (for example, grains of sand), then the mixture is a heterogeneous mixture. Sand stirred into water slowly settles out of the water. *If the particles are between 1 nm and 1000 nm in size, the mixture is a colloid.* Colloidal particles are small enough that they stay dispersed throughout the dispersing medium by collisions with other molecules or atoms. When you view a colloidal particle dispersed in a liquid under a microscope, you can witness its jittery motion, which proceeds along a random path, as shown in Figure 13.20►. This motion, called Brownian motion, is caused by collisions with molecules in the liquid. In the beginning of the twentieth century, Brownian motion was a decisive factor in confirming the molecular and atomic nature of matter.

Soap forms a colloid because of its unique structure, shown in Figure 13.21►. One end of the molecule is ionic and therefore interacts strongly with water molecules via ion–dipole interactions. The other end of the soap molecule is a long, nonpolar, hydrocarbon tail.

▲ **FIGURE 13.19 A Colloid** Soapy water is an example of a colloidal dispersion. The haze is due to the scattering of light by the colloidal particles.

**TABLE 13.10** Types of Colloidal Dispersions

Classification	Dispersing Substance (Solute-like)	Dispersing Medium (Solvent-like)	Example
Aerosol	Liquid	Gas	 Fog (water droplets in air)
Solid aerosol	Solid	Gas	 Smoke (ash in air)
Foam	Gas	Liquid	 Whipped cream (air bubbles in butterfat)
Emulsion	Liquid	Liquid	 Milk (milk fat globules in water)
Solid emulsion	Liquid	Solid	 Opal (water in silica glass)

When enough soap is added to water, the soap molecules aggregate in structures called *micelles* (Figure 13.22▼). In a micelle, the nonpolar hydrocarbon tails crowd into the center of a sphere to maximize their interactions with one another. The ionic heads orient toward the surface of the sphere where they can interact with water molecules. The micelle structures are responsible for the haze seen in soapy water—they are too small to be seen by the naked eye, but they still scatter light (as particles in other types of colloids do).

**▲ FIGURE 13.20 Brownian Motion** A colloidal particle exhibits Brownian motion, moving in a jerky, haphazard path as it undergoes collisions with molecules in the liquid.

**◀ FIGURE 13.22 Micelle Structure** In a micelle, the nonpolar tails of soap molecules (or of other molecules that have properties that are similar to soap) are oriented inward (where they can interact with one another), and the ionic heads are oriented outward (where they can interact with the polar water molecules).

▲ **FIGURE 13.23 The Tyndall Effect** When a light beam passes through a colloidal suspension (left), it is visible because the colloid particles scatter some of the light. The beam is not visible in a noncolloidal solution (right), nor would it be visible in pure water.

▲ Light beams are invisible when they are not scattered by colloiddally dispersed particles such as dust or mist in the air.

This scattering of light by a colloidal dispersion is known as the **Tyndall effect** (Figure 13.23▲). You can observe the Tyndall effect in other colloids such as fog (water droplets dispersed in air) or dusty air. In fact, you can use the Tyndall effect as a test to determine whether a mixture is a solution or a colloid, since solutions contain completely dissolved solute molecules that are too small to scatter light.

Colloidal suspensions of micelles are kept stable by electrostatic repulsions that occur at their surfaces. For example, in soap, the ionic heads of the soap molecules compose the surface of the spherical particle (Figure 13.24▼). These ionic heads interact strongly with water molecules but repel other colloid particles. Heating a colloid composed of micelles can destroy the micelles because collisions occur with enough force to overcome the electrostatic repulsions and allow the molecules within the micelles to coalesce with those in other micelles. Similarly, adding an electrolyte to a colloidal suspension of micelles can also disrupt the electrostatic repulsions that occur between the particles and thus destroy the colloid. For this reason, soap does not work well in a salt-water solution.

The particles in a colloid need not be clusters of molecules. Some colloids, such as many protein solutions, contain dispersed macromolecules. For example, blood contains dispersed hemoglobin. The hemoglobin molecules are so large that they scatter light; thus, blood is considered a colloid.

▲ **FIGURE 13.24 Micelle Repulsions** Micelles do not coalesce because the charged surface of one micelle repels the charged surface of another.

## Self-Assessment Quiz

- Q1.** Which compound do you expect to be soluble in octane ( $C_8H_{18}$ )?  
a)  $CH_3OH$       b)  $CBr_4$       c)  $H_2O$       d)  $NH_3$
- Q2.** An aqueous solution is saturated in both potassium chlorate and carbon dioxide gas at room temperature. What happens when the solution is warmed to  $85^\circ C$ ?  
a) Potassium chlorate precipitates out of solution.  
b) Carbon dioxide bubbles out of solution.  
c) Potassium chlorate precipitates out of solution and carbon dioxide bubbles out of solution.  
d) Nothing happens; all of the potassium chloride and the carbon dioxide remain dissolved in solution.
- Q3.** A 500.0-mL sample of pure water is allowed to come to equilibrium with pure oxygen gas at a pressure of 755 mmHg. What mass of oxygen gas dissolves in the water? (The Henry's law constant for oxygen gas is  $1.3 \times 10^{-3} M/atm$ .)  
a) 15.7 g      b)  $6.5 \times 10^{-3} g$   
c) 0.041 g      d) 0.021 g
- Q4.** A potassium bromide solution is 7.55% potassium bromide by mass and its density is 1.03 g/mL. What mass of potassium bromide is contained in 35.8 mL of the solution?  
a) 2.78 g      b) 2.70 g      c) 4.88 g      d) 2.62 g
- Q5.** A solution contains 22.4 g glucose ( $C_6H_{12}O_6$ ) dissolved in 0.500 L of water. What is the molality of the solution? (Assume a density of 1.00 g/mL for water.)  
a) 0.238 *m*      b) 44.8 *m*      c) 0.249 *m*      d) 4.03 *m*
- Q6.** A sodium nitrate solution is 12.5%  $NaNO_3$  by mass and has a density of 1.02 g/mL. Calculate the molarity of the solution.  
a) 1.44 M      b) 12.8 M  
c) 6.67 M      d) 1.50 M
- Q7.** Determine the vapor pressure at  $25^\circ C$  of an aqueous ethylene glycol ( $C_2H_6O_2$ ) solution that is 14.8%  $C_2H_6O_2$  by mass. The vapor pressure of pure water at  $25^\circ C$  is 23.8 torr.  
a) 3.52 torr      b) 22.7 torr      c) 1.14 torr      d) 20.3 torr
- Q8.** A solution contains a mixture of substance A and substance B, both of which are volatile. The mole fraction of substance A is 0.35. At  $32^\circ C$  the vapor pressure of pure A is 87 mmHg and the vapor pressure of pure B is 122 mmHg. What is the total vapor pressure of the solution at this temperature?  
a) 110 mmHg      b) 209 mmHg  
c) 99.3 mmHg      d) 73.2 mmHg
- Q9.** What mass of glucose ( $C_6H_{12}O_6$ ) should be dissolved in 10.0 kg of water to obtain a solution with a freezing point of  $-4.2^\circ C$ ?  
a) 0.023 kg      b) 4.1 kg  
c) 0.41 kg      d) 14.1 kg
- Q10.** Which of these aqueous solutions has the highest boiling point?  
a) 1.25 M  $C_6H_{12}O_6$   
b) 1.25 M  $KNO_3$   
c) 1.25 M  $Ca(NO_3)_2$   
d) None of the above (they all have the same boiling point)
- Q11.** The osmotic pressure of a solution containing 22.7 mg of an unknown protein in 50.0 mL of solution is 2.88 mmHg at  $25^\circ C$ . Determine the molar mass of the protein.  
a) 246 g/mol  
b) 3.85 g/mol  
c)  $2.93 \times 10^3$  g/mol  
d) 147 g/mol
- Q12.** The enthalpy of solution for NaOH is  $-44.46$  kJ/mol. What can you conclude about the relative magnitudes of the absolute values of  $\Delta H_{solute}$  and  $\Delta H_{hydration}$ , where  $\Delta H_{solute}$  is the heat associated with separating the solute particles and  $\Delta H_{hydration}$  is the heat associated with dissolving the solute particles in water?  
a)  $|\Delta H_{solute}| > |\Delta H_{hydration}|$   
b)  $|\Delta H_{solute}| < |\Delta H_{hydration}|$   
c)  $|\Delta H_{solute}| = |\Delta H_{hydration}|$   
d) None of the above (nothing can be concluded about the relative magnitudes)
- Q13.** A 2.4 *m* aqueous solution of an ionic compound with the formula  $MX_2$  has a boiling point of  $103.4^\circ C$ . Calculate the van't Hoff factor (*i*) for  $MX_2$  at this concentration.  
a) 2.8      b) 83      c) 0.73      d) 1.0
- Q14.** A solution is an equimolar mixture of two volatile components A and B. Pure A has a vapor pressure of 50 torr and pure B has a vapor pressure of 100 torr. The vapor pressure of the mixture is 85 torr. What can you conclude about the relative strengths of the intermolecular forces between particles of A and B (relative to those between particles of A and those between particles of B)?  
a) The intermolecular forces between particles A and B are *weaker* than those between particles of A and those between particles of B.  
b) The intermolecular forces between particles A and B are *stronger* than those between particles of A and those between particles of B.  
c) The intermolecular forces between particles A and B are *the same* as those between particles of A and those between particles of B.  
d) Nothing can be concluded about the relative strengths of intermolecular forces from this observation.
- Q15.** An aqueous solution is in equilibrium with a gaseous mixture containing an equal number of moles of oxygen, nitrogen, and helium. Rank the relative concentrations of each gas in the aqueous solution from highest to lowest.  
a)  $[O_2] > [N_2] > [He]$   
b)  $[He] > [N_2] > [O_2]$   
c)  $[N_2] > [He] > [O_2]$   
d)  $[N_2] > [O_2] > [He]$

Answers: 1. (b) 2. (b) 3. (d) 4. (a) 5. (c) 6. (d) 7. (b) 8. (a) 9. (b) 10. (c) 11. (c) 12. (b) 13. (a) 14. (a) 15. (a)

## Chapter 13 IN REVIEW

### Key Terms

#### Section 13.1

solution (572)  
solvent (572)  
solute (572)

#### Section 13.2

aqueous solution (573)  
solubility (573)  
entropy (574)  
miscible (575)

#### Section 13.3

enthalpy of solution ( $\Delta H_{\text{soln}}$ ) (578)  
heat of hydration ( $\Delta H_{\text{hydration}}$ ) (579)

#### Section 13.4

dynamic equilibrium (582)  
saturated solution (582)  
unsaturated solution (582)

supersaturated solution (582)  
recrystallization (583)  
Henry's law (584)

#### Section 13.5

Tyndall effect (610)

### Key Concepts

#### Solutions (13.1, 13.2)

- ▶ A solution is a homogeneous mixture of two or more substances. In a solution, the majority component is the solvent and the minority component is the solute.
- ▶ The tendency toward greater entropy (or greater energy dispersal) is the driving force for solution formation.
- ▶ In aqueous solutions, water is a solvent, and a solid, liquid, or gas is the solute.

#### Solubility and Energetics of Solution Formation (13.2, 13.3)

- ▶ The solubility of a substance is the amount of the substance that dissolves in a given amount of solvent. The solubility of one substance in another depends on the types of intermolecular forces that exist *between* the substances as well as *within* each substance.
- ▶ We can determine the overall enthalpy change upon solution formation by adding the enthalpy changes for the three steps of solution formation: (1) separation of the solute particles, (2) separation of the solvent particles, and (3) mixing of the solute and solvent particles. The first two steps are both endothermic, whereas the last is exothermic.
- ▶ In aqueous solutions of an ionic compound, the combined change in enthalpy for steps 2 and 3 is the heat of hydration ( $\Delta H_{\text{hydration}}$ ), which is always negative.

#### Solution Equilibrium (13.4)

- ▶ Dynamic equilibrium in a solution occurs when the rates of dissolution and recrystallization in a solution are equal. A solution in this state is saturated. Solutions containing less than or more than the equilibrium amount of solute are unsaturated or supersaturated, respectively.

- ▶ The solubility of most solids in water increases with increasing temperature.
- ▶ The solubility of gases in water generally decreases with increasing temperature, but it increases with increasing pressure.

#### Concentration Units (13.5)

- ▶ Common units to express solution concentration include molarity (M), molality ( $m$ ), mole fraction ( $\chi$ ), mole percent (mol %), percent (%) by mass or volume, parts per million (ppm) by mass or volume, and parts per billion (ppb) by mass or volume. Table 13.5 summarizes these units.

#### Vapor Pressure Lowering, Freezing Point Depression, Boiling Point Elevation, and Osmosis (13.6, 13.7)

- ▶ The presence of a nonvolatile solute in a liquid results in a lower vapor pressure of the solution relative to the vapor pressure of the pure liquid. Raoult's law for an ideal solution predicts this lower vapor pressure.
- ▶ If the solute-solvent interactions are particularly strong, the actual vapor pressure is lower than that predicted by Raoult's law.
- ▶ If the solute-solvent interactions are particularly weak, the actual vapor pressure is higher than that predicted by Raoult's law.
- ▶ The addition of a nonvolatile solute to a liquid results in a solution with a lower freezing point and a higher boiling point than those of the pure solvent.
- ▶ The flow of solvent from a solution of lower concentration to a solution of higher concentration is osmosis.
- ▶ All of these phenomena (vapor pressure lowering, freezing point depression, boiling point elevation, and osmosis) are colligative properties and depend only on the number of solute particles added, not the type of solute particles.

- ▶ Electrolyte solutes have a greater effect on these properties than the corresponding amount of a nonelectrolyte solute as specified by the van't Hoff factor.

### Colloids (13.8)

- ▶ A colloid is a mixture in which a substance is finely divided in a dispersing medium.

- ▶ Colloidal mixtures occur when the dispersed substance ranges in size from 1 nm to 1000 nm.
- ▶ One way to identify colloidal mixtures is by their tendency to scatter light, known as the Tyndall effect.

## Key Equations and Relationships

Henry's Law: Solubility of Gases with Increasing Pressure (13.4)

$$S_{\text{gas}} = k_H P_{\text{gas}} \quad (k_H \text{ is Henry's law constant})$$

Molarity (M) of a Solution (13.5)

$$(M) = \frac{\text{amount solute (in mol)}}{\text{volume solution (in L)}}$$

Molality (m) of a Solution (13.5)

$$(m) = \frac{\text{amount solute (in mol)}}{\text{mass solvent (in kg)}}$$

Concentration of a Solution in Parts by Mass and Parts by Volume (13.5)

$$\text{Percent by mass} = \frac{\text{mass solute} \times 100\%}{\text{mass solution}}$$

$$\text{Parts per million (ppm)} = \frac{\text{mass solute} \times 10^6}{\text{mass solution}}$$

$$\text{Parts per billion (ppb)} = \frac{\text{mass solute} \times 10^9}{\text{mass solution}}$$

$$\text{Parts by volume} = \frac{\text{volume solute} \times \text{multiplication factor}}{\text{volume solution}}$$

Concentration of a Solution in Mole Fraction ( $\chi$ ) and Mole Percent (13.5)

$$\chi_{\text{solute}} = \frac{n_{\text{solute}}}{n_{\text{solute}} + n_{\text{solvent}}}$$

$$\text{Mol \%} = \chi \times 100\%$$

Raoult's Law: Relationship between the Vapor Pressure of a Solution ( $P_{\text{solution}}$ ), the Mole Fraction of the Solvent ( $\chi_{\text{solvent}}$ ), and the Vapor Pressure of the Pure Solvent ( $P_{\text{solvent}}^{\circ}$ ) (13.6)

$$P_{\text{solution}} = \chi_{\text{solvent}} P_{\text{solvent}}^{\circ}$$

The Vapor Pressure of a Solution Containing Two Volatile Components (13.6)

$$P_A = \chi_A P_A^{\circ}$$

$$P_B = \chi_B P_B^{\circ}$$

$$P_{\text{tot}} = P_A + P_B$$

Relationship between Freezing Point Depression ( $\Delta T_f$ ), Molality (m), and Freezing Point Depression Constant ( $K_f$ ) (13.6)

$$\Delta T_f = m \times K_f$$

Relationship between Boiling Point Elevation ( $\Delta T_b$ ), Molality (m), and Boiling Point Elevation Constant ( $K_b$ ) (13.6)

$$\Delta T_b = m \times K_b$$

Relationship between Osmotic Pressure ( $\Pi$ ), Molarity (M), the Ideal Gas Constant (R), and Temperature (T, in K) (13.6)

$$\Pi = MRT \quad (R = 0.08206 \text{ L} \cdot \text{atm/mol} \cdot \text{K})$$

van't Hoff Factor (i): Ratio of Moles of Particles in Solution to Moles of Formula Units Dissolved (13.7)

$$i = \frac{\text{moles of particles in solution}}{\text{moles of formula units dissolved}}$$

## Key Learning Outcomes

CHAPTER OBJECTIVES	ASSESSMENT
Determining Whether a Solute Is Soluble in a Solvent (13.2)	Example 13.1 For Practice 13.1 Exercises 31–34
Using Henry's Law to Predict the Solubility of Gases with Increasing Pressure (13.4)	Example 13.2 For Practice 13.2 Exercises 49, 50
Calculating Concentrations of Solutions (13.5)	Examples 13.3, 13.4 For Practice 13.3, 13.4 For More Practice 13.3 Exercises 51–56, 63, 64
<div> <math>\frac{3.5 \text{ g NaCl}}{100 \text{ g solution}}</math> <span>converts</span> <div>g solution</div> <span>→</span> <div>g NaCl</div> </div>	
Converting between Concentration Units (13.5)	Example 13.5 For Practice 13.5 For More Practice 13.5 Exercises 65–68
Determining the Vapor Pressure of a Solution Containing a Nonelectrolyte and Nonvolatile Solute (13.6)	Example 13.6 For Practice 13.6 For More Practice 13.6 Exercises 71, 72
Determining the Vapor Pressure of a Two-Component Solution (13.6)	Example 13.7 For Practice 13.7 Exercises 73–76
Calculating Freezing Point Depression (13.6)	Example 13.8 For Practice 13.8 Exercises 77–82, 87, 88
Calculating Boiling Point Elevation (13.6)	Example 13.9 For Practice 13.9 Exercises 77–80, 87, 88
Determining the Osmotic Pressure (13.6)	Example 13.10 For Practice 13.10 Exercises 83–86

## Determining and Using the van't Hoff Factor (13.7)

Example 13.11 For Practice 13.11 Exercises 91–96

## Determining the Vapor Pressure of a Solution Containing an Ionic Solute (13.7)

Example 13.12 For Practice 13.12 Exercises 97, 98

## EXERCISES

## Review Questions

- Explain why drinking seawater results in dehydration.
- What is a solution? What are the solute and solvent?
- What does it mean to say that a substance is soluble in another substance? Which units are used in reporting solubility?
- Why do two ideal gases thoroughly mix when combined? What drives the mixing?
- What is entropy? Why is entropy important in discussing the formation of solutions?
- What kinds of intermolecular forces are involved in solution formation?
- Explain how the relative strengths of solute–solute interactions, solvent–solvent interactions, and solvent–solute interactions affect solution formation.
- What does the statement *like dissolves like* mean with respect to solution formation?
- What are the three steps involved in evaluating the enthalpy changes associated with solution formation?
- What is the heat of hydration ( $\Delta H_{\text{hydration}}$ )? How does the enthalpy of solution depend on the relative magnitudes of  $\Delta H_{\text{solute}}$  and  $\Delta H_{\text{hydration}}$ ?
- Explain dynamic equilibrium with respect to solution formation. What is a saturated solution? An unsaturated solution? A supersaturated solution?
- How does the solubility of a solid in a liquid depend on temperature? How is this temperature dependence exploited to purify solids through recrystallization?
- How does the solubility of a gas in a liquid depend on temperature? How does this temperature dependence affect the amount of oxygen available for fish and other aquatic animals?
- How does the solubility of a gas in a liquid depend on pressure? How does this pressure dependence account for the bubbling that occurs upon opening a can of soda?
- What is Henry's law? For what kinds of calculations is Henry's law useful?
- What are the common units for expressing solution concentration?
- How are parts by mass and parts by volume used in calculations?
- What is the effect of a nonvolatile solute on the vapor pressure of a liquid? Why is the vapor pressure of a solution different from the vapor pressure of the pure liquid solvent?
- What is Raoult's law? For what kind of calculations is Raoult's law useful?
- Explain the difference between an ideal and a nonideal solution.
- What is the effect on vapor pressure of a solution with particularly *strong* solute–solvent interactions? With particularly *weak* solute–solvent interactions?
- Explain why the lower vapor pressure for a solution containing a nonvolatile solute results in a higher boiling point and lower melting point compared to the pure solvent.
- What are colligative properties?
- What is osmosis? What is osmotic pressure?
- Explain the meaning of the van't Hoff factor and its role in determining the colligative properties of solutions containing ionic solutes.
- Describe a colloidal dispersion. What is the difference between a colloidal dispersion and a true solution?
- What is the Tyndall effect, and how can it be used to help identify colloidal dispersions?
- What keeps the particles in a colloidal dispersion from coalescing?

## Problems by Topic

## Solubility

- Pick an appropriate solvent from Table 13.3 to dissolve each substance. State the kind of intermolecular forces that would occur between the solute and solvent in each case.
  - motor oil (nonpolar)
  - ethanol (polar, contains an OH group)
  - lard (nonpolar)
  - potassium chloride (ionic)
- Pick an appropriate solvent from Table 13.3 to dissolve each substance. State the kind of intermolecular forces that would occur between the solute and solvent in each case.
  - isopropyl alcohol (polar, contains an OH group)
  - sodium chloride (ionic)
  - vegetable oil (nonpolar)
  - sodium nitrate (ionic)
- Which molecule would you expect to be more soluble in water:  $\text{CH}_3\text{CH}_2\text{CH}_2\text{OH}$  or  $\text{HOCH}_2\text{CH}_2\text{CH}_2\text{OH}$ ?

32. Which molecule would you expect to be more soluble in water:  $\text{CCl}_4$  or  $\text{CH}_2\text{Cl}_2$ ?

33. For each compound, would you expect greater solubility in water or in hexane? Indicate the kinds of intermolecular forces that occur between the solute and the solvent in which the molecule is most soluble.

a. glucose

b. naphthalene

c. dimethyl ether

d. alanine (an amino acid)

34. For each compound, would you expect greater solubility in water or in hexane? Indicate the kinds of intermolecular forces that would occur between the solute and the solvent in which the molecule is most soluble.

a. toluene

b. sucrose  
(table sugar)

c. isobutene

d. ethylene glycol

## Energetics of Solution Formation

35. When ammonium chloride ( $\text{NH}_4\text{Cl}$ ) is dissolved in water, the solution becomes colder.

- Is the dissolution of ammonium chloride endothermic or exothermic?
- What can you conclude about the relative magnitudes of the lattice energy of ammonium chloride and its heat of hydration?
- Sketch a qualitative energy diagram similar to Figure 13.7 for the dissolution of  $\text{NH}_4\text{Cl}$ .
- Why does the solution form? What drives the process?

36. When lithium iodide ( $\text{LiI}$ ) is dissolved in water, the solution becomes hotter.

- Is the dissolution of lithium iodide endothermic or exothermic?
- What can you conclude about the relative magnitudes of the lattice energy of lithium iodide and its heat of hydration?
- Sketch a qualitative energy diagram similar to Figure 13.7 for the dissolution of  $\text{LiI}$ .
- Why does the solution form? What drives the process?

37. Silver nitrate has a lattice energy of  $-820 \text{ kJ/mol}$  and a heat of solution of  $22.6 \text{ kJ/mol}$ . Calculate the heat of hydration for silver nitrate.

38. Use the data to calculate the heats of hydration of lithium chloride and sodium chloride. Which of the two cations, lithium or sodium, has stronger ion-dipole interactions with water? Why?

Compound	Lattice Energy (kJ/mol)	$\Delta H_{\text{soln}}$ (kJ/mol)
LiCl	-834	-37.0
NaCl	-769	+3.88

39. Lithium iodide has a lattice energy of  $-7.3 \times 10^2 \text{ kJ/mol}$  and a heat of hydration of  $-793 \text{ kJ/mol}$ . Find the heat of solution for lithium iodide and determine how much heat is evolved or absorbed when  $15.0 \text{ g}$  of lithium iodide completely dissolves in water.

40. Potassium nitrate has a lattice energy of  $-163.8 \text{ kcal/mol}$  and a heat of hydration of  $-155.5 \text{ kcal/mol}$ . How much potassium nitrate has to dissolve in water to absorb  $1.00 \times 10^2 \text{ kJ}$  of heat?

## Solution Equilibrium and Factors Affecting Solubility

41. A solution contains  $25 \text{ g}$  of  $\text{NaCl}$  per  $100.0 \text{ g}$  of water at  $25^\circ\text{C}$ . Is the solution unsaturated, saturated, or supersaturated? (Use Figure 13.11.)

42. A solution contains  $32 \text{ g}$  of  $\text{KNO}_3$  per  $100.0 \text{ g}$  of water at  $25^\circ\text{C}$ . Is the solution unsaturated, saturated, or supersaturated? (Use Figure 13.11.)

43. A  $\text{KNO}_3$  solution containing  $45 \text{ g}$  of  $\text{KNO}_3$  per  $100.0 \text{ g}$  of water is cooled from  $40^\circ\text{C}$  to  $0^\circ\text{C}$ . What happens during cooling? (Use Figure 13.11.)

44. A  $\text{KCl}$  solution containing  $42 \text{ g}$  of  $\text{KCl}$  per  $100.0 \text{ g}$  of water is cooled from  $60^\circ\text{C}$  to  $0^\circ\text{C}$ . What happens during cooling? (Use Figure 13.11.)

45. Some laboratory procedures involving oxygen-sensitive reactants or products call for using water that has been boiled (and then cooled). Explain.

46. A person preparing a fish tank fills the tank with water that has been boiled (and then cooled). When the person puts fish into the tank, they die. Explain.

47. Scuba divers breathing air at increased pressure can suffer from nitrogen narcosis—a condition resembling drunkenness—when the partial pressure of nitrogen exceeds about 4 atm. What property of gas/water solutions causes this to happen? How can a diver reverse this effect?
48. Scuba divers breathing air at increased pressure can suffer from oxygen toxicity—too much oxygen in their bloodstream—when the partial pressure of oxygen exceeds about 1.4 atm. What happens to the amount of oxygen in a diver's bloodstream when he or she breathes oxygen at elevated pressures? How can this be reversed?
49. Calculate the mass of nitrogen dissolved at room temperature in an 80.0-L home aquarium. Assume a total pressure of 1.0 atm and a mole fraction for nitrogen of 0.78.
50. Use Henry's law to determine the molar solubility of helium at a pressure of 1.0 atm and 25 °C.

### Concentrations of Solutions

51. An aqueous NaCl solution is made using 112 g of NaCl diluted to a total solution volume of 1.00 L. Calculate the molarity, molality, and mass percent of the solution. (Assume a density of 1.08 g/mL for the solution.)
52. An aqueous KNO<sub>3</sub> solution is made using 72.5 g of KNO<sub>3</sub> diluted to a total solution volume of 2.00 L. Calculate the molarity, molality, and mass percent of the solution. (Assume a density of 1.05 g/mL for the solution.)
53. To what volume should you dilute 50.0 mL of a 5.00 M KI solution so that 25.0 mL of the diluted solution contains 3.05 g of KI?
54. To what volume should you dilute 125 mL of an 8.00 M CuCl<sub>2</sub> solution so that 50.0 mL of the diluted solution contains 4.67 g CuCl<sub>2</sub>?
55. Silver nitrate solutions are often used to plate silver onto other metals. What is the maximum amount of silver (in grams) that can be plated out of 4.8 L of an AgNO<sub>3</sub> solution containing 3.4% Ag by mass? Assume that the density of the solution is 1.01 g/mL.
56. A dioxin-contaminated water source contains 0.085% dioxin by mass. How much dioxin is present in 2.5 L of this water? Assume a density of 1.00 g/mL.
57. A hard water sample contains 0.0085% Ca by mass (in the form of Ca<sup>2+</sup> ions). How much water (in grams) contains 1.2 g of Ca? (1.2 g of Ca is the recommended daily allowance of calcium for adults between 19 and 24 years old.)
58. Lead is a toxic metal that affects the central nervous system. A Pb-contaminated water sample contains 0.0011% Pb by mass. How much of the water (in mL) contains 150 mg of Pb? (Assume a density of 1.0 g/mL.)
59. You can purchase nitric acid in a concentrated form that is 70.3% HNO<sub>3</sub> by mass and has a density of 1.41 g/mL. Describe exactly how you would prepare 1.15 L of 0.100 M HNO<sub>3</sub> from the concentrated solution.
60. You can purchase hydrochloric acid in a concentrated form that is 37.0% HCl by mass and that has a density of 1.20 g/mL. Describe exactly how to prepare 2.85 L of 0.500 M HCl from the concentrated solution.
61. Describe how to prepare each solution from the dry solute and the solvent.
- $1.00 \times 10^2$  mL of 0.500 M KCl
  - $1.00 \times 10^2$  g of 0.500 *m* KCl
  - $1.00 \times 10^2$  g of 5.0% KCl solution by mass
62. Describe how to prepare each solution from the dry solute and the solvent.
- 125 mL of 0.100 M NaNO<sub>3</sub>
  - 125 g of 0.100 *m* NaNO<sub>3</sub>
  - 125 g of 1.0% NaNO<sub>3</sub> solution by mass
63. A solution is prepared by dissolving 28.4 g of glucose (C<sub>6</sub>H<sub>12</sub>O<sub>6</sub>) in 355 g of water. The final volume of the solution is 378 mL. For this solution, calculate the concentration in each unit.
- molarity
  - molality
  - percent by mass
  - mole fraction
  - mole percent
64. A solution is prepared by dissolving 20.2 mL of methanol (CH<sub>3</sub>OH) in 100.0 mL of water at 25 °C. The final volume of the solution is 118 mL. The densities of methanol and water at this temperature are 0.782 g/mL and 1.00 g/mL, respectively. For this solution, calculate the concentration in each unit.
- molarity
  - molality
  - percent by mass
  - mole fraction
  - mole percent
65. Household hydrogen peroxide is an aqueous solution containing 3.0% hydrogen peroxide by mass. What is the molarity of this solution? (Assume a density of 1.01 g/mL.)
66. One brand of laundry bleach is an aqueous solution containing 4.55% sodium hypochlorite (NaOCl) by mass. What is the molarity of this solution? (Assume a density of 1.02 g/mL.)
67. An aqueous solution contains 36% HCl by mass. Calculate the molality and mole fraction of the solution.
68. An aqueous solution contains 5.0% NaCl by mass. Calculate the molality and mole fraction of the solution.

### Vapor Pressure of Solutions

69. A beaker contains 100.0 mL of pure water. A second beaker contains 100.0 mL of seawater. The two beakers are left side by side on a lab bench for 1 week. At the end of the week, the liquid level in both beakers has decreased. However, the level has decreased more in one of the beakers than in the other. Which one and why?
70. Which solution has the highest vapor pressure?
- 20.0 g of glucose (C<sub>6</sub>H<sub>12</sub>O<sub>6</sub>) in 100.0 mL of water
  - 20.0 g of sucrose (C<sub>12</sub>H<sub>22</sub>O<sub>11</sub>) in 100.0 mL of water
  - 10.0 g of potassium acetate KC<sub>2</sub>H<sub>3</sub>O<sub>2</sub> in 100.0 mL of water
71. Calculate the vapor pressure of a solution containing 24.5 g of glycerin (C<sub>3</sub>H<sub>8</sub>O<sub>3</sub>) in 135 mL of water at 30.0 °C. The vapor pressure of pure water at this temperature is 31.8 torr. Assume that glycerin is not volatile and dissolves molecularly (i.e., it is not ionic), and use a density of 1.00 g/mL for the water.
72. A solution contains naphthalene (C<sub>10</sub>H<sub>8</sub>) dissolved in hexane (C<sub>6</sub>H<sub>14</sub>) at a concentration of 12.35% naphthalene by mass. Calculate the vapor pressure at 25 °C of hexane above the solution. The vapor pressure of pure hexane at 25 °C is 151 torr.
73. A solution contains 50.0 g of heptane (C<sub>7</sub>H<sub>16</sub>) and 50.0 g of octane (C<sub>8</sub>H<sub>18</sub>) at 25 °C. The vapor pressures of pure heptane and pure octane at 25 °C are 45.8 torr and 10.9 torr, respectively. Assuming ideal behavior, answer the following:
- What is the vapor pressure of each of the solution components in the mixture?
  - What is the total pressure above the solution?
  - What is the composition of the vapor in mass percent?
  - Why is the composition of the vapor different from the composition of the solution?

74. A solution contains a mixture of pentane and hexane at room temperature. The solution has a vapor pressure of 258 torr. Pure pentane and hexane have vapor pressures of 425 torr and 151 torr, respectively, at room temperature. What is the mole fraction composition of the mixture? (Assume ideal behavior.)
75. A solution contains 4.08 g of chloroform ( $\text{CHCl}_3$ ) and 9.29 g of acetone ( $\text{CH}_3\text{COCH}_3$ ). The vapor pressures at 35 °C of pure chloroform and pure acetone are 295 torr and 332 torr, respectively. Assuming ideal behavior, calculate the vapor pressures of each of the components and the total vapor pressure above the solution. The experimentally measured total vapor pressure of the solution at 35 °C is 312 torr. Is the solution ideal? If not, what can you say about the relative strength of chloroform–acetone interactions compared to the acetone–acetone and chloroform–chloroform interactions?
76. A solution of methanol and water has a mole fraction of water of 0.312 and a total vapor pressure of 211 torr at 39.9 °C. The vapor pressures of pure methanol and pure water at this temperature are 256 torr and 55.3 torr, respectively. Is the solution ideal? If not, what can you say about the relative strengths of the solute–solvent interactions compared to the solute–solute and solvent–solvent interactions?

### Freezing Point Depression, Boiling Point Elevation, and Osmosis

77. A glucose solution contains 55.8 g of glucose ( $\text{C}_6\text{H}_{12}\text{O}_6$ ) in 455 g of water. Determine the freezing point and boiling point of the solution.
78. An ethylene glycol solution contains 21.2 g of ethylene glycol ( $\text{C}_2\text{H}_6\text{O}_2$ ) in 85.4 mL of water. Determine the freezing point and boiling point of the solution. (Assume a density of 1.00 g/mL for water.)
79. Calculate the freezing point and boiling point of a solution containing 10.0 g of naphthalene ( $\text{C}_{10}\text{H}_8$ ) in 100.0 mL of benzene. Benzene has a density of 0.877 g/cm<sup>3</sup>.
80. Calculate the freezing point and boiling point of a solution containing 7.55 g of ethylene glycol ( $\text{C}_2\text{H}_6\text{O}_2$ ) in 85.7 mL of ethanol. Ethanol has a density of 0.789 g/cm<sup>3</sup>.
81. An aqueous solution containing 17.5 g of an unknown molecular (nonelectrolyte) compound in 100.0 g of water has a freezing point of  $-1.8^\circ\text{C}$ . Calculate the molar mass of the unknown compound.
82. An aqueous solution containing 35.9 g of an unknown molecular (nonelectrolyte) compound in 150.0 g of water has a freezing point of  $-1.3^\circ\text{C}$ . Calculate the molar mass of the unknown compound.
83. Calculate the osmotic pressure of a solution containing 24.6 g of glycerin ( $\text{C}_3\text{H}_8\text{O}_3$ ) in 250.0 mL of solution at 298 K.
84. What mass of sucrose ( $\text{C}_{12}\text{H}_{22}\text{O}_{11}$ ) would you combine with  $5.00 \times 10^2$  g of water to make a solution with an osmotic pressure of 8.55 atm at 298 K? (Assume a density of 1.0 g/mL for the solution.)
85. A solution containing 27.55 mg of an unknown protein per 25.0 mL solution was found to have an osmotic pressure of 3.22 torr at 25 °C. What is the molar mass of the protein?
86. Calculate the osmotic pressure of a solution containing 18.75 mg of hemoglobin in 15.0 mL of solution at 25 °C. The molar mass of hemoglobin is  $6.5 \times 10^4$  g/mol.
87. Calculate the freezing point and boiling point of each aqueous solution, assuming complete dissociation of the solute.
- 0.100 *m*  $\text{K}_2\text{S}$
  - 21.5 g of  $\text{CuCl}_2$  in  $4.50 \times 10^2$  g water
  - 5.5%  $\text{NaNO}_3$  by mass (in water)
88. Calculate the freezing point and boiling point in each solution, assuming complete dissociation of the solute.
- 10.5 g  $\text{FeCl}_3$  in  $1.50 \times 10^2$  g water
  - 3.5%  $\text{KCl}$  by mass (in water)
  - 0.150 *m*  $\text{MgF}_2$
89. What mass of salt ( $\text{NaCl}$ ) should you add to 1.00 L of water in an ice cream maker to make a solution that freezes at  $-10.0^\circ\text{C}$ ? Assume complete dissociation of the  $\text{NaCl}$  and density of 1.00 g/mL for water.
90. Determine the required concentration (in percent by mass) for an aqueous ethylene glycol ( $\text{C}_2\text{H}_6\text{O}_2$ ) solution to have a boiling point of  $104.0^\circ\text{C}$ .
91. Use the van't Hoff factors in Table 13.9 to calculate each colligative property:
- the melting point of a 0.100 *m* iron(III) chloride solution
  - the osmotic pressure of a 0.085 M potassium sulfate solution at 298 K
  - the boiling point of a 1.22% by mass magnesium chloride solution
92. Using the van't Hoff factors in Table 13.9, calculate the mass of solute required to make each aqueous solution:
- a sodium chloride solution containing  $1.50 \times 10^2$  g of water that has a melting point of  $-1.0^\circ\text{C}$
  - $2.50 \times 10^2$  mL of a magnesium sulfate solution that has an osmotic pressure of 3.82 atm at 298 K
  - an iron(III) chloride solution containing  $2.50 \times 10^2$  g of water that has a boiling point of  $102^\circ\text{C}$
93. A 1.2 *m* aqueous solution of an ionic compound with the formula  $\text{MX}_2$  has a boiling point of  $101.4^\circ\text{C}$ . Calculate the van't Hoff factor (*i*) for  $\text{MX}_2$  at this concentration.
94. A 0.95 *m* aqueous solution of an ionic compound with the formula  $\text{MX}$  has a freezing point of  $-3.0^\circ\text{C}$ . Calculate the van't Hoff factor (*i*) for  $\text{MX}$  at this concentration.
95. A 0.100 M ionic solution has an osmotic pressure of 8.3 atm at 25 °C. Calculate the van't Hoff factor (*i*) for this solution.
96. A solution contains 8.92 g of  $\text{KBr}$  in 500.0 mL of solution and has an osmotic pressure of 6.97 atm at 25 °C. Calculate the van't Hoff factor (*i*) for  $\text{KBr}$  at this concentration.
97. Calculate the vapor pressure at 25 °C of an aqueous solution that is 5.50%  $\text{NaCl}$  by mass. (Assume complete dissociation of the solute.)
98. An aqueous  $\text{CaCl}_2$  solution has a vapor pressure of 81.6 mmHg at 50 °C. The vapor pressure of pure water at this temperature is 92.6 mmHg. What is the concentration of  $\text{CaCl}_2$  in mass percent? (Assume complete dissociation of the solute.)

## Cumulative Problems

99. The solubility of carbon tetrachloride ( $\text{CCl}_4$ ) in water at  $25^\circ\text{C}$  is  $1.2\text{ g/L}$ . The solubility of chloroform ( $\text{CHCl}_3$ ) at the same temperature is  $10.1\text{ g/L}$ . Why is chloroform almost ten times more soluble in water than carbon tetrachloride?
100. The solubility of phenol in water at  $25^\circ\text{C}$  is  $87\text{ g/L}$ . The solubility of naphthol at the same temperature is only  $0.74\text{ g/L}$ . Examine the structures of phenol and naphthol shown here and explain why phenol is so much more soluble than naphthol.

101. Potassium perchlorate ( $\text{KClO}_4$ ) has a lattice energy of  $-599\text{ kJ/mol}$  and a heat of hydration of  $-548\text{ kJ/mol}$ . Find the heat of solution for potassium perchlorate and determine the temperature change that occurs when  $10.0\text{ g}$  of potassium perchlorate is dissolved with enough water to make  $100.0\text{ mL}$  of solution. (Assume a heat capacity of  $4.05\text{ J/g}\cdot^\circ\text{C}$  for the solution and a density of  $1.05\text{ g/mL}$ .)
102. Sodium hydroxide ( $\text{NaOH}$ ) has a lattice energy of  $-887\text{ kJ/mol}$  and a heat of hydration of  $-932\text{ kJ/mol}$ . How much solution could be heated to boiling by the heat evolved by the dissolution of  $25.0\text{ g}$  of  $\text{NaOH}$ ? (For the solution, assume a heat capacity of  $4.0\text{ J/g}\cdot^\circ\text{C}$ , an initial temperature of  $25.0^\circ\text{C}$ , a boiling point of  $100.0^\circ\text{C}$ , and a density of  $1.05\text{ g/mL}$ .)
103. A saturated solution forms when  $0.0537\text{ L}$  of argon, at a pressure of  $1.0\text{ atm}$  and temperature of  $25^\circ\text{C}$ , is dissolved in  $1.0\text{ L}$  of water. Calculate the Henry's law constant for argon.
104. A gas has a Henry's law constant of  $0.112\text{ M/atm}$ . What total volume of solution is needed to completely dissolve  $1.65\text{ L}$  of the gas at a pressure of  $725\text{ torr}$  and a temperature of  $25^\circ\text{C}$ ?
105. The Safe Drinking Water Act (SDWA) sets a limit for mercury—a toxin to the central nervous system—at  $0.0020\text{ ppm}$  by mass. Water suppliers must periodically test their water to ensure that mercury levels do not exceed this limit. Suppose water becomes contaminated with mercury at twice the legal limit ( $0.0040\text{ ppm}$ ). How much of this water would a person have to consume to ingest  $50.0\text{ mg}$  of mercury?
106. Water softeners often replace calcium ions in hard water with sodium ions. Since sodium compounds are soluble, the presence of sodium ions in water does not cause the white, scaly residues caused by calcium ions. However, calcium is more beneficial to human health than sodium because calcium is a necessary part of the human diet, while high levels of sodium intake are linked to increases in blood pressure. The U.S. Food and Drug Administration (FDA) recommends that adults ingest less than  $2.4\text{ g}$  of sodium per day. How many liters of softened water, containing a sodium concentration of  $0.050\%$  sodium by mass, would a person have to consume to exceed the FDA recommendation? (Assume a water density of  $1.0\text{ g/mL}$ .)
107. An aqueous solution contains  $12.5\%$   $\text{NaCl}$  by mass. What mass of water (in grams) is contained in  $2.5\text{ L}$  of the vapor above this solution at  $55^\circ\text{C}$ ? The vapor pressure of pure water at  $55^\circ\text{C}$  is  $118\text{ torr}$ . (Assume complete dissociation of  $\text{NaCl}$ .)
108. The vapor above an aqueous solution contains  $19.5\text{ mg}$  water per liter at  $25^\circ\text{C}$ . Assuming ideal behavior, what is the concentration of the solute within the solution in mole percent?
109. What is the freezing point of an aqueous solution that boils at  $106.5^\circ\text{C}$ ?
110. What is the boiling point of an aqueous solution that has a vapor pressure of  $20.5\text{ torr}$  at  $25^\circ\text{C}$ ? (Assume a nonvolatile solute.)
111. An isotonic solution contains  $0.90\%$   $\text{NaCl}$  mass to volume. Calculate the percent mass to volume for isotonic solutions containing each solute at  $25^\circ\text{C}$ . Assume a van't Hoff factor of  $1.9$  for all ionic solutes.  
 a.  $\text{KCl}$       b.  $\text{NaBr}$       c. glucose ( $\text{C}_6\text{H}_{12}\text{O}_6$ )
112. Magnesium citrate,  $\text{Mg}_3(\text{C}_6\text{H}_5\text{O}_7)_2$ , belongs to a class of laxatives called *hyperosmotics*, which cause rapid emptying of the bowel. When a concentrated solution of magnesium citrate is consumed, it passes through the intestines, drawing water and promoting diarrhea, usually within  $6\text{ hours}$ . Calculate the osmotic pressure of a magnesium citrate laxative solution containing  $28.5\text{ g}$  of magnesium citrate in  $235\text{ mL}$  of solution at  $37^\circ\text{C}$  (approximate body temperature). Assume complete dissociation of the ionic compound.
113. A solution is prepared from  $4.5701\text{ g}$  of magnesium chloride and  $43.238\text{ g}$  of water. The vapor pressure of water above this solution is  $0.3624\text{ atm}$  at  $348.0\text{ K}$ . The vapor pressure of pure water at this temperature is  $0.3804\text{ atm}$ . Find the value of the van't Hoff factor ( $i$ ) for magnesium chloride in this solution.
114. When  $\text{HNO}_2$  is dissolved in water, it partially dissociates according to the equation  $\text{HNO}_2 \rightleftharpoons \text{H}^+ + \text{NO}_2^-$ . A solution is prepared that contains  $7.050\text{ g}$  of  $\text{HNO}_2$  in  $1.000\text{ kg}$  of water. Its freezing point is  $-0.2929^\circ\text{C}$ . Calculate the fraction of  $\text{HNO}_2$  that has dissociated.
115. A solution of a nonvolatile solute in water has a boiling point of  $375.3\text{ K}$ . Calculate the vapor pressure of water above this solution at  $338\text{ K}$ . The vapor pressure of pure water at this temperature is  $0.2467\text{ atm}$ .
116. The density of a  $0.438\text{ M}$  solution of potassium chromate ( $\text{K}_2\text{CrO}_4$ ) at  $298\text{ K}$  is  $1.063\text{ g/mL}$ . Calculate the vapor pressure of water above the solution. The vapor pressure of pure water at this temperature is  $0.0313\text{ atm}$ . (Assume complete dissociation of the solute.)
117. The vapor pressure of carbon tetrachloride,  $\text{CCl}_4$ , is  $0.354\text{ atm}$ , and the vapor pressure of chloroform,  $\text{CHCl}_3$ , is  $0.526\text{ atm}$  at  $316\text{ K}$ . A solution is prepared from equal masses of these two compounds at this temperature. Calculate the mole fraction of the chloroform in the vapor above the solution. If the vapor above the original solution is condensed and isolated into a separate flask, what will the vapor pressure of chloroform be above this new solution?
118. Distillation is a method of purification based on successive separations and recondensations of vapor above a solution. Use the result of the previous problem to calculate the mole fraction of chloroform in the vapor above a solution obtained by three successive separations and condensations of the vapors above the original solution of carbon tetrachloride and chloroform. Show how this result explains the use of distillation as a separation method.
119. A solution of  $49.0\%$   $\text{H}_2\text{SO}_4$  by mass has a density of  $1.39\text{ g/cm}^3$  at  $293\text{ K}$ . A  $25.0\text{-cm}^3$  sample of this solution is mixed with enough water to increase the volume of the solution to  $99.8\text{ cm}^3$ . Find the molarity of sulfuric acid in this solution.

- 120.** Find the mass of urea ( $\text{CH}_4\text{N}_2\text{O}$ ) needed to prepare 50.0 g of a solution in water in which the mole fraction of urea is 0.0770.
- 121.** A solution contains 10.05 g of unknown compound dissolved in 50.0 mL of water. (Assume a density of 1.00 g/mL for water.) The freezing point of the solution is  $-3.16^\circ\text{C}$ . The mass percent composition of the compound is 60.97% C, 11.94% H, and the rest is O. What is the molecular formula of the compound?
- 122.** The osmotic pressure of a solution containing 2.10 g of an unknown compound dissolved in 175.0 mL of solution at  $25^\circ\text{C}$  is 1.93 atm. The combustion of 24.02 g of the unknown compound produced 28.16 g  $\text{CO}_2$  and 8.64 g  $\text{H}_2\text{O}$ . What is the molecular formula of the compound (which contains only carbon, hydrogen, and oxygen)?
- 123.** A 100.0-mL aqueous sodium chloride solution is 13.5% NaCl by mass and has a density of 1.12 g/mL. What would you add (solute or solvent) and what mass of it to make the boiling point of the solution  $104.4^\circ\text{C}$ ? (Use  $i = 1.8$  for NaCl.)
- 124.** A 50.0-mL solution is initially 1.55%  $\text{MgCl}_2$  by mass and has a density of 1.05 g/mL. What is the freezing point of the solution after you add an additional 1.35 g  $\text{MgCl}_2$ ? (Use  $i = 2.5$  for  $\text{MgCl}_2$ .)

## Challenge Problems

- 125.** The small bubbles that form on the bottom of a water pot that is being heated (before boiling) are due to dissolved air coming out of solution. Use Henry's law and the solubilities given to calculate the total volume of nitrogen and oxygen gas that should bubble out of 1.5 L of water upon warming from  $25^\circ\text{C}$  to  $50^\circ\text{C}$ . Assume that the water is initially saturated with nitrogen and oxygen gas at  $25^\circ\text{C}$  and a total pressure of 1.0 atm. Assume that the gas bubbles out at a temperature of  $50^\circ\text{C}$ . The solubility of oxygen gas at  $50^\circ\text{C}$  is 27.8 mg/L at an oxygen pressure of 1.00 atm. The solubility of nitrogen gas at  $50^\circ\text{C}$  is 14.6 mg/L at a nitrogen pressure of 1.00 atm. Assume that the air above the water contains an oxygen partial pressure of 0.21 atm and a nitrogen partial pressure of 0.78 atm.
- 126.** The vapor above a mixture of pentane and hexane at room temperature contains 35.5% pentane by mass. What is the mass percent composition of the solution? Pure pentane and hexane have vapor pressures of 425 torr and 151 torr, respectively, at room temperature.
- 127.** A 1.10-g sample contains only glucose ( $\text{C}_6\text{H}_{12}\text{O}_6$ ) and sucrose ( $\text{C}_{12}\text{H}_{22}\text{O}_{11}$ ). When the sample is dissolved in water to a total solution volume of 25.0 mL, the osmotic pressure of the solution is 3.78 atm at 298 K. What is the mass percent composition of glucose and sucrose in the sample?
- 128.** A solution is prepared by mixing 631 mL of methanol with 501 mL of water. The molarity of methanol in the resulting solution is 14.29 M. The density of methanol at this temperature is 0.792 g/mL. Calculate the difference in volume between this solution and the total volume of water and methanol that were mixed to prepare the solution.
- 129.** Two alcohols, isopropyl alcohol and propyl alcohol, have the same molecular formula,  $\text{C}_3\text{H}_8\text{O}$ . A solution of the two that is two-thirds by mass isopropyl alcohol has a vapor pressure of 0.110 atm at 313 K. A solution that is one-third by mass isopropyl alcohol has a vapor pressure of 0.089 atm at 313 K. Calculate the vapor pressure of each pure alcohol at this temperature. Explain the difference given that the formula of propyl alcohol is  $\text{CH}_3\text{CH}_2\text{CH}_2\text{OH}$  and that of isopropyl alcohol is  $(\text{CH}_3)_2\text{CHOH}$ .
- 130.** A metal, M, of atomic mass 96 amu reacts with fluorine to form a salt that can be represented as  $\text{MF}_x$ . In order to determine  $x$  and therefore the formula of the salt, a boiling point elevation experiment is performed. A 9.18-g sample of the salt is dissolved in 100.0 g of water, and the boiling point of the solution is found to be 374.38 K. Find the formula of the salt. (Assume complete dissociation of the salt in solution.)
- 131.** Sulfuric acid in water dissociates completely into  $\text{H}^+$  and  $\text{HSO}_4^-$  ions. The  $\text{HSO}_4^-$  ion dissociates to a limited extent into  $\text{H}^+$  and  $\text{SO}_4^{2-}$ . The freezing point of a 0.1000  $m$  solution of sulfuric acid in water is 272.76 K. Calculate the molality of  $\text{SO}_4^{2-}$  in the solution, assuming ideal solution behavior.
- 132.** A solution of 75.0 g of benzene ( $\text{C}_6\text{H}_6$ ) and 75.0 g of toluene ( $\text{C}_7\text{H}_8$ ) has a total vapor pressure of 80.9 mmHg at 303 K. Another solution of 100.0 g benzene and 50.0 g toluene has a total vapor pressure of 93.9 mmHg at this temperature. Find the vapor pressure of pure benzene and pure toluene at 303 K.
- 133.** A solution is prepared by dissolving 11.60 g of a mixture of sodium carbonate and sodium bicarbonate in 1.00 L of water. A 300.0  $\text{cm}^3$  sample of the solution is treated with excess  $\text{HNO}_3$  and boiled to remove all the dissolved gas. A total of 0.940 L of dry  $\text{CO}_2$  is collected at 298 K and 0.972 atm. Find the molarity of the carbonate and bicarbonate in the solution.

## Conceptual Problems

- 134.** Substance A is a nonpolar liquid and has only dispersion forces among its constituent particles. Substance B is also a nonpolar liquid and has about the same magnitude of dispersion forces among its constituent particles as substance A. When substance A and substance B are combined, they spontaneously mix.
- Why do the two substances mix?
  - Predict the sign and magnitude of  $\Delta H_{\text{soln}}$ .
  - Determine the signs and relative magnitudes of  $\Delta H_{\text{solvent}}$ ,  $\Delta H_{\text{solvent}}$ , and  $\Delta H_{\text{mix}}$ .
- 135.** A power plant built on a river uses river water as a coolant. The water is warmed as it is used in heat exchangers within the plant. Should the warm water be immediately cycled back into the river? Why or why not?

- 136.** The vapor pressure of a 1 M ionic solution is different from the vapor pressure of a 1 M nonelectrolyte solution. In both cases, the solute is nonvolatile. Which set of diagrams best represents the differences between the two solutions and their vapors?

- 137.** If each substance listed here costs the same amount per kilogram, which would be most cost-effective as a way to lower the freezing point of water? (Assume complete dissociation for all ionic compounds.) Explain.
- a.  $\text{HOCH}_2\text{CH}_2\text{OH}$       b.  $\text{NaCl}$       c.  $\text{KCl}$   
 d.  $\text{MgCl}_2$       e.  $\text{SrCl}_2$

- 138.** A helium balloon inflated on one day will fall to the ground by the next day. The volume of the balloon decreases somewhat overnight but not by enough to explain why it no longer floats. (If you inflate a new balloon with helium to the same size as the balloon that fell to the ground, the newly inflated balloon floats.) Explain.

### Active Classroom Learning

## Questions for Group Work

Discuss these questions with the group and record your consensus answer.

- 139.** Explain why 1-propanol ( $\text{CH}_3\text{CH}_2\text{CH}_2\text{OH}$ ) is miscible in both water ( $\text{H}_2\text{O}$ ) and hexane ( $\text{C}_6\text{H}_6$ ) when hexane and water are barely soluble in each other.
- 140.** Have each group member make a flashcard with one of the following on the front:  $\Delta H_{\text{soln}}$ ,  $\Delta H_{\text{lattice}}$ ,  $\Delta H_{\text{solvent}}$ ,  $\Delta H_{\text{mix}}$ , and  $\Delta H_{\text{hydration}}$ . On the back of the card, each group member should describe (in words) the  $\Delta H$  process his or her card lists and how that  $\Delta H$  relates to other  $\Delta H$  values mathematically. Each member presents his or her  $\Delta H$  to the group. After everyone has presented, members should trade cards and quiz each other.
- 141.** Complete the following table by adding *increases*, *decreases*, or *no effect*:

	Increasing Temperature	Increasing Pressure
solubility of gas in water		
solubility of a solid in water		

- 142.** When 13.62 g (about one tablespoon) of table sugar (sucrose,  $\text{C}_{12}\text{H}_{22}\text{O}_{11}$ ) is dissolved in 241.5 mL of water (density 0.997 g/mL), the final volume is 250.0 mL (about one cup). Have each group member calculate one of the following for the solution and present his or her answer to the group:
- a. mass percent  
 b. molarity  
 c. molality
- 143.** Calculate the expected boiling and freezing point for the solution in the previous problem. If you had to bring this syrup to the boiling point for a recipe, would you expect it to take much more time than it takes to boil the same amount of pure water? Why or why not? Would the syrup freeze in a typical freezer ( $-18^\circ\text{C}$ )? Why or why not?

## Data Interpretation and Analysis

### Freezing Point of Salt Water

- 144.** The coldest seawater ever recorded (in a liquid state) was in a stream under an Antarctic glacier in 2010; it measured  $-2.6^\circ\text{C}$  ( $27.3^\circ\text{F}$ ).

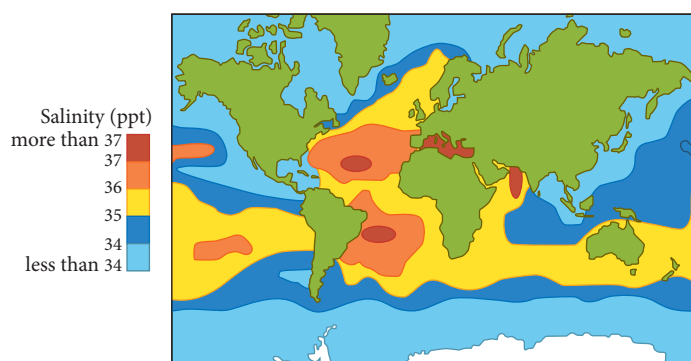

On average, water in the world's oceans has a salinity of about 3.5% (35 g/L, or 599 mM). This means that every kilogram

(roughly one liter by volume) of seawater contains approximately 35 grams (1.2 ounces) of dissolved salts (predominantly sodium ( $\text{Na}^+$ ) and chloride ( $\text{Cl}^-$ ) ions). Figure a provides information on the amounts of various cations and anions in seawater with an average density of 1.025 g/mL.

**▲ FIGURE a** Cations and Anions in Ocean Water

Figure b illustrates the salinity of the oceans on Earth in grams of dissolved material (solute) per kilogram of seawater (solution) or parts per thousand (ppt).

**▲ FIGURE b** Salinity of Seawater in the Earth's Oceans

Because most of the dissolved minerals in seawater is sodium chloride, we can make the assumption that seawater

having a salinity of 35 g/kg contains 35 grams of NaCl per one kilogram of seawater.

Use the information provided in the figures to answer the following questions:

- Calculate the freezing point of a sample of seawater having the highest salinity. Calculate the freezing point of a sample of seawater having the lowest salinity. Use a Van't Hoff Factor of 1.9 in your calculation. Assume the two samples contain water as the solvent and NaCl as the solute.
- Figure c is a proposed graph of the freezing temperature of saltwater versus the amount of salinity. A student claims that saltwater having a salinity of 280 g NaCl/kg of saltwater freezes at  $-20^{\circ}\text{C}$ . Is this claim accurate? Explain.

**▲ FIGURE c** Salinity of Saltwater Versus the Freezing Point of Seawater

- Use the information provided in Figure b and redraw the graph in Figure c using a range of salinity values from six different oceans. The y-axis should be the freezing point of water, and the x-axis should be the salinity of seawater in units of grams of NaCl/kg of seawater. Does Figure c provide an accurate view of the freezing point of the oceans?

## Answers to Conceptual Connections

### Solubility

**13.1** The first alcohol on the list is methanol, which is highly polar and forms hydrogen bonds with water. It is miscible in water and has only limited solubility in hexane, which is nonpolar. However, as the carbon chain gets longer in the series of alcohols, the OH group becomes less important relative to the growing nonpolar carbon chain. Therefore, the alcohols become progressively less soluble in water and more soluble in hexane. This table demonstrates the rule of thumb *like dissolves like*. Methanol is like water and therefore dissolves in water. It is unlike hexane and therefore has limited solubility in hexane. As you move down the list, the alcohols become increasingly like hexane and increasingly unlike water and therefore become increasingly soluble in hexane and increasingly insoluble in water.

### Energetics of Aqueous Solution Formation

**13.2** You can conclude that  $|\Delta H_{\text{solute}}| < |\Delta H_{\text{hydration}}|$ . Since  $\Delta H_{\text{soln}}$  is negative, the absolute value of the negative term ( $\Delta H_{\text{hydration}}$ ) must be greater than the absolute value of the positive term ( $\Delta H_{\text{solute}}$ ).

### Solubility and Temperature

**13.3 (b)** Some potassium bromide precipitates out of solution. The solubility of most solids decreases with decreasing temperature. However, the solubility of gases increases with decreasing

temperature. Therefore, the nitrogen becomes more soluble and will not bubble out of solution.

### Henry's Law

**13.4** Ammonia is the only compound on the list that is polar, so we would expect its solubility in water to be greater than the solubilities of the other gases (which are all nonpolar).

### Molality

**13.5** The solution has a molality of 10.0 m. You combined 1.00 mol of solute with 0.100 kg of solvent, so the molality is 1.00 mol / 0.100 kg = 10.0 m.

### Raoult's Law

**13.6** The solute-solvent interactions must be stronger than the solute-solute and solvent-solvent interactions. The stronger interactions lower the vapor pressure from the expected ideal value of 150 mmHg.

### Boiling Point Elevation

**13.7** Solution B because  $K_b$  for ethanol is greater than  $K_b$  for water.

### Colligative Properties

**13.8 (c)** The 0.50 M  $\text{MgCl}_2$  solution has the highest boiling point because it has the highest concentration of particles. We expect 1 mol of  $\text{MgCl}_2$  to form 3 mol of particles in solution (although it effectively forms slightly fewer).

# Chemical Kinetics

Nobody, I suppose, could devote many years to the study of chemical kinetics without being deeply conscious of the fascination of time and change: this is something that goes outside science into poetry. . . .

—SIR CYRIL N. HINSHELWOOD (1897–1967)

**KEY LEARNING OUTCOMES** 662

In this chapter-opening quotation, Oxford chemistry professor Sir Cyril Hinshelwood calls attention to an aspect of chemistry often overlooked by the casual observer—the mystery of change with time. Since the opening chapter of this book, you have learned that the goal of chemistry is to understand the macroscopic world by examining the molecular one. In this chapter, we focus on understanding how this molecular world changes with time, an area of study called chemical kinetics. The molecular world is anything but static. Thermal energy produces constant molecular motion, causing molecules to repeatedly collide with one another. In a tiny fraction of these collisions, something extraordinary happens—the electrons on one molecule or atom are attracted to the nuclei of another. Some bonds weaken and new bonds form—a chemical reaction occurs. Chemical kinetics is the study of how these kinds of changes occur in time.

▲ Pouring ice water on a lizard slows it down, making it easier to catch.

## 14.1 Catching Lizards

The children who live in my neighborhood (including my own kids) have a unique way of catching lizards. Armed with cups of ice water, they chase one of these cold-blooded reptiles into a corner, and take aim and pour the cold water directly onto the lizard's body. The lizard's body temperature drops and it becomes virtually immobilized—easy prey for little hands. The kids scoop up the lizard and place it in a tub filled with sand and leaves. They then watch as the lizard warms back up and becomes active again. They usually release the lizard back into the yard within hours. I guess you could call them catch-and-release lizard hunters.

Unlike mammals, which actively regulate their body temperature through metabolic activity, lizards are *ectotherms*—their body temperature depends on their surroundings. When splashed with cold water, a lizard's body simply gets colder. The drop in body temperature immobilizes the lizard because its movement depends on chemical reactions that occur within its muscles, and the *rates* of those reactions—how fast they occur—are highly sensitive to temperature. In other words, when the temperature drops, the reactions that produce movement in the lizard occur more slowly; therefore, the movement itself slows down. When reptiles get cold, they become lethargic, unable to move very quickly. For this reason, reptiles try to maintain their body temperature within a narrow range by moving between sun and shade.

The rates of chemical reactions, and especially the ability to *control* those rates, are important not just in reptile movement but in many other phenomena as well. For example, a successful rocket launch depends on the rate at which fuel burns—too quickly and the rocket can explode, too slowly and it will not leave the ground. Chemists must always consider reaction rates when synthesizing compounds. No matter how stable a compound might be, its synthesis is impossible if the rate at which it forms is too slow. As we have seen with reptiles, reaction rates are important to life. In fact, the

human body's ability to switch a specific reaction on or off at a specific time is achieved largely by controlling the rate of that reaction through the use of enzymes (biological molecules that we explore more fully in Section 14.7).

The first person to measure the rate of a chemical reaction carefully was Ludwig Wilhelmy (1812–1864). In 1850, he measured how fast sucrose, upon treatment with acid, hydrolyzed (broke up with the addition of water) into glucose and fructose. This reaction occurred over several hours, and Wilhelmy was able to show how the rate depended on the initial amount of sugar present—the greater the initial amount, the faster the initial rate. Today we can measure the rates of reactions that occur in times as short as several femtoseconds (femto =  $10^{-15}$ ). The knowledge of reaction rates is not only practically important—giving us the ability to control how fast a reaction occurs—but also theoretically important. As we will discuss in Section 14.6, the rate of a reaction can tell us much about how the reaction occurs on the molecular scale.

## 14.2 The Rate of a Chemical Reaction

The rate of a chemical reaction is a measure of how fast the reaction occurs, as shown in Figure 14.1. If a chemical reaction has a fast rate, a large fraction of molecules react to form products in a given period of time. If a chemical reaction has a slow rate, only a relatively small fraction of molecules react to form products in a given period of time.

### Definition of Reaction Rate

When we measure how fast something occurs, or more specifically the *rate* at which it occurs, we usually express the measurement as a change in some quantity per unit of time. For example, we measure the speed of a car—the rate at which it travels—in *miles per hour*, and we measure how quickly (or slowly) people lose weight

▲ **FIGURE 14.1** The Rate of a Chemical Reaction

in *pounds per week*. We report these rates in units that represent the change in what we are measuring (distance or weight) divided by the change in time:

$$\text{Speed} = \frac{\text{change in distance}}{\text{change in time}} = \frac{\Delta x}{\Delta t} \quad \text{Weight loss} = \frac{\text{change in weight}}{\text{change in time}} = \frac{\Delta \text{weight}}{\Delta t}$$

Similarly, the rate of a chemical reaction is measured as a change in the amounts of reactants or products (usually in concentration units) divided by the change in time. For example, consider the gas-phase reaction between  $\text{H}_2(\text{g})$  and  $\text{I}_2(\text{g})$ :

We can define the rate of this reaction in the time interval  $t_1$  to  $t_2$  as follows:

$$\text{Rate} = -\frac{\Delta[\text{H}_2]}{\Delta t} = -\frac{[\text{H}_2]_{t_2} - [\text{H}_2]_{t_1}}{t_2 - t_1} \quad [14.1]$$

Recall that  $[\text{A}]$  means the concentration of A in M (mol/L).

In this expression,  $[\text{H}_2]_{t_2}$  is the hydrogen concentration at time  $t_2$  and  $[\text{H}_2]_{t_1}$  is the hydrogen concentration at time  $t_1$ . The reaction rate is defined as *the negative* of the change in concentration of a reactant divided by the change in time. The negative sign is part of the definition when we define the reaction rate with respect to a reactant because reactant concentrations decrease as a reaction proceeds; therefore, *the change in the concentration of a reactant is negative*. The negative sign thus makes the overall *rate* positive. (By convention, we report reaction rates as positive quantities.)

Similarly, we can define the reaction rate with respect to the other reactant:

$$\text{Rate} = -\frac{\Delta[\text{I}_2]}{\Delta t} \quad [14.2]$$

Since 1 mol of  $\text{H}_2$  reacts with 1 mol of  $\text{I}_2$ , we define the rate in the same way. We can also define the rate with respect to the *product* of the reaction:

$$\text{Rate} = +\frac{1}{2} \frac{\Delta[\text{HI}]}{\Delta t} \quad [14.3]$$

Because product concentrations *increase* as the reaction proceeds, the change in concentration of a product is positive. Therefore, when we define the rate with respect to a product, we do not include a negative sign in the definition—the rate is naturally positive. The factor of  $\frac{1}{2}$  in this definition is related to the stoichiometry of the reaction. In order to have a single rate for the entire reaction, the definition of the rate with respect to each reactant and product must reflect the stoichiometric coefficients of the reaction. For this particular reaction, 2 mol of HI is produced from 1 mol of  $\text{H}_2$  and 1 mol of  $\text{I}_2$ :

The concentration of HI increases at twice the rate that the concentration of  $\text{H}_2$  or  $\text{I}_2$  decreases. In other words, if 100  $\text{I}_2$  molecules react per second, then 200 HI molecules form per second. In order for the overall rate to have the same value when defined with respect to any of the reactants or products, we must multiply the change in HI concentration by a factor of one-half.

Consider the graph in Figure 14.2, which represents the changes in concentration for  $\text{H}_2$  (one of the reactants) and HI (the product) versus time. Let's examine several features of this graph individually.

**FIGURE 14.2** Reactant and Product Concentrations as a Function of Time

The graph shows the concentration of one of the reactants ( $\text{H}_2$ ) and the product (HI) as a function of time. The other reactant ( $\text{I}_2$ ) is omitted for clarity.

### Change in Reactant and Product Concentrations

The reactant concentration, as expected, *decreases* with time because reactants are consumed in a reaction. The product concentration *increases* with time because products are formed in a reaction. The increase in HI concentration occurs at exactly twice the rate of the decrease in H<sub>2</sub> concentration because of the stoichiometry of the reaction: 2 mol of HI form for every 1 mol of H<sub>2</sub> consumed.

### The Average Rate of the Reaction

We can calculate the average rate of the reaction for any time interval using Equation 14.1 for H<sub>2</sub>. The following table lists H<sub>2</sub> concentration ([H<sub>2</sub>]) at various times, the change in H<sub>2</sub> concentration for each interval ( $\Delta[H_2]$ ), the change in time for each interval ( $\Delta t$ ), and the rate for each interval ( $-\Delta[H_2]/\Delta t$ ). The rate is the average rate within the given time interval. For example, the average rate of the reaction in the time interval between 10 and 20 seconds is 0.0149 M/s, whereas the average rate in the time interval between 20 and 30 seconds is 0.0121 M/s.

Time (s)	[H <sub>2</sub> ] (M)	$\Delta[H_2]$ (M)	$\Delta t$ (s)	Rate = $-\Delta[H_2]/\Delta t$ (M/s)
0.000	1.000	}	10.000	0.0181
10.000	0.819			
20.000	0.670		10.000	0.0149
30.000	0.549			
40.000	0.449		10.000	0.0100
50.000	0.368			
60.000	0.301		10.000	0.0067
70.000	0.247			
80.000	0.202		10.000	0.0045
90.000	0.165			
100.000	0.135		10.000	0.0030

Notice that the average rate *decreases* as the reaction progresses. In other words, the reaction slows down as it proceeds. We discuss this further in the next section, where we will see that, for most reactions, the rate depends on the concentrations of the reactants. As the reactants transform to products, their concentrations decrease, and the reaction slows down.

### The Instantaneous Rate of the Reaction

The instantaneous rate of the reaction is the rate at any one point in time and is represented by the instantaneous slope of the curve at that point. We can determine the instantaneous rate by calculating the slope of the tangent to the curve at the point of interest. In Figure 14.2, we have drawn the tangent lines for both [H<sub>2</sub>] and [HI] at 50 seconds. We calculate the instantaneous rate at 50 seconds as follows:

Using [H<sub>2</sub>]

$$\text{Instantaneous rate (at 50 s)} = -\frac{\Delta[H_2]}{\Delta t} = -\frac{-0.28 \text{ M}}{40 \text{ s}} = 0.0070 \text{ M/s}$$

Using [HI]

$$\text{Instantaneous rate (at 50 s)} = +\frac{1}{2} \frac{\Delta[\text{HI}]}{\Delta t} = +\frac{1}{2} \frac{0.56 \text{ M}}{40 \text{ s}} = 0.0070 \text{ M/s}$$

As we would expect, the rate is the same whether we use one of the reactants or the product for the calculation. Notice that the instantaneous rate at 50 seconds (0.0070 M/s) is between the average rates calculated for the 10-second intervals just before and just after 50 seconds.

We can generalize our definition of reaction rate for the generic reaction:

where A and B are reactants, C and D are products, and  $a$ ,  $b$ ,  $c$ , and  $d$  are the stoichiometric coefficients. We define the rate of the reaction as follows:

$$\text{Rate} = -\frac{1}{a} \frac{\Delta[A]}{\Delta t} = -\frac{1}{b} \frac{\Delta[B]}{\Delta t} = +\frac{1}{c} \frac{\Delta[C]}{\Delta t} = +\frac{1}{d} \frac{\Delta[D]}{\Delta t} \quad [14.5]$$

From the definition, we can see that knowing the rate of change in the concentration of any one reactant or product at a point in time allows us to determine the rate of change in the concentration of any other reactant or product at that point in time (from the balanced equation). *However, predicting the rate at some future time is not possible from just the balanced equation.*

### Example 14.1 Expressing Reaction Rates

Consider this balanced chemical equation:

In the first 10.0 seconds of the reaction, the concentration of  $\text{I}^-$  drops from 1.000 M to 0.868 M.

- (a) Calculate the average rate of this reaction in this time interval.  
 (b) Determine the rate of change in the concentration of  $\text{H}^+$  (that is,  $\Delta[\text{H}^+]/\Delta t$ ) during this time interval.

#### SOLUTION

- (a) Use Equation 14.5 to calculate the average rate of the reaction.

$$\begin{aligned} \text{Rate} &= -\frac{1}{3} \frac{\Delta[\text{I}^-]}{\Delta t} \\ &= -\frac{1}{3} \frac{(0.868 \text{ M} - 1.000 \text{ M})}{10.0 \text{ s}} \\ &= 4.40 \times 10^{-3} \text{ M/s} \end{aligned}$$

- (b) Use Equation 14.5 again for the relationship between the rate of the reaction and  $\Delta[\text{H}^+]/\Delta t$ . After solving for  $\Delta[\text{H}^+]/\Delta t$ , substitute the calculated rate from part (a) and calculate  $\Delta[\text{H}^+]/\Delta t$ .

$$\begin{aligned} \text{Rate} &= -\frac{1}{2} \frac{\Delta[\text{H}^+]}{\Delta t} \\ \frac{\Delta[\text{H}^+]}{\Delta t} &= -2(\text{rate}) \\ &= -2(4.40 \times 10^{-3} \text{ M/s}) \\ &= -8.80 \times 10^{-3} \text{ M/s} \end{aligned}$$

**FOR PRACTICE 14.1** For the reaction shown in Example 14.1, predict the rate of change in concentration of  $\text{H}_2\text{O}_2$  ( $\Delta[\text{H}_2\text{O}_2]/\Delta t$ ) and  $\text{I}_3^-$  ( $\Delta[\text{I}_3^-]/\Delta t$ ) during this time interval.

**Reaction Rates** For the reaction  $A + 2B \longrightarrow C$  under a given set of conditions, the initial rate is 0.100 M/s. What is  $\Delta[B]/\Delta t$  under the same conditions?

- (a)  $-0.0500 \text{ M/s}$       (b)  $-0.100 \text{ M/s}$       (c)  $-0.200 \text{ M/s}$

### CONCEPTUAL CONNECTION 14.1

## Measuring Reaction Rates

In order to study the kinetics of a reaction, we must have an experimental way to measure the concentration of at least one of the reactants or products as a function of time. For example, Ludwig Wilhelm, whose experiment on the rate of the conversion of

sucrose to glucose and fructose we discussed briefly in Section 14.1, took advantage of sucrose's ability to rotate polarized light. (Polarized light is light with an electric field oriented along one plane.) When a beam of polarized light is passed through a sucrose solution, the polarization of the light is rotated clockwise. In contrast, the products of the reaction (glucose and fructose) rotate polarized light counterclockwise. By measuring the degree of polarization of light passing through a reacting solution—a technique known as polarimetry—Wilhelmy was able to determine the relative concentrations of the reactants and products as a function of time.

Perhaps the most common way to study the kinetics of a reaction is through spectroscopy (see Section 7.3). For example, the reaction of  $\text{H}_2$  and  $\text{I}_2$  to form  $\text{HI}$  can be followed spectroscopically because  $\text{I}_2$  is violet and  $\text{H}_2$  and  $\text{HI}$  are colorless. As  $\text{I}_2$  reacts with  $\text{H}_2$  to form  $\text{HI}$ , the violet color of the reaction mixture fades. We can monitor the fading color with a spectrometer, a device that passes light through a sample and measures how strongly the light is absorbed (Figure 14.3▼). If the sample contains the reacting mixture, the intensity of the light absorption will decrease as the reaction proceeds, providing a direct measure of the concentration of  $\text{I}_2$  as a function of time. Because light travels so fast and because experimental techniques can produce very short pulses of light, spectroscopy can be used to measure reactions that happen on time scales as short as several femtoseconds.

▼ **FIGURE 14.3 The Spectrometer** In a spectrometer, light of a specific wavelength is passed through the sample, and the intensity of the transmitted light—which depends on how much light is absorbed by the sample—is measured and recorded.

By measuring changes in pressure, we can also monitor reactions in which the number of moles of gaseous reactants and products changes as the reaction proceeds. Consider the reaction in which dinitrogen monoxide reacts to form nitrogen and oxygen gas:

For every 2 mol of  $\text{N}_2\text{O}$  that reacts, the reaction vessel contains one additional mole of gas. As the reaction proceeds and the amount of gas increases, the pressure steadily rises. We can use the rise in pressure to determine the relative concentrations of reactants and products as a function of time.

We can use all of the three techniques mentioned here—polarimetry, spectroscopy, and pressure measurement—to monitor a reaction as it occurs in a reaction vessel. Some reactions occur slowly enough that samples, or *aliquots*, can be periodically withdrawn from the reaction vessel and analyzed to determine the progress of the reaction. We can use instrumental techniques such as gas chromatography (Figure 14.4◀) or mass spectrometry, as well as wet chemical techniques such as titration, to measure the relative amounts of reactants or products in the aliquot. By taking aliquots at regular time intervals, we can determine the relative amounts of reactants and products as a function of time.

▲ **FIGURE 14.4 The Gas Chromatograph** In a gas chromatograph (GC), a sample of the reaction mixture, or aliquot, is injected into a specially constructed column. Because of their characteristic physical and chemical properties, different components of the mixture pass through the column at different rates and thus exit at different times. As each component leaves the column, it is detected electronically and a chromatogram is recorded. The area under each peak in the chromatogram is proportional to the amount of one particular component in the sample mixture.

## 14.3 The Rate Law: The Effect of Concentration on Reaction Rate

The Rate Law for a Chemical Reaction

The rate of a reaction often depends on the concentration of one or more of the reactants. As we have already seen, Ludwig Wilhelmy noticed this effect for the hydrolysis of sucrose. For simplicity, let's consider a reaction in which a single reactant, A, decomposes into products:

As long as the rate of the reverse reaction (in which the products return to reactants) is negligibly slow, we can express the relationship between the rate of the reaction and the concentration of the reactant—called the **rate law**—as follows:

$$\text{Rate} = k[A]^n \quad [14.6]$$

where  $k$  is a constant of proportionality called the **rate constant** and  $n$  is the **reaction order**. The value of  $n$  (usually an integer) determines how the rate depends on the concentration of the reactant:

- If  $n = 0$ , the reaction is *zero order* and the rate is independent of the concentration of A.
- If  $n = 1$ , the reaction is *first order* and the rate is directly proportional to the concentration of A.
- If  $n = 2$ , the reaction is *second order* and the rate is proportional to the square of the concentration of A.

By definition,  $[A]^0 = 1$ , so the rate is equal to  $k$  regardless of  $[A]$ .

Although other orders are possible, including noninteger (or fractional) orders, these three are the most common.

### The Three Common Reaction Orders ( $n = 0, 1$ , and $2$ )

Figure 14.5 shows three plots illustrating how the *concentration of A changes with time* for the three common reaction orders with identical numerical values for the rate constant ( $k$ ) and identical initial concentrations. Figure 14.6 has three plots showing the *rate of the reaction* (the slope of the lines in Figure 14.5) as a function of the *reactant concentration* for each reaction order.

▲ **FIGURE 14.5** Reactant Concentration as a Function of Time for Different Reaction Orders

▲ **FIGURE 14.6** Reaction Rate as a Function of Reactant Concentration for Different Reaction Orders

### Sublimation Is Zero Order

When one layer of particles sublimates, the next layer is exposed. The number of particles available to sublime remains constant.

#### ▲ FIGURE 14.7 Sublimation

When a layer of particles sublimates, another identical layer is just below it. Consequently, the number of particles available to sublime at any one time does not change with the total number of particles in the sample, and the process is zero order.

### Zero-Order Reaction

In a zero-order reaction, the rate of the reaction is independent of the concentration of the reactant:

$$\text{Rate} = k[A]^0 = k \quad [14.7]$$

Consequently, for a zero-order reaction, the concentration of the reactant decreases linearly with time, as shown in Figure 14.5. The slope of the line is constant, indicating a constant rate. The rate is constant because the reaction does not slow down as the concentration of A decreases. The graph in Figure 14.6 shows that the rate of a zero-order reaction is the same at any concentration of A.

Zero-order reactions occur under conditions where the amount of reactant actually *available for reaction* is unaffected by changes in the *overall quantity of reactant*. For example, sublimation is normally zero order because only molecules at the surface of a substance can sublime, and the concentration of the surface molecules does not change as the amount of subliming substance decreases (Figure 14.7 ◀).

### First-Order Reaction

In a first-order reaction, the rate of the reaction is directly proportional to the concentration of the reactant:

$$\text{Rate} = k[A]^1 \quad [14.8]$$

For a first-order reaction, the rate slows down as the reaction proceeds because the concentration of the reactant decreases. We can see this in Figure 14.5—the slope of the curve (the rate) becomes less steep (slower) with time. Figure 14.6 shows the rate as a function of the concentration of A. Notice the linear relationship—the rate is directly proportional to the concentration.

### Second-Order Reaction

In a second-order reaction, the rate of the reaction is proportional to the square of the concentration of the reactant:

$$\text{Rate} = k[A]^2 \quad [14.9]$$

Consequently, for a second-order reaction, the rate is even more sensitive to the reactant concentration. We can see this in Figure 14.5—the slope of the curve (the rate) flattens out more quickly than it does for a first-order reaction. Figure 14.6 shows the rate as a function of the concentration of A. Notice the quadratic relationship—the rate is proportional to the square of the concentration.

## Determining the Order of a Reaction

*The order of a reaction can be determined only by experiment.* A common way to determine reaction order is the *method of initial rates*. In this method, the initial rate—the rate for a short period of time at the beginning of the reaction—is measured by running the reaction several times with different initial reactant concentrations to determine the effect of the concentration on the rate. For example, let's return to our simple reaction in which a single reactant, A, decomposes into products:

In an experiment, the initial rate is measured at several different initial concentrations with the following results:

[A] (M)	Initial Rate (M/s)
0.10	0.015
0.20	0.030
0.40	0.060

In this data set, when the concentration of A doubles, the rate doubles—the initial rate is directly proportional to the initial concentration. The reaction is therefore first order in A, and the rate law takes the first-order form:

$$\text{Rate} = k[A]^1$$

We can determine the value of the rate constant,  $k$ , by solving the rate law for  $k$  and substituting the concentration and the initial rate from any one of the three measurements. Here we use the first measurement:

$$\begin{aligned}\text{Rate} &= k[A]^1 \\ k &= \frac{\text{rate}}{[A]} = \frac{0.015 \text{ M/s}}{0.10 \text{ M}} = 0.15 \text{ s}^{-1}\end{aligned}$$

Notice that the rate constant for a first-order reaction has units of  $\text{s}^{-1}$ .

The following two data sets show how measured initial rates are different for zero-order and for second-order reactions having the same initial rate at  $[A] = 0.10 \text{ M}$ :

Zero Order ( $n = 0$ )		Second Order ( $n = 2$ )	
[A] (M)	Initial Rate (M/s)	[A] (M)	Initial Rate (M/s)
0.10	0.015	0.10	0.015
0.20	0.015	0.20	0.060
0.40	0.015	0.40	0.240

For a zero-order reaction, the initial rate is independent of the reactant concentration—the rate is the same at all measured initial concentrations. For a second-order reaction, the initial rate quadruples for a doubling of the reactant concentration—the relationship between concentration and rate is quadratic. If we are unsure about how the initial rate is changing with the initial reactant concentration, or if the numbers are not as obvious as they are in these examples, we can substitute any two initial concentrations and the corresponding initial rates into a ratio of the rate laws to determine the order ( $n$ ):

$$\frac{\text{rate } 2}{\text{rate } 1} = \frac{k[A]_2^n}{k[A]_1^n}$$

For example, we can substitute the last two measurements in the data set just given for the second-order reaction as follows:

$$\begin{aligned}\frac{0.240 \text{ M/s}}{0.060 \text{ M/s}} &= \frac{k(0.40 \text{ M})^n}{k(0.20 \text{ M})^n} \\ 4.0 &= \left(\frac{0.40}{0.20}\right)^n = 2^n \\ \log 4.0 &= \log(2^n) \\ &= n \log 2 \\ n &= \frac{\log 4}{\log 2} \\ &= 2\end{aligned}$$

Remember that  $\frac{x^n}{y^n} = \left(\frac{x}{y}\right)^n$ .

Remember that  $\log x^n = n \log x$ .

The rate constants for zero- and second-order reactions have different units than for first-order reactions. The rate constant for a zero-order reaction has units of  $\text{M} \cdot \text{s}^{-1}$ , and the rate constant for a second-order reaction has units of  $\text{M}^{-1} \cdot \text{s}^{-1}$ .

The general expression for the units of the rate constant for an  $n$ th-order reaction is  $\text{M}^{(1-n)} \text{s}^{-1}$ .

**Order of Reaction** The reaction  $A \longrightarrow B$  has been experimentally determined to be second order. The initial rate is  $0.0100 \text{ M/s}$  at an initial concentration of A of  $0.100 \text{ M}$ . What is the initial rate at  $[A] = 0.500 \text{ M}$ ?

- (a)  $0.00200 \text{ M/s}$     (b)  $0.0100 \text{ M/s}$     (c)  $0.0500 \text{ M/s}$     (d)  $0.250 \text{ M/s}$

## CONCEPTUAL CONNECTION 14.2

## Reaction Order for Multiple Reactants

So far, we have considered a simple reaction with only one reactant. How do we define the rate law for reactions with more than one reactant? Consider the generic reaction:

As long as the reverse reaction is negligibly slow, the rate law is proportional to the concentration of [A] raised to the  $m$  power multiplied by the concentration of [B] raised to the  $n$  power:

$$\text{Rate} = k[A]^m[B]^n \quad [14.10]$$

where  $m$  is the reaction order with respect to A and  $n$  is the reaction order with respect to B. The **overall order** is the sum of the exponents ( $m + n$ ). For example, the reaction between hydrogen and iodine has been experimentally determined to be first order with respect to hydrogen, first order with respect to iodine, and thus second order overall:

Similarly, the reaction between hydrogen and nitrogen monoxide has been experimentally determined to be first order with respect to hydrogen, second order with respect to nitrogen monoxide, and thus third order overall:

*The rate law for any reaction must always be determined by experiment*, often by the method of initial rates described previously. We can't simply look at a chemical equation and determine the rate law for the reaction. When the reaction has two or more reactants, the concentration of each reactant is usually varied independently of the others to determine the dependence of the rate on the concentration of that reactant. Example 14.2 demonstrates how to use the method of initial rates to determine the order of a reaction with multiple reactants.

### Example 14.2 Determining the Order and Rate Constant of a Reaction

Consider the reaction between nitrogen dioxide and carbon monoxide:

The initial rate of the reaction is measured at several different concentrations of the reactants, and the tabulated results are shown here.

From the data, determine:

- (a) the rate law for the reaction
- (b) the rate constant ( $k$ ) for the reaction

[NO <sub>2</sub> ] (M)	[CO] (M)	Initial Rate (M/s)
0.10	0.10	0.0021
0.20	0.10	0.0082
0.20	0.20	0.0083
0.40	0.10	0.033

#### SOLUTION

- (a) Begin by examining how the rate changes for each change in concentration. Between the first two experiments, the concentration of NO<sub>2</sub> doubles, the concentration of CO stays constant, and the rate quadruples, suggesting that the reaction is second order in NO<sub>2</sub>.

Between the second and third experiments, the concentration of NO<sub>2</sub> stays constant, the concentration of CO doubles, and the rate remains constant (the small change in the least significant figure is simply experimental error), suggesting that the reaction is zero order in CO.

Between the third and fourth experiments, the concentration of NO<sub>2</sub> again doubles and the concentration of CO halves, yet the rate quadruples again, confirming that the reaction is second order in NO<sub>2</sub> and zero order in CO.

[NO <sub>2</sub> ] (M)	[CO] (M)	Initial Rate (M/s)
0.10	0.10	0.0021
↓ × 2	↓ constant	↓ × 4
0.20	0.10	0.0082
↓ constant	↓ × 2	↓ × 1
0.20	0.20	0.0083
↓ × 2	↓ × 1/2	↓ × 4
0.40	0.10	0.033

Write the overall rate expression.

$$\text{Rate} = k[\text{NO}_2]^2[\text{CO}]^0 = k[\text{NO}_2]^2$$

**(a) ALTERNATIVE APPROACH**

If the relationship between the changes in concentrations and the changes in initial rates is not immediately obvious, you can determine the reaction order for any reactant by substituting any two initial rates and the corresponding initial concentrations into a ratio of the rate laws to determine the order ( $n$ ).

For  $\text{NO}_2$  use the first and second concentrations and rates (because  $[\text{NO}_2]$  changes here, but  $[\text{CO}]$  is constant). Substitute the rates and concentrations into the expression for the ratio of the rate constants.

Take the log of both sides of the equation and solve for  $n$ .

For  $\text{CO}$ , use the second and third concentrations and rates (because  $[\text{CO}]$  changes here, but  $[\text{NO}_2]$  is constant).

Substitute the rates and concentrations into the expression for the ratio of the rate laws.

Take the log of both sides of the equation and solve for  $n$ .

Write the overall rate expression from the order of each reactant.

$$\frac{\text{rate 2}}{\text{rate 1}} = \frac{k[\text{A}]_2^n}{k[\text{A}]_1^n}$$

$$\begin{aligned} \text{For NO}_2 \quad \frac{\text{rate 2}}{\text{rate 1}} &= \frac{k[\text{NO}_2]_2^n}{k[\text{NO}_2]_1^n} \\ \frac{0.0082 \text{ M/s}}{0.0021 \text{ M/s}} &= \frac{k(0.20 \text{ M})^n}{k(0.10 \text{ M})^n} \end{aligned}$$

$$3.9 = \left(\frac{0.20}{0.10}\right)^n = 2^n$$

$$\begin{aligned} \log 3.9 &= \log 2^n \\ &= n \log 2 \end{aligned}$$

$$\begin{aligned} n &= \frac{\log 3.9}{\log 2} \\ &= 1.96 = 2 \end{aligned}$$

$$\text{For CO} \quad \frac{\text{rate 3}}{\text{rate 2}} = \frac{k[\text{CO}]_3^n}{k[\text{CO}]_2^n}$$

$$\frac{0.0083 \text{ M/s}}{0.0082 \text{ M/s}} = \frac{k(0.20 \text{ M})^n}{k(0.10 \text{ M})^n}$$

$$1.01 = \left(\frac{0.20}{0.10}\right)^n = 2^n$$

$$\begin{aligned} \log 1.01 &= \log 2^n \\ &= n \log 2 \end{aligned}$$

$$\begin{aligned} n &= \frac{\log 1.01}{\log 2} \\ &= 0.01 = 0 \end{aligned}$$

$$\text{Rate} = k[\text{NO}_2]^2[\text{CO}]^0 = k[\text{NO}_2]^2$$

- (b)** To determine the rate constant for the reaction, solve the rate law for  $k$  and substitute the concentration and the initial rate from any one of the four measurements. In this case, we use the first measurement.

$$\begin{aligned} \text{Rate} &= k[\text{NO}_2]^2 \\ k &= \frac{\text{rate}}{[\text{NO}_2]^2} = \frac{0.0021 \text{ M/s}}{(0.10 \text{ M})^2} = 0.21 \text{ M}^{-1} \cdot \text{s}^{-1} \end{aligned}$$

**FOR PRACTICE 14.2** Consider the equation:

The initial rate of reaction is measured at several different concentrations of the reactants with the tabulated results shown here.

$[\text{CHCl}_3]$ (M)	$[\text{Cl}_2]$ (M)	Initial Rate (M/s)
0.010	0.010	0.0035
0.020	0.010	0.0069
0.020	0.020	0.0098
0.040	0.040	0.027

From the data, determine:

- (a)** the rate law for the reaction

- (b)** the rate constant ( $k$ ) for the reaction

CONCEPTUAL  
CONNECTION 14.3

**Rate and Concentration** This reaction was experimentally determined to be first order with respect to  $O_2$  and second order with respect to  $NO$ :

The diagrams shown here represent reaction mixtures in which the number of each type of molecule represents its relative initial concentration. Which mixture has the fastest initial rate?

## The Integrated Rate Law

## 14.4 The Integrated Rate Law: The Dependence of Concentration on Time

The rate laws we have examined so far show the relationship between *the rate of a reaction and the concentration of a reactant*. But we often want to know the relationship between *the concentration of a reactant and time*. For example, the presence of chlorofluorocarbons (CFCs) in the atmosphere threatens the ozone layer. One of the reasons that CFCs pose

such a significant threat is that the reactions that consume them are so slow (Table 14.1). Legislation has significantly reduced CFC emissions, but even if humans were to completely stop adding CFCs to the atmosphere, their concentration would decrease only very slowly. Nonetheless, we would like to know how their concentration changes with time. How much will be left in 20 years? In 50 years?

TABLE 14.1 Atmospheric Lifetimes of Several CFCs

CFC Name	Structure	Atmospheric Lifetime*
CFC-11 ( $CCl_3F$ ) Trichlorofluoromethane		45 years
CFC-12 ( $CCl_2F_2$ ) Dichlorodifluoromethane		100 years
CFC-113 ( $C_2F_3Cl_3$ ) 1,1,2-Trichloro-1,2,2-trifluoroethane		85 years
CFC-114 ( $C_2F_4Cl_2$ ) 1,2-Dichlorotetrafluoroethane		300 years
CFC-115 ( $C_2F_5Cl$ ) Monochloropentafluoroethane		1700 years

\*Data taken from EPA site (under section 602 of Clean Air Act).

## The Integrated Rate Law

The **integrated rate law** for a chemical reaction is a relationship between the concentrations of the reactants and time. For simplicity, we return to a single reactant decomposing into products:

The integrated rate law for this reaction depends on the order of the reaction; let's examine each of the common reaction orders individually.

## First-Order Integrated Rate Law

If our simple reaction is first order, the rate is directly proportional to the concentration of A:

$$\text{Rate} = k[A]$$

Since  $\text{Rate} = -\Delta[A]/\Delta t$ , we can write:

$$-\frac{\Delta[A]}{\Delta t} = k[A] \quad [14.11]$$

In this form, the rate law is also known as the *differential rate law*.

We can use calculus (see margin) to integrate the differential rate law and obtain the first-order *integrated rate law*:

$$\ln [A]_t = -kt + \ln [A]_0 \quad [14.12]$$

We can also rearrange the integrated rate law by subtracting  $\ln[A]_0$  from both sides of Equation 14.12:

$$\begin{aligned} \ln [A]_t &= -kt + \ln [A]_0 \\ \ln [A]_t - \ln [A]_0 &= -kt \end{aligned}$$

Since  $\ln A - \ln B = \ln (A/B)$ , we can rearrange this equation to get:

$$\ln \frac{[A]_t}{[A]_0} = -kt \quad [14.13]$$

where  $[A]_t$  is the concentration of A at any time  $t$ ,  $k$  is the rate constant, and  $[A]_0$  is the initial concentration of A.

Notice that the integrated rate law shown in Equation 14.12 has the form of an equation for a straight line:

$$\begin{aligned} \ln [A]_t &= -kt + \ln [A]_0 \\ y &= mx + b \end{aligned}$$

For a first-order reaction, a plot of the natural log of the reactant concentration as a function of time yields a straight line with a slope of  $-k$  and a  $y$ -intercept of  $\ln [A]_0$ , as shown in Figure 14.8. (Note that the slope is negative but that the rate constant is always positive.)

$$\begin{aligned} -\frac{d[A]}{dt} &= k[A] \\ \frac{d[A]}{[A]} &= -kdt \\ \int_{[A]_0}^{[A]} \frac{d[A]}{[A]} &= -\int_0^t kdt \\ [\ln[A]]_{[A]_0}^{[A]} &= -k[t]_0^t \\ \ln[A] - \ln[A]_0 &= -kt \\ \ln[A] &= -kt + \ln[A]_0 \end{aligned}$$

**▲ FIGURE 14.8 First-Order Integrated Rate Law** For a first-order reaction, a plot of the natural log of the reactant concentration as a function of time yields a straight line. The slope of the line is equal to  $-k$  and the  $y$ -intercept is  $\ln[A]_0$ .

### Example 14.3

#### The First-Order Integrated Rate Law: Using Graphical Analysis of Reaction Data

Consider the equation for the decomposition of  $\text{SO}_2\text{Cl}_2$ :

The concentration of  $\text{SO}_2\text{Cl}_2$  is monitored at a fixed temperature as a function of time during the decomposition reaction, and the following data are tabulated:

Time (s)	$[\text{SO}_2\text{Cl}_2]$ (M)	Time (s)	$[\text{SO}_2\text{Cl}_2]$ (M)
0	0.100	800	0.0793
100	0.0971	900	0.0770
200	0.0944	1000	0.0748
300	0.0917	1100	0.0727
400	0.0890	1200	0.0706
500	0.0865	1300	0.0686
600	0.0840	1400	0.0666
700	0.0816	1500	0.0647

Show that the reaction is first order, and determine the rate constant for the reaction.

—Continued on the next page

—Continued

**SOLUTION**

In order to show that the reaction is first order, prepare a graph of  $\ln [\text{SO}_2\text{Cl}_2]$  versus time as shown:

The plot is linear, confirming that the reaction is indeed first order. To obtain the rate constant, fit the data to a line. The slope of the line is equal to  $-k$ . Since the slope of the best-fitting line (which is most easily determined on a graphing calculator or with spreadsheet software such as Microsoft Excel) is  $-2.90 \times 10^{-4} \text{ s}^{-1}$ , the rate constant is  $+2.90 \times 10^{-4} \text{ s}^{-1}$ .

**FOR PRACTICE 14.3** Use the graph and the best-fitting line in Example 14.3 to predict the concentration of  $\text{SO}_2\text{Cl}_2$  at 1900 s.

### Example 14.4 The First-Order Integrated Rate Law: Determining the Concentration of a Reactant at a Given Time

In Example 14.3, you determined that the decomposition of  $\text{SO}_2\text{Cl}_2$  (under the given reaction conditions) is first order and has a rate constant of  $+2.90 \times 10^{-4} \text{ s}^{-1}$ . If the reaction is carried out at the same temperature and the initial concentration of  $\text{SO}_2\text{Cl}_2$  is 0.0225 M, what is the  $\text{SO}_2\text{Cl}_2$  concentration after 865 s?

**SORT** You are given the rate constant of a first-order reaction and the initial concentration of the reactant and asked to find the concentration at 865 seconds.

**GIVEN:**  $k = +2.90 \times 10^{-4} \text{ s}^{-1}$   
 $[\text{SO}_2\text{Cl}_2]_0 = 0.0225 \text{ M}$

**FIND:**  $[\text{SO}_2\text{Cl}_2]$  at  $t = 865 \text{ s}$

**STRATEGIZE** Refer to the first-order integrated rate law to determine the  $\text{SO}_2\text{Cl}_2$  concentration at  $t = 865 \text{ s}$ .

**EQUATION**  $\ln [A]_t = -kt + \ln [A]_0$

**SOLVE** Substitute the rate constant, the initial concentration, and the time into the integrated rate law. Solve the integrated rate law for the concentration of  $[\text{SO}_2\text{Cl}_2]_t$ .

**SOLUTION**  
 $\ln [\text{SO}_2\text{Cl}_2]_t = -kt + \ln [\text{SO}_2\text{Cl}_2]_0$   
 $\ln [\text{SO}_2\text{Cl}_2]_t = -(2.90 \times 10^{-4} \text{ s}^{-1})(865 \text{ s}) + \ln(0.0225)$   
 $\ln [\text{SO}_2\text{Cl}_2]_t = -0.251 - 3.79$   
 $[\text{SO}_2\text{Cl}_2]_t = e^{-4.04}$   
 $= 0.0176 \text{ M}$

**CHECK** The concentration is smaller than the original concentration as expected. If the concentration were larger than the initial concentration, this would indicate a mistake in the signs of one of the quantities on the right-hand side of the equation.

**FOR PRACTICE 14.4** Cyclopropane rearranges to form propene in the gas phase.

The reaction is first order in cyclopropane and has a measured rate constant of  $3.36 \times 10^{-5} \text{ s}^{-1}$  at 720 K. If the initial cyclopropane concentration is 0.0445 M, what is the cyclopropane concentration after 235.0 minutes?

## Second-Order Integrated Rate Law

If our simple reaction ( $A \longrightarrow \text{products}$ ) is second order, the rate is proportional to the square of the concentration of A:

$$\text{Rate} = k[A]^2$$

Since  $\text{Rate} = -\Delta[A]/\Delta t$ , we can write the differential rate law:

$$-\frac{\Delta[A]}{\Delta t} = k[A]^2 \quad [14.14]$$

Again, we can use calculus to integrate the second-order differential rate law. We leave this derivation to an exercise (see Exercise 115 at the end of this chapter). The derivation results in the *second-order integrated rate law*:

$$\frac{1}{[A]_t} = kt + \frac{1}{[A]_0} \quad [14.15]$$

The second-order integrated rate law is also in the form of an equation for a straight line:

$$\begin{aligned} \frac{1}{[A]_t} &= kt + \frac{1}{[A]_0} \\ y &= mx + b \end{aligned}$$

However, you must plot the inverse of the concentration of the reactant as a function of time. The plot yields a straight line with a slope of  $k$  and an intercept of  $1/[A]_0$ , as shown in Figure 14.9.

**▲ FIGURE 14.9 Second-Order Integrated Rate Law** For a second-order reaction, a plot of the inverse of the reactant concentration as a function of time yields a straight line. The slope of the line is equal to  $k$  and the y-intercept is  $1/[A]_0$ .

### Example 14.5

#### The Second-Order Integrated Rate Law: Using Graphical Analysis of Reaction Data

Consider the equation for the decomposition of  $\text{NO}_2$ :

The concentration of  $\text{NO}_2$  is monitored at a fixed temperature as a function of time during the decomposition reaction and the data tabulated in the margin at right. Show by graphical analysis that the reaction is not first order and that it is second order. Determine the rate constant for the reaction.

#### SOLUTION

In order to show that the reaction is *not* first order, prepare a graph of  $\ln[\text{NO}_2]$  versus time as shown:

The plot is *not* linear (the straight line does not fit the data points), confirming that the reaction is not first order. In order to show that the reaction is second order, prepare a graph of  $1/[\text{NO}_2]$  versus time as shown:

Time (s)	$[\text{NO}_2]$ (M)
0	0.01000
50	0.00887
100	0.00797
150	0.00723
200	0.00662
250	0.00611
300	0.00567
350	0.00528
400	0.00495
450	0.00466
500	0.00440
550	0.00416
600	0.00395
650	0.00376
700	0.00359
750	0.00343
800	0.00329
850	0.00316
900	0.00303
950	0.00292
1000	0.00282

—Continued on the next page

—Continued

This graph is linear (the data points fit well to a straight line), confirming that the reaction is indeed second order. To obtain the rate constant, determine the slope of the best-fitting line. The slope is  $0.255 \text{ M}^{-1} \cdot \text{s}^{-1}$ ; therefore, the rate constant is  $0.255 \text{ M}^{-1} \cdot \text{s}^{-1}$ .

**FOR PRACTICE 14.5** Use the graph and the best-fitting line in Example 14.5 to predict the concentration of  $\text{NO}_2$  at 2000 s.

$$\begin{aligned} -\frac{d[A]}{dt} &= k[A]^0 \\ -\frac{d[A]}{dt} &= k \\ \int_{[A]_0}^{[A]} d[A] &= -k \int_0^t dt \\ [[A]]_{[A]_0}^{[A]} &= -k[t]_0^t \\ [A] - [A]_0 &= -kt \\ [A] &= -kt + [A]_0 \end{aligned}$$

**FIGURE 14.10 Zero-Order Integrated Rate Law** For a zero-order reaction, a plot of the reactant concentration as a function of time yields a straight line. The slope of the line is equal to  $-k$  and the y-intercept is  $[A]_0$ .

### Zero-Order Integrated Rate Law

If our simple reaction is zero order, the rate is proportional to a constant:

$$\text{Rate} = k[A]^0 = k$$

Since  $\text{Rate} = -\Delta[A]/\Delta t$ , we can write:

$$-\frac{\Delta[A]}{\Delta t} = k \quad [14.16]$$

We can integrate the zero-order differential rate law (see margin) to obtain the *zero-order integrated rate law*:

$$[A]_t = -kt + [A]_0 \quad [14.17]$$

The zero-order integrated rate law in Equation 14.17 is also in the form of an equation for a straight line. A plot of the concentration of the reactant as a function of time yields a straight line with a slope of  $-k$  and an intercept of  $[A]_0$ , shown in Figure 14.10.

### The Half-Life of a Reaction

The **half-life** ( $t_{1/2}$ ) of a reaction is the time required for the concentration of a reactant to fall to one-half of its initial value. For example, if a reaction has a half-life of 100 seconds, and if the initial concentration of the reactant is 1.0 M, the concentration will fall to 0.50 M in 100 s. The half-life expression—which defines the dependence of half-life on the rate constant and the initial concentration—is different for different reaction orders.

#### First-Order Reaction Half-Life

From the definition of half-life and from the integrated rate law, we can derive an expression for the half-life. For a first-order reaction, the integrated rate law is:

$$\ln \frac{[A]_t}{[A]_0} = -kt$$

At a time equal to the half-life ( $t = t_{1/2}$ ), the concentration is exactly half of the initial concentration: ( $[A]_{t_{1/2}} = \frac{1}{2}[A]_0$ ). Therefore, when  $t = t_{1/2}$  we can write the following expression:

$$\ln \frac{\frac{1}{2}[A]_0}{[A]_0} = \ln \frac{1}{2} = -kt_{1/2} \quad [14.18]$$

Solving for  $t_{1/2}$ , and substituting  $-0.693$  for  $\ln \frac{1}{2}$ , we arrive at the expression for the half-life of a first-order reaction:

$$t_{1/2} = \frac{0.693}{k} \quad [14.19]$$

Notice that, for a first-order reaction,  $t_{1/2}$  is *independent of the initial concentration*. For example, if  $t_{1/2}$  is 100 s, and if the initial concentration is 1.0 M, the concentration falls to 0.50 M in 100 s, to 0.25 M in another 100 s, to 0.125 M in another 100 s, and so on (Figure 14.11 ►). Even though the concentration is changing as the reaction proceeds, the half-life (how long it takes for the concentration to halve) is constant. A constant half-life is unique to first-order reactions, making the concept of half-life particularly useful for first-order reactions.

► **FIGURE 14.11** Half-Life: Concentration versus Time for a First-Order Reaction For this reaction, the concentration decreases by one-half every 100 seconds ( $t_{1/2} = 100$  s). The blue spheres represent reactant molecules (the products are omitted for clarity).

**Half-Life Part I** The images shown here depict the first-order reaction  $A \longrightarrow B$  at various times during the reaction process. The black circles represent reactant A and the red circles represent product B. What is the half-life of the reaction?

#### CONCEPTUAL CONNECTION 14.4

**Half-Life Part II** A first-order reaction ( $A \longrightarrow B$ ) has a half-life of 25 minutes. If the initial concentration of A is 0.300 M, what is the concentration of B after 50 minutes? (Do not use a calculator to solve this problem.)

#### CONCEPTUAL CONNECTION 14.5

**Example 14.6** Half-Life

Molecular iodine dissociates at 625 K with a first-order rate constant of  $0.271 \text{ s}^{-1}$ . What is the half-life of this reaction?

**SOLUTION**

Because the reaction is first order, the half-life is given by Equation 14.19. Substitute the value of  $k$  into the expression and calculate  $t_{1/2}$ .

$$\begin{aligned} t_{1/2} &= \frac{0.693}{k} \\ &= \frac{0.693}{0.271 \text{ s}^{-1}} = 2.56 \text{ s} \end{aligned}$$

**FOR PRACTICE 14.6** A first-order reaction has a half-life of 26.4 seconds. How long does it take for the concentration of the reactant in the reaction to fall to one-eighth of its initial value?

**Second-Order Reaction Half-Life**

For a second-order reaction, the integrated rate law is:

$$\frac{1}{[A]_t} = kt + \frac{1}{[A]_0}$$

At a time equal to the half-life ( $t = t_{1/2}$ ), the concentration is exactly one-half of the initial concentration ( $[A]_t = \frac{1}{2}[A]_0$ ). We can therefore write the following expression at  $t = t_{1/2}$ :

$$\frac{1}{\frac{1}{2}[A]_0} = kt_{1/2} + \frac{1}{[A]_0} \quad [14.20]$$

And then solve for  $t_{1/2}$ :

$$kt_{1/2} = \frac{1}{\frac{1}{2}[A]_0} - \frac{1}{[A]_0}$$

$$kt_{1/2} = \frac{2}{[A]_0} - \frac{1}{[A]_0}$$

$$t_{1/2} = \frac{1}{k[A]_0} \quad [14.21]$$

Notice that, for a second-order reaction, the half-life depends on the initial concentration. So if the initial concentration of a reactant in a second-order reaction is 1.0 M, and the half-life is 100 s, the concentration falls to 0.50 M in 100 s. However, the time it takes for the concentration to fall to 0.25 M is now *longer than 100 s* because the initial concentration has decreased. Thus, the half-life continues to get longer as the concentration decreases.

**Zero-Order Reaction Half-Life**

For a zero-order reaction, the integrated rate law is:

$$[A]_t = -kt + [A]_0$$

Making the substitutions ( $t = t_{1/2}$ ;  $[A]_t = \frac{1}{2}[A]_0$ ), we can write the expression at  $t = t_{1/2}$ :

$$\frac{1}{2}[A]_0 = -kt_{1/2} + [A]_0 \quad [14.22]$$

We then solve for  $t_{1/2}$ :

$$t_{1/2} = \frac{[A]_0}{2k} \quad [14.23]$$

Notice that, for a zero-order reaction, the half-life also depends on the initial concentration; however, unlike in the second-order case, the two are directly proportional—the half-life gets shorter as the concentration decreases.

**Summarizing Basic Kinetic Relationships (see Table 14.2):**

- ▶ The reaction order and rate law must be determined experimentally.
- ▶ The rate law relates the *rate* of the reaction to the *concentration* of the reactant(s).
- ▶ The integrated rate law (which is mathematically derived from the rate law) relates the *concentration* of the reactant(s) to *time*.
- ▶ The half-life is the time it takes for the concentration of a reactant to fall to one-half of its initial value.
- ▶ The half-life of a first-order reaction is independent of the initial concentration.
- ▶ The half-lives of zero-order and second-order reactions depend on the initial concentrations.

**CONCEPTUAL CONNECTION 14.6**

**Rate Law and Integrated Rate Law** A decomposition reaction, with a rate that is observed to slow down as the reaction proceeds, has a half-life that depends on the initial concentration of the reactant. Which statement is most likely true for this reaction?

- A plot of the natural log of the concentration of the reactant as a function of time is linear.
- The half-life of the reaction increases as the initial concentration increases.
- A doubling of the initial concentration of the reactant results in a quadrupling of the rate.

**TABLE 14.2** Rate Law Summary Table

Order	Rate Law	Units of $k$	Integrated Rate Law	Straight-Line Plot	Half-Life Expression
0	Rate = $k[A]^0$	$M \cdot s^{-1}$	$[A]_t = -kt + [A]_0$		$t_{1/2} = \frac{[A]_0}{2k} = \frac{1}{k} \frac{[A]_0}{2}$
1	Rate = $k[A]^1$	$s^{-1}$	$\ln[A]_t = -kt + \ln[A]_0$ $\ln \frac{[A]_t}{[A]_0} = -kt$		$t_{1/2} = \frac{0.693}{k} = \frac{1}{k} (0.693)$
2	Rate = $k[A]^2$	$M^{-1} \cdot s^{-1}$	$\frac{1}{[A]_t} = kt + \frac{1}{[A]_0}$		$t_{1/2} = \frac{1}{k[A]_0} = \frac{1}{k} \frac{1}{[A]_0}$

## 14.5 The Effect of Temperature on Reaction Rate

In the opening section of this chapter, we discussed how lizards become lethargic when their body temperature drops and the chemical reactions that control their muscle movement slow. The rates of chemical reactions are, in general, highly sensitive to temperature. For example, at around room temperature, a 10 °C increase in temperature increases the rate of a typical biological reaction by two or three times. How do we explain this highly sensitive temperature dependence?

### The Arrhenius Equation

Recall that the rate law for a reaction is  $\text{Rate} = k[A]^n$ . The temperature dependence of the reaction rate is contained in the rate constant,  $k$  (which is actually a constant only when the temperature remains constant). An increase in temperature generally results in an increase in  $k$ , which results in a faster rate. In 1889, Swedish chemist Svante Arrhenius (1859–1927) wrote a paper quantifying the temperature dependence of the rate constant.

The modern form of the **Arrhenius equation** shows the relationship between the rate constant ( $k$ ) and the temperature in kelvin ( $T$ ):

$$k = A e^{\frac{-E_a}{RT}}$$

Frequency factor
Activation energy
Exponential factor

[14.24]

In this equation,  $R$  is the gas constant (8.314 J/mol · K),  $A$  is a constant called the *frequency factor* (or the *pre-exponential factor*), and  $E_a$  is the *activation energy* (or *activation barrier*).

**▲ FIGURE 14.12 The Activation Energy Barrier** Even though the reaction is energetically favorable (the energy of the products is lower than that of the reactants), an input of energy is needed for the reaction to take place.

The **activation energy** ( $E_a$ ) is an energy barrier or hump that must be surmounted in order for the reactants to transform into products (Figure 14.12▲). We examine the frequency factor more closely in the next section; for now, we can think of the **frequency factor** ( $A$ ) as the number of times that the reactants approach the activation barrier per unit time.

## The Activation Energy, Frequency Factor, and Exponential Factor

To understand each of these quantities better, consider the simple reaction in which  $\text{CH}_3\text{NC}$  (methyl isonitrile) rearranges to form  $\text{CH}_3\text{CN}$  (acetonitrile):

Let's examine the physical meaning of the activation energy, frequency factor, and exponential factor for this reaction.

### The Activation Energy

Figure 14.13 shows the energy of a molecule as the reaction proceeds. The  $x$ -axis represents the progress of the reaction from left (reactant) to right (product). To get from the reactant to the product, the molecule must go through a high-energy state called the **activated complex** or **transition state**. Even though the overall reaction is energetically downhill (exothermic), it must first go uphill to reach the activated complex because energy is required to initially weaken the  $\text{H}_3\text{C}-\text{N}$  bond and allow the  $\text{NC}$  group to begin to rotate:

**▲ FIGURE 14.13 The Activated Complex** The reaction pathway includes a transitional state—the activated complex—that has a higher energy than either the reactant or the product.

The energy required to reach the activated complex is the *activation energy*. *The higher the activation energy, the slower the reaction rate (at a given temperature).*

### The Frequency Factor

Recall that the frequency factor represents the number of approaches to the activation barrier per unit time. Any time that the  $\text{NC}$  group begins to rotate, it approaches the activation barrier. For this reaction, the frequency factor represents the rate at which the  $\text{NC}$  part of the molecule wags (vibrates side to side). With each wag, the reactant approaches the activation barrier:

However, approaching the activation barrier is not equivalent to surmounting it. Most of the approaches do not have enough total energy to make it over the activation barrier.

## The Exponential Factor

The **exponential factor** is a number between 0 and 1 that represents the fraction of molecules that have enough energy to make it over the activation barrier on a given approach. The exponential factor is the fraction of approaches that are actually successful and result in the product. For example, if the frequency factor is  $10^9/\text{s}$  and the exponential factor is  $10^{-7}$  at a certain temperature, then the overall rate constant at that temperature is  $10^9/\text{s} \times 10^{-7} = 10^2/\text{s}$ . In this case, the CN group wags at a rate of  $10^9/\text{s}$ . With each wag, the activation barrier is approached. However, for a given wag only 1 in  $10^7$  molecules has sufficient energy to actually make it over the activation barrier.

The exponential factor depends on both the temperature ( $T$ ) and the activation energy ( $E_a$ ) of the reaction:

$$\text{Exponential factor} = e^{-E_a/RT}$$

A low activation energy and a high temperature make the negative exponent small, so the exponential factor approaches one. For example, if the activation energy is zero, then the exponent is zero, and the exponential factor is exactly one ( $e^{-0} = 1$ )—every approach to the activation barrier is successful. By contrast, a large activation energy and a low temperature make the exponent a very large negative number, so the exponential factor becomes very small. For example, as the temperature approaches 0 K, the exponent approaches an infinitely large negative number, and the exponential factor approaches zero ( $e^{-\infty} = 0$ ).

As the temperature increases, the number of molecules having enough thermal energy to surmount the activation barrier increases. At any given temperature, a sample of molecules has a distribution of energies, as shown in Figure 14.14. Under common circumstances, only a small fraction of the molecules has enough energy to make it over the activation barrier. Because of the shape of the energy distribution curve, however, a small change in temperature results in a large difference in the number of molecules having enough energy to surmount the activation barrier. This explains the sensitivity of reaction rates to temperature.

### Thermal Energy Distribution

As temperature increases, the fraction of molecules with enough energy to surmount the activation energy barrier also increases.

**▲ FIGURE 14.14 Thermal Energy Distribution**

At any given temperature, the atoms or molecules in a gas sample have a range of energies. The higher the temperature, the wider the energy distribution and the greater the average energy. The fraction of molecules with enough energy to surmount the activation energy barrier and react (shaded regions) increases sharply as the temperature rises.

### Summarizing Temperature and Reaction Rate:

- ▶ The frequency factor is the number of times that the reactants approach the activation barrier per unit time.
- ▶ The exponential factor is the fraction of the approaches that are successful in surmounting the activation barrier and forming products.
- ▶ The exponential factor increases with increasing temperature but decreases with increasing activation energy.

## Arrhenius Plots: Experimental Measurements of the Frequency Factor and the Activation Energy

The frequency factor and activation energy are important quantities in understanding the kinetics of any reaction. To see how we measure these factors in the laboratory, consider again Equation 14.24:  $k = Ae^{-E_a/RT}$ . Taking the natural log of both sides of this equation, we get the following result:

$$\ln k = \ln(Ae^{-E_a/RT})$$

$$\ln k = \ln A + \ln e^{-E_a/RT}$$

$$\ln k = \ln A - \frac{E_a}{RT} \quad [14.25]$$

$$\ln k = -\frac{E_a}{R} \left( \frac{1}{T} \right) + \ln A \quad [14.26]$$

$$y = mx + b$$

Remember that  $\ln(AB) = \ln A + \ln B$ .

Remember that  $\ln e^x = x$ .

In an Arrhenius analysis, the pre-exponential factor ( $A$ ) is assumed to be independent of temperature. Although the pre-exponential factor does depend on temperature to some degree, its temperature dependence is much less than that of the exponential factor and is often ignored.

Equation 14.26 is in the form of a straight line. A plot of the natural log of the rate constant ( $\ln k$ ) versus the inverse of the temperature in kelvins ( $1/T$ ) yields a straight line with a slope of  $-E_a/R$  and a y-intercept of  $\ln A$ . Such a plot is called an **Arrhenius plot** and is commonly used in the analysis of kinetic data, as shown in Example 14.7.

### Example 14.7 Using an Arrhenius Plot to Determine Kinetic Parameters

The decomposition of ozone shown here is important to many atmospheric reactions:

A study of the kinetics of the reaction results in the following data:

Temperature (K)	Rate Constant ( $\text{M}^{-1} \cdot \text{s}^{-1}$ )	Temperature (K)	Rate Constant ( $\text{M}^{-1} \cdot \text{s}^{-1}$ )
600	$3.37 \times 10^3$	1300	$7.83 \times 10^7$
700	$4.85 \times 10^4$	1400	$1.45 \times 10^8$
800	$3.58 \times 10^5$	1500	$2.46 \times 10^8$
900	$1.70 \times 10^6$	1600	$3.93 \times 10^8$
1000	$5.90 \times 10^6$	1700	$5.93 \times 10^8$
1100	$1.63 \times 10^7$	1800	$8.55 \times 10^8$
1200	$3.81 \times 10^7$	1900	$1.19 \times 10^9$

Determine the value of the frequency factor and activation energy for the reaction.

#### SOLUTION

To determine the frequency factor and activation energy, prepare a graph of the natural log of the rate constant ( $\ln k$ ) versus the inverse of the temperature ( $1/T$ ).

The plot is linear, as expected for Arrhenius behavior. The line that fits best has a slope of  $-1.12 \times 10^4 \text{ K}$  and a y-intercept of 26.8. Calculate the activation energy from the slope by setting the slope equal to  $-E_a/R$  and solving for  $E_a$ :

$$\begin{aligned} -1.12 \times 10^4 \text{ K} &= \frac{-E_a}{R} \\ E_a &= 1.12 \times 10^4 \text{ K} \left( 8.314 \frac{\text{J}}{\text{mol} \cdot \text{K}} \right) \\ &= 9.31 \times 10^4 \text{ J/mol} \\ &= 93.1 \text{ kJ/mol} \end{aligned}$$

Calculate the frequency factor ( $A$ ) by setting the intercept equal to  $\ln A$ .

$$\begin{aligned} 26.8 &= \ln A \\ A &= e^{26.8} \\ &= 4.36 \times 10^{11} \end{aligned}$$

Since the rate constants are measured in units of  $\text{M}^{-1} \cdot \text{s}^{-1}$ , the frequency factor is in the same units. Consequently, you can conclude that the reaction has an activation energy of 93.1 kJ/mol and a frequency factor of  $4.36 \times 10^{11} \text{ M}^{-1} \cdot \text{s}^{-1}$ .

**FOR PRACTICE 14.7** For the decomposition of ozone reaction in Example 14.7, use the results of the Arrhenius analysis to predict the rate constant at 298 K.

In some cases, when either data are limited or plotting capabilities are absent, we can calculate the activation energy if we know the rate constant at just two different temperatures. We can apply the Arrhenius expression in Equation 14.26 to the two different temperatures as follows:

$$\ln k_2 = -\frac{E_a}{R} \left( \frac{1}{T_2} \right) + \ln A$$

$$\ln k_1 = -\frac{E_a}{R} \left( \frac{1}{T_1} \right) + \ln A$$

We can then subtract  $\ln k_1$  from  $\ln k_2$ :

$$\ln k_2 - \ln k_1 = \left[ -\frac{E_a}{R} \left( \frac{1}{T_2} \right) + \ln A \right] - \left[ -\frac{E_a}{R} \left( \frac{1}{T_1} \right) + \ln A \right]$$

Rearranging, we get the two-point form of the Arrhenius equation:

$$\ln \frac{k_2}{k_1} = \frac{E_a}{R} \left( \frac{1}{T_1} - \frac{1}{T_2} \right) \quad [14.27]$$

Example 14.8 demonstrates how to use this equation to calculate the activation energy from experimental measurements of the rate constant at two different temperatures.

### Example 14.8 Using the Two-Point Form of the Arrhenius Equation

Consider the reaction between nitrogen dioxide and carbon monoxide:

The rate constant at 701 K is measured as  $2.57 \text{ M}^{-1} \cdot \text{s}^{-1}$  and that at 895 K is measured as  $567 \text{ M}^{-1} \cdot \text{s}^{-1}$ . Find the activation energy for the reaction in kJ/mol.

**SORT** You are given the rate constant of a reaction at two different temperatures and asked to find the activation energy.

**GIVEN:**  $T_1 = 701 \text{ K}$ ,  $k_1 = 2.57 \text{ M}^{-1} \cdot \text{s}^{-1}$   
 $T_2 = 895 \text{ K}$ ,  $k_2 = 567 \text{ M}^{-1} \cdot \text{s}^{-1}$

**FIND:**  $E_a$

**STRATEGIZE** Use the two-point form of the Arrhenius equation, which relates the activation energy to the given information and  $R$  (a constant).

**EQUATION**  $\ln \frac{k_2}{k_1} = \frac{E_a}{R} \left( \frac{1}{T_1} - \frac{1}{T_2} \right)$

**SOLVE** Substitute the two rate constants and the two temperatures into the equation.

**SOLUTION**

$$\ln \frac{567 \text{ M}^{-1} \cdot \text{s}^{-1}}{2.57 \text{ M}^{-1} \cdot \text{s}^{-1}} = \frac{E_a}{R} \left( \frac{1}{701 \text{ K}} - \frac{1}{895 \text{ K}} \right)$$

$$5.40 = \frac{E_a}{R} \left( \frac{3.09 \times 10^{-4}}{\text{K}} \right)$$

$$E_a = 5.40 \left( \frac{\text{K}}{3.09 \times 10^{-4}} \right) R$$

$$= 5.40 \left( \frac{\text{K}}{3.09 \times 10^{-4}} \right) 8.314 \frac{\text{J}}{\text{mol} \cdot \text{K}}$$

$$= 1.45 \times 10^5 \text{ J/mol}$$

$$= 1.5 \times 10^2 \text{ kJ/mol}$$

Solve the equation for  $E_a$ , the activation energy, and convert to kJ/mol.

**CHECK** The magnitude of the answer is reasonable. Activation energies for most reactions range from tens to hundreds of kilojoules per mole.

**FOR PRACTICE 14.8** Use the results from Example 14.8 and the given rate constant of the reaction at either of the two temperatures to predict the rate constant for this reaction at 525 K.

**Temperature Dependence of Reaction Rate** Reaction A and reaction B have identical frequency factors. However, reaction B has a higher activation energy than reaction A. Which reaction has a greater rate constant at room temperature?

CONCEPTUAL  
CONNECTION 14.7

## The Collision Model: A Closer Look at the Frequency Factor

Recall that the frequency factor in the Arrhenius equation represents the number of approaches to the activation barrier per unit time. Let's refine that idea for a reaction involving two gas-phase reactants:

In the **collision model**, a chemical reaction occurs after a sufficiently energetic collision between two reactant molecules (Figure 14.15▶). In collision theory, therefore, each approach to the activation barrier is a collision between the reactant molecules. Consequently, the value of the frequency factor should simply be the number of collisions that occur per second. However, the frequency factors of most (though not all) gas-phase chemical reactions tend to be smaller than the number of collisions that occur per second. Why?

In the collision model, we can separate the frequency factor into two distinct parts, as shown in the following equations:

$$k = Ae^{\frac{-E_a}{RT}} = pze^{\frac{-E_a}{RT}}$$

Orientation factor      Collision frequency

where  $p$  is the **orientation factor** and  $z$  is the **collision frequency**. The collision frequency is the number of collisions that occur per unit time, which we calculate for a gas-phase reaction from the pressure of the gases and the temperature of the reaction mixture. Under typical conditions, a single molecule undergoes on the order of  $10^9$  collisions every second. The orientation factor is a number, usually between 0 and 1, which represents the fraction of collisions with an orientation that allows the reaction to occur.

To better understand the orientation factor, consider the reaction represented by the following equation:

In order for the reaction to occur, two NOCl molecules must collide with sufficient energy. However, not all collisions with sufficient energy lead to products because the reactant molecules must also be properly oriented.

Consider the three possible collision orientations of the reactant molecules shown here:

**▲ FIGURE 14.15 The Collision Model** In the collision model, two molecules react after a sufficiently energetic collision with the correct orientation brings the reacting groups together.

The first two collisions, even if they occur with sufficient energy, do not result in a reaction because the reactant molecules are not oriented in a way that allows the chlorine atoms to bond. In other words, if two molecules are to react with each other, they must collide in such a way that allows the necessary bonds to break and form. For the reaction of  $\text{NOCl}(g)$ , the orientation factor is  $p = 0.16$ . This means that only 16 out of 100 sufficiently energetic collisions are actually successful in forming the products.

Some reactions have orientation factors that are much smaller than one. Consider the reaction between hydrogen and ethene:

The orientation factor for this reaction is  $1.7 \times 10^{-6}$ , which means that fewer than two out of each million sufficiently energetic collisions actually form products. The small orientation factor indicates that the orientational requirements for this reaction are very stringent—the molecules must be aligned in a *very specific way* for the reaction to occur.

Reactions between *individual atoms* usually have orientation factors of approximately one because atoms are spherically symmetric and thus any orientation can lead to the formation of products. A few reactions have orientation factors greater than one. Consider the reaction between potassium and bromine:

This reaction has an orientation factor of  $p = 4.8$ . In other words, there are more reactions than collisions—the reactants do not even have to collide to react! Apparently, through a process dubbed *the harpoon mechanism*, a potassium atom can actually transfer an electron to a bromine molecule without a collision. The resulting positive charge on the potassium and the negative charge on the bromine cause the two species to attract each other and form a bond. The potassium atom essentially *harpoons* a passing bromine molecule with an electron and *reels it in* through the coulombic attraction between unlike charges.

We can picture a sample of reactive gases as a frenzy of collisions between the reacting atoms or molecules. At normal temperatures, the vast majority of these collisions do not have sufficient energy to overcome the activation barrier, and the atoms or molecules simply bounce off one another. Of the collisions having sufficient energy to overcome the activation barrier, most do not have the proper orientation for the reaction to occur (for the majority of common reactions). When two molecules with sufficient energy *and* the correct orientation collide, something extraordinary happens. The electrons on one of the atoms or molecules are attracted to the nuclei of the other; some bonds begin to weaken while other bonds begin to form and, if all goes well, the reactants go through the transition state and are transformed into the products. This is how a chemical reaction occurs.

## CONCEPTUAL CONNECTION 14.8

**Collision Theory** Which reaction do you expect to have the smallest orientation factor?

- (a)  $\text{H}(g) + \text{I}(g) \longrightarrow \text{HI}(g)$
- (b)  $\text{H}_2(g) + \text{I}_2(g) \longrightarrow 2 \text{HI}(g)$
- (c)  $\text{HCl}(g) + \text{HCl}(g) \longrightarrow \text{H}_2(g) + \text{Cl}_2(g)$

## 14.6 Reaction Mechanisms

Most chemical reactions do not occur in a single step but rather over the course of several steps. When we write a chemical equation to represent a chemical reaction, *we usually represent the overall reaction, not the series of individual steps by which the reaction occurs*. Consider the reaction in which hydrogen gas reacts with iodine monochloride:

The overall equation shows only the substances present at the beginning of the reaction and the substances formed by the reaction—it does not show the intermediate steps. The **reaction mechanism** is the series of individual chemical steps by which an overall chemical reaction occurs. For example, the proposed mechanism for the reaction between hydrogen and iodine monochloride contains two steps:

In the first step, an  $\text{H}_2$  molecule collides with an  $\text{ICl}$  molecule and forms an  $\text{HI}$  molecule and an  $\text{HCl}$  molecule. In the second step, the  $\text{HI}$  molecule formed in the first step collides with a second  $\text{ICl}$  molecule to form another  $\text{HCl}$  molecule and an  $\text{I}_2$  molecule. Each step in a reaction mechanism is an **elementary step**. Elementary steps cannot be broken down into simpler steps—they occur as written (they represent the exact species that are colliding in the reaction).

One of the requirements for a valid reaction mechanism is that the individual steps in the mechanism add to the overall reaction. For example, the mechanism just shown sums to the overall reaction as shown here:

Notice that the  $\text{HI}$  molecule appears in the reaction mechanism but not in the overall reaction equation. We call species such as  $\text{HI}$  *reaction intermediates*. A **reaction intermediate** forms in one elementary step and is consumed in another. The reaction mechanism is a complete, detailed description of the reaction at the molecular level—it specifies the individual collisions and reactions that result in the overall reaction. As such, reaction mechanisms are highly sought-after pieces of chemical knowledge.

How do we determine reaction mechanisms? Recall from the opening section of this chapter that chemical kinetics are not only practically important (because they allow us to control the rate of a particular reaction), but they are also theoretically important because they can help us determine the mechanism of the reaction. We can piece together possible reaction mechanisms by measuring the kinetics of the overall reaction and working backward to write a mechanism consistent with the measured kinetics.

## Rate Laws for Elementary Steps

We characterize elementary steps by their **molecularity**, the number of reactant particles involved in the step. The most common molecularities are **unimolecular** and **bimolecular**:

Elementary steps in which three reactant particles collide, called **termolecular** steps, are very rare because the probability of three particles simultaneously colliding is small.

Although we cannot deduce the rate law for an *overall chemical reaction* from the balanced chemical equation, we can deduce the rate law for an *elementary step* from its equation. Since we know that an elementary step occurs through the collision of the reactant particles, the rate is proportional to the product of the concentrations of those particles. For example, the rate for the bimolecular elementary step in which  $\text{A}$  reacts with  $\text{B}$  is proportional to the concentration of  $\text{A}$  multiplied by the concentration of  $\text{B}$ :

Similarly, the rate law for the bimolecular step in which  $\text{A}$  reacts with  $\text{A}$  is proportional to the square of the concentration of  $\text{A}$ :

An elementary step represents an actual interaction between the reactant molecules in the step. An overall reaction equation shows only the starting substances and the ending substances, not the path between them.

Table 14.3 summarizes the rate laws for the common elementary steps, as well as those for the rare termolecular step. Notice that the molecularity of the elementary step is equal to the overall order of the step.

**TABLE 14.3** Rate Laws for Elementary Steps

Elementary Step	Molecularity	Rate Law
$A \longrightarrow \text{products}$	1	$\text{Rate} = k[A]$
$A + A \longrightarrow \text{products}$	2	$\text{Rate} = k[A]^2$
$A + B \longrightarrow \text{products}$	2	$\text{Rate} = k[A][B]$
$A + A + A \longrightarrow \text{products}$	3 (rare)	$\text{Rate} = k[A]^3$
$A + A + B \longrightarrow \text{products}$	3 (rare)	$\text{Rate} = k[A]^2[B]$
$A + B + C \longrightarrow \text{products}$	3 (rare)	$\text{Rate} = k[A][B][C]$

### Rate-Determining Steps and Overall Reaction Rate Laws

In most chemical reactions, one of the elementary steps—called the **rate-determining step**—is much slower than the others. The rate-determining step in a chemical reaction is analogous to the narrowest section on a freeway. If a section of a freeway narrows from four lanes to two lanes, for even a short distance, the rate at which cars travel along the freeway is limited by the rate at which they can travel through the narrow section (even though the rate might be much faster along the four-lane section). Similarly, the rate-determining step in a reaction mechanism limits the overall rate of the reaction (even though the other steps occur much faster) and therefore determines *the rate law for the overall reaction*.

► The rate-limiting step in a reaction mechanism limits the overall rate of the reaction just as the narrowest section of a highway limits the rate at which traffic can pass.

As an example, consider the reaction between nitrogen dioxide gas and carbon monoxide gas:

The experimentally determined rate law for this reaction is  $\text{Rate} = k[\text{NO}_2]^2$ . We can see from this rate law that the reaction must not be a single-step reaction—otherwise the rate law would be  $\text{Rate} = k[\text{NO}_2][\text{CO}]$ . A possible mechanism for this reaction involves two steps:

Figure 14.16► shows the energy diagram for this mechanism. The first step has a much larger activation energy than the second step. This greater activation energy results in a much smaller rate constant for the first step compared to the second step. The first step determines the overall rate of the reaction, and the predicted *overall* rate law is therefore  $\text{Rate} = k[\text{NO}_2]^2$ , which is consistent with the observed experimental rate law.

## Energy Diagram for a Two-Step Mechanism

◀ **FIGURE 14.16** Energy Diagram for a Two-Step Mechanism

For a proposed reaction mechanism, such as the one shown here for  $\text{NO}_2$  and  $\text{CO}$ , to be *valid* (mechanisms can only be validated, not proven), two conditions must be met:

- 1. The elementary steps in the mechanism must sum to the overall reaction.**
- 2. The rate law predicted by the mechanism must be consistent with the experimentally observed rate law.**

We have already seen that the rate law predicted by the earlier mechanism is consistent with the experimentally observed rate law. We can check whether the elementary steps sum to the overall reaction by adding them together:

The mechanism fulfills both of the given requirements and is therefore valid. A valid mechanism is not a *proven* mechanism (because other mechanisms may also fulfill both of the given requirements). We can only say that a given mechanism is consistent with kinetic observations of the reaction and is therefore possible. Other types of data—such as the experimental evidence for a proposed intermediate—are necessary to further strengthen the validity of a proposed mechanism.

## Mechanisms with a Fast Initial Step

When the proposed mechanism for a reaction has a slow initial step—such as the one shown previously for the reaction between  $\text{NO}_2$  and  $\text{CO}$ —the rate law predicted by the mechanism normally contains only reactants involved in the overall reaction. However, when a mechanism begins with a fast initial step, some other subsequent step in the mechanism is the rate-limiting step. In these cases, the rate law predicted by the rate-limiting step may contain reaction intermediates. Because reaction intermediates do not appear in the overall reaction equation, a rate law containing intermediates cannot generally correspond to the experimental rate law. Fortunately, however, we can often express the concentration of intermediates in terms of the concentrations of the reactants of the overall reaction.

In a multistep mechanism where the first step is fast, the products of the first step may build up because the rate at which they are consumed is limited by some slower step further down the line. As those products build up, they can begin to react with one another to

re-form the reactants. As long as the first step is fast enough compared to the rate-limiting step, the first-step reaction will reach equilibrium. We indicate equilibrium as follows:

The double arrows indicate that both the forward reaction and the reverse reaction occur. If equilibrium is reached, then the rate of the forward reaction equals the rate of the reverse reaction.

As an example, consider the reaction by which hydrogen reacts with nitrogen monoxide to form water and nitrogen gas:

The experimentally observed rate law is  $\text{Rate} = k[\text{H}_2][\text{NO}]^2$ . The reaction is first order in hydrogen and second order in nitrogen monoxide. The proposed mechanism has a slow second step:

To determine whether the mechanism is valid, we must find whether the two conditions described previously are met. As we can see, the steps do indeed sum to the overall reaction, so the first condition is met.

The second condition is that the rate law predicted by the mechanism must be consistent with the experimentally observed rate law. Because the second step is rate limiting, we write the following expression for the rate law:

$$\text{Rate} = k_2[\text{H}_2][\text{N}_2\text{O}_2] \quad [14.28]$$

This rate law contains an intermediate ( $\text{N}_2\text{O}_2$ ) and therefore cannot be consistent with the experimentally observed rate law (which does not contain intermediates). Because of the equilibrium in the first step, however, *we can express the concentration of the intermediate in terms of the reactants of the overall equation*. Since the first step reaches equilibrium, the rate of the forward reaction in the first step equals the rate of the reverse reaction:

$$\text{Rate (forward)} = \text{Rate (reverse)}$$

The rate of the forward reaction is given by the rate law:

$$\text{Rate} = k_1[\text{NO}]^2$$

The rate of the reverse reaction is given by the rate law:

$$\text{Rate} = k_{-1}[\text{N}_2\text{O}_2]$$

Since these two rates are equal at equilibrium, we write the expression:

$$k_1[\text{NO}]^2 = k_{-1}[\text{N}_2\text{O}_2]$$

Rearranging, we get:

$$[\text{N}_2\text{O}_2] = \frac{k_1}{k_{-1}}[\text{NO}]^2$$

We can now substitute this expression into Equation 14.28, the rate law obtained from the slow step:

$$\begin{aligned} \text{Rate} &= k_2[\text{H}_2][\text{N}_2\text{O}_2] \\ &= k_2[\text{H}_2] \frac{k_1}{k_{-1}}[\text{NO}]^2 \\ &= \frac{k_2 k_1}{k_{-1}}[\text{H}_2][\text{NO}]^2 \end{aligned}$$

If we combine the individual rate constants into one overall rate constant, we get the predicted rate law:

$$\text{Rate} = k[\text{H}_2][\text{NO}]^2 \quad [14.29]$$

Since this rate law is consistent with the experimentally observed rate law, condition 2 is met and the proposed mechanism is valid.

**Example 14.9** Reaction Mechanisms

Ozone naturally decomposes to oxygen by this reaction:

The experimentally observed rate law for this reaction is:

$$\text{Rate} = k[\text{O}_3]^2[\text{O}_2]^{-1}$$

Show that this proposed mechanism is consistent with the experimentally observed rate law.

**SOLUTION**

To determine whether the mechanism is valid, you must first determine whether the steps sum to the overall reaction. The steps do indeed sum to the overall reaction, so the first condition is met.

The second condition is that the rate law predicted by the mechanism is consistent with the experimentally observed rate law. Because the second step is rate limiting, write the rate law based on the second step.

$$\text{Rate} = k_2[\text{O}_3][\text{O}]$$

Because the rate law contains an intermediate (O), you must express the concentration of the intermediate in terms of the concentrations of the reactants of the overall reaction. To do this, set the rates of the forward reaction and the reverse reaction of the first step equal to each other. Solve the expression from the previous step for [O], the concentration of the intermediate.

$$\begin{aligned} \text{Rate (forward)} &= \text{Rate (backward)} \\ k_1[\text{O}_3] &= k_{-1}[\text{O}_2][\text{O}] \\ [\text{O}] &= \frac{k_1[\text{O}_3]}{k_{-1}[\text{O}_2]} \end{aligned}$$

Finally, substitute [O] into the rate law predicted by the slow step.

$$\begin{aligned} \text{Rate} &= k_2[\text{O}_3][\text{O}] \\ &= k_2[\text{O}_3] \frac{k_1[\text{O}_3]}{k_{-1}[\text{O}_2]} \\ &= k_2 \frac{k_1}{k_{-1}} \frac{[\text{O}_3]^2}{[\text{O}_2]} = k[\text{O}_3]^2[\text{O}_2]^{-1} \end{aligned}$$

**CHECK** Because the two steps in the proposed mechanism sum to the overall reaction, and because the rate law obtained from the proposed mechanism is consistent with the experimentally observed rate law, the proposed mechanism is valid. The  $-1$  reaction order with respect to  $[\text{O}_2]$  indicates that the rate slows down as the concentration of oxygen increases—oxygen inhibits, or slows down, the reaction.

**FOR PRACTICE 14.9** Predict the overall reaction and rate law that results from the following two-step mechanism:

**14.7 Catalysis**

Throughout this chapter, we have learned about ways to control the rates of chemical reactions. We can speed up the rate of a reaction by increasing the concentration of the reactants or by increasing the temperature. However, these approaches are not always feasible. There are limits to how concentrated we can make a reaction mixture, and increases in temperature may allow unwanted reactions—such as the decomposition of a reactant—to occur.

Alternatively, we can increase reaction rates by using a **catalyst**, a substance that increases the rate of a chemical reaction but is not consumed by the reaction. A catalyst works by providing an alternative mechanism for the reaction—one in which the rate-determining step has a lower activation energy.

For example, consider the noncatalytic destruction of ozone in the upper atmosphere, discussed in Section 6.10, which happens according to this reaction:

In this reaction, an ozone molecule collides with an oxygen atom to form two oxygen molecules in a single elementary step.

Earth has a protective ozone layer in the upper atmosphere because the activation energy for this reaction is fairly high; the reaction, therefore, proceeds at a fairly slow rate, and the ozone layer does not rapidly decompose into  $O_2$ . However, the addition of Cl atoms (which come from the photodissociation of human-made chlorofluorocarbons) to the upper atmosphere makes available another pathway by which  $O_3$  can be destroyed. The first step in this pathway—called the catalytic destruction of ozone—is the reaction of Cl with  $O_3$  to form ClO and  $O_2$ :

This is followed by a second step in which ClO reacts with O, regenerating Cl:

If we add the two reactions, the overall reaction is identical to the noncatalytic reaction:

However, the activation energy for the rate-limiting step in this pathway is much smaller than for the first, uncatalyzed pathway (as shown in Figure 14.17), and therefore the reaction occurs at a much faster rate. Note that the Cl is not consumed in the overall reaction—this is characteristic of a catalyst.

In the case of the catalytic destruction of ozone, the catalyst speeds up a reaction that we *do not* want to happen. Most of the time, however, catalysts are used to speed up reactions that we *do* want to happen. For example, your car most likely has a catalytic converter in its exhaust system. The catalytic converter contains solid catalysts, such as platinum, rhodium, or palladium, dispersed on an underlying high-surface-area ceramic structure. These catalysts convert exhaust pollutants such as nitrogen monoxide and carbon monoxide into less harmful substances:

The catalytic converter also promotes the complete combustion of any fuel fragments present in the exhaust:

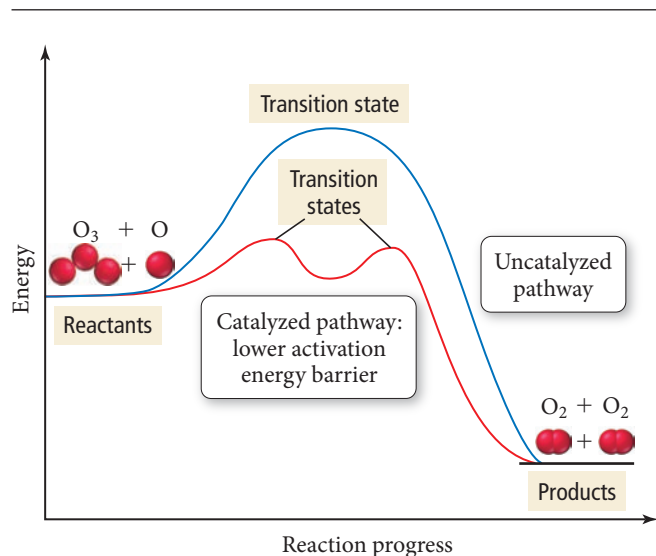

Fuel fragment

Photodissociation means *light-induced* dissociation. The energy from a photon of light can break chemical bonds and therefore dissociate, or break apart, a molecule.

### Energy Diagram for Catalyzed and Uncatalyzed Pathways

**FIGURE 14.17 Catalyzed and Uncatalyzed Decomposition of Ozone** In the catalytic destruction of ozone (red), the activation barrier for the rate-limiting step is much lower than in the uncatalyzed process (blue).

► The catalytic converter in the exhaust system of a car helps eliminate pollutants in the exhaust.

Fuel fragments in exhaust are harmful because they lead to the formation of ozone. Recall from Section 6.10 that although ozone is a natural part of our *upper* atmosphere that protects us from excess exposure to ultraviolet light, it is a pollutant in the *lower* atmosphere, interfering with cardiovascular function and acting as an eye and lung irritant. The use of catalytic converters in motor vehicles has resulted in lower levels of these pollutants over most U.S. cities in the last 30 years, even though the number of cars on the roadways has dramatically increased (see Table 14.4).

## Homogeneous and Heterogeneous Catalysis

We categorize catalysts into two types: homogeneous and heterogeneous (Figure 14.18▼). In **homogeneous catalysis**, the catalyst exists in the same phase (or state) as the reactants. The catalytic destruction of ozone by Cl is an example of homogeneous catalysis—the chlorine atoms exist in the gas phase with the gas-phase reactants. In **heterogeneous catalysis**, the catalyst exists in a different phase than the reactants. The solid catalysts used in catalytic converters are examples of heterogeneous catalysts—they are solids while the reactants are gases. The use of solid catalysts with gas-phase or solution-phase reactants is the most common type of heterogeneous catalysis.

▲ **FIGURE 14.18 Homogeneous and Heterogeneous Catalysis** A homogeneous catalyst exists in the same phase as the reactants. A heterogeneous catalyst exists in a different phase than the reactants. Often, a heterogeneous catalyst provides a solid surface on which the reaction can take place.

Research has shown that heterogeneous catalysis is most likely responsible for the annual formation of an ozone hole over Antarctica. After the discovery of the Antarctic ozone hole in 1985, scientists wondered why there was such a dramatic drop in ozone over Antarctica but not over the rest of the planet. After all, the chlorine from chlorofluorocarbons that catalyzes ozone destruction is evenly distributed throughout the entire atmosphere.

As it turns out, most of the chlorine that enters the atmosphere from chlorofluorocarbons gets bound up in chlorine *reservoirs*, which are substances such as  $\text{ClONO}_2$  that hold chlorine and prevent it from catalyzing ozone destruction. The unique conditions over Antarctica—especially the cold isolated air mass that exists during the long dark winter—result in clouds that contain solid ice particles. These unique clouds are called polar stratospheric clouds (or PSCs), and the surfaces of the ice particles within these clouds appear to catalyze the release of chlorine from their reservoirs:

When the sun rises in the Antarctic spring, the sunlight dissociates the chlorine molecules into chlorine atoms:

The chlorine atoms then catalyze the destruction of ozone by the mechanism discussed previously. This continues until the sun melts the stratospheric clouds, allowing chlorine

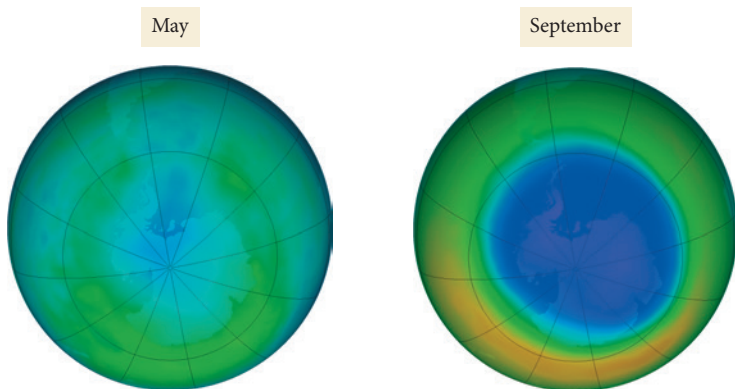

**TABLE 14.4 Change in Pollutant Levels**

Pollutant	Change 1980–2013

▲ Polar stratospheric clouds contain ice particles that catalyze reactions by which chlorine is released from its atmospheric chemical reservoirs.

**▲ FIGURE 14.19 Ozone Depletion in the Antarctic Spring** The concentration of ozone over Antarctica drops sharply during the months of September and October due to the catalyzed destruction of ozone by chlorine. The image on the left shows the average ozone levels in May 2014, and the image on the right shows the average levels from September 2014. (The lowest ozone levels are represented in purple.) Source: NASA Ozone Watch, OMI instrument (KNMI/NASA) onboard the Aura satellite.

atoms to be reincorporated into their reservoirs. The result is an ozone hole that forms every spring and lasts about six to eight weeks (Figure 14.19◀).

A second example of heterogeneous catalysis involves the **hydrogenation** of double bonds within alkenes. Consider the reaction between ethene and hydrogen, which is relatively slow at normal temperatures:

Slow at room temperature

However, in the presence of finely divided platinum, palladium, or nickel, the reaction happens rapidly. The catalysis occurs by the four-step process depicted in Figure 14.20▼:

1. Adsorption: the reactants are adsorbed onto the metal surface.
2. Diffusion: the reactants diffuse on the surface until they approach each other.
3. Reaction: the reactants react to form the products.
4. Desorption: the products desorb from the surface into the gas phase.

The large activation energy of the hydrogenation reaction—due primarily to the strength of the hydrogen–hydrogen bond in  $\text{H}_2$ —is greatly lowered when the reactants adsorb onto the surface.

**▲ FIGURE 14.20 Catalytic Hydrogenation of Ethene**

## Enzymes: Biological Catalysts

We find perhaps the best example of chemical catalysis in living organisms. Most of the thousands of reactions that must occur for an organism to survive are too slow at normal temperatures. So living organisms rely on **enzymes**, biological catalysts that increase the rates of biochemical reactions. Enzymes are usually large protein molecules with complex three-dimensional structures. Within each enzyme's structure is a specific area called the **active site**. The properties and shape of the active site are just right to bind the reactant molecule, usually called the **substrate**. The substrate fits into the active site in a manner

The strategies used to speed up chemical reactions in the laboratory—high temperatures, high pressures, strongly acidic or alkaline conditions—are not available to living organisms, since they would be fatal to cells.

that is analogous to a key fitting into a lock (Figure 14.21 ▽). When the substrate binds to the active site of the enzyme—through intermolecular forces such as hydrogen bonding and dispersion forces, or even covalent bonds—the activation energy of the reaction is greatly lowered, allowing the reaction to occur at a much faster rate. The general mechanism by which an enzyme (E) binds a substrate (S) and then reacts to form the products (P) is:

### Enzyme–Substrate Binding

◀ **FIGURE 14.21 Enzyme–Substrate Binding** A substrate (or reactant) fits into the active site of an enzyme much as a key fits into a lock. Intermolecular forces hold the substrate in place and form an enzyme–substrate complex. (Sometimes temporary covalent bonding may also be involved.) After the reaction occurs, the products are released from the active site.

Sucrase, for example, is an enzyme that catalyzes the breaking up of sucrose (table sugar) into glucose and fructose within the body. At body temperature, sucrose does not

◀ Sucrose breaks up into glucose and fructose during digestion.

break into glucose and fructose because the activation energy is high, resulting in a slow reaction rate. However, when a sucrose molecule binds to the active site within sucrase, the bond between the glucose and fructose units weakens because glucose is forced into a geometry that stresses the bond (Figure 14.22 ▶). Weakening of this bond lowers the activation energy for the reaction, increasing the reaction rate. The reaction can then proceed toward equilibrium—which favors the products—at a much lower temperature.

By allowing otherwise slow reactions to occur at reasonable rates, enzymes give living organisms tremendous control over which reactions occur and when they occur. Enzymes are extremely specific (each enzyme catalyzes only a single reaction) and efficient, speeding up reaction rates by factors of as much as a billion.

To turn a particular reaction on, a living organism produces or activates the correct enzyme to catalyze that reaction. Because organisms are so dependent on the reactions enzymes catalyze,

▶ **FIGURE 14.22 An Enzyme-Catalyzed Reaction** Sucrase catalyzes the conversion of sucrose into glucose and fructose by weakening the bond that joins the two rings.

many substances that inhibit the action of enzymes are highly toxic. Locking up a single enzyme molecule can stop the reaction of billions of substrates, much as one motorist stalled at a tollbooth can paralyze an entire highway full of cars. (For another example of enzyme action, see the *Chemistry and Medicine* box on the role of chymotrypsin in digestion.)

## Chemistry AND Medicine

### Enzyme Catalysis and the Role of Chymotrypsin in Digestion

When we eat foods containing proteins—such as meats, eggs, beans, and nuts—the proteins must be digested. Proteins are large biological molecules composed of individual units called amino acids. (We discuss the structure of proteins and other biologically important molecules more fully in Chapter 22.) The amino acids in proteins are linked together via peptide bonds, as shown in Figure 14.23 ▼.

▲ **FIGURE 14.23 The Structure of a Protein** Proteins are chains of amino acids linked together by peptide bonds.

During digestion, the protein must be broken up into individual amino acids (Figure 14.24 ▼), which can pass through the walls of the small intestine and into the bloodstream. However, the peptide bonds that link amino acids together are relatively stable, and under ordinary conditions the reaction is slow.

The pancreas secretes an enzyme called chymotrypsin (Figure 14.25 ►) into the small intestine. Like many enzymes, chymotrypsin is highly selective in its action—it operates only on peptide bonds between certain kinds of amino acids. When a protein molecule containing such a pair of amino acids is attached to the active site of chymotrypsin, the peptide bond between them is weakened as the chymotrypsin forms a covalent bond with the carbon in the peptide bond. A water molecule can then come in and cleave the bond, with

◀ **FIGURE 14.25 Chymotrypsin, a Digestive Enzyme** This model of chymotrypsin shows a section of a protein substrate (red) in the active site.

an —OH from the water binding to the carbon atom and the remaining —H bonding to the nitrogen (Figure 14.26 ▼).

The amino acid chain is thus clipped at the peptide bond. The products of the reaction leave the active site, another protein binds to the chymotrypsin, and the process is repeated. Other digestive enzymes cleave protein chains between other pairs of amino acids. Together, these enzymes eventually reduce the entire protein to its constituent amino acids.

◀ **FIGURE 14.24 Protein Digestion** During digestion, a protein is broken down into its component amino acids.

## Self-Assessment Quiz

- Q1.** This graph shows the concentration of the reactant A in the reaction  $A \longrightarrow B$ . Determine the average rate of the reaction between 0 and 10 seconds.

- a) 0.07 M/s   b) 0.007 M/s   c) 0.86 M/s   d) 0.014 M/s
- Q2.** Dinitrogen monoxide decomposes into nitrogen and oxygen when heated. The initial rate of the reaction is 0.022 M/s. What is the initial rate of change of the concentration of  $N_2O$  (that is,  $\Delta[N_2O]/\Delta t$ )?
- $$2 N_2O(g) \longrightarrow 2 N_2(g) + O_2(g)$$
- a)  $-0.022 \text{ M/s}$    b)  $-0.011 \text{ M/s}$   
 c)  $-0.044 \text{ M/s}$    d)  $+0.022 \text{ M/s}$
- Q3.** This plot shows the rate of the decomposition of  $SO_2Cl_2$  into  $SO_2$  and  $Cl_2$  as a function of the concentration of  $SO_2Cl_2$ . What is the order of the reaction?

- a) first order   b) second order   c) zero order  
 d) Order cannot be determined without more information.

- Q4.** For the reaction  $2 A + B \longrightarrow C$ , the initial rate is measured at several different reactant concentrations. From the resulting tabulated data, determine the rate law for the reaction.

[A] (M)	[B] (M)	Initial Rate (M/s)
0.05	0.05	0.035
0.10	0.05	0.070
0.20	0.10	0.56

- a)  $\text{Rate} = k[A][B]$    b)  $\text{Rate} = k[A]^2[B]$   
 c)  $\text{Rate} = k[A][B]^2$    d)  $\text{Rate} = k[A]^2[B]^2$
- Q5.** What is the rate constant for the reaction in Question 4?
- a)  $2.8 \times 10^2 \text{ M}^{-2} \cdot \text{s}^{-1}$    b)  $14 \text{ M}^{-2} \cdot \text{s}^{-1}$   
 c)  $1.4 \times 10^2 \text{ M}^{-2} \cdot \text{s}^{-1}$    d)  $1.4 \times 10^3 \text{ M}^{-2} \cdot \text{s}^{-1}$
- Q6.** The decomposition of  $Br_2$  is followed as a function of time; two different plots of the data are shown. Determine the order and rate constant for the reaction.

- a) first order;  $0.030 \text{ s}^{-1}$   
 b) first order;  $33.3 \text{ s}^{-1}$   
 c) second order;  $0.045 \text{ M}^{-1} \cdot \text{s}^{-1}$   
 d) second order;  $22.2 \text{ M}^{-1} \cdot \text{s}^{-1}$

Continued—

- Q7.** The reaction  $X \longrightarrow \text{products}$  is second order in  $X$  and has a rate constant of  $0.035 \text{ M}^{-1}\text{s}^{-1}$ . If a reaction mixture is initially  $0.45 \text{ M}$  in  $X$ , what is the concentration of  $X$  after 155 seconds?

a)  $7.6 \text{ M}$   
 b)  $2.0 \times 10^{-3} \text{ M}$   
 c)  $0.13 \text{ M}$   
 d)  $0.00 \text{ M}$

- Q8.** A decomposition reaction has a half-life that does not depend on the initial concentration of the reactant. What is the order of the reaction?

a) zero order  
 b) first order  
 c) second order  
 d) Order cannot be determined without more information.

- Q9.** The rate constant of a reaction is measured at different temperatures. A plot of the natural log of the rate constant as a function of the inverse of the temperature (in kelvins) yields a straight line with a slope of  $-8.55 \times 10^3 \text{ K}^{-1}$ . What is the activation energy ( $E_a$ ) for the reaction?

a)  $-71 \text{ kJ}$   
 b)  $71 \text{ kJ}$   
 c)  $1.0 \text{ kJ}$   
 d)  $-1.0 \text{ kJ}$

- Q10.** The rate constant for a reaction at  $25.0^\circ\text{C}$  is  $0.010 \text{ s}^{-1}$ , and its activation energy is  $35.8 \text{ kJ}$ . Find the rate constant at  $50.0^\circ\text{C}$ .

a)  $0.021 \text{ s}^{-1}$   
 b)  $0.010 \text{ s}^{-1}$   
 c)  $0.0033 \text{ s}^{-1}$   
 d)  $0.031 \text{ s}^{-1}$

- Q11.** The mechanism shown is proposed for the gas phase reaction,  $2 \text{N}_2\text{O}_5 \longrightarrow 4 \text{NO}_2 + \text{O}_2$ . What rate law does the mechanism predict?

a)  $\text{Rate} = k[\text{N}_2\text{O}_5]$   
 b)  $\text{Rate} = k[\text{N}_2\text{O}_5]^2$   
 c)  $\text{Rate} = k[\text{N}_2\text{O}_5]^0$   
 d)  $\text{Rate} = k[\text{NO}_2][\text{NO}_3]$

- Q12.** Which statement is true regarding the function of a catalyst in a chemical reaction?

a) A catalyst increases the rate of a reaction.  
 b) A catalyst provides an alternate mechanism for the reaction.  
 c) A catalyst is not consumed by the reaction.  
 d) All of the above are true.

- Q13.** These images represent the first-order reaction  $A \longrightarrow B$  initially and at some later time. The rate law for the reaction is  $\text{Rate} = 0.010 \text{ s}^{-1} [A]$ . How much time has passed between the two images?

a) 69 s      b) 139 s      c) 60 s      d) 12.5 s

- Q14.** Use collision theory to determine which single-step reaction has the smallest orientation factor.

a)  $\text{H} + \text{H} \longrightarrow \text{H}_2$   
 b)  $\text{I} + \text{HI} \longrightarrow \text{I}_2 + \text{H}$   
 c)  $\text{H}_2 + \text{H}_2\text{C}=\text{CH}_2 \longrightarrow \text{H}_3\text{C}-\text{CH}_3$   
 d) All of these reactions have the same orientation factor.

- Q15.** Carbon monoxide and chlorine gas react to form phosgene ( $\text{COCl}_2$ ) according to the equation:

The rate law for the reaction is  $\text{Rate} = k[\text{Cl}_2]^{3/2}[\text{CO}]$ . Which representation of a mixture of chlorine gas and carbon monoxide gas has the fastest initial rate?

Answers: 1. (d) 2. (c) 3. (a) 4. (c) 5. (a) 6. (a) 7. (c) 8. (b) 9. (b) 10. (d) 11. (a) 12. (d) 13. (b) 14. (c) 15. (b)

## Chapter 14 IN REVIEW

### Key Terms

#### Section 14.3

rate law (629)  
rate constant ( $k$ ) (629)  
reaction order ( $n$ ) (629)  
overall order (632)

#### Section 14.4

integrated rate law (634)  
half-life ( $t_{1/2}$ ) (638)

#### Section 14.5

Arrhenius equation (642)  
activation energy ( $E_a$ ) (642)

frequency factor ( $A$ ) (642)  
activated complex (transition state) (643)  
exponential factor (644)  
Arrhenius plot (645)  
collision model (647)  
orientation factor (647)  
collision frequency (647)

#### Section 14.6

reaction mechanism (649)  
elementary step (649)  
reaction intermediate (649)  
molecularity (649)

unimolecular (649)  
bimolecular (649)  
termolecular (649)  
rate-determining step (650)

#### Section 14.7

catalyst (653)  
homogeneous catalysis (655)  
heterogeneous catalysis (655)  
hydrogenation (656)  
enzyme (656)  
active site (656)  
substrate (656)

### Key Concepts

#### Reaction Rates, Orders, and Rate Laws (14.1–14.3)

- ▶ The rate of a chemical reaction is a measure of how fast a reaction occurs. The rate reflects the change in the concentration of a reactant or product per unit time and is usually reported in units of M/s.
- ▶ Reaction rates generally depend on the concentration of the reactants. The rate of a first-order reaction is directly proportional to the concentration of the reactant, the rate of a second-order reaction is proportional to the square of the concentration of the reactant, and the rate of a zero-order reaction is independent of the concentration of the reactant.
- ▶ For a reaction with more than one reactant, the order with respect to each reactant is, in general, independent of the order with respect to other reactants. The rate law shows the relationship between the rate and the concentrations of each reactant and must be determined experimentally.

#### Integrated Rate Laws and Half-Life (14.4)

- ▶ The rate law for a reaction describes the relationship between the rate of the reaction and the concentrations of the reactants.
- ▶ The integrated rate law for a reaction describes the relationship between the concentration of a reactant and time.
- ▶ The integrated rate law for a zero-order reaction shows that the concentration of the reactant varies linearly with time. For a first-order reaction, the *natural log* of the concentration of the reactant varies linearly with time, and for a second-order reaction, the *inverse* of the concentration of the reactant varies linearly with time.
- ▶ The half-life of a reaction can be derived from the integrated rate law and represents the time required for the concentration of a reactant to fall to one-half of its initial value. The half-life of a first-order reaction is *independent* of initial concentration of the reactant. The half-life of a zero-order or second-order reaction *depends* on the initial concentration of reactant.

#### The Effect of Temperature on Reaction Rate (14.5)

- ▶ The rate constant of a reaction generally depends on temperature and can be expressed by the Arrhenius equation, which consists of a frequency factor and an exponential factor.

- ▶ The frequency factor represents the number of times that the reactants approach the activation barrier per unit time. The exponential factor is the fraction of approaches that are successful in surmounting the activation barrier and forming products.
- ▶ The exponential factor depends on both the temperature and the activation energy, a barrier that the reactants must overcome to become products. The exponential factor increases with increasing temperature but decreases with increasing activation energy.
- ▶ We can determine the frequency factor and activation energy for a reaction by measuring the rate constant at different temperatures and constructing an Arrhenius plot.
- ▶ For reactions in the gas phase, Arrhenius behavior can be modeled with the collision model. In this model, reactions occur as a result of sufficiently energetic collisions. The colliding molecules must be oriented in such a way that the reaction can occur. The frequency factor contains two terms:  $p$ , which represents the fraction of collisions that have the proper orientation, and  $z$ , which represents the number of collisions per unit time.

#### Reaction Mechanisms (14.6)

- ▶ Most chemical reactions occur not in a single step, but in several steps. The series of individual steps by which a reaction occurs is the reaction mechanism.
- ▶ In order for a proposed reaction mechanism to be valid, it must fulfill two conditions: (a) the steps must sum to the overall reaction, and (b) the mechanism must predict the experimentally observed rate law.
- ▶ For mechanisms with a slow initial step, we derive the rate law from the slow step.
- ▶ For mechanisms with a fast initial step, we first write the rate law based on the slow step but then assume that the fast steps reach equilibrium, so we can write concentrations of intermediates in terms of the reactants.

#### Catalysis (14.7)

- ▶ A catalyst is a substance that increases the rate of a chemical reaction by providing an alternative mechanism that has a lower activation energy for the rate-determining step.

- Catalysts can be homogeneous or heterogeneous. A homogeneous catalyst exists in the same phase as the reactants and forms a homogeneous mixture with them. A heterogeneous catalyst generally exists in a different phase than the reactants.

- Enzymes are biological catalysts capable of increasing the rate of specific biochemical reactions by many orders of magnitude.

## Key Equations and Relationships

The Rate of Reaction (14.2)

For a reaction,  $aA + bB \longrightarrow cC + dD$ , the rate is defined as:

$$\text{Rate} = -\frac{1}{a} \frac{\Delta[A]}{\Delta t} = -\frac{1}{b} \frac{\Delta[B]}{\Delta t} = +\frac{1}{c} \frac{\Delta[C]}{\Delta t} = +\frac{1}{d} \frac{\Delta[D]}{\Delta t}$$

The Rate Law (14.3)

$$\text{Rate} = k[A]^n \quad (\text{single reactant})$$

$$\text{Rate} = k[A]^m[B]^n \quad (\text{multiple reactants})$$

Integrated Rate Laws and Half-Life (14.4)

Reaction Order	Integrated Rate Law	Units of $k$	Half-Life Expression
0	$[A]_t = -kt + [A]_0$	$M \cdot s^{-1}$	$t_{1/2} = \frac{[A]_0}{2k}$
1	$\ln [A]_t = -kt + \ln [A]_0$	$s^{-1}$	$t_{1/2} = \frac{0.693}{k}$
2	$\frac{1}{[A]_t} = kt + \frac{1}{[A]_0}$	$M^{-1} \cdot s^{-1}$	$t_{1/2} = \frac{1}{k[A]_0}$

Arrhenius Equation (14.5)

$$k = Ae^{-E_a/RT}$$

$$\ln k = -\frac{E_a}{R} \left( \frac{1}{T} \right) + \ln A \quad (\text{linearized form})$$

$$\ln \frac{k_2}{k_1} = \frac{E_a}{R} \left( \frac{1}{T_1} - \frac{1}{T_2} \right) \quad (\text{two-point form})$$

$$k = pze^{-E_a/RT} \quad (\text{collision theory})$$

Rate Laws for Elementary Steps (14.6)

Elementary Step	Molecularity	Rate Law
$A \longrightarrow \text{products}$	1	$\text{Rate} = k[A]$
$A + A \longrightarrow \text{products}$	2	$\text{Rate} = k[A]^2$
$A + B \longrightarrow \text{products}$	2	$\text{Rate} = k[A][B]$
$A + A + A \longrightarrow \text{products}$	3 (rare)	$\text{Rate} = k[A]^3$
$A + A + B \longrightarrow \text{products}$	3 (rare)	$\text{Rate} = k[A]^2[B]$
$A + B + C \longrightarrow \text{products}$	3 (rare)	$\text{Rate} = k[A][B][C]$

## Key Learning Outcomes

CHAPTER OBJECTIVES	ASSESSMENT
Expressing Reaction Rates (14.2) 	Example 14.1 For Practice 14.1 Exercises 25–34
Determining the Order, Rate Law, and Rate Constant of a Reaction (14.3)	Example 14.2 For Practice 14.2 Exercises 41–46
Using Graphical Analysis of Reaction Data to Determine Reaction Order and Rate Constants (14.4)	Examples 14.3, 14.5 For Practice 14.3, 14.5 Exercises 49–54
Determining the Concentration of a Reactant at a Given Time (14.4) 	Example 14.4 For Practice 14.4 Exercises 53–56
Working with the Half-Life of a Reaction (14.4)	Example 14.6 For Practice 14.6 Exercises 53–58
Using the Arrhenius Equation to Determine Kinetic Parameters (14.5)	Examples 14.7, 14.8 For Practice 14.7, 14.8 Exercises 61–72
Determining whether a Reaction Mechanism Is Valid (14.6)	Example 14.9 For Practice 14.9 Exercises 75–78

# EXERCISES

## Review Questions

1. Explain why lizards become sluggish in cold weather. How is this phenomenon related to chemistry?
2. Why are reaction rates important (both practically and theoretically)?
3. What units are typically used to express the rate of a reaction?
4. Why is the reaction rate for reactants defined as the *negative* of the change in reactant concentration with respect to time, whereas for products it is defined as the change in reactant concentration with respect to time (with a positive sign)?
5. Explain the difference between the average rate of reaction and the instantaneous rate of reaction.
6. Consider a simple reaction in which reactant A forms products:  

$$A \longrightarrow \text{products}$$

What is the rate law if the reaction is zero order with respect to A? First order? Second order? For each case, explain how a doubling of the concentration of A would affect the rate of reaction.
7. How is the order of a reaction generally determined?
8. For a reaction with multiple reactants, how is the overall order of the reaction defined?
9. Explain the difference between the rate law for a reaction and the integrated rate law for a reaction. What relationship does each kind of rate law express?
10. Write integrated rate laws for zero-order, first-order, and second-order reactions of the form  $A \longrightarrow \text{products}$ .
11. What does the term *half-life* mean? Write the expressions for the half-lives of zero-order, first-order, and second-order reactions.
12. How do reaction rates typically depend on temperature? What part of the rate law is temperature dependent?
13. Explain the meaning of each term within the Arrhenius equation: activation energy, frequency factor, and exponential factor. Use these terms and the Arrhenius equation to explain why small changes in temperature can result in large changes in reaction rates.
14. What is an Arrhenius plot? Explain the significance of the slope and intercept of an Arrhenius plot.
15. Explain how a chemical reaction occurs according to the collision model. Explain the meaning of the orientation factor in this model.
16. Explain the difference between a normal chemical equation for a chemical reaction and the mechanism of that reaction.
17. In a reaction mechanism, what is an elementary step? Write down the three most common elementary steps and the corresponding rate law for each one.
18. What are the two requirements for a proposed mechanism to be valid for a given reaction?
19. What is an intermediate within a reaction mechanism?
20. What is a catalyst? How does a catalyst increase the rate of a chemical reaction?
21. Explain the difference between homogeneous catalysis and heterogeneous catalysis.
22. What are the four basic steps involved in heterogeneous catalysis?
23. What are enzymes? What is the active site of an enzyme? What is a substrate?
24. What is the general two-step mechanism by which most enzymes work?

## Problems by Topic

### Reaction Rates

25. Consider the reaction:

- Express the rate of the reaction in terms of the change in concentration of each of the reactants and products.
  - In the first 25.0 s of this reaction, the concentration of HBr dropped from 0.600 M to 0.512 M. Calculate the average rate of the reaction during this time interval.
  - If the volume of the reaction vessel in part b was 1.50 L, what amount of  $\text{Br}_2$  (in moles) was formed during the first 15.0 s of the reaction?
26. Consider the reaction:
- $$2 \text{N}_2\text{O}(g) \longrightarrow 2 \text{N}_2(g) + \text{O}_2(g)$$
- Express the rate of the reaction in terms of the change in concentration of each of the reactants and products.
  - In the first 15.0 s of the reaction, 0.015 mol of  $\text{O}_2$  is produced in a reaction vessel with a volume of 0.500 L. What is the average rate of the reaction during this time interval?
  - Predict the rate of change in the concentration of  $\text{N}_2\text{O}$  during this time interval. In other words, what is  $\Delta[\text{N}_2\text{O}]/\Delta t$ ?
27. For the reaction  $2 \text{A}(g) + \text{B}(g) \longrightarrow 3 \text{C}(g)$ ,
- determine the expression for the rate of the reaction in terms of the change in concentration of each of the reactants and products.

- when A is decreasing at a rate of 0.100 M/s, how fast is B decreasing? How fast is C increasing?

28. For the reaction  $\text{A}(g) + \frac{1}{2} \text{B}(g) \longrightarrow 2 \text{C}(g)$ ,

- determine the expression for the rate of the reaction in terms of the change in concentration of each of the reactants and products.
- when C is increasing at a rate of 0.025 M/s, how fast is B decreasing? How fast is A decreasing?

29. Consider the reaction:

Complete the table.

$\Delta[\text{Cl}_2]/\Delta t$	$\Delta[\text{F}_2]/\Delta t$	$\Delta[\text{ClF}_3]/\Delta t$	Rate
-0.012 M/s			

30. Consider the reaction:

Complete the table.

$\Delta[\text{H}_2\text{S}]/\Delta t$	$\Delta[\text{O}_2]/\Delta t$	$\Delta[\text{H}_2\text{O}]/\Delta t$	$\Delta[\text{S}_8]/\Delta t$	Rate
-0.080 M/s				

31. Consider the reaction:

The tabulated data were collected for the concentration of  $\text{C}_4\text{H}_8$  as a function of time:

Time (s)	$[\text{C}_4\text{H}_8]$ (M)
0	1.000
10	0.913
20	0.835
30	0.763
40	0.697
50	0.637

- a. What is the average rate of the reaction between 0 and 10 s?  
Between 40 and 50 s?
- b. What is the rate of formation of  $\text{C}_2\text{H}_4$  between 20 and 30 s?
32. Consider the reaction:

The tabulated data were collected for the concentration of  $\text{NO}_2$  as a function of time:

Time (s)	$[\text{NO}_2]$ (M)
0	1.000
10	0.951
20	0.904
30	0.860
40	0.818
50	0.778
60	0.740
70	0.704
80	0.670
90	0.637
100	0.606

- a. What is the average rate of the reaction between 10 and 20 s?  
Between 50 and 60 s?
- b. What is the rate of formation of  $\text{O}_2$  between 50 and 60 s?
33. Consider the reaction:

The graph shows the concentration of  $\text{Br}_2$  as a function of time.

- a. Use the graph to calculate each quantity:
- the average rate of the reaction between 0 and 25 s
  - the instantaneous rate of the reaction at 25 s
  - the instantaneous rate of formation of  $\text{HBr}$  at 50 s
- b. Make a rough sketch of a curve representing the concentration of  $\text{HBr}$  as a function of time. Assume that the initial concentration of  $\text{HBr}$  is zero.

34. Consider the reaction:

The graph shows the concentration of  $\text{H}_2\text{O}_2$  as a function of time.

Use the graph to calculate each quantity:

- the average rate of the reaction between 10 and 20 s
- the instantaneous rate of the reaction at 30 s
- the instantaneous rate of formation of  $\text{O}_2$  at 50 s
- If the initial volume of the  $\text{H}_2\text{O}_2$  is 1.5 L, what total amount of  $\text{O}_2$  (in moles) is formed in the first 50 s of reaction?

### The Rate Law and Reaction Orders

35. This graph shows a plot of the rate of a reaction versus the concentration of the reactant A for the reaction
- $\text{A} \longrightarrow \text{products}$
- .

- What is the order of the reaction with respect to A?
  - Make a rough sketch of a plot of  $[\text{A}]$  versus time.
  - Write a rate law for the reaction including an estimate for the value of  $k$ .
36. This graph shows a plot of the rate of a reaction versus the concentration of the reactant.

- What is the order of the reaction with respect to A?
- Make a rough sketch of a plot of  $[\text{A}]$  versus time.
- Write a rate law for the reaction including the value of  $k$ .

37. What are the units of  $k$  for each type of reaction?

- first-order reaction
- second-order reaction
- zero-order reaction

38. This reaction is first order in  $\text{N}_2\text{O}_5$ :

The rate constant for the reaction at a certain temperature is  $0.053/\text{s}$ .

- Calculate the rate of the reaction when  $[\text{N}_2\text{O}_5] = 0.055 \text{ M}$ .
- What would the rate of the reaction be at the concentration indicated in part a if the reaction were second order? Zero order? (Assume the same *numerical* value for the rate constant with the appropriate units.)

39. A reaction in which A, B, and C react to form products is first order in A, second order in B, and zero order in C.

- Write a rate law for the reaction.
- What is the overall order of the reaction?
- By what factor does the reaction rate change if [A] is doubled (and the other reactant concentrations are held constant)?
- By what factor does the reaction rate change if [B] is doubled (and the other reactant concentrations are held constant)?
- By what factor does the reaction rate change if [C] is doubled (and the other reactant concentrations are held constant)?
- By what factor does the reaction rate change if the concentrations of all three reactants are doubled?

40. A reaction in which A, B, and C react to form products is zero order in A, one-half order in B, and second order in C.

- Write a rate law for the reaction.
- What is the overall order of the reaction?
- By what factor does the reaction rate change if [A] is doubled (and the other reactant concentrations are held constant)?
- By what factor does the reaction rate change if [B] is doubled (and the other reactant concentrations are held constant)?
- By what factor does the reaction rate change if [C] is doubled (and the other reactant concentrations are held constant)?
- By what factor does the reaction rate change if the concentrations of all three reactants are doubled?

41. Consider the data showing the initial rate of a reaction ( $\text{A} \longrightarrow \text{products}$ ) at several different concentrations of A. What is the order of the reaction? Write a rate law for the reaction including the value of the rate constant,  $k$ .

[A] (M)	Initial Rate (M/s)
0.100	0.053
0.200	0.210
0.300	0.473

42. Consider the data showing the initial rate of a reaction ( $\text{A} \longrightarrow \text{products}$ ) at several different concentrations of A. What is the order of the reaction? Write a rate law for the reaction including the value of the rate constant,  $k$ .

[A] (M)	Initial Rate (M/s)
0.15	0.008
0.30	0.016
0.60	0.032

43. Consider the tabulated data showing the initial rate of a reaction ( $\text{A} \longrightarrow \text{products}$ ) at several different concentrations of A.

What is the order of the reaction? Write a rate law for the reaction including the value of the rate constant,  $k$ .

[A] (M)	Initial Rate (M/s)
0.12	0.0078
0.16	0.0104
0.20	0.0130

44. Consider the tabulated data showing the initial rate of a reaction ( $\text{A} \longrightarrow \text{products}$ ) at several different concentrations of A. What is the order of the reaction? Write a rate law for the reaction including the value of the rate constant,  $k$ .

[A] (M)	Initial Rate (M/s)
0.12	$3.89 \times 10^{-4}$
0.18	$8.75 \times 10^{-4}$
0.28	$2.12 \times 10^{-3}$

45. The tabulated data were collected for this reaction:

[NO <sub>2</sub> ] (M)	[F <sub>2</sub> ] (M)	Initial Rate (M/s)
0.100	0.100	0.026
0.200	0.100	0.051
0.200	0.200	0.103
0.400	0.400	0.411

Write an expression for the reaction rate law and calculate the value of the rate constant,  $k$ . What is the overall order of the reaction?

46. The tabulated data were collected for this reaction:

[CH <sub>3</sub> Cl] (M)	[Cl <sub>2</sub> ] (M)	Initial Rate (M/s)
0.050	0.050	0.014
0.100	0.050	0.029
0.100	0.100	0.041
0.200	0.200	0.115

Write an expression for the reaction rate law and calculate the value of the rate constant,  $k$ . What is the overall order of the reaction?

### The Integrated Rate Law and Half-Life

47. Indicate the order of reaction consistent with each observation.

- A plot of the concentration of the reactant versus time yields a straight line.
- The reaction has a half-life that is independent of initial concentration.
- A plot of the inverse of the concentration versus time yields a straight line.

48. Indicate the order of reaction consistent with each observation.

- The half-life of the reaction gets shorter as the initial concentration is increased.
- A plot of the natural log of the concentration of the reactant versus time yields a straight line.
- The half-life of the reaction gets longer as the initial concentration is increased.

49. The tabulated data show the concentration of AB versus time for this reaction:

Time (s)	[AB] (M)
0	0.950
50	0.459
100	0.302
150	0.225
200	0.180
250	0.149
300	0.128
350	0.112
400	0.0994
450	0.0894
500	0.0812

Determine the order of the reaction and the value of the rate constant. Predict the concentration of AB at 25 s.

50. The tabulated data show the concentration of  $\text{N}_2\text{O}_5$  versus time for this reaction:

Time (s)	$[\text{N}_2\text{O}_5]$ (M)
0	1.000
25	0.822
50	0.677
75	0.557
100	0.458
125	0.377
150	0.310
175	0.255
200	0.210

Determine the order of the reaction and the value of the rate constant. Predict the concentration of  $\text{N}_2\text{O}_5$  at 250 s.

51. The tabulated data show the concentration of cyclobutane ( $\text{C}_4\text{H}_8$ ) versus time for this reaction:

Time (s)	$[\text{C}_4\text{H}_8]$ (M)
0	1.000
10	0.894
20	0.799
30	0.714
40	0.638
50	0.571
60	0.510
70	0.456
80	0.408
90	0.364
100	0.326

Determine the order of the reaction and the value of the rate constant. What is the rate of reaction when  $[\text{C}_4\text{H}_8] = 0.25 \text{ M}$ ?

52. The reaction  $\text{A} \longrightarrow \text{products}$  was monitored as a function of time. The results are shown here.

Time (s)	[A] (M)
0	1.000
25	0.914
50	0.829
75	0.744
100	0.659
125	0.573
150	0.488
175	0.403
200	0.318

Determine the order of the reaction and the value of the rate constant. What is the rate of reaction when  $[\text{A}] = 0.10 \text{ M}$ ?

53. This reaction was monitored as a function of time:

A plot of  $\ln[\text{A}]$  versus time yields a straight line with slope  $-0.0045/\text{s}$ .

- What is the value of the rate constant ( $k$ ) for this reaction at this temperature?
- Write the rate law for the reaction.
- What is the half-life?
- If the initial concentration of A is  $0.250 \text{ M}$ , what is the concentration after 225 s?

54. This reaction was monitored as a function of time:

A plot of  $1/[\text{AB}]$  versus time yields a straight line with a slope of  $+0.55/\text{M} \cdot \text{s}$ .

- What is the value of the rate constant ( $k$ ) for this reaction at this temperature?
- Write the rate law for the reaction.
- What is the half-life when the initial concentration is  $0.55 \text{ M}$ ?
- If the initial concentration of AB is  $0.250 \text{ M}$ , and the reaction mixture initially contains no products, what are the concentrations of A and B after 75 s?

55. The decomposition of  $\text{SO}_2\text{Cl}_2$  is first order in  $\text{SO}_2\text{Cl}_2$  and has a rate constant of  $1.42 \times 10^{-4} \text{ s}^{-1}$  at a certain temperature.

- What is the half-life for this reaction?
- How long will it take for the concentration of  $\text{SO}_2\text{Cl}_2$  to decrease to 25% of its initial concentration?
- If the initial concentration of  $\text{SO}_2\text{Cl}_2$  is  $1.00 \text{ M}$ , how long will it take for the concentration to decrease to  $0.78 \text{ M}$ ?
- If the initial concentration of  $\text{SO}_2\text{Cl}_2$  is  $0.150 \text{ M}$ , what is the concentration of  $\text{SO}_2\text{Cl}_2$  after  $2.00 \times 10^2 \text{ s}$ ? After  $5.00 \times 10^2 \text{ s}$ ?

56. The decomposition of XY is second order in XY and has a rate constant of  $7.02 \times 10^{-3} \text{ M}^{-1} \cdot \text{s}^{-1}$  at a certain temperature.

- What is the half-life for this reaction at an initial concentration of  $0.100 \text{ M}$ ?
- How long will it take for the concentration of XY to decrease to 12.5% of its initial concentration when the initial concentration is  $0.100 \text{ M}$ ? When the initial concentration is  $0.200 \text{ M}$ ?
- If the initial concentration of XY is  $0.150 \text{ M}$ , how long will it take for the concentration to decrease to  $0.062 \text{ M}$ ?
- If the initial concentration of XY is  $0.050 \text{ M}$ , what is the concentration of XY after  $5.0 \times 10^1 \text{ s}$ ? After  $5.50 \times 10^2 \text{ s}$ ?

57. The half-life for the radioactive decay of U-238 is 4.5 billion years and is independent of initial concentration. How long will it take for 10% of the U-238 atoms in a sample of U-238 to decay? If a sample of U-238 initially contained  $1.5 \times 10^{18}$  atoms when the universe was formed 13.8 billion years ago, how many U-238 atoms does it contain today?
58. The half-life for the radioactive decay of C-14 is 5730 years and is independent of the initial concentration. How long does it take for 25% of the C-14 atoms in a sample of C-14 to decay? If a sample of C-14 initially contains 1.5 mmol of C-14, how many millimoles are left after 2255 years?

### The Effect of Temperature and the Collision Model

59. The diagram shows the energy of a reaction as the reaction progresses. Label each blank box in the diagram.

- reactants
  - products
  - activation energy ( $E_a$ )
  - enthalpy of reaction ( $\Delta H_{rxn}$ )
60. A chemical reaction is endothermic and has an activation energy that is twice the value of the enthalpy change of the reaction. Draw a diagram depicting the energy of the reaction as it progresses. Label the position of the reactants and products and indicate the activation energy and enthalpy of reaction.
61. The activation energy of a reaction is 56.8 kJ/mol and the frequency factor is  $1.5 \times 10^{11}$  /s. Calculate the rate constant of the reaction at 25 °C.
62. The rate constant of a reaction at 32 °C is 0.055/s. If the frequency factor is  $1.2 \times 10^{13}$ /s, what is the activation barrier?
63. The rate constant ( $k$ ) for a reaction was measured as a function of temperature. A plot of  $\ln k$  versus  $1/T$  (in K) is linear and has a slope of  $-7445$  K. Calculate the activation energy for the reaction.
64. The rate constant ( $k$ ) for a reaction was measured as a function of temperature. A plot of  $\ln k$  versus  $1/T$  (in K) is linear and has a slope of  $-1.01 \times 10^4$  K. Calculate the activation energy for the reaction.
65. The data shown here were collected for the first-order reaction:

Use an Arrhenius plot to determine the activation barrier and frequency factor for the reaction.

Temperature (K)	Rate Constant (1/s)
800	$3.24 \times 10^{-5}$
900	0.00214
1000	0.0614
1100	0.955

66. The tabulated data show the rate constant of a reaction measured at several different temperatures. Use an Arrhenius plot to determine the activation barrier and frequency factor for the reaction.

Temperature (K)	Rate Constant (1/s)
300	0.0134
310	0.0407
320	0.114
330	0.303
340	0.757

67. The tabulated data were collected for the second-order reaction:

Use an Arrhenius plot to determine the activation barrier and frequency factor for the reaction.

Temperature (K)	Rate Constant (L/mol · s)
90	0.00357
100	0.0773
110	0.956
120	7.781

68. The tabulated data show the rate constant of a reaction measured at several different temperatures. Use an Arrhenius plot to determine the activation barrier and frequency factor for the reaction.

Temperature (K)	Rate Constant (1/s)
310	0.00434
320	0.0140
330	0.0421
340	0.118
350	0.316

69. A reaction has a rate constant of 0.0117/s at 400.0 K and 0.689/s at 450.0 K.
- Determine the activation barrier for the reaction.
  - What is the value of the rate constant at 425 K?
70. A reaction has a rate constant of 0.000122/s at 27 °C and 0.228/s at 77 °C.
- Determine the activation barrier for the reaction.
  - What is the value of the rate constant at 17 °C?
71. If a temperature increase from 10.0 °C to 20.0 °C doubles the rate constant for a reaction, what is the value of the activation barrier for the reaction?
72. If a temperature increase from 20.0 °C to 35.0 °C triples the rate constant for a reaction, what is the value of the activation barrier for the reaction?
73. Consider these two gas-phase reactions:
- $\text{AA(g)} + \text{BB(g)} \longrightarrow 2 \text{AB(g)}$
  - $\text{AB(g)} + \text{CD(g)} \longrightarrow \text{AC(g)} + \text{BD(g)}$
- If the reactions have identical activation barriers and are carried out under the same conditions, which one would you expect to have the faster rate?
74. Which of these two reactions would you expect to have the smaller orientation factor? Explain.
- $\text{O(g)} + \text{N}_2\text{(g)} \longrightarrow \text{NO(g)} + \text{N(g)}$
  - $\text{NO(g)} + \text{Cl}_2\text{(g)} \longrightarrow \text{NOCl(g)} + \text{Cl(g)}$

## Reaction Mechanisms

75. Consider this overall reaction, which is experimentally observed to be second order in AB and zero order in C:

Is the following mechanism valid for this reaction?

76. Consider this overall reaction, which is experimentally observed to be second order in X and first order in Y:

- Does the reaction occur in a single step in which X and Y collide?
- Is this two-step mechanism valid?

77. Consider this three-step mechanism for a reaction:

- What is the overall reaction?
- Identify the intermediates in the mechanism.
- What is the predicted rate law?

78. Consider this two-step mechanism for a reaction:

- What is the overall reaction?
- Identify the intermediates in the mechanism.
- What is the predicted rate law?

## Catalysis

79. Many heterogeneous catalysts are deposited on high-surface-area supports. Why?

80. Suppose that the reaction  $A \longrightarrow \text{products}$  is exothermic and has an activation barrier of 75 kJ/mol. Sketch an energy diagram showing the energy of the reaction as a function of the progress of the reaction. Draw a second energy curve showing the effect of a catalyst.

81. Suppose that a catalyst lowers the activation barrier of a reaction from 125 kJ/mol to 55 kJ/mol. By what factor would you expect the reaction rate to increase at 25 °C? (Assume that the frequency factors for the catalyzed and uncatalyzed reactions are identical.)

82. The activation barrier for the hydrolysis of sucrose into glucose and fructose is 108 kJ/mol. If an enzyme increases the rate of the hydrolysis reaction by a factor of 1 million, how much lower must the activation barrier be when sucrose is in the active site of the enzyme? (Assume that the frequency factors for the catalyzed and uncatalyzed reactions are identical and a temperature of 25 °C.)

## Cumulative Problems

83. The tabulated data were collected for this reaction at 500 °C:

Time (h)	[CH <sub>3</sub> CN] (M)
0.0	1.000
5.0	0.794
10.0	0.631
15.0	0.501
20.0	0.398
25.0	0.316

- Determine the order of the reaction and the value of the rate constant at this temperature.
  - What is the half-life for this reaction (at the initial concentration)?
  - How long will it take for 90% of the CH<sub>3</sub>CN to convert to CH<sub>3</sub>NC?
84. The tabulated data were collected for this reaction at a certain temperature:

Time (h)	[X <sub>2</sub> Y] (M)
0.0	0.100
1.0	0.0856
2.0	0.0748
3.0	0.0664
4.0	0.0598
5.0	0.0543

- Determine the order of the reaction and the value of the rate constant at this temperature.

- What is the half-life for this reaction (at the initial concentration)?
- What is the concentration of X after 10.0 hours?

85. Consider the reaction:

The rate law for this reaction is:

$$\text{Rate} = k \frac{[A][C]^2}{[B]^{1/2}}$$

Suppose the rate of the reaction at certain initial concentrations of A, B, and C is 0.0115 M/s. What is the rate of the reaction if the concentrations of A and C are doubled and the concentration of B is tripled?

86. Consider the reaction:

The rate law for this reaction is:

$$\text{Rate} = k \frac{[O_3]^2}{[O_2]}$$

Suppose that a 1.0-L reaction vessel initially contains 1.0 mol of O<sub>3</sub> and 1.0 mol of O<sub>2</sub>. What fraction of the O<sub>3</sub> will have reacted when the rate falls to one-half of its initial value?

87. At 700 K acetaldehyde decomposes in the gas phase to methane and carbon monoxide. The reaction is:

A sample of CH<sub>3</sub>CHO is heated to 700 K and the pressure is measured as 0.22 atm before any reaction takes place. The kinetics of the reaction are followed by measurements of total pressure and these data are obtained:

t (s)	0	1000	3000	7000
P <sub>Total</sub> (atm)	0.22	0.24	0.27	0.31

Find the rate law, the rate constant, and the total pressure after  $2.00 \times 10^4$  s.

88. At 400 K oxalic acid decomposes according to the reaction:

In three separate experiments, the initial pressure of oxalic acid and final total pressure after 20,000 s are measured.

Experiment	1	2	3
$P_{\text{H}_2\text{C}_2\text{O}_4}$ at $t = 0$	65.8	92.1	111
$P_{\text{Total}}$ at $t = 20,000$ s	94.6	132	160

Find the rate law of the reaction and its rate constant.

89. Dinitrogen pentoxide decomposes in the gas phase to form nitrogen dioxide and oxygen gas. The reaction is first order in dinitrogen pentoxide and has a half-life of 2.81 h at 25 °C. If a 1.5-L reaction vessel initially contains 745 torr of  $\text{N}_2\text{O}_5$  at 25 °C, what partial pressure of  $\text{O}_2$  is present in the vessel after 215 minutes?
90. Cyclopropane ( $\text{C}_3\text{H}_6$ ) reacts to form propene ( $\text{C}_3\text{H}_6$ ) in the gas phase. The reaction is first order in cyclopropane and has a rate constant of  $5.87 \times 10^{-4}$  s $^{-1}$  at 485 °C. If a 2.5-L reaction vessel initially contains 722 torr of cyclopropane at 485 °C, how long will it take for the partial pressure of cyclopropane to drop to below  $1.00 \times 10^2$  torr?
91. Iodine atoms combine to form  $\text{I}_2$  in liquid hexane solvent with a rate constant of  $1.5 \times 10^{10}$  L/mol·s. The reaction is second order in I. Since the reaction occurs so quickly, the only way to study the reaction is to create iodine atoms almost instantaneously, usually by photochemical decomposition of  $\text{I}_2$ . Suppose a flash of light creates an initial [I] concentration of 0.0100 M. How long will it take for 95% of the newly created iodine atoms to recombine to form  $\text{I}_2$ ?
92. The hydrolysis of sucrose ( $\text{C}_{12}\text{H}_{22}\text{O}_{11}$ ) into glucose and fructose in acidic water has a rate constant of  $1.8 \times 10^{-4}$  s $^{-1}$  at 25 °C. Assuming the reaction is first order in sucrose, determine the mass of sucrose that is hydrolyzed when 2.55 L of a 0.150 M sucrose solution is allowed to react for 195 minutes.
93. The reaction  $\text{AB}(\text{aq}) \longrightarrow \text{A}(\text{g}) + \text{B}(\text{g})$  is second order in AB and has a rate constant of  $0.0118 \text{ M}^{-1} \cdot \text{s}^{-1}$  at 25.0 °C. A reaction vessel initially contains 250.0 mL of 0.100 M AB that is allowed to react to form the gaseous product. The product is collected over water at 25.0 °C. How much time is required to produce 200.0 mL of the products at a barometric pressure of 755.1 mmHg? (The vapor pressure of water at this temperature is 23.8 mmHg.)
94. The reaction  $2 \text{H}_2\text{O}_2(\text{aq}) \longrightarrow 2 \text{H}_2\text{O}(\text{l}) + \text{O}_2(\text{g})$  is first order in  $\text{H}_2\text{O}_2$  and under certain conditions has a rate constant of  $0.00752 \text{ s}^{-1}$  at 20.0 °C. A reaction vessel initially contains 150.0 mL of 30.0%  $\text{H}_2\text{O}_2$  by mass solution (the density of the solution is 1.11 g/mL). The gaseous oxygen is collected over water at 20.0 °C as it forms. What volume of  $\text{O}_2$  forms in 85.0 seconds at a barometric pressure of 742.5 mmHg? (The vapor pressure of water at this temperature is 17.5 mmHg.)

95. Consider this energy diagram:

- How many elementary steps are involved in this reaction?
- Label the reactants, products, and intermediates.

- Which step is rate limiting?

- Is the overall reaction endothermic or exothermic?

96. Consider the reaction in which HCl adds across the double bond of ethene:

The following mechanism, with the accompanying energy diagram, has been suggested for this reaction:

- Based on the energy diagram, determine which step is rate limiting.
  - What is the expected order of the reaction based on the proposed mechanism?
  - Is the overall reaction exothermic or endothermic?
97. The desorption (leaving of the surface) of a single molecular layer of *n*-butane from a single crystal of aluminum oxide is found to be first order with a rate constant of 0.128/s at 150 K.
- What is the half-life of the desorption reaction?
  - If the surface is initially completely covered with *n*-butane at 150 K, how long will it take for 25% of the molecules to desorb (leave the surface)? For 50% to desorb?
  - If the surface is initially completely covered, what fraction will remain covered after 10 s? After 20 s?
98. The evaporation of a 120-nm film of *n*-pentane from a single crystal of aluminum oxide is zero order with a rate constant of  $1.92 \times 10^{13}$  molecules/cm $^2$ ·s at 120 K.
- If the initial surface coverage is  $8.9 \times 10^{16}$  molecules/cm $^2$ , how long will it take for one-half of the film to evaporate?
  - What fraction of the film is left after 10 s? Assume the same initial coverage as in part a.
99. The kinetics of this reaction were studied as a function of temperature. (The reaction is first order in each reactant and second order overall.)

Temperature (°C)	$k$ (L/mol·s)
25	$8.81 \times 10^{-5}$
35	0.000285
45	0.000854
55	0.00239
65	0.00633

- Determine the activation energy and frequency factor for the reaction.
- Determine the rate constant at 15 °C.
- If a reaction mixture is 0.155 M in  $\text{C}_2\text{H}_5\text{Br}$  and 0.250 M in  $\text{OH}^-$ , what is the initial rate of the reaction at 75 °C?

**100.** The reaction  $2\text{N}_2\text{O}_5 \longrightarrow 2\text{N}_2\text{O}_4 + \text{O}_2$  takes place at around room temperature in solvents such as  $\text{CCl}_4$ . The rate constant at 293 K is found to be  $2.35 \times 10^{-4} \text{ s}^{-1}$ , and at 303 K the rate constant is found to be  $9.15 \times 10^{-4} \text{ s}^{-1}$ . Calculate the frequency factor for the reaction.

**101.** This reaction has an activation energy of zero in the gas phase:

- Would you expect the rate of this reaction to change very much with temperature?
- Why might the activation energy be zero?
- What other types of reactions would you expect to have little or no activation energy?

**102.** Consider the two reactions:

- Why is the activation barrier for the first reaction so much higher than that for the second?
- The frequency factors for these two reactions are very close to each other in value. Assuming that they are the same, calculate the ratio of the reaction rate constants for these two reactions at 25 °C.

**103.** Anthropologists can estimate the age of a bone or other sample of organic matter by its carbon-14 content. The carbon-14 in a living organism is constant until the organism dies, after which carbon-14 decays with first-order kinetics and a half-life of 5730 years. Suppose a bone from an ancient human contains 19.5% of the C-14 found in living organisms. How old is the bone?

**104.** Geologists can estimate the age of rocks by their uranium-238 content. The uranium is incorporated in the rock as it hardens and then decays with first-order kinetics and a half-life of 4.5 billion years. A rock contains 83.2% of the amount of uranium-238 that it contained when it was formed. (The amount that the rock contained when it was formed can be deduced from the presence of the decay products of U-238.) How old is the rock?

**105.** Consider the gas-phase reaction:

The reaction was experimentally determined to be first order in  $\text{H}_2$  and first order in  $\text{I}_2$ . Consider the proposed mechanisms.

Proposed mechanism I:

Proposed mechanism II:

- Show that both of the proposed mechanisms are valid.
- What kind of experimental evidence might lead you to favor mechanism II over mechanism I?

**106.** Consider the reaction:

This three-step mechanism is proposed:

- Show that the mechanism sums to the overall reaction.
- What is the rate law predicted by this mechanism?

**107.** The proposed mechanism for the formation of hydrogen bromide can be written in a simplified form as:

What rate law corresponds to this mechanism?

**108.** A proposed mechanism for the formation of hydrogen iodide can be written in simplified form as

What rate law corresponds to this mechanism?

**109.** A certain substance X decomposes. Fifty percent of X remains after 100 minutes. How much X remains after 200 minutes if the reaction order with respect to X is (a) zero order, (b) first order, (c) second order?

**110.** The half-life for radioactive decay (a first-order process) of plutonium-239 is 24,000 years. How many years does it take for one mole of this radioactive material to decay until just one atom remains?

**111.** The energy of activation for the decomposition of 2 mol of HI to  $\text{H}_2$  and  $\text{I}_2$  in the gas phase is 185 kJ. The heat of formation of  $\text{HI}(\text{g})$  from  $\text{H}_2(\text{g})$  and  $\text{I}_2(\text{g})$  is  $-5.65 \text{ kJ/mol}$ . Find the energy of activation for the reaction of 1 mol of  $\text{H}_2$  and 1 mol of  $\text{I}_2$  to form 2 mol of HI in the gas phase.

**112.** Ethyl chloride vapor decomposes by the first-order reaction:

The activation energy is 249 kJ/mol, and the frequency factor is  $1.6 \times 10^{14} \text{ s}^{-1}$ . Find the value of the rate constant at 710 K. What fraction of the ethyl chloride decomposes in 15 minutes at this temperature? Find the temperature at which the rate of the reaction would be twice as fast.

## Challenge Problems

**113.** In this chapter we have seen a number of reactions in which a single reactant forms products. For example, consider the following first-order reaction:

However, we also learned that gas-phase reactions occur through collisions.

- One possible explanation for how this reaction occurs is that two molecules of  $\text{CH}_3\text{NC}$  collide with each other and form

two molecules of the product in a single elementary step. If that were the case, what reaction order would you expect?

- Another possibility is that the reaction occurs through more than one step. For example, a possible mechanism involves one step in which the two  $\text{CH}_3\text{NC}$  molecules collide, resulting in the “activation” of one of them. In a second step, the activated molecule goes on to form the product. Write down this mechanism and determine which step must be rate

determining in order for the kinetics of the reaction to be first order. Show explicitly how the mechanism predicts first-order kinetics.

- 114.** The first-order *integrated* rate law for the reaction  $A \longrightarrow \text{products}$  is derived from the rate law using calculus:

$$\text{Rate} = k[A] \text{ (first-order rate law)}$$

$$\text{Rate} = -\frac{d[A]}{dt}$$

$$\frac{d[A]}{dt} = -k[A]$$

The equation just given is a first-order, separable differential equation that can be solved by separating the variables and integrating:

$$\frac{d[A]}{[A]} = -k dt$$

$$\int_{[A]_0}^{[A]} \frac{d[A]}{[A]} = -\int_0^t k dt$$

In the integral just given,  $[A]_0$  is the initial concentration of A. We then evaluate the integral:

$$[\ln[A]]_{[A]_0}^{[A]} = -k[t]_0^t$$

$$\ln[A] - \ln[A]_0 = -kt$$

$$\ln[A] = -kt + \ln[A]_0 \text{ (integrated rate law)}$$

- Use a procedure similar to the one just shown to derive an integrated rate law for a reaction  $A \longrightarrow \text{products}$ , which is one-half order in the concentration of A (that is,  $\text{Rate} = k[A]^{1/2}$ ).
  - Use the result from part a to derive an expression for the half-life of a one-half-order reaction.
- 115.** The previous exercise shows how the first-order integrated rate law is derived from the first-order differential rate law. Begin with the second-order differential rate law and derive the second-order integrated rate law.

- 116.** The rate constant for the first-order decomposition of  $\text{N}_2\text{O}_5(\text{g})$  to  $\text{NO}_2(\text{g})$  and  $\text{O}_2(\text{g})$  is  $7.48 \times 10^{-3} \text{ s}^{-1}$  at a given temperature.
- Find the length of time required for the total pressure in a system containing  $\text{N}_2\text{O}_5$  at an initial pressure of 0.100 atm to rise to 0.145 atm.
  - To 0.200 atm.
  - Find the total pressure after 100 s of reaction.

- 117.** Phosgene ( $\text{Cl}_2\text{CO}$ ), a poison gas used in World War I, is formed by the reaction of  $\text{Cl}_2$  and CO. The proposed mechanism for the reaction is:

What rate law is consistent with this mechanism?

- 118.** The rate of decomposition of  $\text{N}_2\text{O}_3(\text{g})$  to  $\text{NO}_2(\text{g})$  and  $\text{NO}(\text{g})$  is followed by measuring  $[\text{NO}_2]$  at different times. The following data are obtained.

$[\text{NO}_2](\text{mol/L})$	0	0.193	0.316	0.427	0.784
$t \text{ (s)}$	0	884	1610	2460	50,000

The reaction follows a first-order rate law. Calculate the rate constant. Assume that after 50,000 s all  $\text{N}_2\text{O}_3(\text{g})$  had decomposed.

- 119.** At 473 K, for the elementary reaction  $2 \text{NOCl}(\text{g}) \xrightleftharpoons[k_{-1}]{k_1} 2 \text{NO}(\text{g}) + \text{Cl}_2(\text{g})$
- $$k_1 = 7.8 \times 10^{-2} \text{ L/mol s} \quad \text{and}$$
- $$k_{-1} = 4.7 \times 10^2 \text{ L}^2/\text{mol}^2 \text{ s}$$

A sample of NOCl is placed in a container and heated to 473 K. When the system comes to equilibrium,  $[\text{NOCl}]$  is found to be 0.12 mol/L. What are the concentrations of NO and  $\text{Cl}_2$ ?

## Conceptual Problems

- 120.** Consider the reaction:

The reaction is first order in  $\text{CHCl}_3$  and one-half order in  $\text{Cl}_2$ . Which reaction mixture would you expect to have the fastest initial rate?

- 121.** The accompanying graph shows the concentration of a reactant as a function of time for two different reactions. One of the reactions is first order and the other is second order. Which of the

two reactions is first order? Second order? How would you change each plot to make it linear?

- 122.** A particular reaction,  $A \longrightarrow \text{products}$ , has a rate that slows down as the reaction proceeds. The half-life of the reaction is found to depend on the initial concentration of A. Determine whether each statement is likely to be true or false for this reaction.
- A doubling of the concentration of A doubles the rate of the reaction.
  - A plot of  $1/[A]$  versus time is linear.
  - The half-life of the reaction gets longer as the initial concentration of A increases.
  - A plot of the concentration of A versus time has a constant slope.

Questions for Group Work

Discuss these questions with the group and record your consensus answer.

123. A student says, “The initial concentration of a reactant was doubled, and the rate doubled. Therefore the reaction is second order in that reactant.” Why might the student say that? What is wrong with the statement? What is the actual order with respect to the reactant? Explain your reasoning clearly.
124. A certain compound, A, reacts to form products according to the reaction  $A \longrightarrow P$ . The amount of A is measured as a function of time under a variety of different conditions and the tabulated results are shown here:

Time (s)	25.0 °C [A] (M)	35.0 °C [A] (M)	45.0 °C [A] (M)
0	1.000	1.000	1.000
10	0.779	0.662	0.561
20	0.591	0.461	0.312
30	0.453	0.306	0.177
40	0.338	0.208	0.100
50	0.259	0.136	0.057
60	0.200	0.093	0.032

Have one group member make a graph of [A] vs. *t*, one group member make a graph of ln[A] vs. *t*, and one group member

make a graph of 1/[A] vs. *t* using the data for 25 °C. Additional group members can make similar graphs for the other temperatures. What is the order of the reaction with respect to A? Explain your answer.

- a. Use the data to determine the rate constant at each temperature.
- b. What is the activation energy for this reaction?
- c. The same reaction is conducted in the presence of a catalyst, and the following data are obtained:

Time (s)	25.0 °C [A] (M)	35.0 °C [A] (M)	45.0 °C [A] (M)
0	1.000	1.000	1.000
0.1	0.724	0.668	0.598
0.2	0.511	0.433	0.341
0.3	0.375	0.291	0.202
0.4	0.275	0.190	0.119
0.5	0.198	0.122	0.071
0.6	0.141	0.080	0.043

What effect does a catalyst have on the rate of the reaction? What is the activation energy for this reaction in the presence of the catalyst? How does it compare with the activation energy for the reaction when the catalyst isn’t present?

Data Interpretation and Analysis

Kinetics of Color Change in Marionberry Preserves

125. The color of food is an important component in consumer decisions. Ultraviolet rays from the sun and other chemical processes can break chemical bonds and cause food color to fade. The time that it takes for the color of food to fade depends on the kinetics of the chemical reactions occurring in the food.

A company makes marionberry preserves and places the food in sealed glass jars. In one experiment, food scientists place some jars near a window where the preserves are exposed to light

and the temperature is kept constant at 25.0 °C. The scientists periodically measure the color intensity of the preserves during a 200-day period. Table a displays the change in color intensity of the preserves (as a percentage of the original) in the presence of light at 25.0 °C. Figure a plots the data in Table a as a graph.

Time (days)	% of Initial Color	Time (days)	% of Initial Color
0	100.0	24	72.18
2	97.32	26	70.25
4	94.71	30	66.53
6	92.17	40	58.08

**TABLE d** Fading of Preserves Color in the Dark as a Function of Time at 40.0 °C

Use the information provided in the figure and the tables to answer the following questions (assume the % initial color is directly proportional to concentration of color-causing compounds in the preserves):

- Which order of reaction does the degradation of the preserve color follow? Explain and justify your answer.
- Determine  $k$ , the rate constant for the preserves stored in the presence of light at 25.0 °C and the rate constant for the preserves stored in darkness at 25.0 °C. Which has the lower rate constant? Assuming color preservation is the goal, is it better to store the preserves in the dark or in the presence of light? Explain.
- Does temperature (5.0 °C, 25.0 °C, and 40.0 °C) influence the degradation of color for the preserves stored in the dark? Explain.
- When storing the preserves in the dark, which temperature (5.0 °C, 25.0 °C, or 40.0 °C) has the lowest rate constant? In the dark, is it better to store the preserves at a cool or warm temperature? Explain.
- Determine the activation energy of the degradation reaction in the dark,  $E_a$ , in units of kJ/mol.

## Answers to Conceptual Connections

### Reaction Rates

**14.1 (c)** The rate at which B changes is twice the rate of the reaction because its coefficient is 2, and it is negative because B is a reactant.

### Order of Reaction

**14.2 (d)** Since the reaction is second order, increasing the concentration of A by a factor of 5 causes the rate to increase by  $5^2$  or 25.

### Rate and Concentration

**14.3** All three mixtures have the same total number of molecules, but mixture (c) has the greatest number of NO molecules. Since the reaction is second order in NO and only first order in  $O_2$ , mixture (c) has the fastest initial rate.

### Half-Life Part I

**14.4** The half-life is 90 s, because it takes 90 s for the reactant to fall to one-half of its initial concentration.

### Half-Life Part II

**14.5** The concentration of B after 50 seconds (two half-lives) is 0.225 M. See table.

Time (min)	[A] (M)	[B] (M)
0	0.300	0.0
25	0.150	0.150
50	0.075	0.225

### Rate Law and Integrated Rate Law

**14.6 (c)** The reaction is most likely second order because its rate depends on the concentration (therefore it cannot be zero order), and its half-life depends on the initial concentration (therefore it cannot be first order). For a second-order reaction, a doubling of the initial concentration results in the quadrupling of the rate.

### Temperature Dependence of Reaction Rate

**14.7** Reaction A has a faster rate because it has a lower activation energy; therefore, the exponential factor is larger at a given temperature, making the rate constant larger. (With a larger rate constant and the same initial concentration, the rate is faster).

### Collision Theory

**14.8 (c)** Since the reactants in part (a) are atoms, the orientation factor should be about one. The reactants in parts (b) and (c) are both molecules, so we expect orientation factors of less than one. Since the reactants in (b) are symmetrical, we would not expect the collision to have as specific an orientation requirement as in (c), where the reactants are asymmetrical and must therefore collide in such way that a hydrogen atom is in close proximity to another hydrogen atom. Therefore, we expect (c) to have the smallest orientation factor.

# Chemical Equilibrium

Every system in chemical equilibrium, under the influence of a change of any one of the factors of equilibrium, undergoes a transformation . . . [that produces a change] . . . in the opposite direction of the factor in question.

KEY LEARNING OUTCOMES 712

In Chapter 14, we examined *how fast* a chemical reaction occurs. In this chapter we examine *how far* a chemical reaction goes. The *speed* of a chemical reaction is determined by kinetics. The *extent* of a chemical reaction is determined by thermodynamics. In this chapter, we focus on describing and quantifying how far a chemical reaction goes based on an experimentally measurable quantity called *the equilibrium constant*. A reaction with a large equilibrium constant proceeds nearly to completion—almost all the reactants react to form products. A reaction with a small equilibrium constant barely proceeds at all—almost all the reactants remain as reactants, hardly forming any products. In this chapter we simply accept the equilibrium constant as an experimentally measurable quantity and learn how to use it to predict and quantify the extent of a reaction. In Chapter 18, we will explore the reasons underlying the magnitude of equilibrium constants.

▲ A developing fetus obtains oxygen from the mother's blood because the reaction between oxygen and fetal hemoglobin has a larger equilibrium constant than the reaction between oxygen and maternal hemoglobin.

## 15.1 Fetal Hemoglobin and Equilibrium

Have you ever wondered how a baby in the womb gets oxygen? Unlike you and me, a fetus does not breathe air. Yet, like you and me, a fetus needs oxygen. Where does that oxygen come from? After we are born, we inhale air into our lungs and that air diffuses into capillaries, where it comes into contact with our blood. Within our red blood cells, a protein called hemoglobin (Hb) reacts with oxygen according to the chemical equation:

▲ Hemoglobin is the oxygen-carrying protein in red blood cells. Oxygen binds to iron atoms, which are depicted here in white.

The double arrows in this equation indicate that the reaction can occur in both the forward and reverse directions and can reach chemical *equilibrium*. We encountered this term in Chapters 11 and 13, and we define it more carefully in the next section. For now, understand that the relative concentrations of the reactants and products in a reaction at equilibrium are described by the *equilibrium constant*,  $K$ . A large value of  $K$  means that the reaction lies far to the right at equilibrium—a high concentration of products and a low concentration of reactants. A small value of  $K$  means that the reaction lies far to the left at equilibrium—a high concentration of reactants and a low concentration of products. In short, the value of  $K$  is a measure of how far a reaction proceeds—the larger the value of  $K$ , the more the reaction proceeds toward the products.

The equilibrium constant for the reaction between hemoglobin and oxygen is such that hemoglobin efficiently binds oxygen at typical lung oxygen concentrations, but it can also release oxygen under the appropriate conditions. Any system at equilibrium, including the hemoglobin–oxygen system, responds to changes in ways that maintain equilibrium. If any of the concentrations of the reactants or products change, the reaction shifts to counteract that change. For the hemoglobin system, as blood flows through the lungs where oxygen concentrations are high, the equilibrium shifts to the right—hemoglobin binds oxygen:

In our bodies, as blood flows out of the lungs and into muscles and organs where oxygen concentrations have been depleted (because muscles and organs use oxygen), the equilibrium shifts to the left—hemoglobin releases oxygen:

In other words, to maintain equilibrium, *hemoglobin binds oxygen when the surrounding oxygen concentration is high, but it releases oxygen when the surrounding oxygen concentration is low*. In this way, hemoglobin transports oxygen from the lungs to all parts of the body that use oxygen.

A fetus has its own circulatory system. The mother's blood never flows into the fetus's body, and the fetus cannot get any air in the womb. How, then, does the fetus get oxygen? The answer lies in the properties of fetal hemoglobin (HbF), which is slightly different from adult hemoglobin. Like adult hemoglobin, fetal hemoglobin is in equilibrium with oxygen:

However, the equilibrium constant for fetal hemoglobin is larger than the equilibrium constant for adult hemoglobin, meaning that the reaction tends to go farther in the direction of the product. Consequently, fetal hemoglobin loads oxygen at a lower oxygen concentration than does adult hemoglobin. In the placenta, fetal blood flows in close proximity to maternal blood. Although the two never mix, because of the different equilibrium constants, the maternal hemoglobin releases oxygen that the fetal hemoglobin then binds and carries into its own circulatory system (Figure 15.1▶). Nature has evolved a chemical system through which the mother's hemoglobin can in effect *hand off* oxygen to the hemoglobin of the fetus.

**FIGURE 15.1 Oxygen Exchange between the Maternal and Fetal Circulation** In the placenta, the blood of the fetus comes into close proximity with the blood of the mother, although the two do not mix directly. Because the reaction of fetal hemoglobin with oxygen has a larger equilibrium constant than the reaction of maternal hemoglobin with oxygen, the fetus receives oxygen from the mother's blood.

## 15.2 The Concept of Dynamic Equilibrium

Recall from the previous chapter that reaction rates generally increase with increasing concentration of the reactants and decrease with decreasing concentration of the reactants (unless the reaction order is zero). With this in mind, consider the reaction between hydrogen and iodine:

In this reaction,  $\text{H}_2$  and  $\text{I}_2$  react to form 2 HI molecules, but the 2 HI molecules can also react to re-form  $\text{H}_2$  and  $\text{I}_2$ . A reaction such as this one—that can proceed in both the forward and reverse directions—is **reversible**. Suppose we begin with only  $\text{H}_2$  and  $\text{I}_2$  in a container (Figure 15.2a on the next page). What happens? Initially  $\text{H}_2$  and  $\text{I}_2$  begin to react to form HI (Figure 15.2b). However, as  $\text{H}_2$  and  $\text{I}_2$  react, their concentrations decrease, which in turn *decreases the rate of the forward reaction*. At the same time, HI begins to form. As the concentration of HI increases, the reverse reaction begins to occur at a faster and faster rate. Eventually the rate of the reverse reaction (which has been increasing) equals the rate of the forward reaction (which has been decreasing). At that point, **dynamic equilibrium** is reached (Figure 15.2c, d):

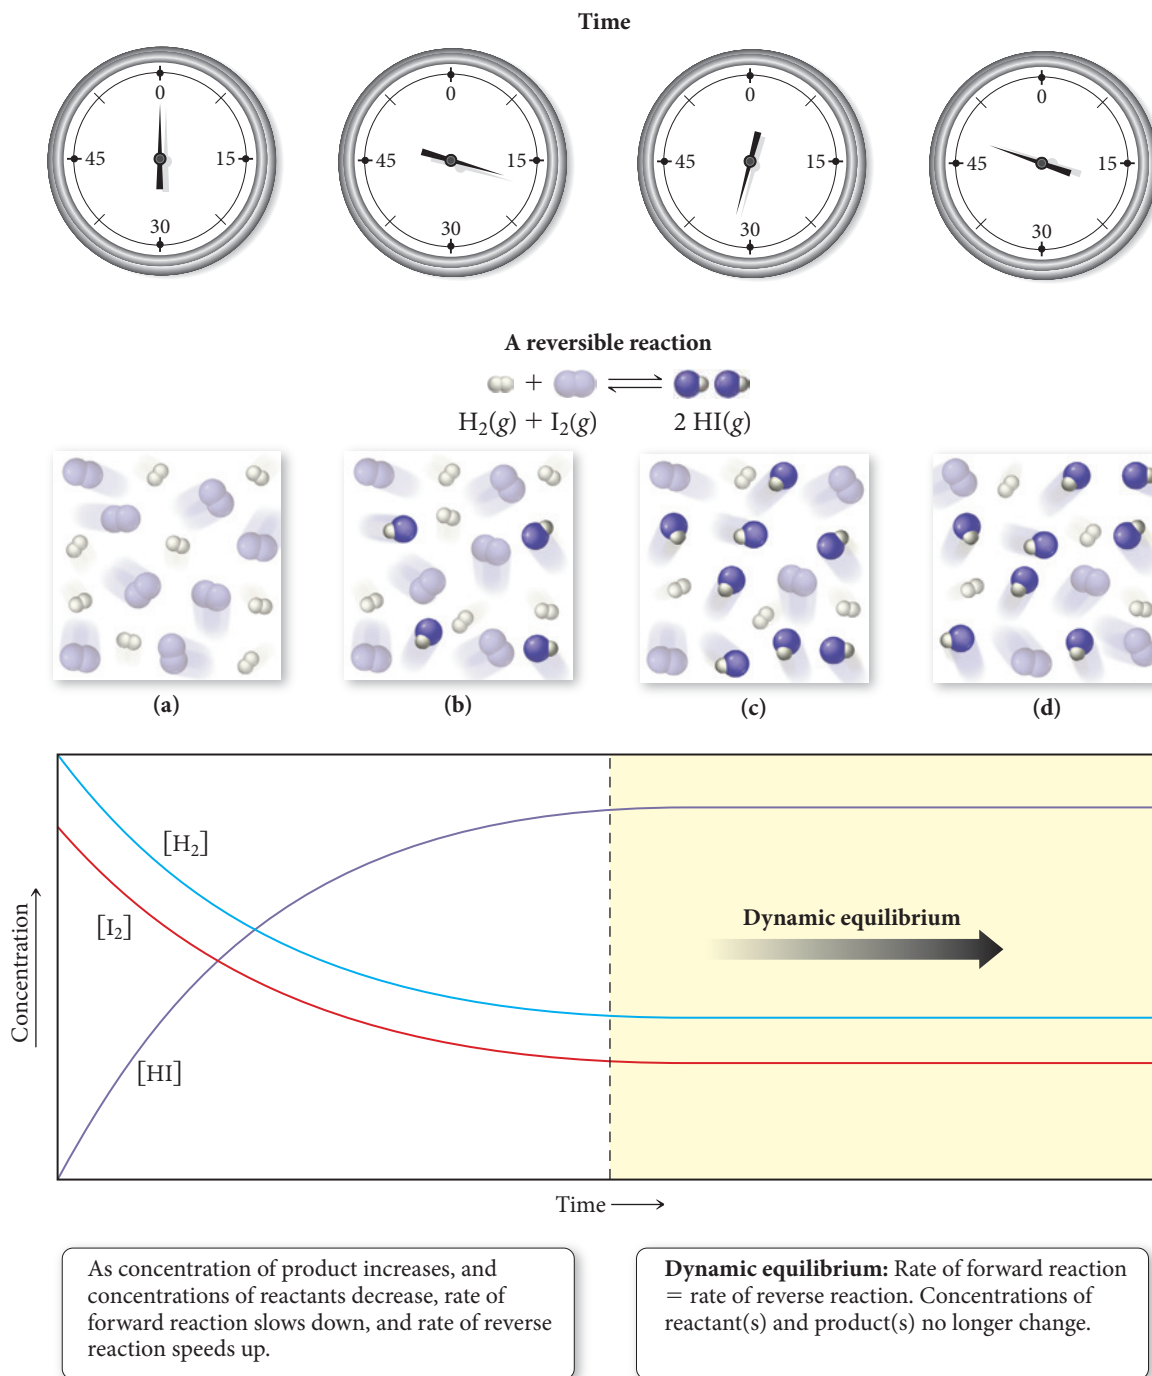

**Dynamic equilibrium for a chemical reaction is the condition in which the rate of the forward reaction equals the rate of the reverse reaction.**

Dynamic equilibrium is “dynamic” because the forward and reverse reactions are still occurring; however, they are occurring at the same rate. When dynamic equilibrium is reached, the concentrations of  $\text{H}_2$ ,  $\text{I}_2$ , and HI no longer change. They remain constant because the reactants and products form at the same rate that they are depleted. Note that just because the concentrations of reactants and products no longer change at equilibrium *does not mean that the concentrations of reactants and products are equal to one another* at equilibrium. Some reactions reach equilibrium only after most of the reactants have formed products. Others reach equilibrium when only a small fraction of the reactants have formed products. It depends on the reaction.

Nearly all chemical reactions are at least theoretically reversible. In many cases, however, the reversibility is so small that it can be ignored.

## Dynamic Equilibrium

**▲ FIGURE 15.2 Dynamic Equilibrium** Equilibrium is reached in a chemical reaction when the concentrations of the reactants and products no longer change. The molecular images depict the progress of the reaction  $\text{H}_2(\text{g}) + \text{I}_2(\text{g}) \rightleftharpoons 2 \text{HI}(\text{g})$ . The graph shows the concentrations of  $\text{H}_2$ ,  $\text{I}_2$ , and  $\text{HI}$  as a function of time. When the reaction reaches equilibrium, both the forward and reverse reactions continue, but at equal rates, so the concentrations of the reactants and products remain constant.

We can better understand dynamic equilibrium with a simple analogy. Imagine two neighboring countries (A and B) with a closed border between them (Figure 15.3▶). Country A is overpopulated and Country B is underpopulated. One day, the border between the two countries opens, and people immediately begin to leave Country A for Country B:

Country A  $\longrightarrow$  Country B

### Dynamic Equilibrium: An Analogy

▲ **FIGURE 15.3 A Population Analogy for Chemical Equilibrium** Because Country A is initially overpopulated, people migrate from Country A to Country B. As the population of Country A falls and that of Country B rises, the rate of migration from Country A to Country B decreases and the rate of migration from Country B to Country A increases. Eventually the two rates become equal. Equilibrium has been reached.

The population of Country A goes down as the population of Country B goes up. As people leave Country A, however, the *rate* at which they leave slows down because as Country A becomes less populated, the pool of potential emigrants gets smaller. (In other words, the rate of emigration is directly proportional to the population—as the population decreases, the emigration rate goes down.) On the other hand, as people move into Country B, it gets more crowded and some people begin to move from Country B to Country A:

As the population of Country B continues to grow, the rate of people moving out of Country B gets faster. Eventually the *rate* of people moving out of Country A (which has been slowing down as people leave) equals the *rate* of people moving out of Country B (which has been increasing as Country B gets more crowded). Dynamic equilibrium has been reached:

Notice that when the two countries reach dynamic equilibrium, their populations no longer change because the number of people moving out of either country equals the number of people moving in. However, one country—because of its charm or the availability of good jobs or lower taxes, or for whatever other reason—may have a higher population than the other country, even when dynamic equilibrium is reached.

Similarly, when a chemical reaction reaches dynamic equilibrium, the rate of the forward reaction equals the rate of the reverse reaction, and the concentrations of reactants and products become *constant*. But the concentrations of reactants and products will not necessarily be *equal* at equilibrium, just as the populations of the two countries are not necessarily equal at equilibrium.

## The Equilibrium Constant

15.3 The Equilibrium Constant (*K*)

We have just seen that the *concentrations of reactants and products* are not equal at equilibrium—rather, the *rates of the forward and reverse reactions* are equal. So what about the concentrations? What can we know about them? The concentrations, as we can see by reexamining Figure 15.2, become constant; they don't change once equilibrium is reached (as long as the temperature is constant). We quantify the relative concentrations of reactants and products at equilibrium with a quantity called the *equilibrium constant* (*K*). Consider an equation for a generic chemical reaction:

where A and B are reactants, C and D are products, and *a*, *b*, *c*, and *d* are the respective stoichiometric coefficients in the chemical equation. The **equilibrium constant (*K*)** for the reaction is defined as the ratio—at *equilibrium*—of the concentrations of the products raised to their stoichiometric coefficients divided by the concentrations of the reactants raised to their stoichiometric coefficients:

$$K = \frac{[C]^c[D]^d}{[A]^a[B]^b}$$

The Law of Mass Action

Products

Reactants

We distinguish between the equilibrium constant (*K*) and the Kelvin unit of temperature (K) by italicizing the equilibrium constant.

In this notation, [A] represents the molar concentration of A.

Why is *this* particular ratio of concentrations at equilibrium—and not some other ratio—defined as the equilibrium constant? *Because this particular ratio is always a constant when the reactants and products are at equilibrium* (at constant temperature). As we can see from the expression, the equilibrium constant *quantifies* the relative concentrations of reactants and products *at equilibrium*. The relationship between the balanced chemical equation and the expression of the equilibrium constant is the **law of mass action**.

## Expressing Equilibrium Constants for Chemical Reactions

To express an equilibrium constant for a chemical reaction, we examine the balanced chemical equation and apply the law of mass action. For example, suppose we want to express the equilibrium constant for the reaction:

The equilibrium constant is [NO<sub>2</sub>] raised to the fourth power multiplied by [O<sub>2</sub>] raised to the first power divided by [N<sub>2</sub>O<sub>5</sub>] raised to the second power:

$$K = \frac{[\text{NO}_2]^4[\text{O}_2]}{[\text{N}_2\text{O}_5]^2}$$

Notice that the *coefficients* in the chemical equation become the *exponents* in the expression of the equilibrium constant.

**Example 15.1** Expressing Equilibrium Constants for Chemical Equations

Express the equilibrium constant for the chemical equation:

**SOLUTION**

The equilibrium constant is the equilibrium concentrations of the products raised to their stoichiometric coefficients divided by the equilibrium concentrations of the reactants raised to their stoichiometric coefficients.

$$K = \frac{[\text{CO}][\text{H}_2]^2}{[\text{CH}_3\text{OH}]}$$

**FOR PRACTICE 15.1** Express the equilibrium constant for the combustion of propane:

**The Significance of the Equilibrium Constant**

You now know how to express the equilibrium constant, but what does it mean? What, for example, does a large equilibrium constant ( $K \gg 1$ ) imply about a reaction? A large equilibrium constant indicates that the numerator (which specifies the amounts of products at equilibrium) is larger than the denominator (which specifies the amounts of reactants at equilibrium). Therefore, when the equilibrium constant is large, the forward reaction is favored. For example, consider the reaction:

The equilibrium constant is large, indicating that the equilibrium point for the reaction lies far to the right—high concentrations of products, low concentrations of reactants (Figure 15.4▶). Remember that the equilibrium constant says nothing about *how fast* a reaction reaches equilibrium, only *how far* the reaction has proceeded once equilibrium is reached. A reaction with a large equilibrium constant may be kinetically very slow and take a long time to reach equilibrium.

Conversely, what does a *small* equilibrium constant ( $K \ll 1$ ) mean? It indicates that the reverse reaction is favored and that there will be more reactants than products when equilibrium is reached. For example, consider the reaction:

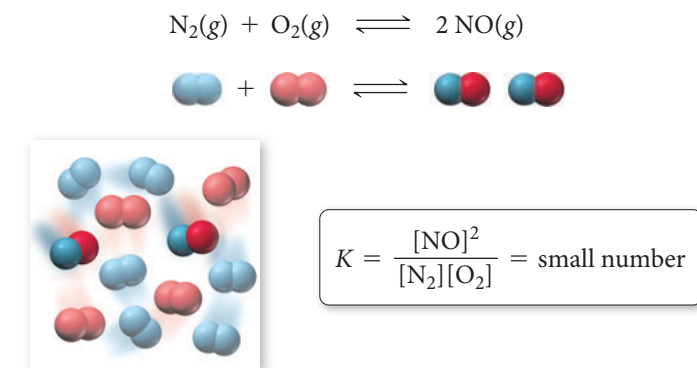

The equilibrium constant is very small, indicating that the equilibrium point for the reaction lies far to the left—high concentrations of reactants, low concentrations of products (Figure 15.5▶). This is fortunate because  $\text{N}_2$  and  $\text{O}_2$  are the main components of air. If this equilibrium constant were large, much of the  $\text{N}_2$  and  $\text{O}_2$  in air would react to form  $\text{NO}$ , a toxic gas.

**Summarizing the Significance of the Equilibrium Constant:**

- ▶  $K \ll 1$  Reverse reaction is favored; forward reaction does not proceed very far.
- ▶  $K \approx 1$  Neither direction is favored; forward reaction proceeds about halfway.
- ▶  $K \gg 1$  Forward reaction is favored; forward reaction proceeds essentially to completion.

▼ **FIGURE 15.4 The Meaning of a Large Equilibrium Constant** If the equilibrium constant for a reaction is large, the equilibrium point of the reaction lies far to the right—the concentration of products is large and the concentration of reactants is small.

▲ **FIGURE 15.5 The Meaning of a Small Equilibrium Constant** If the equilibrium constant for a reaction is small, the equilibrium point of the reaction lies far to the left—the concentration of products is small and the concentration of reactants is large.

CONCEPTUAL  
CONNECTION 15.1

**The Magnitude of the Equilibrium Constant** Consider the reaction  $A(g) \rightleftharpoons B(g)$ . The images shown here illustrate equilibrium mixtures of A (red) and B (black) at three different temperatures. At which temperature is the equilibrium constant the largest?

CONCEPTUAL  
CONNECTION 15.2

**Equilibrium Constants and Equilibrium Concentrations**

The equilibrium constant for the reaction  $A(g) \rightleftharpoons B(g)$  is 10. A reaction mixture initially contains  $[A] = 1.1 \text{ M}$  and  $[B] = 0.0 \text{ M}$ . Which statement is true at equilibrium?

- (a) The reaction mixture contains  $[A] = 1.0 \text{ M}$  and  $[B] = 0.1 \text{ M}$ .
- (b) The reaction mixture contains  $[A] = 0.1 \text{ M}$  and  $[B] = 1.0 \text{ M}$ .
- (c) The reaction mixture contains equal concentrations of A and B.

## Chemistry AND Medicine | Life and Equilibrium

**H**ave you ever tried to define life? If you have, you probably know that a definition is elusive. How are living things different from nonliving things? You may try to define living things as those things that can move. But of course many living things do not move (most plants, for example), and some nonliving things, such as glaciers and Earth itself, do move. So motion is neither unique to nor definitive of life. You may try to define living things as those things that can reproduce. But again, many living things, such as mules or sterile humans, cannot reproduce; yet they are alive. In addition, some nonliving things, such as crystals, for example, reproduce (in some sense). So what is unique about living things?

One definition of life involves the concept of equilibrium—living things *are not* in equilibrium with their surroundings. Our body temperature, for example, is not the same as the temperature of our surroundings. If we jump into a swimming pool, the

◀ What makes these cells alive?

acidity of our blood does not become the same as the acidity of the surrounding water. Living things, even the simplest ones, maintain some measure of *disequilibrium* with their environment.

We must add one more concept, however, to complete our definition of life with respect to equilibrium. A cup of hot water is in disequilibrium with its environment with respect to temperature, yet it is not alive. The cup of hot water has no control over its disequilibrium, however, and will slowly come to equilibrium with its environment. In contrast, living things—as long as they are alive—maintain and *control* their disequilibrium. Your body temperature, for example, is not *only* in disequilibrium with your surroundings—it is in *controlled disequilibrium*. Your body maintains your temperature within a specific range that is not in equilibrium with the surrounding temperature.

So, one criterion for life is that living things are in *controlled disequilibrium* with their environment. Maintaining disequilibrium is a main activity of living organisms, requiring energy obtained from their environment. Plants derive that energy from sunlight; animals eat plants (or other animals that have eaten plants), and thus they too ultimately derive their energy from the sun. A living thing comes into equilibrium with its surroundings only after it dies.

## Relationships between the Equilibrium Constant and the Chemical Equation

If a chemical equation is modified in some way, then the equilibrium constant for the equation changes because of the modification. The following three modifications are common:

- 1. If you reverse the equation, invert the equilibrium constant.** For example, consider this equilibrium equation:

The expression for the equilibrium constant of this reaction is:

$$K_{\text{forward}} = \frac{[C]^3}{[A][B]^2}$$

If you reverse the equation:

then, according to the law of mass action, the expression for the equilibrium constant becomes:

$$K_{\text{reverse}} = \frac{[A][B]^2}{[C]^3} = \frac{1}{K_{\text{forward}}}$$

- 2. If you multiply the coefficients in the equation by a factor, raise the equilibrium constant to the same factor.** Consider again this chemical equation and corresponding expression for the equilibrium constant:

If you multiply the equation by  $n$ , you get:

Applying the law of mass action, the expression for the equilibrium constant becomes:

$$K' = \frac{[C]^{3n}}{[A]^n[B]^{2n}} = \left( \frac{[C]^3}{[A][B]^2} \right)^n = K^n$$

If  $n$  is a fractional quantity, raise  $K$  to the same fractional quantity.

- 3. If you add two or more individual chemical equations to obtain an overall equation, multiply the corresponding equilibrium constants by each other to obtain the overall equilibrium constant.** Consider these two chemical equations and their corresponding equilibrium constant expressions:

The two equations sum as follows:

According to the law of mass action, the equilibrium constant for this overall equation is then:

$$K_{\text{overall}} = \frac{[C]^3}{[A]}$$

Notice that  $K_{\text{overall}}$  is the product of  $K_1$  and  $K_2$ :

$$\begin{aligned} K_{\text{overall}} &= K_1 \times K_2 \\ &= \frac{[B]^2}{[A]} \times \frac{[C]^3}{[B]^2} \\ &= \frac{[C]^3}{[A]} \end{aligned}$$

Remember that  $(x^a)^b = x^{ab}$ .

### CONCEPTUAL CONNECTION 15.3

**The Equilibrium Constant and the Chemical Equation** The reaction  $A(g) \rightleftharpoons 2 B(g)$  has an equilibrium constant of  $K = 0.010$ . What is the equilibrium constant for the reaction  $B(g) \rightleftharpoons \frac{1}{2} A(g)$ ?

- (a) 1      (b) 10      (c) 100      (d) 0.0010

### Example 15.2 Manipulating the Equilibrium Constant to Reflect Changes in the Chemical Equation

Consider the chemical equation and equilibrium constant for the synthesis of ammonia at 25 °C:

Calculate the equilibrium constant for the following reaction at 25 °C:

#### SOLUTION

You want to manipulate the given reaction and value of  $K$  to obtain the desired reaction and value of  $K$ . You can see that the given reaction is the reverse of the desired reaction, and its coefficients are twice those of the desired reaction.

Begin by reversing the given reaction and taking the inverse of the value of $K$ .	$N_2(g) + 3 H_2(g) \rightleftharpoons 2 NH_3(g) \quad K = 5.6 \times 10^5$ $2 NH_3(g) \rightleftharpoons N_2(g) + 3 H_2(g) \quad K_{\text{reverse}} = \frac{1}{5.6 \times 10^5}$
Next, multiply the reaction by $\frac{1}{2}$ and raise the equilibrium constant to the $\frac{1}{2}$ power.	$NH_3(g) \rightleftharpoons \frac{1}{2} N_2(g) + \frac{3}{2} H_2(g)$ $K' = K_{\text{reverse}}^{1/2} = \left( \frac{1}{5.6 \times 10^5} \right)^{1/2}$
Calculate the value of $K'$ .	$K' = 1.3 \times 10^{-3}$

**FOR PRACTICE 15.2** Consider the following chemical equation and equilibrium constant at 25 °C:

Calculate the equilibrium constant for the following reaction at 25 °C:

**FOR MORE PRACTICE 15.2** Predict the equilibrium constant for the first reaction shown here given the equilibrium constants for the second and third reactions:

## 15.4 Expressing the Equilibrium Constant in Terms of Pressure

So far, we have expressed the equilibrium constant only in terms of the *concentrations* of the reactants and products. For gaseous reactions, the partial pressure of a particular gas is proportional to its concentration. Therefore, we can also express the equilibrium constant in terms of the *partial pressures* of the reactants and products. Consider the gaseous reaction:

From this point on, we designate  $K_c$  as the equilibrium constant with respect to concentration in molarity. For the reaction just given, we can express  $K_c$  using the law of mass action:

$$K_c = \frac{[\text{SO}_2]^2[\text{O}_2]}{[\text{SO}_3]^2}$$

We now designate  $K_p$  as the equilibrium constant with respect to partial pressures in atmospheres. *The expression for  $K_p$  takes the form of the expression for  $K_c$ , except that we use the partial pressure of each gas in place of its concentration.* For the  $\text{SO}_3$  reaction, we write  $K_p$  as:

$$K_p = \frac{(P_{\text{SO}_2})^2 P_{\text{O}_2}}{(P_{\text{SO}_3})^2}$$

where  $P_A$  is simply the partial pressure of gas A in units of atmospheres.

## Relationship Between $K_p$ and $K_c$

Since the partial pressure of a gas in atmospheres is not the same as its concentration in molarity, the value of  $K_p$  for a reaction is not necessarily equal to the value of  $K_c$ . However, as long as the gases are behaving ideally, we can derive a relationship between the two constants. The concentration of an ideal gas A is the number of moles of A ( $n_A$ ) divided by its volume ( $V$ ) in liters:

$$[A] = \frac{n_A}{V}$$

From the ideal gas law, we can relate the quantity  $n_A/V$  to the partial pressure of A as follows:

$$P_A V = n_A RT$$

$$P_A = \frac{n_A}{V} RT$$

Since  $[A] = n_A/V$ , we can write:

$$P_A = [A]RT \quad \text{or} \quad [A] = \frac{P_A}{RT} \quad [15.1]$$

Now consider the following general equilibrium chemical equation:

According to the law of mass action, we write  $K_c$  as follows:

$$K_c = \frac{[C]^c [D]^d}{[A]^a [B]^b}$$

Substituting  $[X] = P_X/RT$  for each concentration term, we get:

$$K_c = \frac{\left(\frac{P_C}{RT}\right)^c \left(\frac{P_D}{RT}\right)^d}{\left(\frac{P_A}{RT}\right)^a \left(\frac{P_B}{RT}\right)^b} = \frac{P_C^c P_D^d \left(\frac{1}{RT}\right)^{c+d}}{P_A^a P_B^b \left(\frac{1}{RT}\right)^{a+b}} = \frac{P_C^c P_D^d}{P_A^a P_B^b} \left(\frac{1}{RT}\right)^{c+d-(a+b)}$$

$$= K_p \left(\frac{1}{RT}\right)^{c+d-(a+b)}$$

Rearranging,

$$K_p = K_c (RT)^{c+d-(a+b)}$$

Finally, if we let  $\Delta n = c + d - (a + b)$ , which is the sum of the stoichiometric coefficients of the gaseous products minus the sum of the stoichiometric coefficients of the gaseous reactants, we get the following general result:

$$K_p = K_c (RT)^{\Delta n} \quad [15.2]$$

Notice that if the total number of moles of gas is the same after the reaction as before, then  $\Delta n = 0$ , and  $K_p$  is equal to  $K_c$ .

In the equation  $K_p = K_c (RT)^{\Delta n}$ , the quantity  $\Delta n$  represents the difference between the number of moles of gaseous products and gaseous reactants.

**Example 15.3** Relating  $K_p$  and  $K_c$ 

Nitrogen monoxide, a pollutant in automobile exhaust, is oxidized to nitrogen dioxide in the atmosphere according to the equation:

Find  $K_c$  for this reaction.

**SORT** You are given  $K_p$  for the reaction and asked to find  $K_c$ .

**GIVEN:**  $K_p = 2.2 \times 10^{12}$

**FIND:**  $K_c$

**STRATEGIZE** Use Equation 15.2 to relate  $K_p$  and  $K_c$ .

**EQUATION**  $K_p = K_c(RT)^{\Delta n}$

**SOLVE** Solve the equation for  $K_c$ .

**SOLUTION**

$$K_c = \frac{K_p}{(RT)^{\Delta n}}$$

Calculate  $\Delta n$ .

$$\Delta n = 2 - 3 = -1$$

Substitute the required quantities to calculate  $K_c$ . The temperature must be in kelvins. The units are dropped when reporting  $K_c$  as described later in this section.

$$K_c = \frac{2.2 \times 10^{12}}{\left(0.08206 \frac{\text{L} \cdot \text{atm}}{\text{mol} \cdot \text{K}} \times 298 \text{ K}\right)^{-1}} = 5.4 \times 10^{13}$$

**CHECK** The easiest way to check this answer is to substitute it back into Equation 15.2 and confirm that you get the original value for  $K_p$ .

$$\begin{aligned} K_p &= K_c(RT)^{\Delta n} \\ &= 5.4 \times 10^{13} \left(0.08206 \frac{\text{L} \cdot \text{atm}}{\text{mol} \cdot \text{K}} \times 298 \text{ K}\right)^{-1} \\ &= 2.2 \times 10^{12} \end{aligned}$$

**FOR PRACTICE 15.3** Consider the following reaction and corresponding value of  $K_c$ :

What is the value of  $K_p$  at this temperature?

## Units of $K$

Throughout this book, we express concentrations and partial pressures within the equilibrium constant expression in units of molarity and atmospheres, respectively. When expressing the value of the equilibrium constant, however, we have not included the units. Formally, the values of concentration or partial pressure that we substitute into the equilibrium constant expression are ratios of the concentration or pressure to a reference concentration (exactly 1 M) or a reference pressure (exactly 1 atm).

For example, within the equilibrium constant expression, a pressure of 1.5 atm becomes:

$$\frac{1.5 \text{ atm}}{1 \text{ atm}} = 1.5$$

Similarly, a concentration of 1.5 M becomes:

$$\frac{1.5 \text{ M}}{1 \text{ M}} = 1.5$$

As long as concentration units are expressed in molarity for  $K_c$  and pressure units are expressed in atmospheres for  $K_p$ , we can skip this formality and enter the quantities directly into the equilibrium expression, dropping their corresponding units.

## CONCEPTUAL CONNECTION 15.4

**The Relationship between  $K_p$  and  $K_c$**  Under which circumstances are  $K_p$  and  $K_c$  equal for the reaction shown here?

- (a) If  $a + b = c + d$ .
- (b) If the reaction is reversible.
- (c) If the equilibrium constant is small.

## 15.5 Heterogeneous Equilibria: Reactions Involving Solids and Liquids

Many chemical reactions involve pure solids or pure liquids as reactants or products. Consider, for example, the reaction:

We might expect the expression for the equilibrium constant to be:

$$K_c = \frac{[\text{CO}_2][\text{C}]}{[\text{CO}]^2} \quad (\text{incorrect})$$

However, since carbon is a solid, its concentration is constant (if you double the amount of carbon its *concentration* remains the same). The concentration of a solid does not change because a solid does not expand to fill its container. Its concentration, therefore, depends only on its density, which is constant as long as *some* solid is present (Figure 15.6 ▼). Consequently, pure solids—those reactants or products labeled in the chemical equation with an (s)—are not included in the equilibrium expression (because their constant value is incorporated into the value of  $K$ ). The correct equilibrium expression for this reaction is therefore:

$$K_c = \frac{[\text{CO}_2]}{[\text{CO}]^2}$$

Similarly, the concentration of a pure liquid does not change. So, pure liquids—reactants or products labeled in the chemical equation with an (l)—are also excluded from the equilibrium expression. For example, consider the equilibrium expression for the reaction between carbon dioxide and water:

Since  $\text{H}_2\text{O}(\ell)$  is pure liquid, it is omitted from the equilibrium expression:

$$K_c = \frac{[\text{H}^+][\text{HCO}_3^-]}{[\text{CO}_2]}$$

### A Heterogeneous Equilibrium

**FIGURE 15.6 Heterogeneous Equilibrium** The concentration of solid carbon (the number of atoms per unit volume) is constant as long as some solid carbon is present. The same is true for pure liquids. For this reason, the concentrations of solids and pure liquids are not included in equilibrium constant expressions.

**Example 15.4** Writing Equilibrium Expressions for Reactions Involving a Solid or a Liquid

Write an expression for the equilibrium constant ( $K_c$ ) for this chemical equation:

**SOLUTION**

Since  $\text{CaCO}_3(s)$  and  $\text{CaO}(s)$  are both solids, omit them from the equilibrium expression.

$$K_c = [\text{CO}_2]$$

**FOR PRACTICE 15.4** Write an equilibrium expression ( $K_c$ ) for the equation:

**CONCEPTUAL CONNECTION 15.5**

**Heterogeneous Equilibria,  $K_p$  and  $K_c$**  For which reaction does  $K_p = K_c$ ?

- (a)  $2 \text{Na}_2\text{O}_2(s) + 2 \text{CO}_2(g) \rightleftharpoons 2 \text{Na}_2\text{CO}_3(s) + \text{O}(g)$
- (b)  $\text{Fe}_2\text{O}_3(s) + 3 \text{CO}(g) \rightleftharpoons 2 \text{Fe}(s) + 3 \text{CO}_2(g)$
- (c)  $\text{NH}_4\text{NO}_3(s) \rightleftharpoons \text{N}_2\text{O}(g) + 2 \text{H}_2\text{O}(g)$

## 15.6 Calculating the Equilibrium Constant from Measured Equilibrium Concentrations

The most direct way to obtain an experimental value for the equilibrium constant of a reaction is to measure the concentrations of the reactants and products in a reaction mixture at equilibrium. Consider the following reaction:

Suppose a mixture of  $\text{H}_2$  and  $\text{I}_2$  is allowed to come to equilibrium at  $445^\circ\text{C}$ . The measured equilibrium concentrations are  $[\text{H}_2] = 0.11 \text{ M}$ ,  $[\text{I}_2] = 0.11 \text{ M}$ , and  $[\text{HI}] = 0.78 \text{ M}$ . What is the value of the equilibrium constant at this temperature?

We can write the expression for  $K_c$  from the balanced equation:

$$K_c = \frac{[\text{HI}]^2}{[\text{H}_2][\text{I}_2]}$$

To calculate the value of  $K_c$ , we substitute the correct equilibrium concentrations into the expression for  $K_c$ :

$$\begin{aligned} K_c &= \frac{[\text{HI}]^2}{[\text{H}_2][\text{I}_2]} \\ &= \frac{(0.78)^2}{(0.11)(0.11)} \\ &= 5.0 \times 10^1 \end{aligned}$$

The concentrations within  $K_c$  should always be written in moles per liter (M); however, as noted in Section 15.4, we do not normally include the units when expressing the value of the equilibrium constant, so  $K_c$  is unitless.

For any reaction, the equilibrium *concentrations* of the reactants and products depend on the initial concentrations (and in general vary from one set of initial concentrations to another). However, the equilibrium *constant* is always the same at a given temperature, regardless of the initial concentrations. For example, Table 15.1 shows several different equilibrium concentrations of  $\text{H}_2$ ,  $\text{I}_2$ , and  $\text{HI}$ , each from a different set of

Since equilibrium constants depend on temperature, many equilibrium problems state the temperature even though it has no formal part in the calculation.

**TABLE 15.1** Initial and Equilibrium Concentrations for the Reaction  
 $\text{H}_2(\text{g}) + \text{I}_2(\text{g}) \rightleftharpoons 2 \text{HI}(\text{g})$  at 445 °C

Initial Concentrations			Equilibrium Concentrations			Equilibrium Constant
$[\text{H}_2]$	$[\text{I}_2]$	$[\text{HI}]$	$[\text{H}_2]$	$[\text{I}_2]$	$[\text{HI}]$	$K_c = \frac{[\text{HI}]^2}{[\text{H}_2][\text{I}_2]}$
0.50	0.50	0.0	0.11	0.11	0.78	$\frac{(0.78)^2}{(0.11)(0.11)} = 50$
0.0	0.0	0.50	0.055	0.055	0.39	$\frac{(0.39)^2}{(0.055)(0.055)} = 50$
0.50	0.50	0.50	0.165	0.165	1.17	$\frac{(1.17)^2}{(0.165)(0.165)} = 50$
1.0	0.50	0.0	0.53	0.033	0.934	$\frac{(0.934)^2}{(0.53)(0.033)} = 50$
0.50	1.0	0.0	0.033	0.53	0.934	$\frac{(0.934)^2}{(0.033)(0.53)} = 50$

initial concentrations. Notice that the equilibrium constant is always the same, regardless of the initial concentrations. Whether we start with only reactants or only products, the reaction reaches equilibrium concentrations at which the equilibrium constant is the same. No matter what the initial concentrations are, the reaction always goes in a direction that ensures that the equilibrium concentrations—when substituted into the equilibrium expression—give the same constant,  $K$ .

So far, we have calculated equilibrium constants from values of the equilibrium concentrations of all the reactants and products. In most cases, however, we need only know the initial concentrations of the reactant(s) and the equilibrium concentration of any *one* reactant or product. We can deduce the other equilibrium concentrations from the stoichiometry of the reaction.

For example, consider the simple reaction:

Suppose that we have a reaction mixture in which the initial concentration of A is 1.00 M and the initial concentration of B is 0.00 M. When equilibrium is reached, the concentration of A is 0.75 M. Since  $[\text{A}]$  has changed by  $-0.25 \text{ M}$ , we can deduce (based on the stoichiometry) that  $[\text{B}]$  must have changed by  $2 \times (+0.25 \text{ M})$  or  $+0.50 \text{ M}$ . We summarize the initial conditions, the changes, and the equilibrium conditions in the following table:

	[A]	[B]
Initial	1.00	0.00
Change	$-0.25$	$+2(0.25)$
Equilibrium	0.75	0.50

We refer to this type of table as an ICE table (I = initial, C = change, E = equilibrium). To calculate the equilibrium constant, we use the balanced equation to write an expression for the equilibrium constant and then substitute the equilibrium concentrations from the ICE table:

$$K = \frac{[\text{B}]^2}{[\text{A}]} = \frac{(0.50)^2}{(0.75)} = 0.33$$

In Examples 15.5 and 15.6, we show the general procedure for solving these kinds of equilibrium problems in the left column and work two examples exemplifying the procedure in the center and right columns.

## Procedure for...

## Finding Equilibrium Constants from Experimental Concentration Measurements

To solve these types of problems, follow the given procedure.

- 1. Using the balanced equation as a guide, prepare an ICE table showing the known initial concentrations and equilibrium concentrations of the reactants and products.**

Leave space in the middle of the table for determining the changes in concentration that occur during the reaction.

- 2. For the reactant or product whose concentration is known both initially and at equilibrium, calculate the change in concentration that occurs.**

- 3. Use the change you calculated in step 2 and the stoichiometric relationships from the balanced chemical equation to determine the changes in concentration of all other reactants and products.** Since reactants are consumed during the reaction, the changes in their concentrations are negative. Since products are formed, the changes in their concentrations are positive.

- 4. Sum each column for each reactant and product to determine the equilibrium concentrations.**

- 5. Use the balanced equation to write an expression for the equilibrium constant and substitute the equilibrium concentrations to calculate  $K$ .**

## Example 15.5

## Finding Equilibrium Constants from Experimental Concentration Measurements

Consider the following reaction:

A reaction mixture at 780 °C initially contains  $[\text{CO}] = 0.500 \text{ M}$  and  $[\text{H}_2] = 1.00 \text{ M}$ . At equilibrium, the CO concentration is found to be 0.15 M. What is the value of the equilibrium constant?

	[CO]	[H <sub>2</sub> ]	[CH <sub>3</sub> OH]
Initial	0.500	1.00	0.00
Change			
Equil	0.15		

	[CO]	[H <sub>2</sub> ]	[CH <sub>3</sub> OH]
Initial	0.500	1.00	0.00
Change	-0.35		
Equil	0.15		

	[CO]	[H <sub>2</sub> ]	[CH <sub>3</sub> OH]
Initial	0.500	1.00	0.00
Change	-0.35	-2(0.35)	+0.35
Equil	0.15		

	[CO]	[H <sub>2</sub> ]	[CH <sub>3</sub> OH]
Initial	0.500	1.00	0.00
Change	-0.35	-0.70	+0.35
Equil	0.15	0.30	0.35

$$\begin{aligned}
 K_c &= \frac{[\text{CH}_3\text{OH}]}{[\text{CO}][\text{H}_2]^2} \\
 &= \frac{0.35}{(0.15)(0.30)^2} \\
 &= 26
 \end{aligned}$$

## Example 15.6

## Finding Equilibrium Constants from Experimental Concentration Measurements

Consider the following reaction:

A reaction mixture at 1700 °C initially contains  $[\text{CH}_4] = 0.115 \text{ M}$ . At equilibrium, the mixture contains  $[\text{C}_2\text{H}_2] = 0.035 \text{ M}$ . What is the value of the equilibrium constant?

	[CH <sub>4</sub> ]	[C <sub>2</sub> H <sub>2</sub> ]	[H <sub>2</sub> ]
Initial	0.115	0.00	0.00
Change			
Equil		0.035	

	[CH <sub>4</sub> ]	[C <sub>2</sub> H <sub>2</sub> ]	[H <sub>2</sub> ]
Initial	0.115	0.00	0.00
Change		+0.035	
Equil		0.035	

	[CH <sub>4</sub> ]	[C <sub>2</sub> H <sub>2</sub> ]	[H <sub>2</sub> ]
Initial	0.115	0.00	0.00
Change	-2(0.035)	+0.035	+3(0.035)
Equil		0.035	

	[CH <sub>4</sub> ]	[C <sub>2</sub> H <sub>2</sub> ]	[H <sub>2</sub> ]
Initial	0.115	0.00	0.00
Change	-0.070	+0.035	+0.105
Equil	0.045	0.035	0.105

$$\begin{aligned}
 K_c &= \frac{[\text{C}_2\text{H}_2][\text{H}_2]^3}{[\text{CH}_4]^2} \\
 &= \frac{(0.035)(0.105)^3}{(0.045)^2} \\
 &= 0.020
 \end{aligned}$$

**FOR PRACTICE 15.5** The reaction in Example 15.5 between CO and H<sub>2</sub> is carried out at a different temperature with initial concentrations of [CO] = 0.27 M and [H<sub>2</sub>] = 0.49 M. At equilibrium, the concentration of CH<sub>3</sub>OH is 0.11 M. Find the equilibrium constant at this temperature.

**FOR PRACTICE 15.6** The reaction of CH<sub>4</sub> in Example 15.6 is carried out at a different temperature with an initial concentration of [CH<sub>4</sub>] = 0.087 M. At equilibrium, the concentration of H<sub>2</sub> is 0.012 M. Find the equilibrium constant at this temperature.

## 15.7 The Reaction Quotient: Predicting the Direction of Change

When the reactants of a chemical reaction mix, they generally react to form products—we say that the reaction proceeds to the right (toward the products). The amount of products that forms when a reaction reaches equilibrium depends on the magnitude of the equilibrium constant, as we have seen. However, what if a reaction mixture that is not at equilibrium contains both reactants *and* products? Can we predict the direction of change for such a mixture?

To gauge the progress of a reaction relative to equilibrium, we use a quantity called the *reaction quotient*. The definition of the reaction quotient takes the same form as the definition of the equilibrium constant, except that the reaction need not be at equilibrium. So, for the general reaction:

we define the **reaction quotient ( $Q_c$ )** as the ratio—at any point in the reaction—of the concentrations of the products raised to their stoichiometric coefficients divided by the concentrations of the reactants raised to their stoichiometric coefficients. For gases with amounts measured in atmospheres, the reaction quotient uses the partial pressures in place of concentrations and is called  $Q_p$ :

$$Q_c = \frac{[C]^c[D]^d}{[A]^a[B]^b} \quad Q_p = \frac{P_C^c P_D^d}{P_A^a P_B^b}$$

The difference between the reaction quotient and the equilibrium constant is that, at a given temperature, the equilibrium constant has only one value and it specifies the relative amounts of reactants and products *at equilibrium*. The reaction quotient, by contrast, depends on the current state of the reaction and has many different values as the reaction proceeds. For example, in a reaction mixture containing only reactants, the reaction quotient is zero ( $Q_c = 0$ ):

$$Q_c = \frac{[O]^c[O]^d}{[A]^a[B]^b} = 0$$

In a reaction mixture containing only products, the reaction quotient is infinite ( $Q_c = \infty$ ):

$$Q_c = \frac{[C]^c[D]^d}{[O]^a[O]^b} = \infty$$

In a reaction mixture containing both reactants and products, each at a concentration of 1 M, the reaction quotient is one ( $Q_c = 1$ ):

$$Q_c = \frac{(1)^c(1)^d}{(1)^a(1)^b} = 1$$

The reaction quotient is useful because *the value of  $Q$  relative to  $K$  is a measure of the progress of the reaction toward equilibrium. At equilibrium, the reaction quotient is*

## Q, K, and the Direction of a Reaction

**▲ FIGURE 15.7 Q, K, and the Direction of a Reaction** The graph shows a plot of  $Q$  as a function of the concentrations of the reactants and products in a simple reaction  $A \rightleftharpoons B$ , in which  $K = 1.45$  and the sum of the reactant and product concentrations is 1 M. The far left of the graph represents pure reactant and the far right represents pure product. The midpoint of the graph represents an equal mixture of A and B. When  $Q$  is less than  $K$ , the reaction moves in the forward direction ( $A \rightarrow B$ ). When  $Q$  is greater than  $K$ , the reaction moves in the reverse direction ( $A \leftarrow B$ ). When  $Q$  is equal to  $K$ , the reaction is at equilibrium.

equal to the equilibrium constant. Figure 15.7▲ shows a plot of  $Q$  as a function of the concentrations of A and B for the simple reaction  $A(g) \rightleftharpoons B(g)$ , which has an equilibrium constant of  $K = 1.45$ . The following points are representative of three possible conditions:

$Q$	$K$	Predicted Direction of Reaction
0.55	1.45	To the right (toward products)
2.55	1.45	To the left (toward reactants)
1.45	1.45	No change (at equilibrium)

For the first set of values in the table,  $Q$  is less than  $K$  and must therefore get larger as the reaction proceeds toward equilibrium.  $Q$  becomes larger as the reactant concentration decreases and the product concentration increases—the reaction proceeds to the right. For the second set of values,  $Q$  is greater than  $K$  and must therefore get smaller as the reaction proceeds toward equilibrium.  $Q$  gets smaller as the reactant concentration increases and the product concentration decreases—the reaction proceeds to the left. In the third set of values,  $Q = K$ , implying that the reaction is at equilibrium—the reaction will not proceed in either direction.

#### Summarizing Direction of Change Predictions:

The reaction quotient ( $Q$ ) relative to the equilibrium constant ( $K$ ) is a measure of the progress of a reaction toward equilibrium.

- ▶  $Q < K$  Reaction goes to the right (toward products).
- ▶  $Q > K$  Reaction goes to the left (toward reactants).
- ▶  $Q = K$  Reaction is at equilibrium.

**Example 15.7** Predicting the Direction of a Reaction by Comparing  $Q$  and  $K$ 

Consider the reaction and its equilibrium constant at 25.0 °C:

A reaction mixture contains  $P_{\text{I}_2} = 0.114 \text{ atm}$ ,  $P_{\text{Cl}_2} = 0.102 \text{ atm}$ , and  $P_{\text{ICl}} = 0.355 \text{ atm}$ . Is the reaction mixture at equilibrium? If not, in which direction will the reaction proceed?

**SOLUTION**

To determine the progress of the reaction relative to the equilibrium state, first calculate  $Q$ .

$$\begin{aligned} Q_p &= \left( \frac{P_{\text{ICl}}^2}{P_{\text{I}_2} P_{\text{Cl}_2}} \right) \\ &= \frac{(0.355)^2}{(0.114)(0.102)} \\ &= 10.8 \end{aligned}$$

Compare  $Q$  to  $K$ .

$Q_p = 10.8$ ;  $K_p = 81.9$   
Since  $Q_p < K_p$ , the reaction is not at equilibrium and will proceed to the right.

**FOR PRACTICE 15.7** Consider the reaction and its equilibrium constant:

A reaction mixture contains  $[\text{NO}_2] = 0.0255 \text{ M}$  and  $[\text{N}_2\text{O}_4] = 0.0331 \text{ M}$ . Calculate  $Q_c$  and determine the direction in which the reaction will proceed.

**Q and K** For the reaction  $\text{N}_2\text{O}_4(\text{g}) \rightleftharpoons 2 \text{NO}_2(\text{g})$ , a reaction mixture at a certain temperature initially contains both  $\text{N}_2\text{O}_4$  and  $\text{NO}_2$  in their standard states (see the definition of standard state in Section 6.9). If  $K_p = 0.15$ , which statement is true of the reaction mixture before any reaction occurs?

- (a)  $Q = K$ ; the reaction is at equilibrium.
- (b)  $Q < K$ ; the reaction will proceed to the right.
- (c)  $Q > K$ ; the reaction will proceed to the left.

**CONCEPTUAL CONNECTION 15.6****15.8 Finding Equilibrium Concentrations**

In Section 15.6, we discussed how to calculate an equilibrium constant from the equilibrium concentrations of the reactants and products. Just as commonly we will want to calculate equilibrium concentrations of reactants or products from the equilibrium constant. These kinds of calculations are important because they allow us to calculate the amount of a reactant or product at equilibrium. For example, in a synthesis reaction, we might want to know how much of the product forms when the reaction reaches equilibrium. Or for the hemoglobin–oxygen equilibrium discussed in Section 15.1, we might want to know the concentration of oxygenated hemoglobin present under certain oxygen concentrations within the lungs or muscles.

We divide these types of problems into two categories: (1) finding equilibrium concentrations when we know the equilibrium constant and all but one of the equilibrium concentrations of the reactants and products, and (2) finding equilibrium

**Finding Equilibrium Concentrations from Initial Concentrations**

concentrations when we know the equilibrium constant and only initial concentrations. The second category of problem is more difficult than the first. Let's examine each separately.

### Finding Equilibrium Concentrations from the Equilibrium Constant and All but One of the Equilibrium Concentrations of the Reactants and Products

We can use the equilibrium constant to calculate the equilibrium concentration of one of the reactants or products, given the equilibrium concentrations of the others. To solve this type of problem, we follow our general problem-solving procedure.

#### Example 15.8 Finding Equilibrium Concentrations When You Know the Equilibrium Constant and All but One of the Equilibrium Concentrations of the Reactants and Products

Consider the following reaction:

In an equilibrium mixture, the concentration of  $\text{COF}_2$  is 0.255 M and the concentration of  $\text{CF}_4$  is 0.118 M. What is the equilibrium concentration of  $\text{CO}_2$ ?

**SORT** You are given the equilibrium constant of a chemical reaction, together with the equilibrium concentrations of the reactant and one product. You are asked to find the equilibrium concentration of the other product.

**GIVEN:**  $[\text{COF}_2] = 0.255 \text{ M}$   
 $[\text{CF}_4] = 0.118 \text{ M}$   
 $K_c = 2.00$

**FIND:**  $[\text{CO}_2]$

**STRATEGIZE** Calculate the concentration of the product using the given quantities and the expression for  $K_c$ .

**CONCEPTUAL PLAN**

**SOLVE** Solve the equilibrium expression for  $[\text{CO}_2]$  and then substitute in the appropriate values to calculate it.

**SOLUTION**

$$[\text{CO}_2] = K_c \frac{[\text{COF}_2]^2}{[\text{CF}_4]}$$

$$[\text{CO}_2] = 2.00 \left( \frac{(0.255)^2}{0.118} \right) = 1.10 \text{ M}$$

**CHECK** Check your answer by mentally substituting the given values of  $[\text{COF}_2]$  and  $[\text{CF}_4]$  as well as your calculated value for  $\text{CO}_2$  back into the equilibrium expression:

$$K_c = \frac{[\text{CO}_2][\text{CF}_4]}{[\text{COF}_2]^2}$$

$[\text{CO}_2]$  is roughly equal to 1.  $[\text{COF}_2]^2 \approx 0.06$  and  $[\text{CF}_4] \approx 0.12$ . Therefore  $K_c$  is approximately 2, as given in the problem.

**FOR PRACTICE 15.8** Diatomic iodine  $[\text{I}_2]$  decomposes at high temperature to form I atoms according to the reaction:

In an equilibrium mixture, the concentration of  $\text{I}_2$  is 0.10 M. What is the equilibrium concentration of I?

## Finding Equilibrium Concentrations from the Equilibrium Constant and Initial Concentrations or Pressures

More commonly, we know the equilibrium constant and only initial concentrations of reactants and need to find the *equilibrium concentrations* of the reactants or products. These kinds of problems are generally more involved than those we just examined and require a specific procedure to solve them. The procedure has some similarities to the one used in Examples 15.5 and 15.6 in that we set up an ICE table showing the initial concentrations, the changes, and the equilibrium concentrations. However, unlike in Examples 15.5 and 15.6, here the changes in concentration are not known and are represented with the variable  $x$ .

For example, consider again the simple reaction:

Suppose that, as before (see Section 15.6), we have a reaction mixture in which the initial concentration of A is 1.0 M and the initial concentration of B is 0.00 M. However, now we know the equilibrium constant,  $K = 0.33$ , and want to find the equilibrium concentrations. We know that because  $Q = 0$ , the reaction proceeds to the right (towards the products). We set up the ICE table with the given initial concentrations and then *represent the unknown change in [A] with the variable  $x$*  as follows:

	[A]	[B]
Initial	1.0	0.00
Change	$-x$	$+2x$
Equil	$1.0 - x$	$2x$

Represent changes from initial conditions with the variable  $x$ .

Notice that, due to the stoichiometry of the reaction, the change in [B] must be  $+2x$ . As before, each *equilibrium* concentration is the sum of the two entries above it in the ICE table. In order to find the equilibrium concentrations of A and B, we must find the value of the variable  $x$ . Since we know the value of the equilibrium constant, we can use the equilibrium constant expression to set up an equation in which  $x$  is the only variable:

$$K = \frac{[\text{B}]^2}{[\text{A}]} = \frac{(2x)^2}{1.0 - x} = 0.33$$

or more simply:

$$\frac{4x^2}{1.0 - x} = 0.33$$

This equation is a *quadratic* equation—it contains the variable  $x$  raised to the second power. In general, we can solve quadratic equations with the quadratic formula (see Appendix IC), which we introduce in Example 15.10. If the quadratic equation is a perfect square, however, we can solve it by simpler means, as shown in Example 15.9. For both of these examples, we give the general procedure in the left column and apply the procedure to the two different example problems in the center and right columns. Later in this section, we see that quadratic equations can often be simplified by making some approximations based on our chemical knowledge.

## Procedure for...

**Finding Equilibrium Concentrations from Initial Concentrations and the Equilibrium Constant**

To solve these types of problems, follow the given procedure.

**1. Using the balanced equation as a guide, prepare a table showing the known initial concentrations of the reactants and products.** Leave room in the table for the changes in concentrations and for the equilibrium concentrations.

**2. Use the initial concentrations to calculate the reaction quotient ( $Q$ ) for the initial concentrations. Compare  $Q$  to  $K$  to predict the direction in which the reaction proceeds.**

**3. Represent the change in the concentration of one of the reactants or products with the variable  $x$ . Define the changes in the concentrations of the other reactants or products in terms of  $x$ .** It is usually most convenient to let  $x$  represent the change in concentration of the reactant or product with the smallest stoichiometric coefficient.

**4. Sum each column for each reactant and each product to determine the equilibrium concentrations in terms of the initial concentrations and the variable  $x$ .**

**Example 15.9**

**Finding Equilibrium Concentrations from Initial Concentrations and the Equilibrium Constant**

Consider the reaction:

$$K_c = 0.10 \text{ (at } 2000^\circ\text{C)}$$

A reaction mixture at  $2000^\circ\text{C}$  initially contains  $[\text{N}_2] = 0.200 \text{ M}$  and  $[\text{O}_2] = 0.200 \text{ M}$ . Find the equilibrium concentrations of the reactants and product at this temperature.

	$[\text{N}_2]$	$[\text{O}_2]$	$[\text{NO}]$
Initial	0.200	0.200	0.00
Change			
Equil			

$$Q_c = \frac{[\text{NO}]^2}{[\text{N}_2][\text{O}_2]} = \frac{(0.00)^2}{(0.200)(0.200)} = 0$$

$Q < K$ ; therefore, the reaction will proceed to the right.

	$[\text{N}_2]$	$[\text{O}_2]$	$[\text{NO}]$
Initial	0.200	0.200	0.00
Change	$-x$	$-x$	$+2x$
Equil			

	$[\text{N}_2]$	$[\text{O}_2]$	$[\text{NO}]$
Initial	0.200	0.200	0.00
Change	$-x$	$-x$	$+2x$
Equil	$0.200 - x$	$0.200 - x$	$2x$

**Example 15.10**
**Finding Equilibrium Concentrations from Initial Concentrations and the Equilibrium Constant**

Consider the reaction:

$$K_c = 0.36 \text{ (at } 100^\circ\text{C)}$$

A reaction mixture at  $100^\circ\text{C}$  initially contains  $[\text{NO}_2] = 0.100 \text{ M}$ . Find the equilibrium concentrations of  $\text{NO}_2$  and  $\text{N}_2\text{O}_4$  at this temperature.

	$[\text{N}_2\text{O}_4]$	$[\text{NO}_2]$
Initial	0.00	0.100
Change		
Equil		

$$Q_c = \frac{[\text{NO}_2]^2}{[\text{N}_2\text{O}_4]} = \frac{(0.100)^2}{0.00} = \infty$$

$Q > K$ ; therefore, the reaction will proceed to the left.

	$[\text{N}_2\text{O}_4]$	$[\text{NO}_2]$
Initial	0.00	0.100
Change	$+x$	$-2x$
Equil		

	$[\text{N}_2\text{O}_4]$	$[\text{NO}_2]$
Initial	0.00	0.100
Change	$+x$	$-2x$
Equil	$x$	$0.100 - 2x$

<p><b>5. Substitute the expressions for the equilibrium concentrations (from step 4) into the expression for the equilibrium constant. Using the given value of the equilibrium constant, solve the expression for the variable <math>x</math>.</b> In some cases, such as Example 15.9, you can take the square root of both sides of the expression to solve for <math>x</math>. In other cases, such as Example 15.10, you must solve a quadratic equation to find <math>x</math>. Remember the quadratic formula:</p> $ax^2 + bx + c = 0$ $x = \frac{-b \pm \sqrt{b^2 - 4ac}}{2a}$	$K_c = \frac{[\text{NO}]^2}{[\text{N}_2][\text{O}_2]}$ $= \frac{(2x)^2}{(0.200 - x)(0.200 - x)}$ $0.10 = \frac{(2x)^2}{(0.200 - x)^2}$ $\sqrt{0.10} = \frac{2x}{0.200 - x}$ $\sqrt{0.10} (0.200 - x) = 2x$ $\sqrt{0.10} (0.200) - \sqrt{0.10} x = 2x$ $0.063 = 2x + \sqrt{0.10} x$ $0.063 = 2.3x$ $x = 0.027$	$K_c = \frac{[\text{NO}_2]^2}{[\text{N}_2\text{O}_4]}$ $= \frac{(0.100 - 2x)^2}{x}$ $0.36 = \frac{0.0100 - 0.400x + 4x^2}{x}$ $0.36x = 0.0100 - 0.400x + 4x^2$ $4x^2 - 0.76x + 0.0100 = 0 \text{ (quadratic)}$ $x = \frac{-b \pm \sqrt{b^2 - 4ac}}{2a}$ $= \frac{-(-0.76) \pm \sqrt{(-0.76)^2 - 4(4)(0.0100)}}{2(4)}$ $= \frac{0.76 \pm 0.65}{8}$ $x = 0.176 \text{ or } x = 0.014$
<p><b>6. Substitute <math>x</math> into the expressions for the equilibrium concentrations of the reactants and products (from step 4) and calculate the concentrations.</b> In cases where you solved a quadratic and have two values for <math>x</math>, choose the value for <math>x</math> that gives a physically realistic answer. For example, reject the value of <math>x</math> that results in any negative concentrations.</p>	$[\text{N}_2] = 0.200 - 0.027$ $= 0.173 \text{ M}$ $[\text{O}_2] = 0.200 - 0.027$ $= 0.173 \text{ M}$ $[\text{NO}] = 2(0.027)$ $= 0.054 \text{ M}$	<p>We reject the root <math>x = 0.176</math> because it gives a negative concentration for <math>\text{NO}_2</math>. Using <math>x = 0.014</math>, we get the following concentrations:</p> $[\text{NO}_2] = 0.100 - 2x$ $= 0.100 - 2(0.014) = 0.072 \text{ M}$ $[\text{N}_2\text{O}_4] = x$ $= 0.014 \text{ M}$
<p><b>7. Check your answer by substituting the calculated equilibrium values into the equilibrium expression. The calculated value of <math>K</math> should match the given value of <math>K</math>.</b> Note that rounding errors could cause a difference in the least significant digit when comparing values of the equilibrium constant.</p>	$K_c = \frac{[\text{NO}]^2}{[\text{N}_2][\text{O}_2]}$ $= \frac{(0.054)^2}{(0.173)(0.173)} = 0.097$ <p>Since the calculated value of <math>K_c</math> matches the given value (to within one digit in the least significant figure), the answer is valid.</p>	$K_c = \frac{[\text{NO}_2]^2}{[\text{N}_2\text{O}_4]} = \frac{(0.072)^2}{0.014}$ $= 0.37$ <p>Since the calculated value of <math>K_c</math> matches the given value (to within one digit in the least significant figure), the answer is valid.</p>
	<p><b>FOR PRACTICE 15.9</b></p> <p>The reaction in Example 15.9 is carried out at a different temperature at which <math>K_c = 0.055</math>. This time, however, the reaction mixture starts with only the product, <math>[\text{NO}] = 0.0100 \text{ M}</math>, and no reactants. Find the equilibrium concentrations of <math>\text{N}_2</math>, <math>\text{O}_2</math>, and <math>\text{NO}</math> at equilibrium.</p>	<p><b>FOR PRACTICE 15.10</b></p> <p>The reaction in Example 15.10 is carried out at the same temperature, but this time the reaction mixture initially contains only the reactant, <math>[\text{N}_2\text{O}_4] = 0.0250 \text{ M}</math>, and no <math>\text{NO}_2</math>. Find the equilibrium concentrations of <math>\text{N}_2\text{O}_4</math> and <math>\text{NO}_2</math>.</p>

When the initial conditions are given in terms of partial pressures (instead of concentrations) and the equilibrium constant is given as  $K_p$  instead of  $K_c$ , use the same procedure, but substitute partial pressures for concentrations, as shown in Example 15.11.

### Example 15.11 Finding Equilibrium Partial Pressures When You Are Given the Equilibrium Constant and Initial Partial Pressures

Consider the reaction:

A reaction mixture at  $25^\circ\text{C}$  initially contains  $P_{\text{I}_2} = 0.100 \text{ atm}$ ,  $P_{\text{Cl}_2} = 0.100 \text{ atm}$ , and  $P_{\text{ICl}} = 0.100 \text{ atm}$ . Find the equilibrium partial pressures of  $\text{I}_2$ ,  $\text{Cl}_2$ , and  $\text{ICl}$  at this temperature.

#### SOLUTION

Follow the procedure used in Examples 15.5 and 15.6 (using partial pressures in place of concentrations) to solve the problem.

1. Using the balanced equation as a guide, prepare an ICE table showing the known initial partial pressures of the reactants and products.

$$\text{I}_2(\text{g}) + \text{Cl}_2(\text{g}) \rightleftharpoons 2 \text{ICl}(\text{g})$$

	$P_{\text{I}_2} \text{ (atm)}$	$P_{\text{Cl}_2} \text{ (atm)}$	$P_{\text{ICl}} \text{ (atm)}$
Initial	0.100	0.100	0.100
Change			
Equil			

2. Use the initial partial pressures to calculate the reaction quotient ( $Q$ ). Compare  $Q$  to  $K$  to predict the direction in which the reaction will proceed.

$$Q_p = \frac{(P_{\text{ICl}})^2}{P_{\text{I}_2}P_{\text{Cl}_2}} = \frac{(0.100)^2}{(0.100)(0.100)} = 1$$

$K_p = 81.9$  (given)  
 $Q < K$ ; therefore, the reaction will proceed to the right.

3. Represent the change in the partial pressure of one of the reactants or products with the variable  $x$ . Define the changes in the partial pressures of the other reactants or products in terms of  $x$ .

$$\text{I}_2(\text{g}) + \text{Cl}_2(\text{g}) \rightleftharpoons 2 \text{ICl}(\text{g})$$

	$P_{\text{I}_2} \text{ (atm)}$	$P_{\text{Cl}_2} \text{ (atm)}$	$P_{\text{ICl}} \text{ (atm)}$
Initial	0.100	0.100	0.100
Change	$-x$	$-x$	$+2x$
Equil			

4. Sum each column for each reactant and product to determine the equilibrium partial pressures in terms of the initial partial pressures and the variable  $x$ .

$$\text{I}_2(\text{g}) + \text{Cl}_2(\text{g}) \rightleftharpoons 2 \text{ICl}(\text{g})$$

	$P_{\text{I}_2} \text{ (atm)}$	$P_{\text{Cl}_2} \text{ (atm)}$	$P_{\text{ICl}} \text{ (atm)}$
Initial	0.100	0.100	0.100
Change	$-x$	$-x$	$+2x$
Equil	$0.100 - x$	$0.100 - x$	$0.100 + 2x$

5. Substitute the expressions for the equilibrium partial pressures (from step 4) into the expression for the equilibrium constant. Use the given value of the equilibrium constant to solve the expression for the variable  $x$ .

$$K_p = \frac{(P_{\text{ICl}})^2}{P_{\text{I}_2}P_{\text{Cl}_2}} = \frac{(0.100 + 2x)^2}{(0.100 - x)(0.100 - x)}$$

$$81.9 = \frac{(0.100 + 2x)^2}{(0.100 - x)^2} \quad (\text{perfect square})$$

$$\sqrt{81.9} = \frac{(0.100 + 2x)}{(0.100 - x)}$$

$$\sqrt{81.9}(0.100 - x) = 0.100 + 2x$$

$$\sqrt{81.9}(0.100) - \sqrt{81.9}x = 0.100 + 2x$$

$$\sqrt{81.9}(0.100) - 0.100 = 2x + \sqrt{81.9}x$$

$$0.805 = 11.05x$$

$$x = 0.0729$$

6. Substitute  $x$  into the expressions for the equilibrium partial pressures of the reactants and products (from step 4) and calculate the partial pressures.

$$P_{\text{I}_2} = 0.100 - 0.0729 = 0.027 \text{ atm}$$

$$P_{\text{Cl}_2} = 0.100 - 0.0729 = 0.027 \text{ atm}$$

$$P_{\text{ICl}} = 0.100 + 2(0.0729) = 0.246 \text{ atm}$$

7. Check your answer by substituting the calculated equilibrium partial pressures into the equilibrium expression. The calculated value of  $K$  should match the given value of  $K$ .

$$K_p = \frac{(P_{\text{ICl}})^2}{P_{\text{I}_2}P_{\text{Cl}_2}} = \frac{(0.246)^2}{(0.027)(0.027)} = 83$$

Since the calculated value of  $K_p$  matches the given value (within the uncertainty indicated by the significant figures), the answer is valid.

**FOR PRACTICE 15.11** The reaction between  $\text{I}_2$  and  $\text{Cl}_2$  in Example 15.11 is carried out at the same temperature, but with these initial partial pressures:  $P_{\text{I}_2} = 0.150 \text{ atm}$ ,  $P_{\text{Cl}_2} = 0.150 \text{ atm}$ ,  $P_{\text{ICl}} = 0.00 \text{ atm}$ . Find the equilibrium partial pressures of all three substances.

## Simplifying Approximations in Working Equilibrium Problems

For some equilibrium problems of the type shown in Examples 15.9, 15.10, and 15.11, we can make an approximation that simplifies the calculations without any significant loss of accuracy. For example, if the equilibrium constant is relatively small, the reaction will not proceed very far to the right. Therefore, if the initial reactant concentration is relatively large, we can make the assumption that  $x$  is small relative to the initial concentration of reactant.

To see how this approximation works, consider again the simple reaction  $\text{A} \rightleftharpoons 2 \text{B}$ . Suppose that, as before, we have a reaction mixture in which the initial concentration of A is 1.0 M and the initial concentration of B is 0.0 M and that we want to find the equilibrium concentrations. However, suppose that in this case the equilibrium constant is much smaller, say  $K = 3.3 \times 10^{-5}$ . The ICE table is identical to the one we set up previously:

	[A]	[B]
Initial	1.0	0.0
Change	$-x$	$+2x$
Equil	$1.0 - x$	$2x$

Except for the value of  $K$ , we end up with the exact quadratic equation that we had before:

$$K = \frac{[\text{B}]^2}{[\text{A}]} = \frac{(2x)^2}{1.0 - x} = 3.3 \times 10^{-5}$$

or more simply:

$$\frac{4x^2}{1.0 - x} = 3.3 \times 10^{-5}$$

We can rearrange this quadratic equation into standard form and solve it using the quadratic formula. But since  $K$  is small, the reaction will not proceed very far toward products and, therefore,  $x$  will also be small. If  $x$  is much smaller than 1.0, then  $(1.0 - x)$  (the quantity in the denominator) can be approximated by (1.0):

$$\frac{4x^2}{(1.0 - x)} = 3.3 \times 10^{-5}$$

This approximation greatly simplifies the equation, which we can then solve for  $x$  as follows:

$$\begin{aligned} \frac{4x^2}{1.0} &= 3.3 \times 10^{-5} \\ 4x^2 &= 3.3 \times 10^{-5} \\ x &= \sqrt{\frac{3.3 \times 10^{-5}}{4}} = 0.0029 \end{aligned}$$

We can check the validity of this approximation by comparing the calculated value of  $x$  to the number it was subtracted from. The ratio of  $x$  to the number it is subtracted from should be less than 0.05 (or 5%) for the approximation to be valid. In this case, we subtracted  $x$  from 1.0, and we calculate the ratio of the value of  $x$  to 1.0 as follows:

$$\frac{0.0029}{1.0} \times 100\% = 0.29\%$$

The approximation is therefore valid.

In Examples 15.12 and 15.13, we treat two nearly identical problems—the only difference is the initial concentration of the reactant. In Example 15.12, the initial concentration of the reactant is relatively large, the equilibrium constant is small, and the  $x$  is *small* approximation works well. In Example 15.13, however, the initial concentration of the reactant is much smaller, and even though the equilibrium constant is the same, the  $x$  is *small* approximation does not work (because the initial concentration is also small). In cases such as this, we have a couple of options to solve the problem. We can either solve the equation exactly (using the quadratic formula, for example), or we can use the *method of successive approximations*, which is introduced in Example 15.13. In this method, we essentially solve for  $x$  as if it were small, and then substitute the value obtained back into the equation (where  $x$  was initially neglected) to solve for  $x$  again. We repeat this process until the calculated value of  $x$  stops changing with each iteration, an indication that we have arrived at an acceptable value for  $x$ .

Note that the  $x$  is *small* approximation does not imply that  $x$  is *zero*. If that were the case, the reactant and product concentrations would not change from their initial values. The  $x$  is *small* approximation just means that when  $x$  is added or subtracted to another number, it does not change that number by very much. For example, we can calculate the value of the difference  $1.0 - x$  when  $x = 3.0 \times 10^{-4}$ :

$$1.0 - x = 1.0 - 3.0 \times 10^{-4} = 0.9997 = 1.0$$

Since the value of 1.0 is known only to two significant figures, subtracting the small  $x$  does not change the value at all. This situation is similar to weighing yourself on a bathroom scale with and without a penny in your pocket. Unless your scale is unusually precise, removing the penny from your pocket will not change the reading on the scale. This does not imply that the penny is weightless, only that its weight is small when compared to your body weight. You can neglect the weight of the penny in reading your weight with no detectable loss in accuracy.

## Procedure for...

### Finding Equilibrium Concentrations from Initial Concentrations in Cases with a Small Equilibrium Constant

To solve these types of problems, follow the given procedure.

- Using the balanced equation as a guide, prepare a table showing the known initial concentrations of the reactants and products. (In these examples, you first calculate the concentration of  $\text{H}_2\text{S}$  from the given number of moles and volume.)

### Example 15.12

#### Finding Equilibrium Concentrations from Initial Concentrations in Cases with a Small Equilibrium Constant

Consider the reaction for the decomposition of hydrogen disulfide:

$$K_c = 1.67 \times 10^{-7} \text{ at } 800^\circ\text{C}$$

A 0.500-L reaction vessel initially contains 0.0125 mol of  $\text{H}_2\text{S}$  at  $800^\circ\text{C}$ . Find the equilibrium concentrations of  $\text{H}_2$  and  $\text{S}_2$ .

$$[\text{H}_2\text{S}] = \frac{0.0125 \text{ mol}}{0.500 \text{ L}} = 0.0250 \text{ M}$$

	$[\text{H}_2\text{S}]$	$[\text{H}_2]$	$[\text{S}_2]$

5. Substitute the expressions for the equilibrium concentrations (from step 4) into the expression for the equilibrium constant. Use the given value of the equilibrium constant to solve the resulting equation for the variable $x$ . In this case, the resulting equation is cubic in $x$ . Although cubic equations can be solved, the solutions are not usually simple. However, since the equilibrium constant is small, we know that the reaction does not proceed very far to the right. Therefore, $x$ is a small number and can be dropped from any quantities in which it is added to or subtracted from another number (as long as the number itself is not too small).  Check whether your approximation is valid by comparing the calculated value of $x$ to the number it was added to or subtracted from. The ratio of the two numbers should be less than 0.05 (or 5%) for the approximation to be valid. If the approximation is not valid, proceed to step 5a.	$K_c = \frac{[\text{H}_2]^2[\text{S}_2]}{[\text{H}_2\text{S}]^2}$ $= \frac{(2x)^2x}{(0.0250 - 2x)^2}$ $1.67 \times 10^{-7} = \frac{4x^3}{(0.0250 - 2x)^2}$ $1.67 \times 10^{-7} = \frac{4x^3}{(0.0250 - 2x)^2} \quad \text{\textit{x is small.}}$ $1.67 \times 10^{-7} = \frac{4x^3}{6.25 \times 10^{-4}}$ $6.25 \times 10^{-4}(1.67 \times 10^{-7}) = 4x^3$ $x^3 = \frac{6.25 \times 10^{-4}(1.67 \times 10^{-7})}{4}$ $x = 2.97 \times 10^{-4}$ Checking the $x$ is <i>small</i> approximation: $\frac{2.97 \times 10^{-4}}{0.0250} \times 100\% = 1.19\%$ The $x$ is <i>small</i> approximation is valid; proceed to step 6.	$K_c = \frac{[\text{H}_2]^2[\text{S}_2]}{[\text{H}_2\text{S}]^2}$ $= \frac{(2x)^2x}{(2.50 \times 10^{-4} - 2x)^2}$ $1.67 \times 10^{-7} = \frac{4x^3}{(2.50 \times 10^{-4} - 2x)^2}$ $1.67 \times 10^{-7} = \frac{4x^3}{(2.50 \times 10^{-4} - 2x)^2} \quad \text{\textit{x is small.}}$ $1.67 \times 10^{-7} = \frac{4x^3}{6.25 \times 10^{-8}}$ $6.25 \times 10^{-8}(1.67 \times 10^{-7}) = 4x^3$ $x^3 = \frac{6.25 \times 10^{-8}(1.67 \times 10^{-7})}{4}$ $x = 1.38 \times 10^{-5}$ Checking the $x$ is <i>small</i> approximation: $\frac{1.38 \times 10^{-5}}{2.50 \times 10^{-4}} \times 100\% = 5.52\%$ The approximation does not satisfy the <5% rule (although it is close).  —Continued on the next page

## CONCEPTUAL CONNECTION 15.7

**The  $x$  is small Approximation** For the generic reaction,  $\text{A(g)} \rightleftharpoons \text{B(g)}$ , consider each value of  $K$  and initial concentration of A. For which set of values does the  $x$  is small approximation most likely apply?

(a)  $K = 1.0 \times 10^{-5}$ ;  $[\text{A}] = 0.250 \text{ M}$

(b)  $K = 1.0 \times 10^{-2}$ ;  $[\text{A}] = 0.250 \text{ M}$

(c)  $K = 1.0 \times 10^{-5}$ ;  $[\text{A}] = 0.00250 \text{ M}$

(d)  $K = 1.0 \times 10^{-2}$ ;  $[\text{A}] = 0.00250 \text{ M}$

## 15.9 Le Châtelier's Principle: How a System at Equilibrium Responds to Disturbances

Le Châtelier's Principle

We have seen that a chemical system not in equilibrium tends to progress toward equilibrium and that the relative concentrations of the reactants and products at equilibrium are characterized by the equilibrium constant,  $K$ . What happens, however, when a chemical system already at equilibrium is disturbed? **Le Châtelier's principle** states that the chemical system responds to minimize the disturbance.

| Pronounced "Le-sha-te-lyay"

**Le Châtelier's principle: When a chemical system at equilibrium is disturbed, the system shifts in a direction that minimizes the disturbance.**

In other words, a system at equilibrium tends to maintain that equilibrium—it bounces back when disturbed.

We can understand Le Châtelier's principle by returning to our two neighboring countries analogy. Suppose the populations of Country A and Country B are at equilibrium. This means that the rate of people moving out of Country A and into Country B is equal to the rate of people moving into Country A and out of Country B, and the populations of the two countries are stable:

Now imagine disturbing the balance (Figure 15.8▼). Suppose there is a notable increase in the birthrate in Country B. What happens? After Country B becomes more crowded, the rate of people leaving Country B increases. The net flow of people is out of Country B and into Country A. Equilibrium is disturbed by the addition of more people to Country B, and people leave Country B in response. In effect, the system responded by shifting in the direction that minimized the disturbance.

On the other hand, what happens if there is a baby boom in Country A? As Country A gets more crowded, the rate of people leaving Country A increases. The net flow of people is out of Country A and into Country B. The number of people in Country A initially increases, and the system responds; people move out of Country A.

The two-country analogy should help you see the effects of disturbing a system in equilibrium—it should not be taken as an exact parallel.

### Le Châtelier's Principle: An Analogy

◀ **FIGURE 15.8 A Population Analogy for Le Châtelier's Principle** A baby boom in Country B shifts the equilibrium to the left. People leave Country B (because it has become too crowded) and migrate to Country A until equilibrium is reestablished.

Chemical systems behave similarly: when their equilibrium is disturbed, they react to counter the disturbance. We can disturb a system in chemical equilibrium in several different ways, including changing the concentration of a reactant or product, changing the volume or pressure, and changing the temperature. We consider each of these separately.

## The Effect of a Concentration Change on Equilibrium

Consider the following reaction in chemical equilibrium:

Suppose we disturb the equilibrium by adding  $\text{NO}_2$  to the equilibrium mixture (Figure 15.9▼). In other words, we increase the concentration of  $\text{NO}_2$ , the product. What happens? According to Le Châtelier's principle, the system shifts in a direction to minimize the disturbance. The reaction goes to the left (it proceeds in the reverse direction), consuming some of the added  $\text{NO}_2$  and thus bringing its concentration back down, as shown graphically in Figure 15.10a►:

The reaction shifts to the left because the value of  $Q$  changes as follows:

- Before addition of  $\text{NO}_2$  :  $Q = K$ .
- Immediately after addition of  $\text{NO}_2$  :  $Q > K$ .
- Reaction shifts to the left to reestablish equilibrium.

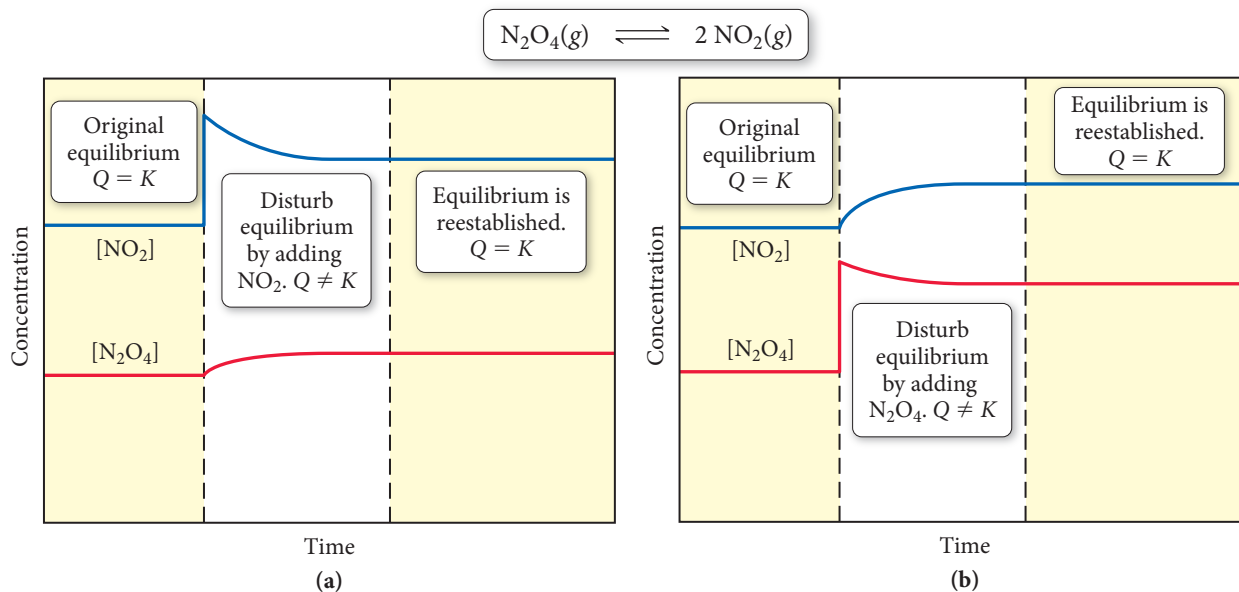

On the other hand, what happens if we add extra  $\text{N}_2\text{O}_4$  (the reactant), increasing its concentration? In this case, the reaction shifts to the right, consuming some of

### Le Châtelier's Principle: Changing Concentration

▲ **FIGURE 15.9** Le Châtelier's Principle: The Effect of a Concentration Change Adding  $\text{NO}_2$  causes the reaction to shift left, consuming some of the added  $\text{NO}_2$  and forming more  $\text{N}_2\text{O}_4$ .

## Le Châtelier's Principle: Graphical Representation

**▲ FIGURE 15.10 Le Châtelier's Principle: Changing Concentration**

The graph shows the concentrations of  $\text{NO}_2$  and  $\text{N}_2\text{O}_4$  for the reaction  $\text{N}_2\text{O}_4(\text{g}) \rightleftharpoons 2 \text{NO}_2(\text{g})$  as a function of time in three distinct stages of the reaction: initially at equilibrium (left), upon disturbance of the equilibrium by addition of more  $\text{NO}_2$  (**a**) or  $\text{N}_2\text{O}_4$  (**b**) to the reaction mixture (center), and upon reestablishment of equilibrium (right).

the added  $\text{N}_2\text{O}_4$  and bringing *its* concentration back down, as shown graphically in Figure 15.10b▲:

The reaction shifts to the right because the value of  $Q$  changes as follows:

- Before addition of  $\text{N}_2\text{O}_4$ :  $Q = K$ .
- Immediately after addition of  $\text{N}_2\text{O}_4$ :  $Q < K$ .
- Reaction shifts to the right to reestablish equilibrium.

In both of these cases (either adding  $\text{NO}_2$  or adding  $\text{N}_2\text{O}_4$ ), the system shifts in a direction that minimizes the disturbance. Lowering the concentration of a reactant (which makes  $Q > K$ ) causes the system to shift in the direction of the reactants to minimize the disturbance. Lowering the concentration of a product (which makes  $Q < K$ ) causes the system to shift in the direction of products.

**Summarizing the Effect of a Concentration Change on Equilibrium:**

If a chemical system is at equilibrium:

- ▶ Increasing the concentration of one or more of the *reactants* (which makes  $Q < K$ ) causes the reaction to *shift to the right* (in the direction of the products).
- ▶ Increasing the concentration of one or more of the *products* (which makes  $Q > K$ ) causes the reaction to *shift to the left* (in the direction of the reactants).
- ▶ Decreasing the concentration of one or more of the *reactants* (which makes  $Q > K$ ) causes the reaction to *shift to the left* (in the direction of the reactants).
- ▶ Decreasing the concentration of one or more of the *products* (which makes  $Q < K$ ) causes the reaction to *shift to the right* (in the direction of the products).

**Example 15.14** The Effect of a Concentration Change on Equilibrium

Consider the following reaction at equilibrium:

What is the effect of adding additional  $\text{CO}_2$  to the reaction mixture? What is the effect of adding additional  $\text{CaCO}_3$ ?

**SOLUTION**

Adding additional  $\text{CO}_2$  increases the concentration of  $\text{CO}_2$  and causes the reaction to shift to the left. Adding additional  $\text{CaCO}_3$ , however, does *not* increase the concentration of  $\text{CaCO}_3$  because  $\text{CaCO}_3$  is a solid and therefore has a constant concentration. Thus, adding additional  $\text{CaCO}_3$  has no effect on the position of the equilibrium. (Note that, as we saw in Section 15.5, solids are not included in the equilibrium expression.)

**FOR PRACTICE 15.14** Consider the following reaction in chemical equilibrium:

What is the effect of adding additional  $\text{Br}_2$  to the reaction mixture? What is the effect of adding additional  $\text{BrNO}$ ?

**The Effect of a Volume (or Pressure) Change on Equilibrium**

In considering the effect of a change in volume, we are assuming that the change in volume is carried out at constant temperature.

How does a system in chemical equilibrium respond to a volume change? Recall from Chapter 5 that changing the volume of a gas (or a gas mixture) results in a change in pressure. Remember also that pressure and volume are inversely related: a *decrease* in volume causes an *increase* in pressure, and an *increase* in volume causes a *decrease* in pressure. So, if the volume of a reaction mixture at chemical equilibrium is changed, the pressure changes and the system shifts in a direction to minimize that change.

For example, consider the following reaction at equilibrium in a cylinder equipped with a moveable piston:

What happens if we push down on the piston, lowering the volume and raising the pressure (Figure 15.11a)? How can the chemical system respond to bring the pressure back down? Look carefully at the reaction coefficients. If the reaction shifts to the right, 4 mol of gas particles are converted to 2 mol of gas particles. From the ideal gas law ( $PV = nRT$ ), we know that decreasing the number of moles of a gas ( $n$ ) results in a lower pressure ( $P$ ). Therefore, the system shifts to the right, decreasing the number of gas molecules and bringing the pressure back down, minimizing the disturbance.

Consider the same reaction mixture at equilibrium again. What happens if, this time, we pull *up* on the piston, *increasing* the volume (Figure 15.11b)? The higher volume results in a lower pressure and the system responds to bring the pressure back up. It does this by shifting to the left, converting 2 mol of gas particles into 4 mol of gas particles, increasing the pressure and minimizing the disturbance.

Consider again the same reaction mixture at equilibrium. What happens if, this time, we keep the volume the same but increase the pressure by *adding an inert gas* to the mixture? Although the overall pressure of the mixture increases, the partial pressures of the reactants and products do not change. Consequently, there is no effect, and the reaction does not shift in either direction.

**Summarizing the Effect of Volume Change on Equilibrium:**

If a chemical system is at equilibrium:

- ▶ *Decreasing* the volume causes the reaction to shift in the direction that has *the fewer moles of gas particles*.
- ▶ *Increasing* the volume causes the reaction to shift in the direction that has *the greater number of moles of gas particles*.

- ▶ If a reaction has an equal number of moles of gas on both sides of the chemical equation, then a change in volume produces no effect on the equilibrium.
- ▶ Adding an inert gas to the mixture at a fixed volume has no effect on the equilibrium.

### Le Châtelier's Principle: Changing Pressure

**FIGURE 15.11** Le Châtelier's Principle: The Effect of a Pressure Change (a) Decreasing the volume increases the pressure, causing the reaction to shift to the right (fewer moles of gas, lower pressure). (b) Increasing the volume reduces the pressure, causing the reaction to shift to the left (more moles of gas, higher pressure).

### Example 15.15 The Effect of a Volume Change on Equilibrium

Consider the following reaction at chemical equilibrium:

What is the effect of decreasing the volume of the reaction mixture? Increasing the volume of the reaction mixture? Adding an inert gas at constant volume?

#### SOLUTION

The chemical equation has 3 mol of gas on the right and zero moles of gas on the left. Decreasing the volume of the reaction mixture increases the pressure and causes the reaction to shift to the left (toward the side with fewer moles of gas particles). Increasing the volume of the reaction mixture decreases the pressure and causes the reaction to shift to the right (toward the side with more moles of gas particles.) Adding an inert gas has no effect.

**FOR PRACTICE 15.15** Consider the following reaction at chemical equilibrium:

What is the effect of decreasing the volume of the reaction mixture? Increasing the volume of the reaction mixture?

When a system at equilibrium is disturbed by a change in concentration or a change in volume, the equilibrium shifts to counter the change, but *the equilibrium constant does not change*. In other words, changes in volume or concentration generally change  $Q$ , not  $K$ , and the system responds by shifting so that  $Q$  becomes equal to  $K$ . In contrast, a change in temperature changes the actual value of the equilibrium constant. Nonetheless, we can use Le Châtelier's principle to predict the effects of a temperature change.

Exothermic reaction:  $A + B \rightleftharpoons C + D + \text{heat}$

Endothermic reaction:  $A + B + \text{heat} \rightleftharpoons C + D$

At constant pressure, raising the temperature of an *exothermic* reaction—think of this as adding heat—is similar to adding more product, causing the reaction to shift left. For example, the reaction of nitrogen with hydrogen to form ammonia is exothermic:

Conversely, lowering the temperature causes the reaction to shift right, releasing heat and producing more products because the value of  $K$  has increased:

Add heat  
 $\text{N}_2\text{O}_4(\text{g}) + \text{heat} \rightleftharpoons 2 \text{NO}_2(\text{g})$   
 colorless brown  
 Reaction shifts right.  
 Larger  $K$

## Le Châtelier's Principle: Changing Temperature

▲ **FIGURE 15.12** Le Châtelier's Principle: The Effect of a Temperature Change

Because the reaction is endothermic, raising the temperature causes a shift to the right, toward the formation of brown NO<sub>2</sub>.

Raising the temperature of an equilibrium mixture of these two gases causes the reaction to shift right, absorbing some of the added heat and producing more products because the value of  $K$  has increased. Because N<sub>2</sub>O<sub>4</sub> is colorless and NO<sub>2</sub> is brown, the effects of changing the temperature of this reaction are easily seen (Figure 15.12▲).

On the other hand, lowering the temperature (removing heat) of a reaction mixture of these two gases causes the reaction to shift left, releasing heat, forming less products, and lowering the value of  $K$ :

**Summarizing the Effect of a Temperature Change on Equilibrium:**

In an *exothermic* chemical reaction, heat is a product.

- ▶ Increasing the temperature causes an exothermic reaction to *shift left* (in the direction of the reactants); the value of the equilibrium constant decreases.
- ▶ Decreasing the temperature causes an exothermic reaction to *shift right* (in the direction of the products); the value of the equilibrium constant increases.

In an *endothermic* chemical reaction, heat is a reactant.

- ▶ Increasing the temperature causes an endothermic reaction to *shift right* (in the direction of the products); the equilibrium constant increases.
- ▶ Decreasing the temperature causes an endothermic reaction to *shift left* (in the direction of the reactants); the equilibrium constant decreases.

Adding heat favors the endothermic direction. Removing heat favors the exothermic direction.

### Example 15.16 The Effect of a Temperature Change on Equilibrium

The following reaction is endothermic:

What is the effect of increasing the temperature of the reaction mixture? Decreasing the temperature?

#### SOLUTION

Since the reaction is endothermic, we can think of heat as a reactant:

Raising the temperature is like adding a reactant, causing the reaction to shift to the right. Lowering the temperature is equivalent to removing a reactant, causing the reaction to shift to the left.

**FOR PRACTICE 15.16** The following reaction is exothermic:

What is the effect of increasing the temperature of the reaction mixture? Decreasing the temperature?

## Self-Assessment Quiz

- Q1.** What is the correct expression for the equilibrium constant ( $K_c$ ) for the reaction between carbon and hydrogen gas to form methane shown here?

- a)  $K_c = \frac{[\text{CH}_4]}{[\text{H}_2]}$       b)  $K_c = \frac{[\text{CH}_4]}{[\text{C}][\text{H}_2]}$   
 c)  $K_c = \frac{[\text{CH}_4]}{[\text{C}][\text{H}_2]^2}$       d)  $K_c = \frac{[\text{CH}_4]}{[\text{H}_2]^2}$
- Q2.** The equilibrium constant for the reaction shown here is  $K_c = 1.0 \times 10^3$ . A reaction mixture at equilibrium contains  $[\text{A}] = 1.0 \times 10^{-3} \text{ M}$ . What is the concentration of B in the mixture?

- a)  $1.0 \times 10^{-3} \text{ M}$       b)  $1.0 \text{ M}$   
 c)  $2.0 \text{ M}$       d)  $1.0 \times 10^3 \text{ M}$
- Q3.** Use the data shown here to find the equilibrium constant ( $K_c$ ) for the reaction  $\text{A}(\text{g}) \rightleftharpoons 2 \text{B}(\text{g}) + \text{C}(\text{g})$ .
- $$\text{A}(\text{g}) \rightleftharpoons 2 \text{X}(\text{g}) + \text{C}(\text{g}) \quad K_c = 1.55$$
- $$\text{B}(\text{g}) \rightleftharpoons \text{X}(\text{g}) \quad K_c = 25.2$$
- a) 984    b) 26.8    c)  $6.10 \times 10^{-4}$     d)  $2.44 \times 10^{-3}$
- Q4.** The reaction shown here has a  $K_p = 4.5 \times 10^2$  at 825 K. Find  $K_c$  for the reaction at this temperature.
- $$\text{CH}_4(\text{g}) + \text{CO}_2(\text{g}) \rightleftharpoons 2 \text{CO}(\text{g}) + 2 \text{H}_2(\text{g})$$
- a) 0.098    b)  $2.1 \times 10^6$     c) 6.6    d)  $4.5 \times 10^{-2}$
- Q5.** Consider the reaction between NO and  $\text{Cl}_2$  to form NOCl:

A reaction mixture at a certain temperature initially contains only  $[\text{NO}] = 0.50 \text{ M}$  and  $[\text{Cl}_2] = 0.50 \text{ M}$ .

After the reaction comes to equilibrium, the concentration of NOCl is 0.30 M. Find the value of the equilibrium constant ( $K_c$ ) at this temperature.

- a) 11      b) 4.3  
 c) 6.4      d) 0.22
- Q6.** For the reaction  $2 \text{A}(\text{g}) \rightleftharpoons \text{B}(\text{g})$ , the equilibrium constant is  $K_p = 0.76$ . A reaction mixture initially contains 2.0 atm of each gas ( $P_A = 2.0 \text{ atm}$  and  $P_B = 2.0 \text{ atm}$ ). Which statement is true of the reaction mixture?
- a) The reaction mixture is at equilibrium.  
 b) The reaction mixture will proceed toward products.  
 c) The reaction mixture will proceed toward reactants.  
 d) It is not possible to determine from the information given the future direction of the reaction mixture.
- Q7.** Consider the reaction between iodine gas and chlorine gas to form iodine monochloride:

A reaction mixture at 298 K initially contains  $P_{\text{I}_2} = 0.25 \text{ atm}$  and  $P_{\text{Cl}_2} = 0.25 \text{ atm}$ . What is the partial pressure of iodine monochloride when the reaction reaches equilibrium?

- a) 0.17 atm      b) 0.64 atm  
 c) 0.41 atm      d) 2.3 atm
- Q8.** Consider the reaction of A to form B:
- $$2 \text{A}(\text{g}) \rightleftharpoons \text{B}(\text{g}) \quad K_c = 1.8 \times 10^{-5} \text{ (at 298 K)}$$
- A reaction mixture at 298 K initially contains  $[\text{A}] = 0.50 \text{ M}$ . What is the concentration of B when the reaction reaches equilibrium?
- a)  $9.0 \times 10^{-6} \text{ M}$       b) 0.060 M  
 c) 0.030 M      d)  $4.5 \times 10^{-6} \text{ M}$
- Q9.** The decomposition of  $\text{NH}_4\text{HS}$  is endothermic:

Which change to an equilibrium mixture of this reaction results in the formation of more  $\text{H}_2\text{S}$ ?

- a) a decrease in the volume of the reaction vessel (at constant temperature)
- b) an increase in the amount of  $\text{NH}_4\text{HS}$  in the reaction vessel
- c) an increase in temperature
- d) all of the above

**Q10.** The solid  $\text{XY}$  decomposes into gaseous  $\text{X}$  and  $\text{Y}$ :

If the reaction is carried out in a 22.4-L container, which initial amounts of  $\text{X}$  and  $\text{Y}$  result in the formation of solid  $\text{XY}$ ?

- a) 5 mol  $\text{X}$ ; 0.5 mol  $\text{Y}$
- b) 2.0 mol  $\text{X}$ ; 2.0 mol  $\text{Y}$
- c) 1 mol  $\text{X}$ ; 1 mol  $\text{Y}$
- d) none of the above

**Q11.** What is the effect of adding helium gas (at constant volume) to an equilibrium mixture of the reaction:

- a) The reaction shifts toward the products.
- b) The reaction shifts toward the reactants.
- c) The reaction does not shift in either direction.
- d) The reaction slows down.

**Q12.** The reaction  $\text{X}_2\text{(g)} \rightleftharpoons 2 \text{X(g)}$  occurs in a closed reaction vessel at constant volume and temperature. Initially, the vessel contains only  $\text{X}_2$  at a pressure of 1.55 atm. After the reaction reaches equilibrium, the total pressure is 2.85 atm. What is the value of the equilibrium constant,  $K_p$ , for the reaction?

- a) 27
- b) 10
- c) 5.2
- d) 32

Answers: 1. (d) 2. (b) 3. (d) 4. (a) 5. (c) 6. (b) 7. (c) 8. (d) 9. (c) 10. (d) 11. (c) 12. (a)

## Chapter 15 IN REVIEW

### Key Terms

#### Section 15.2

reversible (677)  
dynamic equilibrium (677)

#### Section 15.3

equilibrium constant ( $K$ ) (680)  
law of mass action (680)

#### Section 15.7

reaction quotient ( $Q_c$ ) (691)

#### Section 15.9

Le Châtelier's principle (703)

### Key Concepts

#### The Equilibrium Constant (15.1)

- The relative concentrations of the reactants and the products at equilibrium are expressed by the equilibrium constant,  $K$ .
- The equilibrium constant measures how far a reaction proceeds toward products: a large  $K$  (greater than 1) indicates a high concentration of products at equilibrium, and a small  $K$  (less than 1) indicates a low concentration of products at equilibrium.

#### Dynamic Equilibrium (15.2)

- Most chemical reactions are reversible; they can proceed in either the forward or the reverse direction.
- When a chemical reaction is in dynamic equilibrium, the rate of the forward reaction equals the rate of the reverse reaction, so the net concentrations of reactants and products do not change. However, this does *not* imply that the concentrations of the reactants and the products are equal at equilibrium.

#### The Equilibrium Constant Expression (15.3)

- The equilibrium constant expression is given by the law of mass action and is equal to the concentrations of the products, raised to their stoichiometric coefficients, divided by the concentrations of the reactants, raised to their stoichiometric coefficients.
- When the equation for a chemical reaction is reversed, multiplied, or added to another equation,  $K$  must be modified accordingly.

#### The Equilibrium Constant, $K$ (15.4)

- The equilibrium constant can be expressed in terms of concentrations ( $K_c$ ) or in terms of partial pressures ( $K_p$ ). These two constants are related by Equation 15.2. Concentration must always be expressed in units of molarity for  $K_c$ . Partial pressures must always be expressed in units of atmospheres for  $K_p$ .

#### States of Matter and the Equilibrium Constant (15.5)

- The equilibrium constant expression contains only partial pressures or concentrations of reactants and products that exist as gases or solutes dissolved in solution. Pure liquids and solids are not included in the expression for the equilibrium constant.

#### Calculating $K$ (15.6)

- We can calculate the equilibrium constant from equilibrium concentrations or partial pressures by substituting measured values into the expression for the equilibrium constant (as obtained from the law of mass action).
- In most cases, we can calculate the equilibrium concentrations of the reactants and products—and therefore the value of the equilibrium constant—from the initial concentrations of the reactants and products and the equilibrium concentration of *just one* reactant or product.

**The Reaction Quotient,  $Q$  (15.7)**

- ▶ The reaction quotient,  $Q$ , is the ratio of the concentrations (or partial pressures) of products raised to their stoichiometric coefficients to the concentrations of reactants raised to their stoichiometric coefficients *at any point in the reaction*.
- ▶ Like  $K$ ,  $Q$  can be expressed in terms of concentrations ( $Q_c$ ) or partial pressures ( $Q_p$ ).
- ▶ At equilibrium,  $Q$  is equal to  $K$ ; therefore, we can determine the direction in which a reaction proceeds by comparing  $Q$  to  $K$ . If  $Q < K$ , the reaction moves in the direction of the products; if  $Q > K$ , the reaction moves in the reverse direction.

**Finding Equilibrium Concentrations (15.8)**

- ▶ There are two general types of problems in which  $K$  is given and we can determine one (or more) equilibrium concentrations:

- (1) We are given  $K$  and all but one equilibrium concentration.
  - (2) We are given  $K$  and *only* initial concentrations.
- ▶ We solve the first type by rearranging the law of mass action and substituting the given values.
  - ▶ We solve the second type by creating an ICE table and using a variable  $x$  to represent the change in concentration.

**Le Châtelier's Principle (15.9)**

- ▶ When a system at equilibrium is disturbed—by a change in the amount of a reactant or product, a change in volume, or a change in temperature—the system shifts in the direction that minimizes the disturbance.

**Key Equations and Relationships**Expression for the Equilibrium Constant,  $K_c$  (15.3)

$$aA + bB \rightleftharpoons cC + dD$$

$$K = \frac{[C]^c[D]^d}{[A]^a[B]^b} \quad (\text{equilibrium concentrations only})$$

Relationship between the Equilibrium Constant and the Chemical Equation (15.3)

1. If you reverse the equation, invert the equilibrium constant.
2. If you multiply the coefficients in the equation by a factor, raise the equilibrium constant to the same factor.
3. If you add two or more individual chemical equations to obtain an overall equation, multiply the corresponding equilibrium constants by each other to obtain the overall equilibrium constant.

Expression for the Equilibrium Constant,  $K_p$  (15.4)

$$aA + bB \rightleftharpoons cC + dD$$

$$K_p = \frac{P_C^c P_D^d}{P_A^a P_B^b} \quad (\text{equilibrium partial pressures only})$$

Relationship between the Equilibrium Constants,  $K_c$  and  $K_p$  (15.4)

$$K_p = K_c(RT)^{\Delta n}$$

The Reaction Quotient,  $Q_c$  (15.7)

$$aA + bB \rightleftharpoons cC + dD$$

$$Q_c = \frac{[C]^c[D]^d}{[A]^a[B]^b} \quad (\text{concentrations at any point in the reaction})$$

The Reaction Quotient,  $Q_p$  (15.7)

$$aA + bB \rightleftharpoons cC + dD$$

$$Q_p = \frac{P_C^c P_D^d}{P_A^a P_B^b} \quad (\text{partial pressures at any point in the reaction})$$

Relationship of  $Q$  to the Direction of the Reaction (15.7)

- $Q < K$  Reaction goes to the right.
- $Q > K$  Reaction goes to the left.
- $Q = K$  Reaction is at equilibrium.

## EXERCISES

### Review Questions

- How does a developing fetus get oxygen in the womb?
- What is dynamic equilibrium? Why is it called *dynamic*?
- Give the general expression for the equilibrium constant of the following generic reaction:  

$$a\text{A} + b\text{B} \rightleftharpoons c\text{C} + d\text{D}$$
- What is the significance of the equilibrium constant? What does a large equilibrium constant tell us about a reaction? A small one?
- What happens to the value of the equilibrium constant for a reaction if the reaction equation is reversed? Multiplied by a constant?
- If two reactions sum to an overall reaction, and the equilibrium constants for the two reactions are  $K_1$  and  $K_2$ , what is the equilibrium constant for the overall reaction?
- Explain the difference between  $K_c$  and  $K_p$ . For a given reaction, how are the two constants related?
- What units should be used when expressing concentrations or partial pressures in the equilibrium constant? What are the units of  $K_p$  and  $K_c$ ? Explain.
- Why are the concentrations of solids and liquids omitted from equilibrium expressions?
- Does the value of the equilibrium constant depend on the initial concentrations of the reactants and products? Do the equilibrium concentrations of the reactants and products depend on their initial concentrations? Explain.
- Explain how you might deduce the equilibrium constant for a reaction in which you know the initial concentrations of the reactants and products and the equilibrium concentration of only one reactant or product.
- What is the definition of the reaction quotient ( $Q$ ) for a reaction? What does  $Q$  measure?
- What is the value of  $Q$  when each reactant and product is in its standard state? (See Section 6.9 for the definition of standard states.)
- In what direction will a reaction proceed for each condition: (a)  $Q < K$ ; (b)  $Q > K$ ; and (c)  $Q = K$ ?
- Many equilibrium calculations involve finding the equilibrium concentrations of reactants and products given their initial concentrations and the equilibrium constant. Outline the general procedure used in solving these kinds of problems.
- In equilibrium problems involving equilibrium constants that are small relative to the initial concentrations of reactants, we can often assume that the quantity  $x$  (which represents how far the reaction proceeds toward products) is small. When this assumption is made, we can ignore the quantity  $x$  when it is subtracted from a large number but not when it is multiplied by a large number. In other words,  $2.5 - x \approx 2.5$ , but  $2.5x \neq 2.5$ . Explain why we can ignore a small  $x$  in the first case, but not in the second.
- What happens to a chemical system at equilibrium when that equilibrium is disturbed?
- What is the effect of a change in concentration of a reactant or product on a chemical reaction initially at equilibrium?
- What is the effect of a change in volume on a chemical reaction (that includes gaseous reactants or products) initially at equilibrium?
- What is the effect of a temperature change on a chemical reaction initially at equilibrium? How does the effect differ for an exothermic reaction compared to an endothermic one?

## Problems by Topic

## Equilibrium and the Equilibrium Constant Expression

21. Write an expression for the equilibrium constant of each chemical equation.

- $\text{SbCl}_5(g) \rightleftharpoons \text{SbCl}_3(g) + \text{Cl}_2(g)$
- $2 \text{BrNO}(g) \rightleftharpoons 2 \text{NO}(g) + \text{Br}_2(g)$
- $\text{CH}_4(g) + 2 \text{H}_2\text{S}(g) \rightleftharpoons \text{CS}_2(g) + 4 \text{H}_2(g)$
- $2 \text{CO}(g) + \text{O}_2(g) \rightleftharpoons 2 \text{CO}_2(g)$

22. Find and fix each mistake in the equilibrium constant expressions.

- $2 \text{H}_2\text{S}(g) \rightleftharpoons 2 \text{H}_2(g) + \text{S}_2(g) \quad K = \frac{[\text{H}_2][\text{S}_2]}{[\text{H}_2\text{S}]}$
- $\text{CO}(g) + \text{Cl}_2(g) \rightleftharpoons \text{COCl}_2(g) \quad K = \frac{[\text{CO}][\text{Cl}_2]}{[\text{COCl}_2]}$

23. When this reaction comes to equilibrium, will the concentrations of the reactants or products be greater? Does the answer to this question depend on the initial concentrations of the reactants and products?

24. Ethene ( $\text{C}_2\text{H}_4$ ) can be halogenated by this reaction:

where  $\text{X}_2$  can be  $\text{Cl}_2$  (green),  $\text{Br}_2$  (brown), or  $\text{I}_2$  (purple). Examine the three figures representing equilibrium concentrations in this reaction at the same temperature for the three different halogens. Rank the equilibrium constants for the three reactions from largest to smallest.

25.  $\text{H}_2$  and  $\text{I}_2$  are combined in a flask and allowed to react according to the reaction:

Examine the figures (sequential in time) and answer the questions:

- Which figure represents the point at which equilibrium is reached?
- How would the series of figures change in the presence of a catalyst?
- Would there be different amounts of reactants and products in the final figure (vi) in the presence of a catalyst?

26. A chemist trying to synthesize a particular compound attempts two different synthesis reactions. The equilibrium constants for the two reactions are 23.3 and  $2.2 \times 10^4$  at room temperature. However, upon carrying out both reactions for 15 minutes, the chemist finds that the reaction with the smaller equilibrium constant produces more of the desired product. Explain how this might be possible.

27. This reaction has an equilibrium constant of  $K_p = 2.26 \times 10^4$  at 298 K.

Calculate  $K_p$  for each reaction and predict whether reactants or products will be favored at equilibrium.

- $\text{CH}_3\text{OH}(g) \rightleftharpoons \text{CO}(g) + 2 \text{H}_2(g)$
- $\frac{1}{2} \text{CO}(g) + \text{H}_2(g) \rightleftharpoons \frac{1}{2} \text{CH}_3\text{OH}(g)$
- $2 \text{CH}_3\text{OH}(g) \rightleftharpoons 2 \text{CO}(g) + 4 \text{H}_2(g)$

28. This reaction has an equilibrium constant of  $K_p = 2.2 \times 10^6$  at 298 K.

Calculate  $K_p$  for each reaction and predict whether reactants or products will be favored at equilibrium.

- $\text{COF}_2(g) \rightleftharpoons \frac{1}{2} \text{CO}_2(g) + \frac{1}{2} \text{CF}_4(g)$
- $6 \text{COF}_2(g) \rightleftharpoons 3 \text{CO}_2(g) + 3 \text{CF}_4(g)$
- $2 \text{CO}_2(g) + 2 \text{CF}_4(g) \rightleftharpoons 4 \text{COF}_2(g)$

29. Consider the reactions and their respective equilibrium constants:

Use these reactions and their equilibrium constants to predict the equilibrium constant for the following reaction:

30. Use the reactions and their equilibrium constants to predict the equilibrium constant for the reaction  $2 \text{A}(s) \rightleftharpoons 3 \text{D}(g)$ .

**$K_p$ ,  $K_c$ , and Heterogeneous Equilibria**31. Calculate  $K_c$  for each reaction.32. Calculate  $K_p$  for each reaction.

33. Write an equilibrium expression for each chemical equation involving one or more solid or liquid reactants or products.

34. Find and fix the mistake in the equilibrium expression.

**Relating the Equilibrium Constant to Equilibrium Concentrations and Equilibrium Partial Pressures**

35. Consider the reaction:

An equilibrium mixture of this reaction at a certain temperature has  $[\text{CO}] = 0.105 \text{ M}$ ,  $[\text{H}_2] = 0.114 \text{ M}$ , and  $[\text{CH}_3\text{OH}] = 0.185 \text{ M}$ . What is the value of the equilibrium constant ( $K_c$ ) at this temperature?

36. Consider the reaction:

An equilibrium mixture of this reaction at a certain temperature has  $[\text{NH}_3] = 0.278 \text{ M}$  and  $[\text{H}_2\text{S}] = 0.355 \text{ M}$ . What is the value of the equilibrium constant ( $K_c$ ) at this temperature?

37. Consider the reaction:

Complete the table. Assume that all concentrations are equilibrium concentrations in M.

$T$ (K)	$[\text{N}_2]$	$[\text{H}_2]$	$[\text{NH}_3]$	$K_c$
500	0.115	0.105	0.439	_____
575	0.110	_____	0.128	9.6
775	0.120	0.140	_____	0.0584

38. Consider the following reaction:

Complete the table. Assume that all concentrations are equilibrium concentrations in M.

$T$ ( $^{\circ}\text{C}$ )	$[\text{H}_2]$	$[\text{I}_2]$	$[\text{HI}]$	$K_c$
25	0.0355	0.0388	0.922	_____
340	_____	0.0455	0.387	9.6
445	0.0485	0.0468	_____	50.2

39. Consider the reaction:

In a reaction mixture at equilibrium, the partial pressure of NO is 108 torr and that of  $\text{Br}_2$  is 126 torr. What is the partial pressure of NOBr in this mixture?

40. Consider the reaction:

In a reaction at equilibrium, the partial pressure of  $\text{SO}_2$  is 137 torr and that of  $\text{Cl}_2$  is 285 torr. What is the partial pressure of  $\text{SO}_2\text{Cl}_2$  in this mixture?

41. For the reaction  $\text{A}(\text{g}) \rightleftharpoons 2 \text{B}(\text{g})$ , a reaction vessel initially contains only A at a pressure of  $P_A = 1.32 \text{ atm}$ . At equilibrium,  $P_A = 0.25 \text{ atm}$ . Calculate the value of  $K_p$ . (Assume no changes in volume or temperature.)42. For the reaction  $2 \text{A}(\text{g}) \rightleftharpoons \text{B}(\text{g}) + 2 \text{C}(\text{g})$ , a reaction vessel initially contains only A at a pressure of  $P_A = 255 \text{ mmHg}$ . At equilibrium,  $P_A = 55 \text{ mmHg}$ . Calculate the value of  $K_p$ . (Assume no changes in volume or temperature.)

43. Consider the reaction:

A solution is made containing an initial  $[\text{Fe}^{3+}]$  of  $1.0 \times 10^{-3} \text{ M}$  and an initial  $[\text{SCN}^-]$  of  $8.0 \times 10^{-4} \text{ M}$ . At equilibrium,  $[\text{FeSCN}^{2+}] = 1.7 \times 10^{-4} \text{ M}$ . Calculate the value of the equilibrium constant ( $K_c$ ).

44. Consider the reaction:

A reaction mixture is made containing an initial  $[\text{SO}_2\text{Cl}_2]$  of 0.020 M. At equilibrium,  $[\text{Cl}_2] = 1.2 \times 10^{-2} \text{ M}$ . Calculate the value of the equilibrium constant ( $K_c$ ).

45. Consider the reaction:

A reaction mixture in a 3.67-L flask at a certain temperature initially contains 0.763 g  $\text{H}_2$  and 96.9 g  $\text{I}_2$ . At equilibrium, the flask contains 90.4 g HI. Calculate the equilibrium constant ( $K_c$ ) for the reaction at this temperature.

46. Consider the reaction:

A reaction mixture in a 5.19-L flask at a certain temperature contains 26.9 g CO and 2.34 g  $\text{H}_2$ . At equilibrium, the flask contains 8.65 g  $\text{CH}_3\text{OH}$ . Calculate the equilibrium constant ( $K_c$ ) for the reaction at this temperature.

**The Reaction Quotient and Reaction Direction**

47. Consider the reaction:

At a certain temperature,  $K_c = 8.5 \times 10^{-3}$ . A reaction mixture at this temperature containing solid  $\text{NH}_4\text{HS}$  has  $[\text{NH}_3] = 0.166 \text{ M}$  and  $[\text{H}_2\text{S}] = 0.166 \text{ M}$ . Will more of the solid form or will some of the existing solid decompose as equilibrium is reached?

48. Consider the reaction:

A reaction mixture contains 0.112 atm of  $\text{H}_2$ , 0.055 atm of  $\text{S}_2$ , and 0.445 atm of  $\text{H}_2\text{S}$ . Is the reaction mixture at equilibrium? If not, in what direction will the reaction proceed?

49. Silver sulfate dissolves in water according to the reaction:

$$K_c = 1.1 \times 10^{-5}$$
 at 298 K

A 1.5-L solution contains 6.55 g of dissolved silver sulfate. If additional solid silver sulfate is added to the solution, will it dissolve?

50. Nitrogen dioxide dimerizes according to the reaction:

A 2.25-L container contains 0.055 mol of  $\text{NO}_2$  and 0.082 mol of  $\text{N}_2\text{O}_4$  at 298 K. Is the reaction at equilibrium? If not, in what direction will the reaction proceed?

### Finding Equilibrium Concentrations from Initial Concentrations and the Equilibrium Constant

51. Consider the reaction and the associated equilibrium constant:

Find the equilibrium concentrations of A and B for each value of  $a$  and  $b$ . Assume that the initial concentration of A in each case is 1.0 M and that no B is present at the beginning of the reaction.

- a.  $a = 1; b = 1$     b.  $a = 2; b = 2$     c.  $a = 1; b = 2$

52. Consider the reaction and the associated equilibrium constant:

Find the equilibrium concentrations of A, B, and C for each value of  $a$ ,  $b$ , and  $c$ . Assume that the initial concentrations of A and B are each 1.0 M and that no product is present at the beginning of the reaction.

- a.  $a = 1; b = 1; c = 2$   
 b.  $a = 1; b = 1; c = 1$   
 c.  $a = 2; b = 1; c = 1$  (set up equation for  $x$ ; don't solve)

53. For the reaction shown here,  $K_c = 0.513$  at 500 K.

If a reaction vessel initially contains an  $N_2O_4$  concentration of 0.0500 M at 500 K, what are the equilibrium concentrations of  $N_2O_4$  and  $NO_2$  at 500 K?

54. For the reaction shown here,  $K_c = 255$  at 1000 K.

If a reaction mixture initially contains a CO concentration of 0.1500 M and a  $Cl_2$  concentration of 0.175 M at 1000 K, what are the equilibrium concentrations of CO,  $Cl_2$ , and  $COCl_2$  at 1000 K?

55. Consider the reaction:

If a mixture of solid nickel(II) oxide and 0.20 M carbon monoxide comes to equilibrium at 1500 K, what is the equilibrium concentration of  $CO_2$ ?

56. Consider the reaction:

If a reaction mixture initially contains 0.110 M CO and 0.110 M  $H_2O$ , what will the equilibrium concentration of each of the reactants and products be?

57. Consider the reaction:

If a solution initially contains 0.210 M  $HC_2H_3O_2$ , what is the equilibrium concentration of  $H_3O^+$  at  $25^\circ C$ ?

58. Consider the reaction:

If a reaction mixture initially contains 0.175 M  $SO_2Cl_2$ , what is the equilibrium concentration of  $Cl_2$  at  $227^\circ C$ ?

59. Consider the reaction:

A reaction mixture initially contains a  $Br_2$  partial pressure of 755 torr and a  $Cl_2$  partial pressure of 735 torr at 150 K. Calculate the equilibrium partial pressure of  $BrCl$ .

60. Consider the reaction:

A reaction mixture initially contains a CO partial pressure of 1344 torr and a  $H_2O$  partial pressure of 1766 torr at 2000 K. Calculate the equilibrium partial pressures of each of the products.

61. Consider the reaction:

Find the equilibrium concentrations of A, B, and C for each value of  $K_c$ . Assume that the initial concentration of A in each case is 1.0 M and that the reaction mixture initially contains no products. Make any appropriate simplifying assumptions.

- a.  $K_c = 1.0$   
 b.  $K_c = 0.010$   
 c.  $K_c = 1.0 \times 10^{-5}$

62. Consider the reaction:

Find the equilibrium partial pressures of A and B for each value of  $K$ . Assume that the initial partial pressure of B in each case is 1.0 atm and that the initial partial pressure of A is 0.0 atm. Make any appropriate simplifying assumptions.

- a.  $K_p = 1.0$   
 b.  $K_p = 1.0 \times 10^{-4}$   
 c.  $K_p = 1.0 \times 10^5$

### Le Châtelier's Principle

63. Consider this reaction at equilibrium:

Predict whether the reaction will shift left, shift right, or remain unchanged after each disturbance.

- a.  $COCl_2$  is added to the reaction mixture.  
 b.  $Cl_2$  is added to the reaction mixture.  
 c.  $COCl_2$  is removed from the reaction mixture.

64. Consider this reaction at equilibrium:

Predict whether the reaction will shift left, shift right, or remain unchanged after each disturbance.

- a. NO is added to the reaction mixture.  
 b.  $BrNO$  is added to the reaction mixture.  
 c.  $Br_2$  is removed from the reaction mixture.

65. Consider this reaction at equilibrium:

Predict whether the reaction will shift left, shift right, or remain unchanged after each disturbance.

- a.  $O_2$  is removed from the reaction mixture.  
 b. KCl is added to the reaction mixture.  
 c.  $KClO_3$  is added to the reaction mixture.  
 d.  $O_2$  is added to the reaction mixture.

66. Consider this reaction at equilibrium:

Predict whether the reaction will shift left, shift right, or remain unchanged after each disturbance.

- a. C is added to the reaction mixture.  
 b.  $H_2O$  is condensed and removed from the reaction mixture.  
 c. CO is added to the reaction mixture.  
 d.  $H_2$  is removed from the reaction mixture.

67. Each reaction is allowed to come to equilibrium, and then the volume is changed as indicated. Predict the effect (shift right, shift left, or no effect) of the indicated volume change.

- a.  $I_2(g) \rightleftharpoons 2I(g)$  (volume is increased)  
 b.  $2H_2S(g) \rightleftharpoons 2H_2(g) + S_2(g)$  (volume is decreased)  
 c.  $I_2(g) + Cl_2(g) \rightleftharpoons 2ICl(g)$  (volume is decreased)

68. Each reaction is allowed to come to equilibrium, and then the volume is changed as indicated. Predict the effect (shift right, shift left, or no effect) of the indicated volume change.
- $\text{CO(g)} + \text{H}_2\text{O(g)} \rightleftharpoons \text{CO}_2\text{(g)} + \text{H}_2\text{(g)}$  (volume is decreased)
  - $\text{PCl}_3\text{(g)} + \text{Cl}_2\text{(g)} \rightleftharpoons \text{PCl}_5\text{(g)}$  (volume is increased)
  - $\text{CaCO}_3\text{(s)} \rightleftharpoons \text{CaO(s)} + \text{CO}_2\text{(g)}$  (volume is increased)
69. This reaction is endothermic.
- $$\text{C(s)} + \text{CO}_2\text{(g)} \rightleftharpoons 2 \text{CO(g)}$$
- Predict the effect (shift right, shift left, or no effect) of increasing and decreasing the reaction temperature. How does the value of the equilibrium constant depend on temperature?
70. This reaction is exothermic.
- $$\text{C}_6\text{H}_{12}\text{O}_6\text{(s)} + 6 \text{O}_2\text{(g)} \rightleftharpoons 6 \text{CO}_2\text{(g)} + 6 \text{H}_2\text{O(g)}$$
- Predict the effect (shift right, shift left, or no effect) of increasing and decreasing the reaction temperature. How does the value of the equilibrium constant depend on temperature?
71. Coal, which is primarily carbon, can be converted to natural gas, primarily  $\text{CH}_4$ , by the exothermic reaction:
- $$\text{C(s)} + 2 \text{H}_2\text{(g)} \rightleftharpoons \text{CH}_4\text{(g)}$$

Which disturbance will favor  $\text{CH}_4$  at equilibrium?

- adding more C to the reaction mixture
  - adding more  $\text{H}_2$  to the reaction mixture
  - raising the temperature of the reaction mixture
  - lowering the volume of the reaction mixture
  - adding a catalyst to the reaction mixture
  - adding neon gas to the reaction mixture
72. Coal can be used to generate hydrogen gas (a potential fuel) by the endothermic reaction:

If this reaction mixture is at equilibrium, predict whether each disturbance will result in the formation of additional hydrogen gas, the formation of less hydrogen gas, or have no effect on the quantity of hydrogen gas.

- adding more C to the reaction mixture
- adding more  $\text{H}_2\text{O}$  to the reaction mixture
- raising the temperature of the reaction mixture
- increasing the volume of the reaction mixture
- adding a catalyst to the reaction mixture
- adding an inert gas to the reaction mixture

## Cumulative Problems

73. Carbon monoxide replaces oxygen in oxygenated hemoglobin according to the reaction:
- $$\text{HbO}_2\text{(aq)} + \text{CO(aq)} \rightleftharpoons \text{HbCO(aq)} + \text{O}_2\text{(aq)}$$
- Use the reactions and associated equilibrium constants at body temperature given here to find the equilibrium constant for the reaction just shown.
- $$\text{Hb(aq)} + \text{O}_2\text{(aq)} \rightleftharpoons \text{HbO}_2\text{(aq)} \quad K_c = 1.8$$
- $$\text{Hb(aq)} + \text{CO(aq)} \rightleftharpoons \text{HbCO(aq)} \quad K_c = 306$$
- Suppose that an air mixture becomes polluted with carbon monoxide at a level of 0.10% (by volume). Assuming the air contains 20.0% oxygen, and that the oxygen and carbon monoxide ratios that dissolve in the blood are identical to the ratios in the air, what is the ratio of  $\text{HbCO}$  to  $\text{HbO}_2$  in the bloodstream? Comment on the toxicity of carbon monoxide.
74. Nitrogen monoxide is a pollutant in the lower atmosphere that irritates the eyes and lungs and leads to the formation of acid rain. Nitrogen monoxide forms naturally in atmosphere according to the endothermic reaction:
- $$\text{N}_2\text{(g)} + \text{O}_2\text{(g)} \rightleftharpoons 2 \text{NO(g)} \quad K_p = 4.1 \times 10^{-31} \text{ at } 298 \text{ K}$$
- Use the ideal gas law to calculate the concentrations of nitrogen and oxygen present in air at a pressure of 1.0 atm and a temperature of 298 K. Assume that nitrogen composes 78% of air by volume and that oxygen composes 21% of air. Find the "natural" equilibrium concentration of  $\text{NO}$  in air in units of molecules/ $\text{cm}^3$ . How would you expect this concentration to change in an automobile engine in which combustion is occurring?
75. The reaction  $\text{CO}_2\text{(g)} + \text{C(s)} \rightleftharpoons 2 \text{CO(g)}$  has  $K_p = 5.78$  at 1200 K.
- Calculate the total pressure at equilibrium when 4.45 g of  $\text{CO}_2$  is introduced into a 10.0-L container and heated to 1200 K in the presence of 2.00 g of graphite.
  - Repeat the calculation of part a in the presence of 0.50 g of graphite.
76. A mixture of water and graphite is heated to 600 K. When the system comes to equilibrium, it contains 0.13 mol of  $\text{H}_2$ , 0.13 mol of  $\text{CO}$ , 0.43 mol of  $\text{H}_2\text{O}$ , and some graphite. Some  $\text{O}_2$  is added to the

system, and a spark is applied so that the  $\text{H}_2$  reacts completely with the  $\text{O}_2$ . Find the amount of  $\text{CO}$  in the flask when the system returns to equilibrium.

77. At 650 K, the reaction  $\text{MgCO}_3\text{(s)} \rightleftharpoons \text{MgO(s)} + \text{CO}_2\text{(g)}$  has  $K_p = 0.026$ . A 10.0-L container at 650 K has 1.0 g of  $\text{MgO(s)}$  and  $\text{CO}_2$  at  $P = 0.0260$  atm. The container is then compressed to a volume of 0.100 L. Find the mass of  $\text{MgCO}_3$  that is formed.
78. A system at equilibrium contains  $\text{I}_2\text{(g)}$  at a pressure of 0.21 atm and  $\text{I(g)}$  at a pressure of 0.23 atm. The system is then compressed to half its volume. Find the pressure of each gas when the system returns to equilibrium.
79. Consider the exothermic reaction:
- $$\text{C}_2\text{H}_4\text{(g)} + \text{Cl}_2\text{(g)} \rightleftharpoons \text{C}_2\text{H}_4\text{Cl}_2\text{(g)}$$
- If you were trying to maximize the amount of  $\text{C}_2\text{H}_4\text{Cl}_2$  produced, which tactic might you try? Assume that the reaction mixture reaches equilibrium.
- increasing the reaction volume
  - removing  $\text{C}_2\text{H}_4\text{Cl}_2$  from the reaction mixture as it forms
  - lowering the reaction temperature
  - adding  $\text{Cl}_2$
80. Consider the endothermic reaction:
- $$\text{C}_2\text{H}_4\text{(g)} + \text{I}_2\text{(g)} \rightleftharpoons \text{C}_2\text{H}_4\text{I}_2\text{(g)}$$
- If you were trying to maximize the amount of  $\text{C}_2\text{H}_4\text{I}_2$  produced, which tactic might you try? Assume that the reaction mixture reaches equilibrium.
- decreasing the reaction volume
  - removing  $\text{I}_2$  from the reaction mixture
  - raising the reaction temperature
  - adding  $\text{C}_2\text{H}_4$  to the reaction mixture
81. Consider the reaction:
- $$\text{H}_2\text{(g)} + \text{I}_2\text{(g)} \rightleftharpoons 2 \text{HI(g)}$$

A reaction mixture at equilibrium at 175 K contains  $P_{\text{H}_2} = 0.958$  atm,  $P_{\text{I}_2} = 0.877$  atm, and  $P_{\text{HI}} = 0.020$  atm. A second reaction mixture, also at 175 K, contains  $P_{\text{H}_2} = P_{\text{I}_2} = 0.621$  atm and  $P_{\text{HI}} = 0.101$  atm. Is the second reaction at equilibrium? If not, what will be the partial pressure of  $\text{HI}$  when the reaction reaches equilibrium at 175 K?

82. Consider the reaction:

A reaction mixture initially containing 0.500 M  $\text{H}_2\text{S}$  and 0.500 M  $\text{SO}_2$  contains 0.0011 M  $\text{H}_2\text{O}$  at equilibrium at a certain temperature. A second reaction mixture at the same temperature initially contains  $[\text{H}_2\text{S}] = 0.250 \text{ M}$  and  $[\text{SO}_2] = 0.325 \text{ M}$ . Calculate the equilibrium concentration of  $\text{H}_2\text{O}$  in the second mixture at this temperature.

83. Ammonia can be synthesized according to the reaction:

A 200.0-L reaction container initially contains 1.27 kg of  $\text{N}_2$  and 0.310 kg of  $\text{H}_2$  at 725 K. Assuming ideal gas behavior, calculate the mass of  $\text{NH}_3$  (in g) present in the reaction mixture at equilibrium. What is the percent yield of the reaction under these conditions?

84. Hydrogen can be extracted from natural gas according to the reaction:

An 85.0-L reaction container initially contains 22.3 kg of  $\text{CH}_4$  and 55.4 kg of  $\text{CO}_2$  at 825 K. Assuming ideal gas behavior, calculate the mass of  $\text{H}_2$  (in g) present in the reaction mixture at equilibrium. What is the percent yield of the reaction under these conditions?

85. The system described by the reaction:
- $\text{CO}(\text{g}) + \text{Cl}_2(\text{g}) \rightleftharpoons \text{COCl}_2(\text{g})$
- is at equilibrium at a given temperature when
- $P_{\text{CO}} = 0.30 \text{ atm}$
- ,
- $P_{\text{Cl}_2} = 0.10 \text{ atm}$
- , and
- $P_{\text{COCl}_2} = 0.60 \text{ atm}$
- . An additional pressure of
- $\text{Cl}_2(\text{g}) = 0.40 \text{ atm}$
- is added. Find the pressure of CO when the system returns to equilibrium.

86. A reaction vessel at 27 °C contains a mixture of
- $\text{SO}_2$
- (
- $P = 3.00 \text{ atm}$
- ) and
- $\text{O}_2$
- (
- $P = 1.00 \text{ atm}$
- ). When a catalyst is added,

this reaction takes place:  $2 \text{SO}_2(\text{g}) + \text{O}_2(\text{g}) \rightleftharpoons 2 \text{SO}_3(\text{g})$ . At equilibrium, the total pressure is 3.75 atm. Find the value of  $K_c$ .

87. At 70 K,
- $\text{CCl}_4$
- decomposes to carbon and chlorine. The
- $K_p$
- for the decomposition is 0.76. Find the starting pressure of
- $\text{CCl}_4$
- at this temperature that will produce a total pressure of 1.0 atm at equilibrium.

88. The equilibrium constant for the reaction
- $\text{SO}_2(\text{g}) + \text{NO}_2(\text{g}) \rightleftharpoons \text{SO}_3(\text{g}) + \text{NO}(\text{g})$
- is
- $K_c = 3.0$
- . Find the amount of
- $\text{NO}_2$
- that must be added to 2.4 mol of
- $\text{SO}_2$
- in order to form 1.2 mol of
- $\text{SO}_3$
- at equilibrium.

89. A sample of
- $\text{CaCO}_3(\text{s})$
- is introduced into a sealed container of volume 0.654 L and heated to 1000 K until equilibrium is reached. The
- $K_p$
- for the reaction
- $\text{CaCO}_3(\text{s}) \rightleftharpoons \text{CaO}(\text{s}) + \text{CO}_2(\text{g})$
- is
- $3.9 \times 10^{-2}$
- at this temperature. Calculate the mass of
- $\text{CaO}(\text{s})$
- that is present at equilibrium.

90. An equilibrium mixture contains
- $\text{N}_2\text{O}_4$
- (
- $P = 0.28 \text{ atm}$
- ) and
- $\text{NO}_2$
- (
- $P = 1.1 \text{ atm}$
- ) at 350 K. The volume of the container is doubled at constant temperature. Write a balanced chemical equation for the reaction and calculate the equilibrium pressures of the two gases when the system reaches a new equilibrium.

91. Carbon monoxide and chlorine gas react to form phosgene:

If a reaction mixture initially contains 215 torr of CO and 245 torr of  $\text{Cl}_2$ , what is the mole fraction of  $\text{COCl}_2$  when equilibrium is reached?

92. Solid carbon can react with gaseous water to form carbon monoxide gas and hydrogen gas. The equilibrium constant for the reaction at 700.0 K is
- $K_p = 1.60 \times 10^{-3}$
- . If a 1.55-L reaction vessel initially contains 145 torr of water at 700.0 K in contact with excess solid carbon, find the percent by mass of hydrogen gas of the gaseous reaction mixture at equilibrium.

## Challenge Problems

93. Consider the reaction:

- a. A reaction mixture at 175 K initially contains 522 torr of NO and 421 torr of  $\text{O}_2$ . At equilibrium, the total pressure in the reaction mixture is 748 torr. Calculate  $K_p$  at this temperature.
- b. A second reaction mixture at 175 K initially contains 255 torr of NO and 185 torr of  $\text{O}_2$ . What is the equilibrium partial pressure of  $\text{NO}_2$  in this mixture?

94. Consider the reaction:

A 2.75-L reaction vessel at 950 K initially contains 0.100 mol of  $\text{SO}_2$  and 0.100 mol of  $\text{O}_2$ . Calculate the total pressure (in atmospheres) in the reaction vessel when equilibrium is reached.

95. Nitric oxide reacts with chlorine gas according to the reaction:

A reaction mixture initially contains equal partial pressures of NO and  $\text{Cl}_2$ . At equilibrium, the partial pressure of NOCl is 115 torr. What were the initial partial pressures of NO and  $\text{Cl}_2$ ?

96. At a given temperature, a system containing
- $\text{O}_2(\text{g})$
- and some oxides of nitrogen can be described by these reactions:

A pressure of 1 atm of  $\text{N}_2\text{O}_4(\text{g})$  is placed in a container at this temperature. Predict which, if any, component (other than  $\text{N}_2\text{O}_4$ ) will be present at a pressure greater than 0.2 atm at equilibrium.

97. A sample of pure
- $\text{NO}_2$
- is heated to 337 °C, at which temperature it partially dissociates according to the equation:

At equilibrium the density of the gas mixture is 0.520 g/L at 0.750 atm. Calculate  $K_c$  for the reaction.

98. When
- $\text{N}_2\text{O}_5(\text{g})$
- is heated, it dissociates into
- $\text{N}_2\text{O}_3(\text{g})$
- and
- $\text{O}_2(\text{g})$
- according to the reaction:

The  $\text{N}_2\text{O}_3(\text{g})$  dissociates to give  $\text{N}_2\text{O}(\text{g})$  and  $\text{O}_2(\text{g})$  according to the reaction:

When 4.00 mol of  $\text{N}_2\text{O}_5(\text{g})$  is heated in a 1.00-L reaction vessel to this temperature, the concentration of  $\text{O}_2(\text{g})$  at equilibrium is 4.50 mol/L. Find the concentrations of all the other species in the equilibrium system.

99. A sample of
- $\text{SO}_3$
- is introduced into an evacuated sealed container and heated to 600 K. The following equilibrium is established:

The total pressure in the system is 3.0 atm and the mole fraction of  $\text{O}_2$  is 0.12. Find  $K_p$ .

## Conceptual Problems

**100.** A reaction  $A(g) \rightleftharpoons B(g)$  has an equilibrium constant of  $1.0 \times 10^{-4}$ . For which of the initial reaction mixtures is the  $x$  is *small* approximation most likely to apply?

- $[A] = 0.0010 \text{ M}$ ;  $[B] = 0.00 \text{ M}$
- $[A] = 0.00 \text{ M}$ ;  $[B] = 0.10 \text{ M}$
- $[A] = 0.10 \text{ M}$ ;  $[B] = 0.10 \text{ M}$
- $[A] = 0.10 \text{ M}$ ;  $[B] = 0.00 \text{ M}$

**101.** The reaction  $A(g) \rightleftharpoons 2B(g)$  has an equilibrium constant of  $K_c = 1.0$  at a given temperature. If a reaction vessel contains equal initial amounts (in moles) of A and B, does the direction in which the reaction proceeds depend on the volume of the reaction vessel? Explain.

**102.** A particular reaction has an equilibrium constant of  $K_p = 0.50$ . A reaction mixture is prepared in which all the reactants and products are in their standard states. In which direction does the reaction proceed?

**103.** Consider the reaction:

Each of the entries in the following table represents equilibrium partial pressures of A and B under different initial conditions. What are the values of  $a$  and  $b$  in the reaction?

$P_A$ (atm)	$P_B$ (atm)
4.0	2.0
2.0	1.4
1.0	1.0
0.50	0.71
0.25	0.50

**104.** Consider the simple one-step reaction:

Since the reaction occurs in a single step, the forward reaction has a rate of  $k_{\text{for}}[A]$  and the reverse reaction has a rate of  $k_{\text{rev}}[B]$ . What happens to the rate of the forward reaction when we increase the concentration of A? How does this explain the reason behind Le Châtelier's principle?

**105.** Consider the reaction:  $A(g) \rightleftharpoons 2B(g)$ . The graph plots the concentrations of A and B as a function of time at a constant temperature. What is the equilibrium constant for this reaction at this temperature?

## Questions for Group Work

Discuss these questions with the group and record your consensus answer.

**106.** The reactions shown here can be combined to make the overall reaction  $C(s) + H_2O(g) \longrightarrow CO(g) + H_2(g)$  by reversing some and/or dividing all the coefficients by a number. As a group, determine how the reactions need to be modified to sum to the overall process. Then have each group member determine the value of  $K$  for one of the reactions to be combined. Finally, combine all the values of  $K$  to determine the value of  $K$  for the overall reaction.

- $C(s) + O_2(g) \longrightarrow CO_2(g)$   $K = 1.363 \times 10^{69}$
- $2H_2(g) + O_2(g) \longrightarrow 2H_2O(g)$   $K = 1.389 \times 10^{80}$
- $2CO(g) + O_2(g) \longrightarrow 2CO_2(g)$   $K = 1.477 \times 10^{90}$

**107.** Consider the reaction:  $N_2(g) + 3H_2(g) \longrightarrow 2NH_3(g)$ .

- Write the equilibrium constant expression for this reaction. If some hydrogen is added, before the reaction shifts, how will the numerator and denominator of the expression in part a compare to the value at equilibrium?
- Will  $Q$  be larger or smaller than  $K$ ? Why?
- Will the reaction have to shift forward or backward to retain equilibrium? Explain.
- Are your answers above consistent with Le Châtelier's principle? Explain.

**108.** For the reaction  $A \longrightarrow B$ , the ratio of products to reactants at equilibrium is always the same number, no matter how much A or B is initially present. Interestingly, in contrast, the ratio of products to reactants for the reaction  $C \longrightarrow 2D$  does depend on how much of C and D you have initially. Explain this observation. Which ratio is independent of the starting amounts of C and D? Answer in complete sentences.

**109.** Solve each of the expressions for  $x$  using the quadratic formula and the  $x$  is *small* approximation. In which of the following expressions is the  $x$  is *small* approximation valid?

- $x^2/(0.2 - x) = 1.3 \times 10^4$
- $x^2/(0.2 - x) = 1.3$
- $x^2/(0.2 - x) = 1.3 \times 10^{-4}$
- $x^2/(0.01 - x) = 1.3 \times 10^{-4}$

In a complete sentence, describe the factor(s) that tend to make the  $x$  is *small* approximation valid in an expression.

**110.** Have each group member explain to the group what happens if a system at equilibrium is subject to one of the following changes and why:

- the concentration of a reactant is increased
- a solid product is added
- the volume is decreased
- the temperature is raised

## Data Interpretation and Analysis

### Chemical Equilibrium on Venus

**111.** The atmosphere of Venus is currently composed of 96.5% carbon dioxide, 3.5% nitrogen, trace amounts of sulfur dioxide, and clouds of sulfuric acid. The average temperature on this planet is 740 K and the average pressure is 94 atm. Research suggests that, due to different pressure and temperature conditions, carbon dioxide may have existed in different states on Venus in the past. A phase diagram of carbon dioxide (Figure a) can help estimate the state of carbon dioxide.

▲ **FIGURE a** Phase Diagram of CO<sub>2</sub>.

Because of the large quantities of CO<sub>2</sub> on Venus, the concentration of CO<sub>2</sub> in the atmosphere could depend on one or more equilibrium systems with carbonate ions in minerals. For example, carbon dioxide gas might react with calcium silicate (CaSiO<sub>3</sub>) according to the following equilibrium:

An alternative viewpoint suggests that the concentration of CO<sub>2</sub> gas in the atmosphere of Venus depends on the following equilibrium:

Temperature plays an important role in equilibrium systems. The graph in Figure b plots temperature in units of Kelvin versus the log of the partial pressure of CO<sub>2</sub> gas for each of the two possible reactions. The area marked as region 1 corresponds to the equilibrium system for Reaction 1, whereas the area marked as region 2 corresponds to the equilibrium system for Reaction 2.

For the questions that follow, choose a point in the middle of the colored band (which represents the range of possible values). For example, according to the graph, on Earth, at a temperature of 298 K, the  $\log P_{\text{CO}_2} = -3.90$  for Reaction 2. This corresponds to a partial pressure of  $1.3 \times 10^{-4}$  atm.

Use the information provided in the figures to answer the following questions:

- If the partial pressure of CO<sub>2</sub> on Venus is 91 atm, calculate the equilibrium constant ( $K_p$ ) for Reactions 1 and 2.
- Determine the partial pressure of CO<sub>2</sub> on Venus if the temperature cooled from 750 K to 400 K using Reaction 1? Using Reaction 2? Choose values in the middle of colored bands of the graph in Figure b.
- Refer to the phase diagram in Figure a. At what minimum pressure can supercritical CO<sub>2</sub> form? If the pressure of the Venusian atmosphere in the distant past was much higher than it is today, could supercritical carbon dioxide have existed on the surface of Venus?

▲ **FIGURE b** A Representation of Two Types of Equilibrium Systems Involving Carbon Dioxide on Venus.

## Answers to Conceptual Connections

### The Magnitude of the Equilibrium Constant

**15.1** The equilibrium constant is largest for temperature  $T_3$  (because the reaction mixture has the most products relative to reactants at that temperature).

### Equilibrium Constants and Equilibrium Concentrations

**15.2 (b)** The reaction mixture will contain  $[A] = 0.1 \text{ M}$  and  $[B] = 1.0 \text{ M}$  so that  $[B]/[A] = 10$ .

### The Equilibrium Constant and the Chemical Equation

**15.3 (b)** The reaction is reversed and divided through by two. Therefore, you invert the equilibrium constant and take the square root of the result.  $K = (1/0.010)^{1/2} = 10$ .

### The Relationship between $K_p$ and $K_c$

**15.4 (a)** When  $a + b = c + d$ , the quantity  $\Delta n$  is zero so that  $K_p = K_c(RT)^0$ . Since  $(RT)^0$  is equal to 1,  $K_p = K_c$ .

### Heterogeneous Equilibria, $K_p$ , and $K_c$

**15.5 (b)** Since  $\Delta n$  for gaseous reactants and products is zero,  $K_p = K_c$ .

### Q and K

**15.6 (c)** Because  $\text{N}_2\text{O}_4$  and  $\text{NO}_2$  are both in their standard states, they each have a partial pressure of 1.0 atm. Consequently,  $Q_p = 1$ . Since  $K_p = 0.15$ ,  $Q_p > K_p$ , and the reaction proceeds to the left.

### The $x$ is small Approximation

**15.7 (a)** The  $x$  is small approximation is most likely to apply to a reaction with a small equilibrium constant and an initial concentration of reactant that is not too small. The bigger the equilibrium constant and the smaller the initial concentration of reactant, the less likely that the  $x$  is small approximation will apply.

# Acids and Bases

The differences between the various acid–base concepts are not concerned with which is right, but which is most convenient to use in a particular situation.

**KEY LEARNING OUTCOMES 770**

In this chapter, we apply the equilibrium concepts learned in the previous chapter to acid–base phenomena. Acids are common in many foods, such as limes, lemons, and vinegar, and in a number of consumer products, such as toilet cleaners and batteries. Bases are less common in foods but are key ingredients in consumer products such as drain openers and antacids. We will examine three different models for acid–base behavior, all of which define that behavior differently. In spite of their differences, the three models co-exist, each being useful at explaining a particular range of acid–base phenomena. We also examine how to calculate the acidity or basicity of solutions and define a useful scale, called the pH scale, to quantify acidity and basicity. These types of calculations often involve solving the kind of equilibrium problems that we explored in Chapter 15.

▲ Milk of magnesia contains a base that can neutralize stomach acid and relieve heartburn.

## 16.1 Heartburn

Heartburn is a painful burning sensation in the esophagus (the tube that joins the throat to the stomach) just below the chest. The pain is caused by hydrochloric acid (HCl), which the stomach excretes to kill microorganisms and to activate enzymes that break down food. Hydrochloric acid sometimes backs up out of the stomach and into the esophagus, a phenomenon called *acid reflux*. Recall from Section 4.8 that acids are substances that—by one definition that we elaborate on shortly—produce  $H^+$  ions in solution. When hydrochloric acid from the stomach comes in contact with the lining of the esophagus, the  $H^+$  ions irritate the tissues, resulting in the burning sensation. Some of the acid can work its way into the lower throat and even the mouth, producing pain

Bases were first defined in Section 4.8.

The bicarbonate ion neutralizes stomach acid according to the reaction:  $\text{H}^+(\text{aq}) + \text{HCO}_3^-(\text{aq}) \longrightarrow \text{H}_2\text{O}(\text{l}) + \text{CO}_2(\text{g})$ .

The concentration of stomach acid,  $[\text{H}_3\text{O}^+]$ , varies from about 0.01 to 0.1 M.

For a review of acid naming, see Section 3.6.  
Litmus paper contains dyes that change color in the presence of acids and bases.

The formula for acetic acid can also be written as  $\text{CH}_3\text{COOH}$ .

in the throat and a sour taste (characteristic of acids) in the mouth. Almost everyone experiences heartburn at some time, most commonly after a large meal when the stomach is full. Strenuous activity or lying in a horizontal position after a large meal increases the likelihood of stomach acid reflux and the resulting heartburn.

The simplest way to relieve mild heartburn is to swallow repeatedly. Saliva contains the bicarbonate ion ( $\text{HCO}_3^-$ ), which acts as a base and, when swallowed, neutralizes some of the acid in the esophagus. Later in this chapter, we will see how bicarbonate acts as a base. You can also treat heartburn with antacids such as Tums, milk of magnesia, or Mylanta. These over-the-counter medications contain more base than saliva does and therefore are effective at neutralizing esophageal acid. We look at the bases in these medicines more carefully later (see *Chemistry and Medicine: What's in My Antacid?* in Section 16.7).

For some people, heartburn becomes a chronic problem. Gastroesophageal reflux disease (GERD) is the medical condition associated with chronic heartburn. In patients with GERD, the band of muscles (called the esophageal sphincter) at the bottom of the esophagus just above the stomach does not close tightly enough, allowing stomach contents to leak back into the esophagus on a regular basis. Medical researchers have developed a wireless sensor to help diagnose and evaluate treatment of GERD. Using a tube that goes down through the throat, a physician attaches the sensor to tissues in the patient's esophagus. The sensor reads pH—a measure of acidity that we discuss in Section 16.5—and transmits the readings to a recorder worn on the patient's body. The patient goes about his or her normal activities for the next few days while the recorder monitors esophageal pH. The physician then reads the record of esophageal pH to make a diagnosis or evaluate treatment.

In this chapter, we examine acid and base behavior. Acids and bases are not only important to our health (as we have just seen), but are also found in many household products, foods, medicines, and of course in nearly every chemistry laboratory. Acid–base chemistry is central to much of biochemistry and molecular biology. The building blocks of proteins, for example, are acids (called amino acids) and the molecules that carry the genetic code in DNA are bases.

## 16.2 The Nature of Acids and Bases

*Acids* have the following general properties: a sour taste, the ability to dissolve many metals, the ability to turn blue litmus paper red, and the ability to neutralize bases. Table 16.1 lists some common acids.

TABLE 16.1 Some Common Acids

Name	Occurrence / Uses
Hydrochloric acid (HCl)	Metal cleaning; food preparation; ore refining; primary component of stomach acid
Sulfuric acid (H <sub>2</sub> SO <sub>4</sub> )	Fertilizer and explosives manufacturing; dye and glue production; in automobile batteries; electroplating of copper
Nitric acid (HNO <sub>3</sub> )	Fertilizer and explosives manufacturing; dye and glue production
Acetic acid (HC <sub>2</sub> H <sub>3</sub> O <sub>2</sub> )	Plastic and rubber manufacturing; food preservation; active component of vinegar
Citric acid (H <sub>3</sub> C <sub>6</sub> H <sub>5</sub> O <sub>7</sub> )	In citrus fruits such as lemons and limes; used to adjust pH in foods and beverages
Carbonic acid (H <sub>2</sub> CO <sub>3</sub> )	In carbonated beverages due to the reaction of carbon dioxide with water
Hydrofluoric acid (HF)	Metal cleaning; glass frosting and etching
Phosphoric acid (H <sub>3</sub> PO <sub>4</sub> )	Fertilizer manufacturing; biological buffering; beverage preservation

You can find hydrochloric acid in most chemistry laboratories. In industry, it is used to clean metals, to prepare and process some foods, and to refine metal ores. As we discussed in Section 16.1, hydrochloric acid is also the main component of stomach acid.

Hydrochloric acid

Sulfuric acid and nitric acid are also common in the laboratory. They play major roles in the manufacture of fertilizers, explosives, dyes, and glues. Sulfuric acid, produced in larger quantities than any other industrial chemical, is used in most automobile batteries.

Sulfuric acid

Nitric acid

Acetic acid

You can probably find acetic acid in your home—it is the active component of vinegar. It is also produced in improperly stored wines. The word *vinegar* originates from the French words *vin aigre*, which means “sour wine.” Wine experts consider the presence of vinegar in wines a serious fault, since it makes the wine taste like salad dressing.

Acetic acid is a **carboxylic acid**, an acid that contains the following grouping of atoms:

Carboxylic acid group

Carboxylic acids are often found in substances derived from living organisms. Other examples of carboxylic acids are citric acid, found in lemons and limes, and malic acid, found in apples, grapes, and wine.

Citric acid

Malic acid

▲ Citrus fruits, apples, and grapes all contain acids.

▲ Acetic acid makes vinegar taste sour.

▲ Many common household products and remedies contain bases.

Coffee is acidic overall, but bases present in coffee—such as caffeine—and other compounds impart a bitter flavor.

**TABLE 16.2** Common Bases

Name	Occurrence / Uses
Sodium hydroxide (NaOH)	Petroleum processing; soap and plastic manufacturing
Potassium hydroxide (KOH)	Cotton processing; electroplating; soap production; batteries
Sodium bicarbonate (NaHCO <sub>3</sub> )	Sold as baking soda; antacid; source of CO <sub>2</sub>
Sodium carbonate (Na <sub>2</sub> CO <sub>3</sub> )	Glass and soap manufacturing; general cleanser; water softener
Ammonia (NH <sub>3</sub> )	Detergent; fertilizer and explosives manufacturing; synthetic fiber production

Bases have the following general properties: a bitter taste, a slippery feel, the ability to turn red litmus paper blue, and the ability to neutralize acids. Because of their bitterness, bases are less common in foods than are acids. Our aversion to the taste of bases is probably an evolutionary adaptation to warn us against **alkaloids**, organic bases found in plants that are often poisonous. (For example, the active component of hemlock—the poisonous plant that killed the Greek philosopher Socrates—is the alkaloid coniine.) Nonetheless, some foods, such as coffee and chocolate (especially dark chocolate), contain bitter flavors. Many people enjoy the bitterness, but only after acquiring the taste over time.

Bases feel slippery because they react with oils on the skin to form soap-like substances. Some household cleaning solutions, such as ammonia, are basic and have the characteristic slippery feel of a base. Bases turn red litmus paper blue; in the laboratory, litmus paper is routinely used to test the basicity of solutions.

Some common bases are listed in Table 16.2. You can find sodium hydroxide and potassium hydroxide in most chemistry laboratories. They are used in petroleum and cotton processing and in soap and plastic manufacturing. Sodium hydroxide is the active ingredient in products such as Drano that unclog drains. In many homes, you can find sodium bicarbonate in the medicine cabinet (it is an active ingredient in some antacids) as well as in the kitchen (labeled as baking soda).

### Definitions of Acids and Bases

## 16.3 Definitions of Acids and Bases

What are the key characteristics of the molecules and ions that exhibit acid and base behavior? In this chapter, we examine three different definitions: the Arrhenius definition, the Brønsted–Lowry definition, and the Lewis definition. Why three definitions, and which one is correct? As inorganic chemist and author James Huheey notes in the quotation that opens this chapter, no single definition is “correct.” Rather, each definition is useful in a given instance. We discuss the Lewis definition of acids and bases in Section 16.11; here we discuss the other two.

### The Arrhenius Definition

In the 1880s, Swedish chemist Svante Arrhenius (1859–1927) proposed the following molecular definitions of acids and bases:

**Acid:** A substance that produces H<sup>+</sup> ions in aqueous solution.

**Base:** A substance that produces OH<sup>−</sup> ions in aqueous solution.

According to the **Arrhenius definition**, HCl is an acid because it produces H<sup>+</sup> ions in solution (Figure 16.1 ◀):

Hydrogen chloride (HCl) is a covalent compound and does not contain ions. However, in water it *ionizes* completely to form H<sup>+</sup>(aq) ions and Cl<sup>−</sup>(aq) ions. The H<sup>+</sup> ions are highly reactive. In aqueous solution, the H<sup>+</sup> ions bond to water to form H<sub>3</sub>O<sup>+</sup>:

Arrhenius Acid

▲ **FIGURE 16.1** Arrhenius Acid  
An Arrhenius acid produces H<sup>+</sup> ions in solution.

The  $\text{H}_3\text{O}^+$  ion is the **hydronium ion**. In water,  $\text{H}^+$  ions *always* associate with  $\text{H}_2\text{O}$  molecules to form hydronium ions and other associated species with the general formula  $\text{H}(\text{H}_2\text{O})_n^+$ . For example, an  $\text{H}^+$  ion can associate with two water molecules to form  $\text{H}(\text{H}_2\text{O})_2^+$ , with three to form  $\text{H}(\text{H}_2\text{O})_3^+$ , and so on. Chemists often use  $\text{H}^+(\text{aq})$  and  $\text{H}_3\text{O}^+(\text{aq})$  interchangeably to mean the same thing—an  $\text{H}^+$  ion that has been solvated (or dissolved) in water.

According to the Arrhenius definition,  $\text{NaOH}$  is a base because it produces  $\text{OH}^-$  ions in solution (Figure 16.2▶):

$\text{NaOH}$  is an ionic compound and therefore contains  $\text{Na}^+$  and  $\text{OH}^-$  ions. When  $\text{NaOH}$  is added to water, it *dissociates* (breaks apart) into its component ions.

Under the Arrhenius definition, acids and bases combine to form water, neutralizing each other in the process:

**▲ FIGURE 16.2 Arrhenius Base** An Arrhenius base produces  $\text{OH}^-$  ions in solution.

## The Brønsted–Lowry Definition

A second, more widely applicable definition of acids and bases, the **Brønsted–Lowry definition**, was introduced in 1923. This definition focuses on the *transfer of  $\text{H}^+$  ions* in an acid–base reaction. Since an  $\text{H}^+$  ion is a proton—a hydrogen atom without its electron—this definition focuses on the idea of a proton donor and a proton acceptor:

**Acid:** proton ( $\text{H}^+$  ion) *donor*

**Base:** proton ( $\text{H}^+$  ion) *acceptor*

According to this definition,  $\text{HCl}$  is an acid because, in solution, it donates a proton to water:

This definition clearly describes what happens to the  $\text{H}^+$  ion from an acid—it associates with a water molecule to form  $\text{H}_3\text{O}^+$  (a hydronium ion). The Brønsted–Lowry definition also applies nicely to bases (such as  $\text{NH}_3$ ) that do not inherently contain  $\text{OH}^-$  ions but still produce  $\text{OH}^-$  ions in solution. According to the Brønsted–Lowry definition,  $\text{NH}_3$  is a base because it accepts a proton from water:

According to the Brønsted–Lowry definition, acids (proton donors) and bases (proton acceptors) always occur together in an acid–base reaction. In the reaction between  $\text{HCl}$  and  $\text{H}_2\text{O}$ ,  $\text{HCl}$  is the proton donor (acid) and  $\text{H}_2\text{O}$  is the proton acceptor (base):

In the reaction between  $\text{NH}_3$  and  $\text{H}_2\text{O}$ ,  $\text{H}_2\text{O}$  is the proton donor (acid) and  $\text{NH}_3$  is the proton acceptor (base):

According to the Brønsted–Lowry definition, some substances—such as water in the previous two equations—can act as acids *or* bases. Substances that can act as acids or bases are **amphoteric**. Notice what happens when we reverse an equation representing a Brønsted–Lowry acid–base reaction:

All Arrhenius acids and bases are acids and bases under the Brønsted–Lowry definition. However, some Brønsted–Lowry acids and bases cannot be classified as Arrhenius acids and bases.

► **FIGURE 16.3** Conjugate

**Acid–Base Pairs** A conjugate acid–base pair consists of two substances related to each other by the transfer of a proton.

In this reaction,  $\text{NH}_4^+$  is the proton donor (acid) and  $\text{OH}^-$  is the proton acceptor (base). The substance that was the base ( $\text{NH}_3$ ) has become the acid ( $\text{NH}_4^+$ ) and vice versa.  $\text{NH}_4^+$  and  $\text{NH}_3$  are often referred to as a **conjugate acid–base pair**, two substances related to each other by the transfer of a proton (Figure 16.3▲). A **conjugate acid** is any base to which a proton has been added, and a **conjugate base** is any acid from which a proton has been removed. Going back to the original forward reaction, we can identify the conjugate acid–base pairs:

**Summarizing the Brønsted–Lowry Definition of Acids and Bases:**

- A base accepts a proton and becomes a conjugate acid.
- An acid donates a proton and becomes a conjugate base.

**Example 16.1** Identifying Brønsted–Lowry Acids and Bases and Their Conjugates

In each reaction, identify the Brønsted–Lowry acid, the Brønsted–Lowry base, the conjugate acid, and the conjugate base.

**SOLUTION**

- (a) Because  $\text{H}_2\text{SO}_4$  donates a proton to  $\text{H}_2\text{O}$  in this reaction, it is the acid (proton donor). After  $\text{H}_2\text{SO}_4$  donates the proton, it becomes  $\text{HSO}_4^-$ , the conjugate base. Because  $\text{H}_2\text{O}$  accepts a proton, it is the base (proton acceptor). After  $\text{H}_2\text{O}$  accepts the proton, it becomes  $\text{H}_3\text{O}^+$ , the conjugate acid.

- (b) Because  $\text{H}_2\text{O}$  donates a proton to  $\text{HCO}_3^-$  in this reaction, it is the acid (proton donor). After  $\text{H}_2\text{O}$  donates the proton, it becomes  $\text{OH}^-$ , the conjugate base. Because  $\text{HCO}_3^-$  accepts a proton, it is the base (proton acceptor). After  $\text{HCO}_3^-$  accepts the proton, it becomes  $\text{H}_2\text{CO}_3$ , the conjugate acid.

**FOR PRACTICE 16.1** In each reaction, identify the Brønsted–Lowry acid, the Brønsted–Lowry base, the conjugate acid, and the conjugate base.

## CONCEPTUAL CONNECTION 16.1

### Conjugate Acid–Base Pairs Which pair is *not* a conjugate acid–base pair?

- (a)  $(\text{CH}_3)_3\text{N}; (\text{CH}_3)_3\text{NH}^+$     (b)  $\text{H}_2\text{SO}_4; \text{H}_2\text{SO}_3$     (c)  $\text{HNO}_2; \text{NO}_2^-$

## 16.4 Acid Strength and the Acid Ionization Constant ( $K_a$ )

The strength of an electrolyte, first discussed in Section 4.5, depends on the extent of its dissociation into its component ions in solution. A *strong electrolyte* completely dissociates into ions in solution, whereas a *weak electrolyte* only partially dissociates. We define strong and weak acids accordingly. A **strong acid** completely ionizes in solution, whereas a **weak acid** only partially ionizes. In other words, the strength of an acid depends on the equilibrium:

In the preceding equation, HA is a generic formula for an acid. If the equilibrium lies far to the right, the acid is strong—it completely ionizes. If the equilibrium lies to the left, the acid is weak—only a small percentage of the acid molecules ionize. Of course, the range of acid strength is continuous, but for most purposes, the categories of strong and weak are useful.

### Strong Acids

Hydrochloric acid (HCl) is an example of a strong acid:

An HCl solution contains virtually no intact HCl; the HCl has essentially all ionized to form  $\text{H}_3\text{O}^+(aq)$  and  $\text{Cl}^-(aq)$  (Figure 16.4▼). A 1.0 M HCl solution has an  $\text{H}_3\text{O}^+$  concentration of 1.0 M. Abbreviating the concentration of  $\text{H}_3\text{O}^+$  as  $[\text{H}_3\text{O}^+]$ , we say that a 1.0 M HCl solution has  $[\text{H}_3\text{O}^+] = 1.0 \text{ M}$ .

Table 16.3 lists the six important strong acids. The first five acids in the table are **monoprotic acids**, acids containing only one ionizable proton. Sulfuric acid is an example of a **diprotic acid**, an acid containing two ionizable protons.

An ionizable proton is one that ionizes in solution. We discuss polyprotic acids in more detail in Section 16.9.

**TABLE 16.3 Strong Acids**

Hydrochloric acid (HCl)	Nitric acid ( $\text{HNO}_3$ )
Hydrobromic acid (HBr)	Perchloric acid ( $\text{HClO}_4$ )
Hydriodic acid (HI)	Sulfuric acid ( $\text{H}_2\text{SO}_4$ ) ( <i>diprotic</i> )

### A Strong Acid

When HCl dissolves in water, it ionizes completely.

◀ **FIGURE 16.4 Ionization of a Strong Acid** When HCl dissolves in water, it completely ionizes to form  $\text{H}_3\text{O}^+$  and  $\text{Cl}^-$ . The solution contains virtually no intact HCl.

## A Weak Acid

When HF dissolves in water, only a fraction of the molecules ionize.

▲ **FIGURE 16.5 Ionization of a Weak Acid** When HF dissolves in water, only a fraction of the dissolved molecules ionize to form  $\text{H}_3\text{O}^+$  and  $\text{F}^-$ . The solution contains many intact HF molecules.

## Weak Acids

In contrast to HCl, HF is a weak acid, one that does not completely ionize in solution:

The terms *strong* and *weak* acids are often confused with the terms *concentrated* and *dilute* acids. Can you articulate the difference between these terms?

▲ **FIGURE 16.6 Ionic Attraction and Acid Strength** In a strong acid, the attraction between  $\text{H}^+$  and  $\text{A}^-$  is weak, resulting in complete ionization. In a weak acid, the attraction between  $\text{H}^+$  and  $\text{A}^-$  is strong, resulting in only partial ionization.

Alternatively, we can write the formulas for acetic acid and formic acid as  $\text{CH}_3\text{COOH}$  and  $\text{HCOOH}$ , respectively, to indicate that in these compounds the only H that ionizes is the one attached to an oxygen atom.

An HF solution contains a large number of intact (or un-ionized) HF molecules; it also contains some  $\text{H}_3\text{O}^+(aq)$  and  $\text{F}^-(aq)$  (Figure 16.5▲). In other words, a 1.0 M HF solution has an  $[\text{H}_3\text{O}^+]$  that is much less than 1.0 M because only some of the HF molecules ionize to form  $\text{H}_3\text{O}^+$ .

The degree to which an acid is strong or weak depends on the attraction between the anion of the acid (the conjugate base) and the hydrogen ion, relative to the attractions of these ions to water. Recall that HA is a generic formula for an acid. The degree to which the following reaction proceeds in the forward direction depends on the strength of the attraction between  $\text{H}^+$  and  $\text{A}^-$ :

If the attraction between  $\text{H}^+$  and  $\text{A}^-$  is *weak*, then the reaction favors the forward direction and the acid is *strong*. If the attraction between  $\text{H}^+$  and  $\text{A}^-$  is *strong*, then the reaction favors the reverse direction and the acid is *weak*, as shown in Figure 16.6◀.

For example, in HCl, the conjugate base ( $\text{Cl}^-$ ) has a relatively weak attraction to  $\text{H}^+$ —the reverse reaction does not occur to any significant extent. In HF, on the other hand, the conjugate base ( $\text{F}^-$ ) has a greater attraction to  $\text{H}^+$ —the reverse reaction occurs to a significant degree. *In general, the stronger the acid, the weaker the conjugate base and vice versa.* If the forward reaction (that of the acid) has a high tendency to occur, then the reverse reaction (that of the conjugate base) has a low tendency to occur. Table 16.4 lists some common weak acids.

Notice that two of the weak acids in Table 16.4 are diprotic, meaning that they have two ionizable protons, and one is a **triprotic acid** (three ionizable protons). We discuss polyprotic acids in more detail in Section 16.9.

**TABLE 16.4 Some Weak Acids**

Hydrofluoric acid ( $\text{HF}$ )	Sulfurous acid ( $\text{H}_2\text{SO}_3$ ) (diprotic)
Acetic acid ( $\text{HC}_2\text{H}_3\text{O}_2$ )	Carbonic acid ( $\text{H}_2\text{CO}_3$ ) (diprotic)
Formic acid ( $\text{HCHO}_2$ )	Phosphoric acid ( $\text{H}_3\text{PO}_4$ ) (triprotic)

## The Acid Ionization Constant ( $K_a$ )

We quantify the relative strength of a weak acid with the **acid ionization constant ( $K_a$ )**, which is the equilibrium constant for the ionization reaction of the weak acid. As we saw in Section 15.3, for the two equivalent reactions:

the equilibrium constant is:

$$K_a = \frac{[\text{H}_3\text{O}^+][\text{A}^-]}{[\text{HA}]} = \frac{[\text{H}^+][\text{A}^-]}{[\text{HA}]}$$

Since  $[\text{H}_3\text{O}^+]$  is equivalent to  $[\text{H}^+]$ , both forms of the expression are equal. Although the ionization constants for all weak acids are relatively small (otherwise the acid would not be a weak acid), they do vary in magnitude. The smaller the constant, the less the acid ionizes, and the weaker the acid. Table 16.5 lists the acid ionization constants for a number of common weak acids in order of decreasing acid strength. Appendix II C contains a more complete list.

Sometimes  $K_a$  is referred to as the acid dissociation constant.

Recall from Chapter 15 that the concentrations of pure solids or pure liquids are not included in the expression for  $K_c$ ; therefore,  $\text{H}_2\text{O}(l)$  is not included in the expression for  $K_a$ .

**TABLE 16.5** Acid Ionization Constants ( $K_a$ ) for Some Monoprotic Weak Acids at 25 °C

Acid	Formula	Structural Formula	Ionization Reaction	$K_a$	$\text{p}K_a$
Chlorous acid	$\text{HClO}_2$	$\text{H}-\text{O}-\text{Cl}=\text{O}$	$\text{HClO}_2(aq) + \text{H}_2\text{O}(l) \rightleftharpoons \text{H}_3\text{O}^+(aq) + \text{ClO}_2^-(aq)$	$1.1 \times 10^{-2}$	1.96
Nitrous acid	$\text{HNO}_2$	$\text{H}-\text{O}-\text{N}=\text{O}$	$\text{HNO}_2(aq) + \text{H}_2\text{O}(l) \rightleftharpoons \text{H}_3\text{O}^+(aq) + \text{NO}_2^-(aq)$	$4.6 \times 10^{-4}$	3.34
Hydrofluoric acid	$\text{HF}$	$\text{H}-\text{F}$	$\text{HF}(aq) + \text{H}_2\text{O}(l) \rightleftharpoons \text{H}_3\text{O}^+(aq) + \text{F}^-(aq)$	$6.8 \times 10^{-4}$	3.17
Formic acid	$\text{HCHO}_2$	$\text{H}-\text{O}-\overset{\text{O}}{\parallel}{\text{C}}-\text{H}$	$\text{HCHO}_2(aq) + \text{H}_2\text{O}(l) \rightleftharpoons \text{H}_3\text{O}^+(aq) + \text{CHO}_2^-(aq)$	$1.8 \times 10^{-4}$	3.74
Benzoic acid	$\text{HC}_7\text{H}_5\text{O}_2$	$\text{H}-\text{O}-\overset{\text{O}}{\parallel}{\text{C}}-\text{C}_6\text{H}_5$	$\text{HC}_7\text{H}_5\text{O}_2(aq) + \text{H}_2\text{O}(l) \rightleftharpoons \text{H}_3\text{O}^+(aq) + \text{C}_7\text{H}_5\text{O}_2^-(aq)$	$6.5 \times 10^{-5}$	4.19
Acetic acid	$\text{HC}_2\text{H}_3\text{O}_2$	$\text{H}-\text{O}-\overset{\text{O}}{\parallel}{\text{C}}-\text{CH}_3$	$\text{HC}_2\text{H}_3\text{O}_2(aq) + \text{H}_2\text{O}(l) \rightleftharpoons \text{H}_3\text{O}^+(aq) + \text{C}_2\text{H}_3\text{O}_2^-(aq)$	$1.8 \times 10^{-5}$	4.74
Hypochlorous acid	$\text{HClO}$	$\text{H}-\text{O}-\text{Cl}$	$\text{HClO}(aq) + \text{H}_2\text{O}(l) \rightleftharpoons \text{H}_3\text{O}^+(aq) + \text{ClO}^-(aq)$	$2.9 \times 10^{-8}$	7.54
Hydrocyanic acid	$\text{HCN}$	$\text{H}-\text{C}\equiv\text{N}$	$\text{HCN}(aq) + \text{H}_2\text{O}(l) \rightleftharpoons \text{H}_3\text{O}^+(aq) + \text{CN}^-(aq)$	$4.9 \times 10^{-10}$	9.31
Phenol	$\text{HC}_6\text{H}_5\text{O}$	$\text{H}-\text{O}-\text{C}_6\text{H}_5$	$\text{HC}_6\text{H}_5\text{O}(aq) + \text{H}_2\text{O}(l) \rightleftharpoons \text{H}_3\text{O}^+(aq) + \text{C}_6\text{H}_5\text{O}^-(aq)$	$1.3 \times 10^{-10}$	9.89

Which acid is stronger?

## 16.5 Autoionization of Water and pH

We saw previously that water acts as a base when it reacts with HCl and as an acid when it reacts with  $\text{NH}_3$ :

Water is *amphoteric*; it can act as either an acid or a base. Even when pure, water acts as an acid and a base with itself, a process called **autoionization**:

We can write the autoionization reaction as:

The equilibrium constant expression for this reaction is the product of the concentration of the two ions:

$$K_w = [\text{H}_3\text{O}^+][\text{OH}^-] = [\text{H}^+][\text{OH}^-]$$

This equilibrium constant is called the **ion product constant for water ( $K_w$ )** (sometimes called the *dissociation constant for water*). At 25 °C,  $K_w = 1.0 \times 10^{-14}$ . In pure water, since  $H_2O$  is the only source of these ions, the concentrations of  $H_3O^+$  and  $OH^-$  are equal, and the solution is **neutral**. Since the concentrations of the two ions are equal, we can easily calculate them from  $K_w$ .

$$[H_3O^+] = [OH^-] = \sqrt{K_w} = 1.0 \times 10^{-7} \quad (\text{in pure water at } 25^\circ\text{C})$$

As you can see, in pure water, the concentrations of  $H_3O^+$  and  $OH^-$  are *very small* ( $1.0 \times 10^{-7}$  M) at room temperature.

An **acidic solution** contains an acid that creates additional  $H_3O^+$  ions, causing  $[H_3O^+]$  to increase. However, the *ion product constant still applies*:

$$[H_3O^+][OH^-] = K_w = 1.0 \times 10^{-14}$$

The concentration of  $H_3O^+$  times the concentration of  $OH^-$  is always  $1.0 \times 10^{-14}$  at 25 °C. If  $[H_3O^+]$  increases, then  $[OH^-]$  must decrease for the ion product constant to remain  $1.0 \times 10^{-14}$ . For example, if  $[H_3O^+] = 1.0 \times 10^{-3}$ , then we can find  $[OH^-]$  by solving the ion product constant expression for  $[OH^-]$ :

$$\begin{aligned} (1.0 \times 10^{-3}) [OH^-] &= 1.0 \times 10^{-14} \\ [OH^-] &= \frac{1.0 \times 10^{-14}}{1.0 \times 10^{-3}} = 1.0 \times 10^{-11} \text{ M} \end{aligned}$$

In an acidic solution  $[H_3O^+] > [OH^-]$ .

A **basic solution** contains a base that creates additional  $OH^-$  ions, causing  $[OH^-]$  to increase and  $[H_3O^+]$  to decrease, but again the *ion product constant still applies*. Suppose  $[OH^-] = 1.0 \times 10^{-2}$ ; we can find  $[H_3O^+]$  by solving the ion product constant expression for  $[H_3O^+]$ :

$$\begin{aligned} [H_3O^+](1.0 \times 10^{-2}) &= 1.0 \times 10^{-14} \\ [H_3O^+] &= \frac{1.0 \times 10^{-14}}{1.0 \times 10^{-2}} = 1.0 \times 10^{-12} \text{ M} \end{aligned}$$

In a basic solution  $[OH^-] > [H_3O^+]$ .

Notice that changing  $[H_3O^+]$  in an aqueous solution produces an inverse change in  $[OH^-]$  and vice versa.

#### Summarizing $K_w$ :

- ▶ A *neutral solution* contains  $[H_3O^+] = [OH^-] = 1.0 \times 10^{-7}$  M (at 25 °C).
- ▶ An *acidic solution* contains  $[H_3O^+] > [OH^-]$ .
- ▶ A *basic solution* contains  $[OH^-] > [H_3O^+]$ .
- ▶ In *all aqueous solutions* both  $H_3O^+$  and  $OH^-$  are present, with  $[H_3O^+][OH^-] = K_w = 1.0 \times 10^{-14}$  (at 25 °C).

The ion product constant  $K_w$  depends on temperature. For all calculations in this book, assume 25 °C unless otherwise noted.

### Example 16.2 Using $K_w$ in Calculations

Calculate  $[OH^-]$  at 25 °C for each solution and determine if the solution is acidic, basic, or neutral.

(a)  $[H_3O^+] = 7.5 \times 10^{-5}$  M

(b)  $[H_3O^+] = 1.5 \times 10^{-9}$  M

(c)  $[H_3O^+] = 1.0 \times 10^{-7}$  M

#### SOLUTION

- (a) To find  $[OH^-]$  use the ion product constant. Substitute the given value for  $[H_3O^+]$  and solve the equation for  $[OH^-]$ .

Since  $[H_3O^+] > [OH^-]$ , the solution is acidic.

$$\begin{aligned} [H_3O^+][OH^-] &= K_w = 1.0 \times 10^{-14} \\ (7.5 \times 10^{-5})[OH^-] &= 1.0 \times 10^{-14} \\ [OH^-] &= \frac{1.0 \times 10^{-14}}{7.5 \times 10^{-5}} = 1.3 \times 10^{-10} \text{ M} \\ \text{Acidic solution} \end{aligned}$$

—Continued on the next page

Continued—

<b>(b)</b> Substitute the given value for $[\text{H}_3\text{O}^+]$ and solve the acid ionization equation for $[\text{OH}^-]$ . Since $[\text{H}_3\text{O}^+] < [\text{OH}^-]$ , the solution is basic.	$(1.5 \times 10^{-9})[\text{OH}^-] = 1.0 \times 10^{-14}$ $[\text{OH}^-] = \frac{1.0 \times 10^{-14}}{1.5 \times 10^{-9}} = 6.7 \times 10^{-6} \text{ M}$ Basic solution
<b>(c)</b> Substitute the given value for $[\text{H}_3\text{O}^+]$ and solve the acid ionization equation for $[\text{OH}^-]$ . Since $[\text{H}_3\text{O}^+] = 1.0 \times 10^{-7}$ and $[\text{OH}^-] = 1.0 \times 10^{-7}$ , the solution is neutral.	$(1.0 \times 10^{-7})[\text{OH}^-] = 1.0 \times 10^{-14}$ $[\text{OH}^-] = \frac{1.0 \times 10^{-14}}{1.0 \times 10^{-7}} = 1.0 \times 10^{-7} \text{ M}$ Neutral solution
<b>FOR PRACTICE 16.2</b> Calculate $[\text{H}_3\text{O}^+]$ at 25 °C for each solution and determine if the solution is acidic, basic, or neutral.	
<b>(a)</b> $[\text{OH}^-] = 1.5 \times 10^{-2} \text{ M}$	<b>(b)</b> $[\text{OH}^-] = 1.0 \times 10^{-7} \text{ M}$
	<b>(c)</b> $[\text{OH}^-] = 8.2 \times 10^{-10} \text{ M}$

The log of a number is the exponent to which 10 must be raised to obtain that number. Thus,  $\log 10^1 = 1$ ;  $\log 10^2 = 2$ ;  $\log 10^{-1} = -1$ ;  $\log 10^{-2} = -2$ , etc. (see Appendix I).

When we take the log of a quantity, the result has the same number of decimal places as the number of significant figures in the original quantity.

Concentrated acid solutions can have negative pH. For example, if  $[\text{H}_3\text{O}^+] = 2.0 \text{ M}$ , the pH is  $-0.30$ .

**TABLE 16.6** The pH of Some Common Substances

Substance	pH
Gastric juice (human stomach)	1.0–3.0
Limes	1.8–2.0
Lemons	2.2–2.4
Soft drinks	2.0–4.0
Plums	2.8–3.0
Wines	2.8–3.8
Apples	2.9–3.3
Peaches	3.4–3.6
Cherries	3.2–4.0
Beers	4.0–5.0
Rainwater (unpolluted)	5.6
Human blood	7.3–7.4
Egg whites	7.6–8.0
Milk of magnesia	10.5
Household ammonia	10.5–11.5
4% NaOH solution	14

## The pH Scale: A Way to Quantify Acidity and Basicity

The pH scale is a compact way to specify the acidity of a solution. We define **pH** as the negative of the log of the hydronium ion concentration:

$$\text{pH} = -\log[\text{H}_3\text{O}^+]$$

A solution with  $[\text{H}_3\text{O}^+] = 1.0 \times 10^{-3} \text{ M}$  (acidic) has a pH of:

$$\begin{aligned}\text{pH} &= -\log[\text{H}_3\text{O}^+] \\ &= -\log(1.0 \times 10^{-3}) \\ &= -(-3.00) \\ &= 3.00\end{aligned}$$

Notice that we report the pH to two *decimal places* in this example. This is because only the numbers to the right of the decimal point are significant in a logarithm. Because our original value for the concentration had two significant figures, the log of that number has two decimal places:

$$\begin{array}{cc}\text{2 significant digits} & \text{2 decimal places} \\ \log \underline{1.0} \times 10^{-3} & = \underline{3.00}\end{array}$$

If the original number has three significant digits, we report the log to three decimal places:

$$\begin{array}{cc}\text{3 significant digits} & \text{3 decimal places} \\ \log \underline{1.00} \times 10^{-3} & = \underline{3.000}\end{array}$$

A solution with  $[\text{H}_3\text{O}^+] = 1.0 \times 10^{-7} \text{ M}$  (neutral at 25 °C) has a pH of:

$$\begin{aligned}\text{pH} &= -\log[\text{H}_3\text{O}^+] \\ &= -\log(1.0 \times 10^{-7}) \\ &= -(-7.00) \\ &= 7.00\end{aligned}$$

In general, at 25 °C:

- $\text{pH} < 7$  The solution is *acidic*.
- $\text{pH} > 7$  The solution is *basic*.
- $\text{pH} = 7$  The solution is *neutral*.

Table 16.6 lists the pH of some common substances. As we discussed in Section 16.2, many foods, especially fruits, are acidic and have low pH values. Relatively few foods are basic. The foods with the lowest pH values are limes and lemons, and they are among the sourest. Because the pH scale is a *logarithmic scale*, a change of 1 pH unit corresponds to a 10-fold change in  $\text{H}_3\text{O}^+$  concentration (Figure 16.7►). For example, a lime with a pH of 2.0 is 10 times more acidic than a plum with a pH of 3.0 and 100 times more acidic than a cherry with a pH of 4.0.

## The pH Scale

▲ **FIGURE 16.7** The pH Scale An increase of 1 on the pH scale corresponds to a factor of 10 decrease in  $[H_3O^+]$ .

### Example 16.3 Calculating pH from $[H_3O^+]$ or $[OH^-]$

Calculate the pH of each solution at 25 °C and indicate whether the solution is acidic or basic.

(a)  $[H_3O^+] = 1.8 \times 10^{-4} \text{ M}$

(b)  $[OH^-] = 1.3 \times 10^{-2} \text{ M}$

#### SOLUTION

- (a) To calculate pH, substitute the given  $[H_3O^+]$  into the pH equation.  
Since  $\text{pH} < 7$ , this solution is acidic.

$$\begin{aligned}\text{pH} &= -\log[H_3O^+] \\ &= -\log(1.8 \times 10^{-4}) \\ &= -(-3.74) \\ &= 3.74 \text{ (acidic)}\end{aligned}$$

- (b) First use  $K_w$  to find  $[H_3O^+]$  from  $[OH^-]$ .

Then substitute  $[H_3O^+]$  into the pH expression to find pH.

Since  $\text{pH} > 7$ , this solution is basic.

$$\begin{aligned}[H_3O^+][OH^-] &= K_w = 1.0 \times 10^{-14} \\ [H_3O^+](1.3 \times 10^{-2}) &= 1.0 \times 10^{-14} \\ [H_3O^+] &= \frac{1.0 \times 10^{-14}}{1.3 \times 10^{-2}} = 7.7 \times 10^{-13} \text{ M} \\ \text{pH} &= -\log[H_3O^+] \\ &= -\log(7.7 \times 10^{-13}) \\ &= -(-12.11) \\ &= 12.11 \text{ (basic)}\end{aligned}$$

**FOR PRACTICE 16.3** Calculate the pH of each solution and indicate whether the solution is acidic or basic.

(a)  $[H_3O^+] = 9.5 \times 10^{-9} \text{ M}$

(b)  $[OH^-] = 7.1 \times 10^{-3} \text{ M}$

### Example 16.4 Calculating $[H_3O^+]$ from pH

Calculate  $[H_3O^+]$  for a solution with a pH of 4.80.

#### SOLUTION

To find  $[H_3O^+]$  from pH, start with the equation that defines pH. Substitute the given value of pH and then solve for  $[H_3O^+]$ . Since the given pH value was reported to two decimal places, report the  $[H_3O^+]$  to two significant figures. (Remember that  $10^{\log x} = x$  (see Appendix I). Some calculators use an inv log key to represent this function.)

$$\begin{aligned}\text{pH} &= -\log[H_3O^+] \\ 4.80 &= -\log[H_3O^+] \\ -4.80 &= \log[H_3O^+] \\ 10^{-4.80} &= 10^{\log[H_3O^+]} \\ 10^{-4.80} &= [H_3O^+] \\ [H_3O^+] &= 1.6 \times 10^{-5} \text{ M}\end{aligned}$$

**FOR PRACTICE 16.4** Calculate  $[H_3O^+]$  for a solution with a pH of 8.37.

## pOH and Other p Scales

The pOH scale is analogous to the pH scale but is defined with respect to  $[OH^-]$  instead of  $[H_3O^+]$ :

$$\text{pOH} = -\log[OH^-]$$

▲ FIGURE 16.8 pH and pOH

Notice that p is the mathematical operator  $-\log$ ; thus,  $\text{p}X = -\log X$ .

A solution with an  $[\text{OH}^-]$  of  $1.0 \times 10^{-3} \text{ M}$  (basic) has a pOH of 3.00. On the pOH scale, a pOH less than 7 is basic and a pOH greater than 7 is acidic. A pOH of 7 is neutral (Figure 16.8▲). We can derive a relationship between pH and pOH at 25 °C from the expression for  $K_w$ :

$$[\text{H}_3\text{O}^+][\text{OH}^-] = 1.0 \times 10^{-14}$$

Taking the log of both sides, we get:

$$\log([\text{H}_3\text{O}^+][\text{OH}^-]) = \log(1.0 \times 10^{-14})$$

$$\log[\text{H}_3\text{O}^+] + \log[\text{OH}^-] = -14.00$$

$$-\log[\text{H}_3\text{O}^+] - \log[\text{OH}^-] = 14.00$$

$$\text{pH} + \text{pOH} = 14.00$$

The sum of pH and pOH is always equal to 14.00 at 25 °C. Therefore, a solution with a pH of 3 has a pOH of 11.

Another common p scale is the  $\text{p}K_a$  scale defined as:

$$\text{p}K_a = -\log K_a$$

The  $\text{p}K_a$  of a weak acid is another way to quantify its strength. The smaller the  $\text{p}K_a$ , the stronger the acid. For example, chlorous acid, with a  $K_a$  of  $1.1 \times 10^{-2}$ , has a  $\text{p}K_a$  of 1.96; and formic acid, with a  $K_a$  of  $1.8 \times 10^{-4}$ , has a  $\text{p}K_a$  of 3.74 (See Table 16.5).

## CONCEPTUAL CONNECTION 16.4

**pH and Acidity** As the pH of a solution increases (gets higher), what happens to the acidity of the solution?

- (a) The acidity increases.                      (b) The acidity decreases.  
(c) The acidity remains constant.

## Chemistry AND Medicine | Ulcers

**A**n ulcer is a lesion on the wall of the stomach or small intestine. Under normal circumstances, a thick layer of mucus lines the stomach wall and protects it from the hydrochloric acid and other gastric juices in the stomach. If that mucous layer is damaged, however, stomach juices come in direct contact with the stomach wall and begin to digest it, creating an ulcer. The main symptom of an ulcer is a burning or gnawing pain in the stomach.

Acidic drugs, such as aspirin, and acidic foods, such as citrus fruits and pickling fluids, irritate ulcers. When consumed, these substances increase the acidity of the stomach juices, exacerbating the irritation to the stomach wall. On the other hand, antacids—which contain bases—relieve ulcers. Common antacids include Tums and milk of magnesia.

The causes of ulcers are manifold. For many years, a stressful lifestyle and a rich diet were blamed. More recent research, however, has shown that a bacterial infection of the stomach lining is responsible for many ulcers. (The 2005 Nobel Prize in Physiology or Medicine was awarded to Australians Barry J. Marshall and J. Robin Warren, for their discovery of the bacterial cause of ulcers.) Long-term use of some over-the-counter pain relievers, such as aspirin, is also believed to produce ulcers.

▲ An ulcer is a lesion in the stomach wall.

### QUESTION

Which dessert is less likely to irritate an ulcer, key lime pie or meringue (made of egg whites)?

## 16.6 Finding the $[\text{H}_3\text{O}^+]$ and pH of Strong and Weak Acid Solutions

Finding the  $[\text{H}_3\text{O}^+]$  and pH of Strong and Weak Acid Solutions

A solution containing a strong or weak acid has two potential sources of  $\text{H}_3\text{O}^+$ : the ionization of the acid itself and the autoionization of water. If we let HA be a strong or weak acid, the ionization equations are:

Except in extremely dilute acid solutions, the autoionization of water contributes a negligibly small amount of  $\text{H}_3\text{O}^+$  compared to the ionization of the strong or weak acid. Recall from Section 16.5 that autoionization in pure water at 25 °C produces an  $\text{H}_3\text{O}^+$  concentration of  $1.0 \times 10^{-7} \text{ M}$ . In a strong or weak acid solution, the additional  $\text{H}_3\text{O}^+$  from the acid causes the autoionization of water equilibrium to shift left (as described by Le Châtelier's principle). Consequently, in most strong or weak acid solutions, the autoionization of water produces even less  $\text{H}_3\text{O}^+$  than in pure water and can be ignored. Therefore we can focus exclusively on the amount of  $\text{H}_3\text{O}^+$  produced by the acid.

The only exceptions would be extremely dilute ( $<10^{-5} \text{ M}$ ) strong acid solutions.

### Strong Acids

Because strong acids, by definition, completely ionize in solution, and because we can (in nearly all cases) ignore the contribution of the autoionization of water, *the concentration of  $\text{H}_3\text{O}^+$  in a strong acid solution is equal to the concentration of the strong acid.* For example, a 0.10 M HCl solution has an  $\text{H}_3\text{O}^+$  concentration of 0.10 M and a pH of 1.00:

$$0.10 \text{ M HCl} \Rightarrow [\text{H}_3\text{O}^+] = 0.10 \text{ M} \Rightarrow \text{pH} = -\log(0.10) = 1.00$$

### Weak Acids

Finding the pH of a weak acid solution is more complicated because the concentration of  $\text{H}_3\text{O}^+$  is *not equal* to the concentration of the weak acid. For example, if we make a solution of 0.10 M HCl (a strong acid) and a solution of 0.10 M acetic acid (a weak acid) in the laboratory and measure the pH of each, we get the following results:

$$0.10 \text{ M HCl} \quad \text{pH} = 1.00$$

$$0.10 \text{ M HC}_2\text{H}_3\text{O}_2 \quad \text{pH} = 2.87$$

The pH of the acetic acid solution is higher (it is less acidic) because acetic acid only partially ionizes. Calculating the  $[\text{H}_3\text{O}^+]$  formed by the ionization of a weak acid requires solving an equilibrium problem similar to those in Chapter 15. Consider, for example, a 0.10 M solution of the generic weak acid HA with an acid ionization constant  $K_a$ . Since we can ignore the contribution of the autoionization of water, we only have to determine the concentration of  $\text{H}_3\text{O}^+$  formed by the following equilibrium:

We can summarize the initial conditions, the changes, and the equilibrium conditions in the following ICE table:

	[HA]	$[\text{H}_3\text{O}^+]$	$[\text{A}^-]$
Initial	0.10	$\approx 0.00$	0.00
Change	$-x$	$+x$	$+x$
Equilibrium	$0.10 - x$	$x$	$x$

The initial  $\text{H}_3\text{O}^+$  concentration is listed as *approximately* zero because of the negligibly small contribution of  $\text{H}_3\text{O}^+$  due to the autoionization of water (discussed previously). The variable  $x$  represents the amount of HA that ionizes. As discussed in Chapter 15, each *equilibrium* concentration is the sum of the two entries above it in the ICE table. In order

ICE tables were first introduced in Section 15.6. The reactant  $\text{H}_2\text{O}(l)$  is a pure liquid and is therefore not included either in the equilibrium constant or in the ICE table (see Section 15.5).

to find the equilibrium concentration of  $\text{H}_3\text{O}^+$ , we must find the value of the variable  $x$ . We can use the equilibrium expression to set up an equation in which  $x$  is the only variable:

$$K_a = \frac{[\text{H}_3\text{O}^+][\text{A}^-]}{[\text{HA}]}$$

$$= \frac{x^2}{0.10 - x}$$

As is often the case with equilibrium problems, we arrive at a quadratic equation in  $x$ , which we can solve using the quadratic formula (see Appendix IC). However, in many cases we can apply the  $x$  is *small* approximation (first discussed in Section 15.8). In Examples 16.5 and 16.6, we examine the general procedure for solving weak acid equilibrium problems. In both of these examples, the  $x$  is *small* approximation works well. In Example 16.7, we solve a problem in which the  $x$  is *small* approximation does not work. In such cases, we can solve the quadratic equation explicitly, or apply the method of successive approximations (also discussed in Section 15.8). Finally, in Example 16.8, we work a problem in which we find the equilibrium constant of a weak acid from its pH.

### Procedure for...

#### Finding the pH (or $[\text{H}_3\text{O}^+]$ ) of a Weak Acid Solution

To solve these types of problems, follow the outlined procedure.

1. **Write the balanced equation for the ionization of the acid and use it as a guide to prepare an ICE table showing the given concentration of the weak acid as its initial concentration.**

Leave room in the table for the changes in concentrations and for the equilibrium concentrations. (Note that  $[\text{H}_3\text{O}^+]$  is listed as approximately zero because the autoionization of water produces a negligibly small amount of  $\text{H}_3\text{O}^+$ .)

2. **Represent the change in the concentration of  $\text{H}_3\text{O}^+$  with the variable  $x$ . Define the changes in the concentrations of the other reactants and products in terms of  $x$ . Always keep in mind the stoichiometry of the reaction.**

3. **Sum each column to determine the equilibrium concentrations in terms of the initial concentrations and the variable  $x$ .**

#### Example 16.5

##### Finding the $[\text{H}_3\text{O}^+]$ of a Weak Acid Solution

Find the  $[\text{H}_3\text{O}^+]$  of a 0.100 M HCN solution.

	[HCN]	$[\text{H}_3\text{O}^+]$	$[\text{CN}^-]$
Initial	0.100	$\approx 0.00$	0.00
Change			
Equil			

	[HCN]	$[\text{H}_3\text{O}^+]$	$[\text{CN}^-]$
Initial	0.100	$\approx 0.00$	0.00
Change	$-x$	$+x$	$+x$
Equil			

	[HCN]	$[\text{H}_3\text{O}^+]$	$[\text{CN}^-]$
Initial	0.100	$\approx 0.00$	0.00
Change	$-x$	$+x$	$+x$
Equil	$0.100 - x$	$x$	$x$

#### Example 16.6

##### Finding the pH of a Weak Acid Solution

Find the pH of a 0.200 M  $\text{HNO}_2$  solution.

	[HNO <sub>2</sub> ]	$[\text{H}_3\text{O}^+]$	$[\text{NO}_2^-]$
Initial	0.200	$\approx 0.00$	0.00
Change			
Equil			

	[HNO <sub>2</sub> ]	$[\text{H}_3\text{O}^+]$	$[\text{NO}_2^-]$
Initial	0.200	$\approx 0.00$	0.00
Change	$-x$	$+x$	$+x$
Equil			

	[HNO <sub>2</sub> ]	$[\text{H}_3\text{O}^+]$	$[\text{NO}_2^-]$
Initial	0.200	$\approx 0.00$	0.00
Change	$-x$	$+x$	$+x$
Equil	$0.200 - x$	$x$	$x$

<p><b>4. Substitute the expressions for the equilibrium concentrations (from step 3) into the expression for the acid ionization constant (<math>K_a</math>).</b> In many cases, you can make the approximation that <math>x</math> is <i>small</i> (as discussed in Section 15.8). <b>Substitute the value of the acid ionization constant (from Table 16.5) into the <math>K_a</math> expression and solve for <math>x</math>.</b> Confirm that the <math>x</math> is <i>small</i> approximation is valid by calculating the ratio of <math>x</math> to the number it was subtracted from in the approximation. The ratio should be less than 0.05 (or 5%).</p>	$K_a = \frac{[\text{H}_3\text{O}^+][\text{CN}^-]}{[\text{HCN}]}$ $= \frac{x^2}{0.100 - x} \quad (x \text{ is small})$ $4.9 \times 10^{-10} = \frac{x^2}{0.100}$ $\sqrt{4.9 \times 10^{-10}} = \sqrt{\frac{x^2}{0.100}}$ $x = \sqrt{(0.100)(4.9 \times 10^{-10})}$ $= 7.0 \times 10^{-6}$ $\frac{7.0 \times 10^{-6}}{0.100} \times 100\% = 7.0 \times 10^{-3}\%$ <p>Therefore the approximation is valid.</p>	$K_a = \frac{[\text{H}_3\text{O}^+][\text{NO}_2^-]}{[\text{HNO}_2]}$ $= \frac{x^2}{0.200 - x} \quad (x \text{ is small})$ $4.6 \times 10^{-4} = \frac{x^2}{0.200}$ $\sqrt{4.6 \times 10^{-4}} = \sqrt{\frac{x^2}{0.200}}$ $x = \sqrt{(0.200)(4.6 \times 10^{-4})}$ $= 9.6 \times 10^{-3}$ $\frac{9.6 \times 10^{-3}}{0.200} \times 100\% = 4.8\%$ <p>Therefore the approximation is valid (but barely so).</p>

### Example 16.7 Finding the pH of a Weak Acid Solution in Cases Where the $x$ is small Approximation Does Not Work

Find the pH of a 0.100 M  $\text{HClO}_2$  solution.

#### SOLUTION

- Write the balanced equation for the ionization of the acid and use it as a guide to prepare an ICE table showing the given concentration of the weak acid as its initial concentration.  
(Note that the  $\text{H}_3\text{O}^+$  concentration is listed as approximately zero. Although a little  $\text{H}_3\text{O}^+$  is present from the autoionization of water, this amount is negligibly small compared to the amount of  $\text{HClO}_2$  or  $\text{H}_3\text{O}^+$  formed by the acid.)

	$[\text{HClO}_2]$	$[\text{H}_3\text{O}^+]$	$[\text{ClO}_2^-]$
Initial	0.100	$\approx 0.00$	0.00
Change			
Equil			

- Represent the change in  $[\text{H}_3\text{O}^+]$  with the variable  $x$ . Define the changes in the concentrations of the other reactants and products in terms of  $x$ .

	$[\text{HClO}_2]$	$[\text{H}_3\text{O}^+]$	$[\text{ClO}_2^-]$
Initial	0.100	$\approx 0.00$	0.00
Change	$-x$	$+x$	$+x$
Equil

3. Sum each column to determine the equilibrium concentrations in terms of the initial concentrations and the variable $x$ .	$\text{HClO}_2(aq) + \text{H}_2\text{O}(l) \rightleftharpoons \text{H}_3\text{O}^+(aq) + \text{ClO}_2^-(aq)$ <table><tr><th></th><th><math>[\text{HClO}_2]</math></th><th><math>[\text{H}_3\text{O}^+]</math></th><th><math>[\text{ClO}_2^-]</math></th></tr><tr><td>Initial</td><td>0.100</td><td><math>\approx 0.00</math></td><td>0.00</td></tr><tr><td>Change</td><td><math>-x</math></td><td><math>+x</math></td><td><math>+x</math></td></tr><tr><td>Equil</td><td><math>0.100 - x</math></td><td><math>x</math></td><td><math>x</math></td></tr></table>		$[\text{HClO}_2]$	$[\text{H}_3\text{O}^+]$	$[\text{ClO}_2^-]$	Initial	0.100	$\approx 0.00$	0.00	Change	$-x$	$+x$	$+x$	Equil	$0.100 - x$	$x$	$x$
	$[\text{HClO}_2]$	$[\text{H}_3\text{O}^+]$	$[\text{ClO}_2^-]$														
Initial	0.100	$\approx 0.00$	0.00														
Change	$-x$	$+x$	$+x$														
Equil	$0.100 - x$	$x$	$x$														
4. Substitute the expressions for the equilibrium concentrations (from step 3) into the expression for the acid ionization constant ( $K_a$ ). Make the $x$ is <i>small</i> approximation and substitute the value of the acid ionization constant (from Table 16.5) into the $K_a$ expression. Solve for $x$ .	$K_a = \frac{[\text{H}_3\text{O}^+][\text{ClO}_2^-]}{[\text{HClO}_2]}$ $= \frac{x^2}{0.100 - x} \quad (x \text{ is small})$ $0.011 = \frac{x^2}{0.100}$ $\sqrt{0.011} = \sqrt{\frac{x^2}{0.100}}$ $x = \sqrt{(0.100)(0.011)}$ $= 0.033$																
Check to see if the $x$ is <i>small</i> approximation is valid by calculating the ratio of $x$ to the number it was subtracted from in the approximation. The ratio should be less than 0.05 (or 5%).	$\frac{0.033}{0.100} \times 100\% = 33\%$ <p>Therefore, the <math>x</math> is <i>small</i> approximation is <i>not valid</i>.</p>																
4a. If the $x$ is <i>small</i> approximation is not valid, solve the quadratic equation explicitly or use the method of successive approximations to find $x$ . In this case, you solve the quadratic equation.	$0.011 = \frac{x^2}{0.100 - x}$ $0.011(0.100 - x) = x^2$ $0.0011 - 0.011x = x^2$ $x^2 + 0.011x - 0.0011 = 0$ $x = \frac{-b \pm \sqrt{b^2 - 4ac}}{2a}$ $= \frac{-(0.011) \pm \sqrt{(0.011)^2 - 4(1)(-0.0011)}}{2(1)}$ $= \frac{-0.011 \pm 0.0672}{2}$ $x = -0.039 \text{ or } x = 0.028$ <p>Since <math>x</math> represents the concentration of <math>\text{H}_3\text{O}^+</math>, and since concentrations cannot be negative, you reject the negative root.</p> $x = 0.028$																
5. Determine the $\text{H}_3\text{O}^+$ concentration from the calculated value of $x$ and calculate the pH (if necessary).	$[\text{H}_3\text{O}^+] = 0.028 \text{ M}$ $\text{pH} = -\log[\text{H}_3\text{O}^+]$ $= -\log 0.028$ $= 1.55$																
6. Check your answer by substituting the calculated equilibrium values into the acid ionization expression. The calculated value of $K_a$ should match the given value of $K_a$ . Note that rounding errors could result in a difference in the least significant digit when comparing values of $K_a$ .	$K_a = \frac{[\text{H}_3\text{O}^+][\text{ClO}_2^-]}{[\text{HClO}_2]} = \frac{0.028^2}{0.100 - 0.028}$ $= 0.011$ <p>Since the calculated value of <math>K_a</math> matches the given value, the answer is valid.</p>																

**FOR PRACTICE 16.7** Find the pH of a 0.010 M  $\text{HNO}_2$  solution.

**Example 16.8** Finding the Equilibrium Constant from pH

A 0.100 M weak acid (HA) solution has a pH of 4.25. Find  $K_a$  for the acid.

**SOLUTION**

Use the given pH to find the equilibrium concentration of  $\text{H}_3\text{O}^+$ . Then write the balanced equation for the ionization of the acid and use it as a guide to prepare an ICE table showing all known concentrations.

$$\text{pH} = -\log[\text{H}_3\text{O}^+]$$

$$4.25 = -\log[\text{H}_3\text{O}^+]$$

$$[\text{H}_3\text{O}^+] = 5.6 \times 10^{-5} \text{ M}$$

	[HA]	$[\text{H}_3\text{O}^+]$	$[\text{A}^-]$
Initial	0.100	$\approx 0.00$	0.00
Change			
Equil		$5.6 \times 10^{-5}$	

Use the equilibrium concentration of  $\text{H}_3\text{O}^+$  and the stoichiometry of the reaction to predict the changes and equilibrium concentration for all species. For most weak acids, the initial and equilibrium concentrations of the weak acid (HA) are effectively equal because the amount that ionizes is usually very small compared to the initial concentration.

	[HA]	$[\text{H}_3\text{O}^+]$	$[\text{A}^-]$
Initial	0.100	$\approx 0.00$	0.00
Change	$-5.6 \times 10^{-5}$	$+5.6 \times 10^{-5}$	$+5.6 \times 10^{-5}$
Equil	$(0.100 - 5.6 \times 10^{-5})$ $\approx 0.100$	$5.6 \times 10^{-5}$	$5.6 \times 10^{-5}$

Substitute the equilibrium concentrations into the expression for  $K_a$  and calculate its value.

$$\begin{aligned} K_a &= \frac{[\text{H}_3\text{O}^+][\text{A}^-]}{[\text{HA}]} \\ &= \frac{(5.6 \times 10^{-5})(5.6 \times 10^{-5})}{0.100} \\ &= 3.1 \times 10^{-8} \end{aligned}$$

**FOR PRACTICE 16.8** A 0.175 M weak acid solution has a pH of 3.25. Find  $K_a$  for the acid.

**The  $x$  is small Approximation** The initial concentration and  $K_a$  of several weak acid (HA) solutions are listed. For which solution is the  $x$  is small approximation least likely to work in finding the pH?

- (a) initial  $[\text{HA}] = 0.100 \text{ M}$ ;  $K_a = 1.0 \times 10^{-5}$
- (b) initial  $[\text{HA}] = 1.00 \text{ M}$ ;  $K_a = 1.0 \times 10^{-6}$
- (c) initial  $[\text{HA}] = 0.0100 \text{ M}$ ;  $K_a = 1.0 \times 10^{-3}$
- (d) initial  $[\text{HA}] = 1.0 \text{ M}$ ;  $K_a = 1.5 \times 10^{-3}$

**CONCEPTUAL CONNECTION 16.5**

**Strong and Weak Acids** Which solution is most acidic (that is, which one has the lowest pH)?

- (a) 0.10 M HCl
- (b) 0.10 M HF
- (c) 0.20 M HF

**CONCEPTUAL CONNECTION 16.6**

## Percent Ionization of a Weak Acid

We can quantify the ionization of a weak acid according to the percentage of acid molecules that actually ionizes. We define the **percent ionization** of a weak acid as the ratio of the ionized acid concentration to the initial acid concentration, multiplied by 100%:

$$\text{Percent ionization} = \frac{\text{concentration of ionized acid}}{\text{initial concentration of acid}} \times 100\% = \frac{[\text{H}_3\text{O}^+]_{\text{equil}}}{[\text{HA}]_{\text{init}}} \times 100\%$$

Since the concentration of ionized acid is equal to the  $\text{H}_3\text{O}^+$  concentration at equilibrium (for a monoprotic acid), we can use  $[\text{H}_3\text{O}^+]_{\text{equil}}$  and  $[\text{HA}]_{\text{init}}$  in the formula to calculate the percent ionization. For example, in Example 16.6, we found that a 0.200 M  $\text{HNO}_2$  solution contains  $9.6 \times 10^{-3}$  M  $\text{H}_3\text{O}^+$ . The 0.200 M  $\text{HNO}_2$  solution therefore has the following percent ionization:

$$\begin{aligned} \% \text{ ionization} &= \frac{[\text{H}_3\text{O}^+]_{\text{equil}}}{[\text{HA}]_{\text{init}}} \times 100\% \\ &= \frac{9.6 \times 10^{-3} \text{ M}}{0.200 \text{ M}} \times 100\% \\ &= 4.8\% \end{aligned}$$

As you can see, the percent ionization is relatively small. In this case, even though  $\text{HNO}_2$  has the second largest  $K_a$  in Table 16.5, fewer than 5 molecules out of 100 ionize. For most other weak acids (with smaller  $K_a$  values) the percent ionization is even less.

In Example 16.9, we calculate the percent ionization of a more concentrated  $\text{HNO}_2$  solution. In the example, notice that the calculated  $\text{H}_3\text{O}^+$  concentration is much greater (as we would expect for a more concentrated solution), but the *percent ionization* is actually smaller.

### Example 16.9 Finding the Percent Ionization of a Weak Acid

Find the percent ionization of a 2.5 M  $\text{HNO}_2$  solution.

#### SOLUTION

To find the percent ionization, you must find the equilibrium concentration of  $\text{H}_3\text{O}^+$ . Follow the procedure in Example 16.5, shown in condensed form here.

	$[\text{HNO}_2]$	$[\text{H}_3\text{O}^+]$	$[\text{NO}_2^-]$
Initial	2.5	$\approx 0.00$	0.00
Change	$-x$	$+x$	$+x$
Equil	$2.5 - x$	$x$	$x$

$$K_a = \frac{[\text{H}_3\text{O}^+][\text{NO}_2^-]}{[\text{HNO}_2]} = \frac{x^2}{2.5 - x} \quad (x \text{ is small})$$

$$4.6 \times 10^{-4} = \frac{x^2}{2.5}$$

$$x = 0.034$$

Therefore,  $[\text{H}_3\text{O}^+] = 0.034$  M.

Use the definition of percent ionization to calculate it. (Since the percent ionization is less than 5%, the  $x$  is *small* approximation is valid.)

$$\begin{aligned} \% \text{ ionization} &= \frac{[\text{H}_3\text{O}^+]_{\text{equil}}}{[\text{HA}]_{\text{init}}} \times 100\% \\ &= \frac{0.034 \text{ M}}{2.5 \text{ M}} \times 100\% \\ &= 1.4\% \end{aligned}$$

**FOR PRACTICE 16.9** Find the percent ionization of a 0.250 M  $\text{HC}_2\text{H}_3\text{O}_2$  solution at 25 °C.

We can now compare the results of Examples 16.6 and 16.9. From the table shown here, we can see that the more concentrated  $\text{HNO}_2$  solution has a lower percent ionization. This trend applies to all weak acid solutions.

$[\text{HNO}_2]$	$[\text{H}_3\text{O}^+]$	Percent Ionization
0.200	0.0096	4.8%
2.5	0.034	1.4%

#### Summarizing $[\text{H}_3\text{O}^+]$ and Percent Ionization:

- ▶ The *equilibrium  $\text{H}_3\text{O}^+$  concentration* of a weak acid *increases* with increasing initial concentration of the acid.
- ▶ The *percent ionization* of a weak acid *decreases* with increasing concentration of the acid.

In other words, as the concentration of a weak acid solution increases, the concentration of the hydronium ion also increases, but the increase is not linear. The  $\text{H}_3\text{O}^+$  concentration increases less than the concentration of the acid because as the acid concentration increases, a smaller fraction of weak acid molecules ionize.

We can understand this behavior by analogy with Le Châtelier's principle. Consider the following weak acid ionization equilibrium:

If we dilute a weak acid solution initially at equilibrium, the system (according to Le Châtelier's principle) responds to minimize the disturbance. The equilibrium shifts to the right because the right side of the equation contains more particles in solution (2 mol versus 1 mol) than the left side. If the system shifts to the right, the percent ionization is greater in the more dilute solution, which is what we observe.

**Percent Ionization** Which weak acid solution has the greatest percent ionization? Which solution has the lowest (most acidic) pH?

- (a) 0.100 M  $\text{HC}_2\text{H}_3\text{O}_2$
- (b) 0.500 M  $\text{HC}_2\text{H}_3\text{O}_2$
- (c) 0.0100 M  $\text{HC}_2\text{H}_3\text{O}_2$

#### CONCEPTUAL CONNECTION 16.7

## Mixtures of Acids

Finding the pH of a mixture of acids may seem difficult at first. However, in many cases, the relative strengths of the acids in the mixture allow us to neglect the weaker acid and focus only on the stronger one. Here, we consider two possible acid mixtures: a strong acid with a weak acid and a weak acid with another weak acid.

### A Strong Acid and a Weak Acid

Consider a mixture that is 0.10 M in  $\text{HCl}$  and 0.10 M in  $\text{HCHO}_2$ . There are three sources of  $\text{H}_3\text{O}^+$  ions: the strong acid ( $\text{HCl}$ ), the weak acid ( $\text{HCHO}_2$ ), and the autoionization of water:

Since  $\text{HCl}$  is strong, we know that it completely ionizes to produce a significant concentration of  $\text{H}_3\text{O}^+$  (0.10 M). The  $\text{H}_3\text{O}^+$  formed by  $\text{HCl}$  then *suppresses* the formation of additional  $\text{H}_3\text{O}^+$  formed by the ionization of  $\text{HCHO}_2$  or the autoionization of water. In other words, according to Le Châtelier's principle, the formation of  $\text{H}_3\text{O}^+$  by the strong acid causes the weak acid to ionize even less than it would in the absence of the strong acid. To see this clearly, we calculate  $[\text{H}_3\text{O}^+]$  and  $[\text{CHO}_2^-]$  in this solution.

In an initial estimate of  $[\text{H}_3\text{O}^+]$ , we can neglect the contribution of  $\text{HCHO}_2$  and  $\text{H}_2\text{O}$ . The concentration of  $\text{H}_3\text{O}^+$  is then equal to the initial concentration of  $\text{HCl}$ :

$$[\text{H}_3\text{O}^+] = [\text{HCl}] = 0.10 \text{ M}$$

To find  $[\text{CHO}_2^-]$  we must solve an equilibrium problem. However, the initial concentration of  $\text{H}_3\text{O}^+$  in this case is not negligible (as it has been in all the other weak acid equilibrium problems that we have worked so far) because  $\text{HCl}$  has formed a significant amount of  $\text{H}_3\text{O}^+$ . The concentration of  $\text{H}_3\text{O}^+$  formed by  $\text{HCl}$  becomes the *initial* concentration of  $\text{H}_3\text{O}^+$  in the ICE table for  $\text{HCHO}_2$  as shown here:

	$[\text{HCHO}_2]$	$[\text{H}_3\text{O}^+]$	$[\text{CHO}_2^-]$
Initial	0.10	0.10	0.00
Change	$-x$	$+x$	$+x$
Equil	$0.10 - x$	$0.10 + x$	$x$

We then use the equilibrium expression to set up an equation in which  $x$  is the only variable:

$$\begin{aligned} K_a &= \frac{[\text{H}_3\text{O}^+][\text{CHO}_2^-]}{[\text{HCHO}_2]} \\ &= \frac{(0.10 + x)x}{0.10 - x} \end{aligned}$$

Since the equilibrium constant is small relative to the initial concentration of the acid, we can make the  $x$  is *small* approximation:

$$\begin{aligned} K_a &= \frac{(0.10 + x)x}{0.10 - x} \\ 1.8 \times 10^{-4} &= \frac{(0.10)x}{0.10} \\ x &= 1.8 \times 10^{-4} \end{aligned}$$

Checking the  $x$  is *small* approximation:

$$\frac{1.8 \times 10^{-4}}{0.10} \times 100\% = 0.18\%$$

We find that the approximation is valid. Therefore,  $[\text{CHO}_2^-] = 1.8 \times 10^{-4} \text{ M}$ . We can now see that we can completely ignore the ionization of the weak acid ( $\text{HCHO}_2$ ) in calculating  $[\text{H}_3\text{O}^+]$  for the mixture. The contribution to the concentration of  $\text{H}_3\text{O}^+$  by the weak acid must necessarily be equal to the concentration of  $\text{CHO}_2^-$  that we just calculated (because of the stoichiometry of the ionization reaction). Therefore, we have the following contributions to  $[\text{H}_3\text{O}^+]$ :

$\text{HCl}$  contributes  $0.10 \text{ M}$

$\text{HCHO}_2$  contributes  $1.8 \times 10^{-4} \text{ M}$  or  $0.00018 \text{ M}$

Total  $[\text{H}_3\text{O}^+] = 0.10 \text{ M} + 0.00018 \text{ M} = 0.10 \text{ M}$

As we can see, since the significant figure rules for addition limit the answer to two decimal places, the amount of  $\text{H}_3\text{O}^+$  contributed by  $\text{HCHO}_2$  is completely negligible. The amount of  $\text{H}_3\text{O}^+$  contributed by the autoionization of water is even smaller and therefore similarly negligible.

### A Mixture of Two Weak Acids

When two weak acids are mixed, we again have three potential sources of  $\text{H}_3\text{O}^+$  to consider: each of the two weak acids and the autoionization of water. However, if the values of  $K_a$  for the two weak acids are sufficiently different in magnitude (if they differ by more than a factor of several hundred), then as long as the concentrations of the two acids are similar in magnitude (or the concentration of the stronger one is greater than that of the weaker), we can assume that the weaker acid will not make a significant contribution to

the concentration of  $\text{H}_3\text{O}^+$ . We make this assumption for the same reason that we made a similar assumption for a mixture of a strong acid and a weak one: the  $\text{H}_3\text{O}^+$  formed by the stronger acid suppresses the ionization of the weaker one, in accordance with Le Châtelier's principle. Example 16.10 shows how to calculate the concentration of  $\text{H}_3\text{O}^+$  in a mixture of two weak acids.

### Example 16.10 Mixtures of Weak Acids

Find the pH of a mixture that is 0.300 M in HF and 0.100 M in HClO.

#### SOLUTION

The three possible sources of  $\text{H}_3\text{O}^+$  ions are HF, HClO, and  $\text{H}_2\text{O}$ . Write the ionization equations for the three sources and their corresponding equilibrium constants. Since the equilibrium constant for the ionization of HF is about 24,000 times larger than that for the ionization of HClO, the contribution of HF to  $[\text{H}_3\text{O}^+]$  is by far the greatest. You can therefore just calculate the  $[\text{H}_3\text{O}^+]$  formed by HF and neglect the other two potential sources of  $\text{H}_3\text{O}^+$ .

Write the balanced equation for the ionization of HF and use it as a guide to prepare an ICE table.

	[HF]	$[\text{H}_3\text{O}^+]$	$[\text{F}^-]$
Initial	0.300	$\approx 0.00$	0.00
Change	$-x$	$+x$	$+x$
Equil	$0.300 - x$	$x$	$x$

Substitute the expressions for the equilibrium concentrations into the expression for the acid ionization constant ( $K_a$ ). Since the equilibrium constant is small relative to the initial concentration of HF, you can make the  $x$  *is small* approximation. Substitute the value of the acid ionization constant (from Table 16.5) into the  $K_a$  expression and solve for  $x$ .

$$K_a = \frac{[\text{H}_3\text{O}^+][\text{F}^-]}{[\text{HF}]} = \frac{x^2}{0.300 - x} \quad (x \text{ is small})$$

$$6.8 \times 10^{-4} = \frac{x^2}{0.300}$$

$$\sqrt{(0.300)(6.8 \times 10^{-4})} = \sqrt{x^2}$$

$$x = 1.428 \times 10^{-2}$$

$$\frac{1.428 \times 10^{-2}}{0.300} \times 100\% = 4.8\%$$

Therefore, the approximation is valid (though barely so).

Determine the  $\text{H}_3\text{O}^+$  concentration from the calculated value of  $x$  and find the pH.

$$\begin{array}{l} [\text{H}_3\text{O}^+] = 1.4 \times 10^{-2} \text{ M} \\ \text{pH} = -\log(1.4 \times 10^{-2}) = 1.85 \end{array}$$

**FOR PRACTICE 16.10** Find the  $\text{ClO}^-$  concentration of the mixture of HF and HClO discussed in Example 16.10.

**Judging Relative pH** Which solution is most acidic (that is, has the lowest pH)?

- (a) 1.0 M HCl
- (b) 2.0 M HF
- (c) A solution that is 1.0 M in HF and 1.0 M in HClO

## 16.7 Base Solutions

We have seen that bases are solutions that produce  $\text{OH}^-$  in solution (Arrhenius definition) or accept protons (Brønsted–Lowry definition). In analogy to acids, which can be strong or weak, bases can also be strong or weak.

### Strong Bases

Just as we define a strong acid as one that completely ionizes in solution, analogously we define a **strong base** as a base that completely dissociates in solution. NaOH, for example, is a strong base:

An NaOH solution contains no intact NaOH—it has all dissociated to form  $\text{Na}^+(aq)$  and  $\text{OH}^-(aq)$  (Figure 16.9▼). In other words, a 1.0 M NaOH solution has  $[\text{OH}^-] = 1.0 \text{ M}$  and  $[\text{Na}^+] = 1.0 \text{ M}$ . Table 16.7 lists the common strong bases.

► **FIGURE 16.9 Ionization of a Strong Base** When NaOH dissolves in water, it dissociates completely into  $\text{Na}^+$  and  $\text{OH}^-$ . The solution contains virtually no intact NaOH.

**TABLE 16.7 Strong Bases**

Lithium hydroxide ( $\text{LiOH}$ )	Strontium hydroxide [ $\text{Sr}(\text{OH})_2$ ]
Sodium hydroxide ( $\text{NaOH}$ )	Calcium hydroxide [ $\text{Ca}(\text{OH})_2$ ]
Potassium hydroxide ( $\text{KOH}$ )	Barium hydroxide [ $\text{Ba}(\text{OH})_2$ ]

As we can see in the table, most strong bases are group 1A or group 2A metal hydroxides. The group 1A metal hydroxides are highly soluble in water and can form concentrated base solutions. The group 2A metal hydroxides, however, are only slightly soluble, a useful property for some applications (see *Chemistry and Medicine: What's in My Antacid?* in this section). Notice that the general formula for the group 2A metal hydroxides is  $\text{M}(\text{OH})_2$ . When they dissolve in water, they produce 2 mol of  $\text{OH}^-$  per mole of the base. For example,  $\text{Sr}(\text{OH})_2$  dissociates as follows:

Unlike diprotic acids, which ionize in two steps, bases containing two  $\text{OH}^-$  ions dissociate in one step.

### Weak Bases

The behavior of a **weak base** is analogous to that of a weak acid. Unlike strong bases that contain  $\text{OH}^-$  and *dissociate* in water, the most common weak bases produce  $\text{OH}^-$  by accepting a proton from water, ionizing water to form  $\text{OH}^-$  according to the general equation:

In this equation, B is a generic symbol for a weak base. Ammonia, for example, ionizes water as follows:

## A Weak Base

◀ **FIGURE 16.10** Ionization of a Weak Base When  $\text{NH}_3$  dissolves in water, it partially ionizes water to form  $\text{NH}_4^+$  and  $\text{OH}^-$ . Most of the  $\text{NH}_3$  molecules in solution remain as  $\text{NH}_3$ .

The double arrow indicates that the ionization is not complete. An  $\text{NH}_3$  solution contains mostly  $\text{NH}_3$  with only some  $\text{NH}_4^+$  and  $\text{OH}^-$  (Figure 16.10▲). A 1.0 M  $\text{NH}_3$  solution will have  $[\text{OH}^-] < 1.0 \text{ M}$ .

The extent of ionization of a weak base is quantified with the **base ionization constant**,  $K_b$ . For the general reaction in which a weak base ionizes water, we define  $K_b$  as follows:

$$\text{B}(aq) + \text{H}_2\text{O}(l) \rightleftharpoons \text{BH}^+(aq) + \text{OH}^-(aq) \quad K_b = \frac{[\text{BH}^+][\text{OH}^-]}{[\text{B}]}$$

By analogy with  $K_a$ , the smaller the value of  $K_b$ , the weaker the base. Table 16.8 lists some common weak bases, their ionization reactions, and values for  $K_b$ . Appendix IIC contains a more complete table. We can also apply the “p” scale to  $K_b$ , so that  $\text{p}K_b = -\log K_b$ .

All but two of the weak bases listed in Table 16.8 are either ammonia or an amine, which we can think of as ammonia with one or more hydrocarbon groups substituted for one or more hydrogen atoms. All of these bases have a nitrogen atom with a lone pair (Figure 16.11▶). This lone pair acts as the proton acceptor that makes the substance a base, as shown in the reactions for ammonia and methylamine:

**TABLE 16.8** Some Common Weak Bases

Weak Base	Ionization Reaction	$K_b$ (at 25 °C)
Carbonate ion ( $\text{CO}_3^{2-}$ )*	$\text{CO}_3^{2-}(aq) + \text{H}_2\text{O}(l) \rightleftharpoons \text{HCO}_3^-(aq) + \text{OH}^-(aq)$	$1.8 \times 10^{-4}$
Methylamine ( $\text{CH}_3\text{NH}_2$ )	$\text{CH}_3\text{NH}_2(aq) + \text{H}_2\text{O}(l) \rightleftharpoons \text{CH}_3\text{NH}_3^+(aq) + \text{OH}^-(aq)$	$4.4 \times 10^{-4}$
Ethylamine ( $\text{C}_2\text{H}_5\text{NH}_2$ )	$\text{C}_2\text{H}_5\text{NH}_2(aq) + \text{H}_2\text{O}(l) \rightleftharpoons \text{C}_2\text{H}_5\text{NH}_3^+(aq) + \text{OH}^-(aq)$	$5.6 \times 10^{-4}$
Ammonia ( $\text{NH}_3$ )	$\text{NH}_3(aq) + \text{H}_2\text{O}(l) \rightleftharpoons \text{NH}_4^+(aq) + \text{OH}^-(aq)$	$1.76 \times 10^{-5}$
Bicarbonate ion ( $\text{HCO}_3^-$ )* (or hydrogen carbonate)	$\text{HCO}_3^-(aq) + \text{H}_2\text{O}(l) \rightleftharpoons \text{H}_2\text{CO}_3(aq) + \text{OH}^-(aq)$	$2.3 \times 10^{-8}$
Pyridine ( $\text{C}_5\text{H}_5\text{N}$ )	$\text{C}_5\text{H}_5\text{N}(aq) + \text{H}_2\text{O}(l) \rightleftharpoons \text{C}_5\text{H}_5\text{NH}^+(aq) + \text{OH}^-(aq)$	$1.7 \times 10^{-9}$
Aniline ( $\text{C}_6\text{H}_5\text{NH}_2$ )	$\text{C}_6\text{H}_5\text{NH}_2(aq) + \text{H}_2\text{O}(l) \rightleftharpoons \text{C}_6\text{H}_5\text{NH}_3^+(aq) + \text{OH}^-(aq)$	$3.9 \times 10^{-10}$

\*The carbonate and bicarbonate ions must occur with a positively charged ion such as  $\text{Na}^+$  that serves to balance the charge but does not have any part in the ionization reaction. For example, it is the bicarbonate ion that makes sodium bicarbonate ( $\text{NaHCO}_3$ ) basic. We look more closely at ionic bases in Section 16.8.

► **FIGURE 16.11 Lone Pairs in Weak Bases** Many weak bases have a nitrogen atom with a lone pair that acts as the proton acceptor.

### Finding the $[\text{OH}^-]$ and pH of Basic Solutions

Finding the  $[\text{OH}^-]$  and pH of a strong base solution is relatively straightforward, as shown in Example 16.11. As we did in calculating the  $[\text{H}_3\text{O}^+]$  in strong acid solutions, we can neglect the contribution of the autoionization of water to the  $[\text{OH}^-]$  and focus solely on the strong base itself.

#### Example 16.11 Finding the $[\text{OH}^-]$ and pH of a Strong Base Solution

Determine the  $\text{OH}^-$  concentration and pH in each solution.

(a) 0.225 M KOH

(b) 0.0015 M  $\text{Sr}(\text{OH})_2$

##### SOLUTION

- (a) Since KOH is a strong base, it completely dissociates into  $\text{K}^+$  and  $\text{OH}^-$  in solution. The concentration of  $\text{OH}^-$  is therefore the same as the given concentration of KOH. Use this concentration and  $K_w$  to find  $[\text{H}_3\text{O}^+]$ .

Then substitute  $[\text{H}_3\text{O}^+]$  into the pH expression to find the pH.

$$[\text{H}_3\text{O}^+][\text{OH}^-] = K_w = 1.0 \times 10^{-14}$$

$$[\text{H}_3\text{O}^+](0.225) = 1.0 \times 10^{-14}$$

$$[\text{H}_3\text{O}^+] = 4.44 \times 10^{-14} \text{ M}$$

$$\text{pH} = -\log[\text{H}_3\text{O}^+]$$

$$= -\log(4.44 \times 10^{-14})$$

$$= 13.35$$

- (b) Since  $\text{Sr}(\text{OH})_2$  is a strong base, 1 mol of  $\text{Sr}(\text{OH})_2$  completely dissociates into 1 mol of  $\text{Sr}^{2+}$  and 2 mol of  $\text{OH}^-$  in solution. The concentration of  $\text{OH}^-$  is therefore twice the given concentration of  $\text{Sr}(\text{OH})_2$ .

Use this concentration and  $K_w$  to find  $[\text{H}_3\text{O}^+]$ .

Substitute  $[\text{H}_3\text{O}^+]$  into the pH expression to find the pH.

$$[\text{H}_3\text{O}^+][\text{OH}^-] = K_w = 1.0 \times 10^{-14}$$

$$[\text{H}_3\text{O}^+](0.0030) = 1.0 \times 10^{-14}$$

$$[\text{H}_3\text{O}^+] = 3.3 \times 10^{-12} \text{ M}$$

$$\text{pH} = -\log[\text{H}_3\text{O}^+]$$

$$= -\log(3.3 \times 10^{-12})$$

$$= 11.48$$

**FOR PRACTICE 16.11** Find the  $[\text{OH}^-]$  and pH of a 0.010 M  $\text{Ba}(\text{OH})_2$  solution.

Finding the  $[\text{OH}^-]$  and pH of a *weak base* solution is analogous to finding the  $[\text{H}_3\text{O}^+]$  and pH of a weak acid. Similarly, we neglect the contribution of the autoionization of water to the  $[\text{OH}^-]$  and focus solely on the weak base itself. We find the contribution of the weak base by preparing an ICE table showing the relevant concentrations of all species and then use the base ionization constant expression to find the  $[\text{OH}^-]$ . Example 16.12 demonstrates how to find the  $[\text{OH}^-]$  and pH of a weak base solution.

**Example 16.12** Finding the  $[\text{OH}^-]$  and pH of a Weak Base Solution

Find the  $[\text{OH}^-]$  and pH of a 0.100 M  $\text{NH}_3$  solution.

**SOLUTION**

1. Write the balanced equation for the ionization of water by the base and use it as a guide to prepare an ICE table showing the given concentration of the weak base as its initial concentration. Leave room in the table for the changes in concentrations and for the equilibrium concentrations. (Note that you should list the  $\text{OH}^-$  concentration as approximately zero. Although a little  $\text{OH}^-$  is present from the autoionization of water, this amount is negligibly small compared to the amount of  $\text{OH}^-$  formed by the base.)

	$[\text{NH}_3]$	$[\text{NH}_4^+]$	$[\text{OH}^-]$
Initial	0.100	0.00	$\approx 0.00$
Change			
Equil			

2. Represent the change in the concentration of  $\text{OH}^-$  with the variable  $x$ . Define the changes in the concentrations of the other reactants and products in terms of  $x$ .

	$[\text{NH}_3]$	$[\text{NH}_4^+]$	$[\text{OH}^-]$
Initial	0.100	0.00	$\approx 0.00$
Change	$-x$	$+x$	$+x$
Equil			

3. Sum each column to determine the equilibrium concentrations in terms of the initial concentrations and the variable  $x$ .

	$[\text{NH}_3]$	$[\text{NH}_4^+]$	$[\text{OH}^-]$
Initial	0.100	0.00	$\approx 0.00$
Change	$-x$	$+x$	$+x$
Equil	$0.100 - x$	$x$	$x$

4. Substitute the expressions for the equilibrium concentrations (from step 3) into the expression for the base ionization constant. In many cases, you can make the approximation that  $x$  is *small* (as discussed in Chapter 15).

Substitute the value of the base ionization constant (from Table 16.8) into the  $K_b$  expression and solve for  $x$ .

Confirm that the  $x$  is *small* approximation is valid by calculating the ratio of  $x$  to the number it was subtracted from in the approximation. The ratio should be less than 0.05 (or 5%).

$$\begin{aligned} K_b &= \frac{[\text{NH}_4^+][\text{OH}^-]}{[\text{NH}_3]} \\ &= \frac{x^2}{0.100 - x} \quad (x \text{ is small}) \\ 1.76 \times 10^{-5} &= \frac{x^2}{0.100} \\ \sqrt{1.76 \times 10^{-5}} &= \sqrt{\frac{x^2}{0.100}} \\ x &= \sqrt{(0.100)(1.76 \times 10^{-5})} \\ &= 1.33 \times 10^{-3} \\ \frac{1.33 \times 10^{-3}}{0.100} \times 100\% &= 1.33\% \\ \text{Therefore, the approximation is valid.} \end{aligned}$$

5. Determine the  $\text{OH}^-$  concentration from the calculated value of  $x$ . Use the expression for  $K_w$  to find  $[\text{H}_3\text{O}^+]$ .

Substitute  $[\text{H}_3\text{O}^+]$  into the pH equation to find pH.

$$\begin{aligned} [\text{OH}^-] &= 1.33 \times 10^{-3} \text{ M} \\ [\text{H}_3\text{O}^+][\text{OH}^-] &= K_w = 1.00 \times 10^{-14} \\ [\text{H}_3\text{O}^+](1.33 \times 10^{-3}) &= 1.00 \times 10^{-14} \\ [\text{H}_3\text{O}^+] &= 7.52 \times 10^{-12} \text{ M} \\ \text{pH} &= -\log[\text{H}_3\text{O}^+] \\ &= -\log(7.52 \times 10^{-12}) \\ &= 11.124 \end{aligned}$$

**FOR PRACTICE 16.12** Find the  $[\text{OH}^-]$  and pH of a 0.33 M methylamine solution.

## Chemistry AND Medicine

## What's in My Antacid?

In the opening section of this chapter, we discussed heartburn and its treatment with antacids. Some common antacids and their active ingredients include the following:

Amphogel	$\text{Al}(\text{OH})_3$
Milk of magnesia	$\text{Mg}(\text{OH})_2$
Maalox	$\text{Mg}(\text{OH})_2$ and $\text{Al}(\text{OH})_3$
Mylanta	$\text{Mg}(\text{OH})_2$ and $\text{Al}(\text{OH})_3$
Tums	$\text{CaCO}_3$

We categorize antacids into three main groups: calcium-based, magnesium-based, and aluminum-based. Calcium-based antacids may cause acid rebound—which means that, although they initially relieve heartburn, they can also cause the stomach to produce more acid, resulting in a quick return of the symptoms. Aluminum- and magnesium-based antacids do not cause acid rebound but have downsides of their own. Aluminum-based antacids tend to cause constipation, and magnesium-based ones tend to cause diarrhea. (In fact, milk of magnesia is sometimes used as a laxative.) A person who takes repeated doses of these antacids should alternate between the two or choose a product that contains both.

Notice the absence of group 1A metal hydroxides, such as KOH or NaOH, in the list of antacids. Why are those substances—which are completely soluble and act as strong bases—not used in antacids? Because a solution that contains sufficient KOH or NaOH to neutralize stomach acid would also burn the mouth and throat. In contrast,  $\text{Mg}(\text{OH})_2$  and  $\text{Al}(\text{OH})_3$  are only slightly soluble. Therefore liquid antacids

containing these are actually *suspensions* of  $\text{Mg}(\text{OH})_2$  and  $\text{Al}(\text{OH})_3$ —they are heterogeneous mixtures in which the solid is finely divided into the liquid. As a result, the concentration of  $\text{OH}^-$  in these suspensions is relatively small compared to what it would be with a group 1A metal hydroxide.

► Antacids contain a variety of bases that effectively neutralize excess stomach acid.

Initially, it might seem as though the relatively lower  $\text{OH}^-$  concentration would make the antacid much less effective. However, the solid  $\text{Mg}(\text{OH})_2$  or  $\text{Al}(\text{OH})_3$  continues to dissolve as the  $\text{OH}^-$  neutralizes stomach acid. For example, a suspension of magnesium hydroxide contains solid  $\text{Mg}(\text{OH})_2$  in equilibrium with dissolved  $\text{Mg}^{2+}$  and  $\text{OH}^-$  ions:

As stomach acid is neutralized,  $\text{OH}^-$  is used up, and the equilibrium shifts to the right providing additional  $\text{OH}^-$  ions. In this way, a suspension of  $\text{Mg}(\text{OH})_2$  provides a steady concentration of dissolved  $\text{OH}^-$  ions to neutralize stomach acid.

## QUESTION

Write chemical equations showing the reactions of each of the bases in the antacids discussed here with stomach acid (HCl).

The Acid-Base Properties of Ions and Salts

## 16.8 The Acid-Base Properties of Ions and Salts

We have already seen that some ions act as bases. For example, the bicarbonate ion acts as a base according to the following equation:

The bicarbonate ion, like any ion, does not exist by itself—in order to be charge-neutral, it must pair with a counter ion (in this case a cation) to form an ionic compound, called a *salt*. For example, the sodium salt of bicarbonate is sodium bicarbonate. Like all soluble salts, sodium bicarbonate dissociates in solution to form a sodium cation and bicarbonate anion:

The sodium ion has neither acidic nor basic properties (it does not ionize water), as we will see shortly. The bicarbonate ion, by contrast, acts as a weak base, ionizing water as just shown to form a basic solution. Consequently, the pH of a sodium bicarbonate solution is above 7 (the solution is basic). In this section, we consider some of the acid-base properties of salts and the ions they contain. Some salts are pH-neutral when put into water, others are acidic, and still others are basic, depending on their constituent anions and cations. In general, anions tend to form either *basic* or neutral solutions, while cations tend to form either *acidic* or neutral solutions.

## Anions as Weak Bases

We can think of any anion as the conjugate base of an acid. Consider the following anions and their corresponding acids:

This anion	is the conjugate base of	this acid
$\text{Cl}^-$		$\text{HCl}$
$\text{F}^-$		$\text{HF}$
$\text{NO}_3^-$		$\text{HNO}_3$
$\text{C}_2\text{H}_3\text{O}_2^-$		$\text{HC}_2\text{H}_3\text{O}_2$

In general, the anion  $\text{A}^-$  is the conjugate base of the acid  $\text{HA}$ . Since every anion can be regarded as the conjugate base of an acid, every anion itself can potentially act as a base. However, *not every anion does act as a base*—it depends on the strength of the corresponding acid. In general:

- An anion that is the conjugate base of a *weak acid* is itself a *weak base*.
- An anion that is the conjugate base of a *strong acid* is *pH-neutral* (forms solutions that are neither acidic nor basic).

For example, the  $\text{Cl}^-$  anion is the conjugate base of  $\text{HCl}$ , a strong acid. Therefore the  $\text{Cl}^-$  anion is pH-neutral (neither acidic nor basic). The  $\text{F}^-$  anion, however, is the conjugate base of  $\text{HF}$ , a weak acid. Therefore, the  $\text{F}^-$  ion is itself a weak base and ionizes water according to the reaction:

We can understand why the conjugate base of a weak acid is basic by asking ourselves why an acid is weak to begin with. Hydrofluoric acid is a weak acid because the following reaction lies to the left:

The equilibrium lies to the left because the  $\text{F}^-$  ion has a significant affinity for  $\text{H}^+$  ions. Consequently, when  $\text{F}^-$  is put into water, its affinity for  $\text{H}^+$  ions allows it to remove  $\text{H}^+$  ions from water molecules, thus acting as a weak base. In general, as shown in Figure 16.12▼,

Acid		Base	
Strong	$\text{HCl}$	$\text{Cl}^-$	Neutral
	$\text{H}_2\text{SO}_4$	$\text{HSO}_4^-$	
	$\text{HNO}_3$	$\text{NO}_3^-$	
	$\text{H}_3\text{O}^+$	$\text{H}_2\text{O}$	Weak
	$\text{HSO}_4^-$	$\text{SO}_4^{2-}$	
	$\text{H}_2\text{SO}_3$	$\text{HSO}_3^-$	
	$\text{H}_3\text{PO}_4$	$\text{H}_2\text{PO}_4^-$	
	$\text{HF}$	$\text{F}^-$	
	$\text{HC}_2\text{H}_3\text{O}_2$	$\text{C}_2\text{H}_3\text{O}_2^-$	
	$\text{H}_2\text{CO}_3$	$\text{HCO}_3^-$	
Weak	$\text{H}_2\text{S}$	$\text{HS}^-$	
	$\text{HSO}_3^-$	$\text{SO}_3^{2-}$	
	$\text{H}_2\text{PO}_4^-$	$\text{HPO}_4^{2-}$	
	$\text{HCN}$	$\text{CN}^-$	
	$\text{NH}_4^+$	$\text{NH}_3$	
	$\text{HCO}_3^-$	$\text{CO}_3^{2-}$	
	$\text{HPO}_4^{2-}$	$\text{PO}_4^{3-}$	
	$\text{H}_2\text{O}$	$\text{OH}^-$	Strong
	$\text{HS}^-$	$\text{S}^{2-}$	
	$\text{OH}^-$	$\text{O}^{2-}$	
Negligible			

◀ **FIGURE 16.12** Strength of Conjugate Acid–Base Pairs The stronger an acid, the weaker its conjugate base.

the weaker the acid, the stronger the conjugate base (as we saw in Section 16.4). In contrast, the conjugate base of a strong acid, such as  $\text{Cl}^-$ , does not act as a base because this reaction lies far to the right:

The reaction lies far to the right because the  $\text{Cl}^-$  ion has a low affinity for  $\text{H}^+$  ions. Consequently, when  $\text{Cl}^-$  is put into water, it does not remove  $\text{H}^+$  ions from water molecules.

### Example 16.13 Determining Whether an Anion Is Basic or pH-Neutral

Classify each anion as a weak base or pH-neutral.

- (a)  $\text{NO}_3^-$                       (b)  $\text{NO}_2^-$                       (c)  $\text{C}_2\text{H}_3\text{O}_2^-$

#### SOLUTION

- (a) From Table 16.3, you can see that  $\text{NO}_3^-$  is the conjugate base of a *strong* acid ( $\text{HNO}_3$ ) and is therefore pH-neutral.  
 (b) From Table 16.5 (or from its absence in Table 16.3), you know that  $\text{NO}_2^-$  is the conjugate base of a weak acid ( $\text{HNO}_2$ ) and is therefore a weak base.  
 (c) From Table 16.5 (or from its absence in Table 16.3), you know that  $\text{C}_2\text{H}_3\text{O}_2^-$  is the conjugate base of a weak acid ( $\text{HC}_2\text{H}_3\text{O}_2$ ) and is therefore a weak base.

**FOR PRACTICE 16.13** Classify each anion as a weak base or pH-neutral.

- (a)  $\text{CHO}_2^-$                       (b)  $\text{ClO}_4^-$

We can determine the pH of a solution containing an anion that acts as a weak base in a manner similar to how we determine the pH of any weak base solution. However, we need to know  $K_b$  for the anion acting as a base, which we can readily determine from  $K_a$  of the corresponding acid. Recall from Section 16.4 the expression for  $K_a$  for a generic acid HA:

Similarly, the expression for  $K_b$  for the conjugate base ( $\text{A}^-$ ) is:

If we multiply the expressions for  $K_a$  and  $K_b$ , we get  $K_w$ :

$$K_a \times K_b = \frac{[\text{H}_3\text{O}^+][\text{A}^-][\text{OH}^-][\text{HA}]}{[\text{HA}][\text{A}^-]} = [\text{H}_3\text{O}^+][\text{OH}^-] = K_w$$

Or simply,

$$K_a \times K_b = K_w$$

The product of  $K_a$  for an acid and  $K_b$  for its conjugate base is  $K_w$  ( $1.0 \times 10^{-14}$  at  $25^\circ\text{C}$ ). Consequently, we can find  $K_b$  for an anion acting as a base from the value of  $K_a$  for the corresponding acid. For example, for acetic acid ( $\text{HC}_2\text{H}_3\text{O}_2$ ),  $K_a = 1.8 \times 10^{-5}$ . We calculate  $K_b$  for the conjugate base ( $\text{C}_2\text{H}_3\text{O}_2^-$ ) by substituting into the equation:

$$K_a \times K_b = K_w$$

$$K_b = \frac{K_w}{K_a} = \frac{1.0 \times 10^{-14}}{1.8 \times 10^{-5}} = 5.6 \times 10^{-10}$$

Knowing  $K_b$ , we can find the pH of a solution containing an anion acting as a base, as Example 16.14 demonstrates.

**Example 16.14** Determining the pH of a Solution Containing an Anion Acting as a Base

Find the pH of a 0.100 M  $\text{NaCHO}_2$  solution. The salt completely dissociates into  $\text{Na}^+(aq)$  and  $\text{CHO}_2^-(aq)$ , and the  $\text{Na}^+$  ion has no acid or base properties.

**SOLUTION**

1. Since the  $\text{Na}^+$  ion does not have any acidic or basic properties, you can ignore it. Write the balanced equation for the ionization of water by the basic anion and use it as a guide to prepare an ICE table showing the given concentration of the weak base as its initial concentration.

	$[\text{CHO}_2^-]$	$[\text{HCHO}_2]$	$[\text{OH}^-]$
Initial	0.100	0.00	$\approx 0.00$
Change			
Equil			

2. Represent the change in the concentration of  $\text{OH}^-$  with the variable  $x$ . Define the changes in the concentrations of the other reactants and products in terms of  $x$ .

	$[\text{CHO}_2^-]$	$[\text{HCHO}_2]$	$[\text{OH}^-]$
Initial	0.100	0.00	$\approx 0.00$
Change	$-x$	$+x$	$+x$
Equil			

3. Sum each column to determine the equilibrium concentrations in terms of the initial concentrations and the variable  $x$ .

	$[\text{CHO}_2^-]$	$[\text{HCHO}_2]$	$[\text{OH}^-]$
Initial	0.100	0.00	$\approx 0.00$
Change	$-x$	$+x$	$+x$
Equil	$0.100 - x$	$x$	$x$

4. Find  $K_b$  from  $K_a$  (for the conjugate acid).

Substitute the expressions for the equilibrium concentrations (from step 3) into the expression for  $K_b$ . In many cases, you can make the approximation that  $x$  is *small*.

Substitute the value of  $K_b$  into the  $K_b$  expression and solve for  $x$ .

Confirm that the  $x$  is *small* approximation is valid by calculating the ratio of  $x$  to the number it was subtracted from in the approximation. The ratio should be less than 0.05 (or 5%).

$$\begin{aligned} K_a \times K_b &= K_w \\ K_b &= \frac{K_w}{K_a} = \frac{1.0 \times 10^{-14}}{1.8 \times 10^{-4}} = 5.6 \times 10^{-11} \\ K_b &= \frac{[\text{HCHO}_2][\text{OH}^-]}{[\text{CHO}_2^-]} \\ &= \frac{x^2}{0.100 - x} \\ 5.6 \times 10^{-11} &= \frac{x^2}{0.100} \\ x &= 2.4 \times 10^{-6} \\ \frac{2.4 \times 10^{-6}}{0.100} \times 100\% &= 0.0024\% \\ \text{Therefore, the approximation is valid.} \end{aligned}$$

5. Determine the  $\text{OH}^-$  concentration from the calculated value of  $x$ .

Use the expression for  $K_w$  to find  $[\text{H}_3\text{O}^+]$ .

Substitute  $[\text{H}_3\text{O}^+]$  into the pH equation to find pH.

$$\begin{aligned} [\text{OH}^-] &= 2.4 \times 10^{-6} \text{ M} \\ [\text{H}_3\text{O}^+][\text{OH}^-] &= K_w = 1.0 \times 10^{-14} \\ [\text{H}_3\text{O}^+](2.4 \times 10^{-6}) &= 1.0 \times 10^{-14} \\ [\text{H}_3\text{O}^+] &= 4.2 \times 10^{-9} \text{ M} \\ \text{pH} &= -\log[\text{H}_3\text{O}^+] \\ &= -\log(4.2 \times 10^{-9}) \\ &= 8.38 \end{aligned}$$

**FOR PRACTICE 16.14** Find the pH of a 0.250 M  $\text{NaC}_2\text{H}_3\text{O}_2$  solution.

We can also express the relationship between  $K_a$  and  $K_b$  in terms of  $pK_a$  and  $pK_b$ . By taking the log of both sides of  $K_a \times K_b = K_w$ , we get:

$$\begin{aligned}\log(K_a \times K_b) &= \log K_w \\ \log K_a + \log K_b &= \log K_w\end{aligned}$$

Since  $K_w = 10^{-14}$ , we can rearrange the equation to get:

$$\log K_a + \log K_b = \log 10^{-14} = -14$$

Rearranging further:

$$-\log K_a - \log K_b = 14$$

Since  $-\log K = pK$ , we get:

$$pK_a + pK_b = 14$$

## Cations as Weak Acids

In contrast to anions, which in some cases act as weak bases, cations can in some cases act as *weak acids*. Although some exceptions exist, we can generally divide cations into three categories: cations that are the counterions of strong bases; cations that are the conjugate acids of *weak* bases; and cations that are small, highly charged metals. We examine each individually.

### Cations That Are the Counterions of Strong Bases

Strong bases such as NaOH or  $\text{Ca}(\text{OH})_2$  generally contain hydroxide ions and a counterion. In solution, a strong base completely dissociates to form  $\text{OH}^-(aq)$  and the solvated (in solution) counterion. Although these counterions interact with water molecules via ion-dipole forces, they do not ionize water and they do not contribute to the acidity or basicity of the solution. In general *cations that are the counterions of strong bases are themselves pH-neutral* (they form solutions that are neither acidic nor basic). For example,  $\text{Na}^+$ ,  $\text{K}^+$ , and  $\text{Ca}^{2+}$  are the counterions of the strong bases NaOH, KOH, and  $\text{Ca}(\text{OH})_2$  and are therefore themselves pH-neutral.

### Cations That Are the Conjugate Acids of Weak Bases

A cation can be formed from any nonionic weak base by adding a proton ( $\text{H}^+$ ) to its formula. The cation is the conjugate acid of the base. Consider the following cations and their corresponding weak bases:

This cation	is the conjugate acid of	this weak base
$\text{NH}_4^+$		$\text{NH}_3$
$\text{C}_2\text{H}_5\text{NH}_3^+$		$\text{C}_2\text{H}_5\text{NH}_2$
$\text{CH}_3\text{NH}_3^+$		$\text{CH}_3\text{NH}_2$

Any of these cations, with the general formula  $\text{BH}^+$ , will act as a weak acid according to the equation:

In general, *a cation that is the conjugate acid of a weak base is a weak acid*.

We can calculate the pH of a solution containing the conjugate acid of a weak base just like that of any other weak acidic solution. However, we must derive the value of  $K_a$  for the acid from  $K_b$  using the previously derived relationship:  $K_a \times K_b = K_w$ .

### Cations That Are Small, Highly Charged Metals

*Small, highly charged metal cations such as  $\text{Al}^{3+}$  and  $\text{Fe}^{3+}$  form weakly acidic solutions.* For example, when  $\text{Al}^{3+}$  is dissolved in water, it becomes hydrated according to the equation:

The hydrated form of the ion then acts as a Brønsted–Lowry acid:

In effect, the binding of a water molecule to the cation makes the water more acidic. See Section 16.10.

Neither the alkali metal cations nor the alkaline earth metal cations ionize water in this way, but the cations of many other metals do. The smaller and more highly charged the cation, the more acidic its behavior.

### Example 16.15 Determining Whether a Cation Is Acidic or pH-Neutral

Classify each cation as a weak acid or pH-neutral.

- (a)  $\text{C}_5\text{H}_5\text{NH}^+$       (b)  $\text{Ca}^{2+}$       (c)  $\text{Cr}^{3+}$

#### SOLUTION

- (a) The  $\text{C}_5\text{H}_5\text{NH}^+$  cation is the conjugate acid of a weak base and is therefore a weak acid.  
 (b) The  $\text{Ca}^{2+}$  cation is the counterion of a strong base and is therefore pH-neutral (neither acidic nor basic).  
 (c) The  $\text{Cr}^{3+}$  cation is a small, highly charged metal cation and is therefore a weak acid.

**FOR PRACTICE 16.15** Classify each cation as a weak acid or pH-neutral.

- (a)  $\text{Li}^+$       (b)  $\text{CH}_3\text{NH}_3^+$       (c)  $\text{Fe}^{3+}$

## Classifying Salt Solutions as Acidic, Basic, or Neutral

Since salts contain both a cation and an anion, they can form acidic, basic, or neutral solutions when dissolved in water. The pH of the solution depends on the specific cation and anion involved. We examine the four possibilities individually.

- 1. Salts in which neither the cation nor the anion acts as an acid or a base form pH-neutral solutions.** A salt in which the cation is the counterion of a strong base and in which the anion is the conjugate base of strong acid forms a *neutral* solution. Some salts in this category include:

$\text{NaCl}$   
sodium chloride

$\text{Ca}(\text{NO}_3)_2$   
calcium nitrate

$\text{KBr}$   
potassium bromide

Cations are pH-neutral.

Anions are conjugate bases of strong acids.

- 2. Salts in which the cation does not act as an acid and the anion acts as a base form basic solutions.** A salt in which the cation is the counterion of a strong base and in which the anion is the conjugate base of *weak* acid forms a *basic* solution. Salts in this category include:

$\text{NaF}$   
sodium fluoride

$\text{Ca}(\text{C}_2\text{H}_3\text{O}_2)_2$   
calcium acetate

$\text{KNO}_2$   
potassium nitrite

Cations are pH-neutral.

Anions are conjugate bases of weak acids.

**3. Salts in which the cation acts as an acid and the anion does not act as a base form acidic solutions.** A salt in which the cation is either the conjugate acid of a weak base or a small, highly charged metal ion and in which the anion is the conjugate base of *strong* acid forms an *acidic* solution. Salts in this category include:

Cations are conjugate acids of *weak* bases or small, highly charged metal ions.

Anions are conjugate bases of *strong* acids.

**4. Salts in which the cation acts as an acid and the anion acts as a base form solutions in which the pH depends on the relative strengths of the acid and the base.** A salt in which the cation is either the conjugate acid of a weak base or a small, highly charged metal ion and in which the anion is the conjugate base of a *weak* acid forms a solution in which the pH depends on the relative strengths of the acid and base. Salts in this category include:

Cations are conjugate acids of *weak* bases or small, highly charged metal ions.

Anions are conjugate bases of *weak* acids.

We can determine the overall acidity or basicity of a solution containing one of these salts by comparing the  $K_a$  of the acid to the  $K_b$  of the base—the ion with the higher value of  $K$  dominates and determines whether the solution will be acidic or basic, as shown in part (e) of Example 16.16. Table 16.9 summarizes all of these possibilities.

**TABLE 16.9** pH of Salt Solutions

		ANION	
		Conjugate base of strong acid	Conjugate base of weak acid
CATION	Conjugate acid of weak base	Acidic	Depends on relative strengths
	Small, highly charged metal ion	Acidic	Depends on relative strengths
	Counterion of strong base	Neutral	Basic

### Example 16.16 Determining the Overall Acidity or Basicity of Salt Solutions

Determine if the solution formed by each salt is acidic, basic, or neutral.

- (a)  $\text{SrCl}_2$                       (b)  $\text{AlBr}_3$                       (c)  $\text{CH}_3\text{NH}_3\text{NO}_3$   
 (d)  $\text{NaCHO}_2$                       (e)  $\text{NH}_4\text{F}$

#### SOLUTION

- (a) The  $\text{Sr}^{2+}$  cation is the counterion of a strong base ( $\text{Sr}(\text{OH})_2$ ) and is pH-neutral. The  $\text{Cl}^-$  anion is the conjugate base of a strong acid ( $\text{HCl}$ ) and is pH-neutral as well. The  $\text{SrCl}_2$  solution is therefore pH-neutral (neither acidic nor basic).

<p><b>(b)</b> The <math>\text{Al}^{3+}</math> cation is a small, highly charged metal ion (that is not an alkali metal or an alkaline earth metal) and is a weak acid. The <math>\text{Br}^-</math> anion is the conjugate base of a strong acid (<math>\text{HBr}</math>) and is pH-neutral. The <math>\text{AlBr}_3</math> solution is therefore acidic.</p>	
<p><b>(c)</b> The <math>\text{CH}_3\text{NH}_3^+</math> ion is the conjugate acid of a weak base (<math>\text{CH}_3\text{NH}_2</math>) and is acidic. The <math>\text{NO}_3^-</math> anion is the conjugate base of a strong acid (<math>\text{HNO}_3</math>) and is pH-neutral. The <math>\text{CH}_3\text{NH}_3\text{NO}_3</math> solution is therefore acidic.</p>	
<p><b>(d)</b> The <math>\text{Na}^+</math> cation is the counterion of a strong base and is pH-neutral. The <math>\text{CHO}_2^-</math> anion is the conjugate base of a weak acid and is basic. The <math>\text{NaCHO}_2</math> solution is therefore basic.</p>	
<p><b>(e)</b> The <math>\text{NH}_4^+</math> ion is the conjugate acid of a weak base (<math>\text{NH}_3</math>) and is acidic. The <math>\text{F}^-</math> ion is the conjugate base of a weak acid and is basic. To determine the overall acidity or basicity of the solution, compare the values of <math>K_a</math> for the acidic cation and <math>K_b</math> for the basic anion. Obtain each value of <math>K</math> from the conjugate by using <math>K_a \times K_b = K_w</math>.</p> <p>Since <math>K_a</math> is greater than <math>K_b</math>, the solution is acidic.</p>	 $K_a(\text{NH}_4^+) = \frac{K_w}{K_b(\text{NH}_3)} = \frac{1.0 \times 10^{-14}}{1.76 \times 10^{-5}} = 5.68 \times 10^{-10}$ $K_b(\text{F}^-) = \frac{K_w}{K_a(\text{HF})} = \frac{1.0 \times 10^{-14}}{3.5 \times 10^{-4}} = 2.9 \times 10^{-11}$ <p><math>K_a &gt; K_b</math></p> <div>Acidic solution</div>
<p><b>FOR PRACTICE 16.16</b> Determine if the solution formed by each salt is acidic, basic, or neutral.</p> <p><b>(a)</b> <math>\text{NaHCO}_3</math>      <b>(b)</b> <math>\text{CH}_3\text{CH}_2\text{NH}_3\text{Cl}</math>      <b>(c)</b> <math>\text{KNO}_3</math>      <b>(d)</b> <math>\text{Fe}(\text{NO}_3)_3</math></p>	

## 16.9 Polyprotic Acids

In Section 16.4, we discussed that some acids, called polyprotic acids, contain two or more ionizable protons. Recall that sulfurous acid ( $\text{H}_2\text{SO}_3$ ) is a diprotic acid containing two ionizable protons and phosphoric acid ( $\text{H}_3\text{PO}_4$ ) is a triprotic acid containing three ionizable protons.

Typically, a **polyprotic acid** ionizes in successive steps, each with its own  $K_a$ . For example, sulfurous acid ionizes in two steps:

$K_{a_1}$  is the acid ionization constant for the first step, and  $K_{a_2}$  is the acid ionization constant for the second step. Notice that  $K_{a_2}$  is much smaller than  $K_{a_1}$ . This is true for all polyprotic acids and makes sense because the first proton separates from a neutral molecule, while

the second must separate from an anion. The negatively charged anion holds the positively charged proton more tightly, making the proton more difficult to remove and resulting in a smaller value of  $K_a$ .

Table 16.10 lists some common polyprotic acids and their acid ionization constants. Notice that in all cases, the value of  $K_a$  for each step becomes successively smaller. The value of  $K_{a1}$  for sulfuric acid is identified as strong because sulfuric acid is strong in the first step and weak in the second.

**TABLE 16.10** Common Polyprotic Acids and Ionization Constants at 25 °C

Name (Formula)	Structure	Space-filling model	$K_{a1}$	$K_{a2}$	$K_{a3}$
Sulfuric Acid ( $H_2SO_4$ )			Strong	$1.2 \times 10^{-2}$	
Oxalic Acid ( $H_2C_2O_4$ )			$6.0 \times 10^{-2}$	$6.1 \times 10^{-5}$	
Sulfurous Acid ( $H_2SO_3$ )			$1.6 \times 10^{-2}$	$6.4 \times 10^{-8}$	
Phosphoric Acid ( $H_3PO_4$ )			$7.5 \times 10^{-3}$	$6.2 \times 10^{-8}$	$4.2 \times 10^{-13}$
Citric Acid ( $H_3C_6H_5O_7$ )			$7.4 \times 10^{-4}$	$1.7 \times 10^{-5}$	$4.0 \times 10^{-7}$
Ascorbic Acid ( $H_2C_6H_6O_6$ )			$8.0 \times 10^{-5}$	$1.6 \times 10^{-12}$	
Carbonic Acid ( $H_2CO_3$ )			$4.3 \times 10^{-7}$	$5.6 \times 10^{-11}$	

### Finding the pH of Polyprotic Acid Solutions

Finding the pH of a polyprotic acid solution is less difficult than we might first imagine because, for most polyprotic acids,  $K_{a1}$  is much larger than  $K_{a2}$  (or  $K_{a3}$  for triprotic acids). Therefore the amount of  $H_3O^+$  formed by the first ionization step is much larger than

that formed by the second or third ionization step. In addition, the formation of  $\text{H}_3\text{O}^+$  in the first step inhibits the formation of additional  $\text{H}_3\text{O}^+$  in the second step (because of Le Châtelier's principle). Consequently, we treat most polyprotic acid solutions as if the first step were the only one that contributes to the  $\text{H}_3\text{O}^+$  concentration, as illustrated in Example 16.17. A major exception is a dilute solution of sulfuric acid, which we examine in Example 16.18.

### Example 16.17 Finding the pH of a Polyprotic Acid Solution

Find the pH of a 0.100 M ascorbic acid ( $\text{H}_2\text{C}_6\text{H}_6\text{O}_6$ ) solution.

#### SOLUTION

To find the pH, you must find the equilibrium concentration of  $\text{H}_3\text{O}^+$ . Treat the problem as a weak acid pH problem with a single ionizable proton. The second proton contributes a negligible amount to the concentration of  $\text{H}_3\text{O}^+$  and can be ignored. Follow the procedure from Example 16.6, shown in condensed form here. Use  $K_{a1}$  for ascorbic acid from Table 16.10.

Confirm that the  $x$  is *small* approximation is valid by calculating the ratio of  $x$  to the number it was subtracted from in the approximation. The ratio should be less than 0.05 (or 5%).

Calculate the pH from  $\text{H}_3\text{O}^+$  concentration.

	$[\text{H}_2\text{C}_6\text{H}_6\text{O}_6]$	$[\text{H}_3\text{O}^+]$	$[\text{HC}_6\text{H}_6\text{O}_6^-]$
Initial	0.100	$\approx 0.00$	0.00
Change	$-x$	$+x$	$+x$
Equil	$0.100 - x$	$x$	$x$

$$K_{a1} = \frac{[\text{H}_3\text{O}^+][\text{HC}_6\text{H}_6\text{O}_6^-]}{[\text{H}_2\text{C}_6\text{H}_6\text{O}_6]}$$

$$= \frac{x^2}{0.100 - x} \quad (x \text{ is small})$$

$$8.0 \times 10^{-5} = \frac{x^2}{0.100}$$

$$x = 2.8 \times 10^{-3}$$

$$\frac{2.8 \times 10^{-3}}{0.100} \times 100\% = 2.8\%$$

The approximation is valid. Therefore,

$$[\text{H}_3\text{O}^+] = 2.8 \times 10^{-3} \text{ M}$$

$$\text{pH} = -\log(2.8 \times 10^{-3}) = 2.55$$

**FOR PRACTICE 16.17** Find the pH of a 0.050 M  $\text{H}_2\text{CO}_3$  solution.

### Example 16.18 Dilute $\text{H}_2\text{SO}_4$ Solutions

Find the pH of a 0.0100 M sulfuric acid ( $\text{H}_2\text{SO}_4$ ) solution.

#### SOLUTION

Sulfuric acid is strong in its first ionization step and weak in its second. Begin by writing the equations for the two steps. As the concentration of an  $\text{H}_2\text{SO}_4$  solution becomes smaller, the second ionization step becomes more significant because the percent ionization increases (as discussed in Section 16.6). Therefore, for a concentration of 0.0100 M, you can't neglect the  $\text{H}_3\text{O}^+$  contribution from the second step, as you can for other polyprotic acids. You must calculate the  $\text{H}_3\text{O}^+$  contributions from both steps.

—Continued on the next page

Continued—

The $[\text{H}_3\text{O}^+]$ that results from the first ionization step is 0.0100 M (because the first step is strong). To determine the $[\text{H}_3\text{O}^+]$ formed by the second step, prepare an ICE table for the second step in which the initial concentration of $\text{H}_3\text{O}^+$ is 0.0100 M. The initial concentration of $\text{HSO}_4^-$ must also be 0.0100 M (due to the stoichiometry of the ionization reaction).	<table><tr><th></th><th><math>[\text{HSO}_4^-]</math></th><th><math>[\text{H}_3\text{O}^+]</math></th><th><math>[\text{SO}_4^{2-}]</math></th></tr><tr><td>Initial</td><td>0.0100</td><td><math>\approx 0.0100</math></td><td>0.000</td></tr><tr><td>Change</td><td><math>-x</math></td><td><math>+x</math></td><td><math>+x</math></td></tr><tr><td>Equil</td><td><math>0.0100 - x</math></td><td><math>0.0100 + x</math></td><td><math>x</math></td></tr></table>		$[\text{HSO}_4^-]$	$[\text{H}_3\text{O}^+]$	$[\text{SO}_4^{2-}]$	Initial	0.0100	$\approx 0.0100$	0.000	Change	$-x$	$+x$	$+x$	Equil	$0.0100 - x$	$0.0100 + x$	$x$
	$[\text{HSO}_4^-]$	$[\text{H}_3\text{O}^+]$	$[\text{SO}_4^{2-}]$														
Initial	0.0100	$\approx 0.0100$	0.000														
Change	$-x$	$+x$	$+x$														
Equil	$0.0100 - x$	$0.0100 + x$	$x$														
Substitute the expressions for the equilibrium concentrations (from the table just shown) into the expression for $K_{a_2}$ . In this case, you cannot make the $x$ is <i>small</i> approximation because the equilibrium constant (0.012) is <i>not small</i> relative to the initial concentration (0.0100).  Substitute the value of $K_{a_2}$ and multiply out the expression to arrive at the standard quadratic form.	$K_{a_2} = \frac{[\text{H}_3\text{O}^+][\text{SO}_4^{2-}]}{[\text{HSO}_4^-]}$ $= \frac{(0.0100 + x)x}{0.0100 - x}$ $0.012 = \frac{0.0100x + x^2}{0.0100 - x}$ $0.012(0.0100 - x) = 0.0100x + x^2$ $0.00012 - 0.012x = 0.0100x + x^2$ $x^2 + 0.022x - 0.00012 = 0$																
Solve the quadratic equation using the quadratic formula.	$x = \frac{-b \pm \sqrt{b^2 - 4ac}}{2a}$ $= \frac{-(0.022) \pm \sqrt{(0.022)^2 - 4(1)(-0.00012)}}{2(1)}$ $= \frac{-0.022 \pm 0.031}{2}$ $x = -0.027 \text{ or } x = 0.0045$ <p>Since <math>x</math> represents a concentration, and since concentrations cannot be negative, we reject the negative root.</p> $x = 0.0045$																
Determine the $\text{H}_3\text{O}^+$ concentration from the calculated value of $x$ and calculate the pH. Notice that the second step produces almost half as much $\text{H}_3\text{O}^+$ as the first step—an amount that must not be ignored. This is always the case with dilute $\text{H}_2\text{SO}_4$ solutions.	$[\text{H}_3\text{O}^+] = 0.0100 + x$ $= 0.0100 + 0.0045$ $= 0.0145 \text{ M}$ $\text{pH} = -\log[\text{H}_3\text{O}^+]$ $= -\log(0.0145)$ $= 1.84$																
<b>FOR PRACTICE 16.18</b> Find the pH and $[\text{SO}_4^{2-}]$ of a 0.0075 M sulfuric acid solution.																	

## Finding the Concentration of the Anions for a Weak Diprotic Acid Solution

In some cases, we may want to know the concentrations of the anions formed by a polyprotic acid. Consider the following generic polyprotic acid  $\text{H}_2\text{X}$  and its ionization steps:

In Examples 16.17 and 16.18, we illustrated how to find the concentration of  $\text{H}_3\text{O}^+$  for such a solution, which is equal to the concentration of  $\text{HX}^-$ . What if instead we needed to find the concentration of  $\text{X}^{2-}$ ? To find the concentration of  $\text{X}^{2-}$ , we use the concentration of  $\text{HX}^-$  and  $\text{H}_3\text{O}^+$  (from the first ionization step) as the initial concentrations for the second ionization step. We then solve a second equilibrium problem using the second ionization equation and  $K_{a_2}$ , as demonstrated in Example 16.19.

## 16.10 Acid Strength and Molecular Structure

We have learned that a Brønsted–Lowry acid is a proton ( $\text{H}^+$ ) donor. However, we have not explored why some hydrogen-containing molecules act as acids while others do not, or why some acids are strong and others weak. For example, why is  $\text{H}_2\text{S}$  acidic while  $\text{CH}_4$  is not? Or why is  $\text{HF}$  a weak acid while  $\text{HCl}$  is a strong acid? We divide our discussion about these issues into two categories: binary acids (those containing hydrogen and only one other element) and oxyacids (those containing hydrogen bonded to an oxygen atom that is bonded to another element).

### Binary Acids

Consider the bond between a hydrogen atom and some other generic element (which we call Y):

The factors affecting the ease with which this hydrogen is donated (and therefore will be acidic) are the *polarity* of the bond and the *strength* of the bond.

### Bond Polarity

Using the notation introduced in Chapter 9, the  $\text{H}—\text{Y}$  bond must be polarized with the hydrogen atom as the positive pole in order for  $\text{HY}$  to be acidic:

This requirement makes physical sense because the hydrogen atom must be lost as a positively charged ion ( $\text{H}^+$ ). A partial positive charge on the hydrogen atom facilitates its loss. Consider the following three bonds and their corresponding dipole moments:

$\text{LiH}$  is ionic with *the negative charge on the hydrogen atom*; therefore,  $\text{LiH}$  is not acidic. The  $\text{C}—\text{H}$  bond is virtually nonpolar because the electronegativities of carbon and hydrogen are similar; therefore  $\text{C}—\text{H}$  is not acidic. In contrast, the  $\text{H}—\text{F}$  bond is polar with the positive charge on the hydrogen atom. As we have discussed in this chapter,  $\text{HF}$  is an acid. This is because the partial positive charge on the hydrogen atom makes it easier for the hydrogen to be lost as an  $\text{H}^+$  ion.

### Bond Strength

The strength of the  $\text{H}—\text{Y}$  bond also affects the strength of the corresponding acid. As we might expect, the stronger the bond, the weaker the acid—the more tightly the hydrogen atom is held, the less likely it is to come off. We can see the effect of bond strength by comparing the bond strengths and acidities of the hydrogen halides:

Acid	Bond Energy (kJ/mol)	Type of Acid
$\text{H}—\text{F}$	565	Weak
$\text{H}—\text{Cl}$	431	Strong
$\text{H}—\text{Br}$	364	Strong

$\text{HCl}$  and  $\text{HBr}$  have weaker bonds and are both strong acids.  $\text{HF}$ , however, has a stronger bond and is therefore a weak acid, despite the greater bond polarity of  $\text{HF}$ .

### The Combined Effect of Bond Polarity and Bond Strength

We can see the combined effect of bond polarity and bond strength by examining the trends in acidity of the group 6A and 7A hydrides as shown in Figure 16.14. The hydrides become more acidic from left to right as the  $\text{H}—\text{Y}$  bond becomes more polar. The hydrides also become more acidic from top to bottom as the  $\text{H}—\text{Y}$  bond becomes weaker.

Increasing electronegativity  
Increasing acidity  
→

	6A	7A
	$\text{H}_2\text{O}$	$\text{HF}$
	$\text{H}_2\text{S}$	$\text{HCl}$
	$\text{H}_2\text{Se}$	$\text{HBr}$
	$\text{H}_2\text{Te}$	$\text{HI}$

↓  
Decreasing bond strength  
Increasing acidity

**▲ FIGURE 16.14 Acidity of the Group 6A and 7A Hydrides** From left to right, the hydrides become more acidic because the  $\text{H}—\text{Y}$  bond becomes more polar. From top to bottom, these hydrides become more acidic because the  $\text{H}—\text{Y}$  bond becomes weaker.

## Oxyacids

Oxyacids contain a hydrogen atom bonded to an oxygen atom. The oxygen atom is in turn bonded to another atom (which we call Y):

Y may or may not be bonded to yet other atoms. The factors affecting the ease with which the hydrogen in an oxyacid is donated (and therefore is acidic) are the *electronegativity of the element Y* and the *number of oxygen atoms attached to the element Y*.

Oxyacids are sometimes called oxoacids.

### The Electronegativity of Y

The more electronegative the element Y, the more it weakens and polarizes the H—O bond and the more acidic the oxyacid is. We can see this effect by comparing the electronegativity of Y and the acid ionization constants of the following oxyacids:

Acid	Electronegativity of Y	$K_a$
$\text{H}-\text{O}-\text{I}$	2.5	$2.3 \times 10^{-11}$
$\text{H}-\text{O}-\text{Br}$	2.8	$2.0 \times 10^{-9}$
$\text{H}-\text{O}-\text{Cl}$	3.0	$2.9 \times 10^{-8}$

Chlorine is the most electronegative of the three elements, and the corresponding acid has the greatest  $K_a$ .

### The Number of Oxygen Atoms Bonded to Y

Oxyacids may contain additional oxygen atoms bonded to the element Y. Because these additional oxygen atoms are electronegative, they draw electron density away from Y, which in turn draws electron density away from the H—O bond, further weakening and polarizing it, and leading to increasing acidity. We can see this effect by comparing the following series of acid ionization constants:

Acid	Structure	$K_a$
$\text{HClO}_4$	$\begin{array}{c} \text{O} \\    \\ \text{H}-\text{O}-\text{Cl}=\text{O} \\    \\ \text{O} \end{array}$	Strong
$\text{HClO}_3$	$\begin{array}{c} \text{O} \\    \\ \text{H}-\text{O}-\text{Cl}=\text{O} \end{array}$	1
$\text{HClO}_2$	$\text{H}-\text{O}-\text{Cl}=\text{O}$	$1.1 \times 10^{-2}$
$\text{HClO}$	$\text{H}-\text{O}-\text{Cl}$	$2.9 \times 10^{-8}$

The greater the number of oxygen atoms bonded to Y, the stronger the acid. On this basis we would predict that  $\text{H}_2\text{SO}_4$  is a stronger acid than  $\text{H}_2\text{SO}_3$  and that  $\text{HNO}_3$  is stronger than  $\text{HNO}_2$ . As we have seen in this chapter, both  $\text{H}_2\text{SO}_4$  and  $\text{HNO}_3$  are strong acids, while  $\text{H}_2\text{SO}_3$  and  $\text{HNO}_2$  are weak acids, as predicted.

## 16.11 Lewis Acids and Bases

We began our definitions of acids and bases with the Arrhenius model. We then saw how the Brønsted–Lowry model, by introducing the concept of a proton donor and proton acceptor, expands the range of substances that we consider acids and bases. We now introduce a third model, which further broadens the range of substances that we can consider acids. This third model is the *Lewis model*, named after G. N. Lewis, the American chemist who devised the electron-dot representation of chemical bonding (Section 9.1).

While the Brønsted–Lowry model focuses on the transfer of a proton, the Lewis model focuses on the transfer of an electron pair. Consider the simple acid–base reaction between the  $\text{H}^+$  ion and  $\text{NH}_3$ , shown here with Lewis structures:

According to the Brønsted–Lowry model, the ammonia accepts a proton, thus acting as a base. According to the Lewis model, the ammonia acts as a base by *donating an electron pair*. The general definitions of acids and bases according to the Lewis model focus on the electron pair:

**Lewis acid:** electron pair acceptor

**Lewis base:** electron pair donor

According to the Lewis definition,  $\text{H}^+$  in the reaction just shown is acting as an acid because it is accepting an electron pair from  $\text{NH}_3$ .  $\text{NH}_3$  is acting as a Lewis base because it is donating an electron pair to  $\text{H}^+$ .

Although the Lewis model does not significantly expand the substances that can be considered bases—because all proton acceptors must have an electron pair to bind the proton—it does significantly expand the substances that can be considered acids. According to the Lewis model, a substance need not even contain hydrogen to be an acid. For example, consider the gas-phase reaction between boron trifluoride and ammonia shown here:

Boron trifluoride has an empty orbital that can accept the electron pair from ammonia and form the product (the product of a Lewis acid–base reaction is sometimes called an *adduct*). The reaction just shown demonstrates an important property of Lewis acids:

*A Lewis acid has an empty orbital (or can rearrange electrons to create an empty orbital) that can accept an electron pair.*

Consequently, the Lewis definition subsumes a whole new class of acids. Next we examine a few examples.

### Molecules That Act as Lewis Acids

Since molecules with incomplete octets have empty orbitals, they can serve as Lewis acids. For example, both  $\text{AlCl}_3$  and  $\text{BCl}_3$  have incomplete octets:

These both act as Lewis acids, as shown in the following reactions:

Some molecules that may not initially contain empty orbitals can rearrange their electrons to act as Lewis acids. Consider the reaction between carbon dioxide and water:

The electrons in the double bond on carbon move to the terminal oxygen atom, allowing carbon dioxide to act as a Lewis acid by accepting an electron pair from water. The molecule then undergoes a rearrangement in which the hydrogen atom shown in red bonds with the terminal oxygen atom instead of the internal one.

## Cations That Act as Lewis Acids

Some cations, because they are positively charged and have lost some electrons, have empty orbitals that allow them to also act as Lewis acids. Consider the hydration process of the  $\text{Al}^{3+}$  ion discussed in Section 16.8 shown here:

The aluminum ion acts as a Lewis acid, accepting lone pairs from six water molecules to form the hydrated ion. Many other small, highly charged metal ions also act as Lewis acids in this way.

## 16.12 Acid Rain

About 82% of U.S. energy comes from the combustion of fossil fuels, including petroleum, natural gas, and coal (Figure 16.15). Some fossil fuels, especially coal, contain small amounts of sulfur impurities. During combustion, these impurities react with oxygen to form  $\text{SO}_2$ . In addition, during combustion of any fossil fuel, nitrogen from the air reacts with oxygen to form  $\text{NO}_2$ . Sulfur dioxide and nitrogen dioxide react with water and diatomic oxygen ( $\text{O}_2$ ) in the atmosphere to form sulfuric acid and nitric acid:

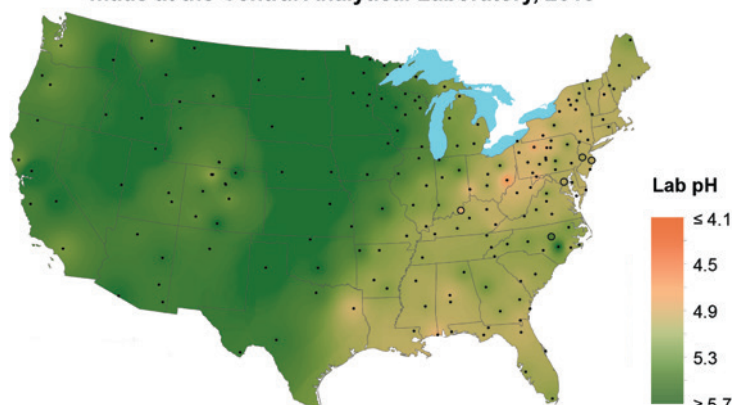

U.S. Energy Consumption by Source, 2013

■ Fossil Fuels: 82%  
 ■ Nuclear: 10%  
 ■ Renewable Energy: 8%

**▲ FIGURE 16.15 Sources of U.S. Energy** About 82% of U.S. energy comes from fossil fuel combustion. Source: U.S. EIA Annual Energy Review 2015

Hydrogen ion concentration as pH from measurements made at the Central Analytical Laboratory, 2013

### ▲ FIGURE 16.16 Acid Rain

Acid rain is a significant problem in the northeastern United States. The map shows the pH of rain that falls across the United States.

Source: National Atmospheric Deposition Program, National Trends Network

These acids combine with rain to form *acid rain*. The problem is greatest in the northeastern portion of the United States, where the rain is significantly acidic because the sulfur and nitrogen oxides produced by coal combustion in the Midwest are carried toward the Northeast by natural air currents.

Even in relatively unpolluted areas, rain is naturally somewhat acidic because of atmospheric carbon dioxide. Carbon dioxide combines with rainwater to form carbonic acid:

However, carbonic acid is a relatively weak acid. Rain that is saturated with  $\text{CO}_2$  has a pH of about 5.6, which is only mildly acidic. When nitric acid and sulfuric acid mix with rain, the pH of the rain can fall below 4.3 (Figure 16.16◀). Remember that because of

the logarithmic nature of the pH scale, rain with a pH of 4.3 has an  $[\text{H}_3\text{O}^+]$  that is 20 times greater than rain with a pH of 5.6. Rain that is this acidic has a harmful impact.

## Effects of Acid Rain

Acids dissolve metals and acid rain degrades metal structures. Bridges, railroads, and even automobiles can be damaged by acid rain. Since acids react with carbonates, acid rain also harms building materials that contain carbonates ( $\text{CO}_3^{2-}$ ), including marble, cement, and limestone. Statues, buildings, and pathways in the Northeast show significant signs of acid rain damage (Figure 16.17a▼).

Acid rain also accumulates in lakes and rivers and affects aquatic life. Many lakes, especially those that are surrounded by land that contains significant amounts of limestone ( $\text{CaCO}_3$ ), have the ability to neutralize acidic rain. In the Midwest, for example, limestone-rich soils prevent most lakes from becoming acidified. In the northeastern United States, however, the lack of limestone makes lakes more susceptible, and over 2000 lakes and streams have increased acidity levels due to acid rain. Aquatic plants, frogs, salamanders, and some species of fish are sensitive to acid levels and cannot survive in the acidified water. Trees can also be affected by acid rain because the acid removes nutrients from the soil, making survival difficult (Figure 16.17b▼).

▼ FIGURE 16.17 The Effects of Acid Rain (a) Buildings, gravestones, and statues damaged by acid rain are a common sight in the northeastern United States and in many other industrialized nations. (b) Some species of trees are highly susceptible to the effects of acid rain.

(a)

(b)

## Acid Rain Legislation

In 1990, the U.S. Congress passed amendments to the Clean Air Act specifically targeted at reducing acid rain. These amendments force electrical utilities—which are the most significant source of  $\text{SO}_2$ —to lower their  $\text{SO}_2$  emissions gradually over time. The result has been a 76% decrease in  $\text{SO}_2$  pollutant levels in the United States since 1990 (Figure 16.18). The acidity of rain over the northeastern United States has begun to decrease, and lakes are beginning to recover. In the early 1990s, scientists categorized 30% of the lakes in the Northeast as being of *acute concern*, which means that a complete loss of fish population is expected. Today, the fraction of lakes in this category has been reduced to less than 18%. The acid rain program has been a dramatic success, and today's environmental legislation—such as legislation aimed at global warming—is using the acid rain legislation as a model for what can work.

### $\text{SO}_2$ AIR QUALITY, 1990–2013

**▲ FIGURE 16.18 U.S. Sulfur Dioxide Pollutant Levels** As a result of amendments to the Clean Air Act passed in 1990,  $\text{SO}_2$  levels continue to decrease.

## Self-Assessment Quiz

**Q1.** Identify the conjugate base in the reaction shown here:

- a)  $\text{HClO}_2$     b)  $\text{H}_2\text{O}$     c)  $\text{H}_3\text{O}^+$     d)  $\text{ClO}_2^-$

**Q2.** Which pair is a Brønsted–Lowry conjugate acid–base pair?

- a)  $\text{NH}_3$ ;  $\text{NH}_4^+$     b)  $\text{H}_3\text{O}^+$ ;  $\text{OH}^-$   
c)  $\text{HCl}$ ;  $\text{HBr}$     d)  $\text{ClO}_4^-$ ;  $\text{ClO}_3^-$

**Q3.** Consider the given acid ionization constants. Identify the strongest conjugate base.

Acid	$K_a$
$\text{HNO}_2(aq)$	$4.6 \times 10^{-4}$
$\text{HCHO}_2(aq)$	$1.8 \times 10^{-4}$
$\text{HClO}(aq)$	$2.9 \times 10^{-8}$
$\text{HCN}(aq)$	$4.9 \times 10^{-10}$

- a)  $\text{NO}_2^-(aq)$     b)  $\text{CHO}_2^-(aq)$   
c)  $\text{ClO}^-(aq)$     d)  $\text{CN}^-(aq)$

**Q4.** What is the  $\text{OH}^-$  concentration in an aqueous solution at  $25^\circ\text{C}$  in which  $[\text{H}_3\text{O}^+] = 1.9 \times 10^{-9} \text{ M}$ ?

- a)  $1.9 \times 10^{-9} \text{ M}$     b)  $5.3 \times 10^{-6} \text{ M}$   
c)  $5.3 \times 10^6 \text{ M}$     d)  $1.9 \times 10^{-23} \text{ M}$

**Q5.** An  $\text{HNO}_3(aq)$  solution has a pH of 1.75. What is the molar concentration of the  $\text{HNO}_3(aq)$  solution?

- a) 1.75 M    b)  $5.6 \times 10^{-13} \text{ M}$   
c) 56 M    d) 0.018 M

**Q6.** Find the pH of a 0.350 M aqueous benzoic acid solution. For benzoic acid,  $K_a = 6.5 \times 10^{-5}$ .

- a) 4.64    b) 4.19  
c) 2.32    d) 11.68

**Q7.** Find the pH of a 0.155 M  $\text{HClO}_2(aq)$  solution. For  $\text{HClO}_2$ ,  $K_a = 0.011$ .

- a) 0.92    b) 1.44  
c) 1.39    d) 0.69

**Q8.** Calculate the percent ionization of 1.45 M aqueous acetic acid solution. For acetic acid,  $K_a = 1.8 \times 10^{-5}$ .

- a) 0.35%    b) 0.0018%  
c) 0.29%    d) 0.0051%

Continued—

- Q9.** Consider two aqueous solutions of nitrous acid ( $\text{HNO}_2$ ). Solution A has a concentration of  $[\text{HNO}_2] = 0.55 \text{ M}$  and solution B has a concentration of  $[\text{HNO}_2] = 1.25 \text{ M}$ . Which statement about the two solutions is true?
- Solution A has the higher percent ionization and the higher pH.
  - Solution B has the higher percent ionization and the higher pH.
  - Solution A has the higher percent ionization and solution B has the higher pH.
  - Solution B has the higher percent ionization and solution A has the higher pH.
- Q10.** Find the  $[\text{OH}^-]$  in a  $0.200 \text{ M}$  solution of ethylamine ( $\text{C}_2\text{H}_5\text{NH}_2$ ). For ethylamine,  $K_b = 5.6 \times 10^{-4}$ .
- $11.52 \text{ M}$
  - $2.48 \text{ M}$
  - $0.033 \text{ M}$
  - $0.011 \text{ M}$
- Q11.** Which ion forms a basic solution when dissolved in water?
- $\text{Br}^-$
  - $\text{NO}_3^-$
  - $\text{HSO}_4^-$
  - $\text{SO}_3^{2-}$
- Q12.** Which compound forms an acidic solution when dissolved in water?
- $\text{NH}_4\text{Cl}$
  - $\text{NaCl}$
  - $\text{KNO}_2$
  - $\text{Ca}(\text{NO}_3)_2$
- Q13.** Find the pH of  $0.175 \text{ M}$   $\text{NaCN}$  solution. For  $\text{HCN}$ ,  $K_a = 4.9 \times 10^{-10}$ .
- 5.03
  - 11.28
  - 2.31
  - 8.97
- Q14.** What is the concentration of  $\text{X}^{2-}$  in a  $0.150 \text{ M}$  solution of the diprotic acid  $\text{H}_2\text{X}$ ? For  $\text{H}_2\text{X}$ ,  $K_{a1} = 4.5 \times 10^{-6}$  and  $K_{a2} = 1.2 \times 10^{-11}$ .
- $9.9 \times 10^{-8} \text{ M}$
  - $2.0 \times 10^{-9} \text{ M}$
  - $8.2 \times 10^{-4} \text{ M}$
  - $1.2 \times 10^{-11} \text{ M}$
- Q15.** Which acid has the largest  $K_a$ :  $\text{HClO}_2(aq)$ ,  $\text{HBrO}_2(aq)$ , or  $\text{HIO}_2(aq)$ ?
- $\text{HClO}_2(aq)$
  - $\text{HBrO}_2(aq)$
  - $\text{HIO}_2(aq)$
  - All three acids have the same  $K_a$ .
- Answers: 1. (d) 2. (a) 3. (d) 4. (b) 5. (d) 6. (c) 7. (b) 8. (a) 9. (a) 10. (d) 11. (d) 12. (a) 13. (b) 14. (d) 15. (d)**

## Chapter 16 IN REVIEW

### Key Terms

#### Section 16.2

carboxylic acid (725)  
alkaloid (726)

#### Section 16.3

Arrhenius definitions (of acids and bases) (726)  
hydronium ion (727)  
Brønsted–Lowry definitions (of acids and bases) (727)  
amphoteric (727)  
conjugate acid–base pair (728)  
conjugate acid (728)  
conjugate base (728)

#### Section 16.4

strong acid (729)  
weak acid (729)  
monoprotic acid (729)  
diprotic acid (729)  
triprotic acid (730)  
acid ionization constant ( $K_a$ ) (731)

#### Section 16.5

autoionization (732)  
ion product constant for water ( $K_w$ ) (733)  
neutral (733)  
acidic solution (733)  
basic solution (733)  
pH (734)

#### Section 16.6

percent ionization (742)

#### Section 16.7

strong base (746)  
weak base (746)  
base ionization constant ( $K_b$ ) (747)

#### Section 16.9

polyprotic acid (757)

#### Section 16.11

Lewis acid (764)  
Lewis base (764)

### Key Concepts

#### Heartburn (16.1)

- Hydrochloric acid from the stomach sometimes comes in contact with the esophageal lining, resulting in irritation, called heartburn. Heartburn is treated with antacids, bases that neutralize stomach acid.

#### The Nature of Acids and Bases (16.2)

- Acids generally taste sour, dissolve metals, turn blue litmus paper red, and neutralize bases. Common acids are hydrochloric, sulfuric, nitric, and carboxylic acids.

- ▶ Bases generally taste bitter, feel slippery, turn red litmus paper blue, and neutralize acids. Common bases are sodium hydroxide, sodium bicarbonate, and potassium hydroxide.

### Definitions of Acids and Bases (16.3)

- ▶ The Arrhenius definition of acids and bases states that in an aqueous solution, an acid produces hydrogen ions and a base produces hydroxide ions.
- ▶ The Brønsted–Lowry definition states that an acid is a proton (hydrogen ion) donor and a base is a proton acceptor. According to the Brønsted–Lowry definition, two substances related by the transfer of a proton are a conjugate acid–base pair.

### Acid Strength and the Acid Dissociation Constant, $K_a$ (16.4)

- ▶ In a solution, a strong acid completely ionizes but a weak acid only partially ionizes.
- ▶ Generally, the stronger the acid, the weaker the conjugate base, and vice versa.
- ▶ The extent of dissociation of a weak acid is quantified by the acid dissociation constant,  $K_a$ , which is the equilibrium constant for the ionization of the weak acid.

### Autoionization of Water and pH (16.5)

- ▶ In an acidic solution, the concentration of hydrogen ions is always greater than the concentration of hydroxide ions.  $[\text{H}_3\text{O}^+]$  multiplied by  $[\text{OH}^-]$  is always constant at a constant temperature.
- ▶ There are two types of logarithmic acid–base scales: pH and pOH. At 25 °C, the sum of a solution's pH and pOH is always 14.

### Finding the $[\text{H}_3\text{O}^+]$ and pH of Strong and Weak Acid Solutions (16.6)

- ▶ In a strong acid solution, the hydrogen ion concentration equals the initial concentration of the acid.
- ▶ In a weak acid solution, the hydrogen ion concentration—which can be determined by solving an equilibrium problem—is lower than the initial acid concentration.
- ▶ The percent ionization of weak acids decreases as the acid (and hydrogen ion) concentration increases.
- ▶ In mixtures of two acids with large  $K_a$  differences, the concentration of hydrogen ions can usually be determined by considering only the stronger of the two acids.

### Base Solutions (16.7)

- ▶ A strong base dissociates completely; a weak base does not.
- ▶ Most weak bases produce hydroxide ions through the ionization of water. The base ionization constant,  $K_b$ , indicates the extent of ionization.

### Ions as Acids and Bases (16.8)

- ▶ A cation is a weak acid if it is the conjugate acid of a weak base; it is neutral if it is the counter ion of a strong base.
- ▶ An anion is a weak base if it is the conjugate base of a weak acid; it is neutral if it is the conjugate base of a strong acid.
- ▶ To calculate the pH of a solution of an acidic cation or basic anion, we determine  $K_a$  or  $K_b$  from the equation  $K_a \times K_b = K_w$ .

### Polyprotic Acids (16.9)

- ▶ Polyprotic acids contain two or more ionizable protons.
- ▶ Generally, polyprotic acids ionize in successive steps, and the value of  $K_a$  becomes smaller for each step.
- ▶ In many cases, we can determine the  $[\text{H}_3\text{O}^+]$  of a polyprotic acid solution by considering only the first ionization step; then, the concentration of the anion formed in the second ionization step is equivalent to the value of  $K_{a2}$ .

### Acid Strength and Molecular Structure (16.10)

- ▶ For binary acids, acid strength decreases with increasing bond energy and increases with increasing bond polarity.
- ▶ For oxyacids, acid strength increases with the electronegativity of the atoms bonded to the oxygen atom and also increases with the number of oxygen atoms in the molecule.

### Lewis Acids and Bases (16.11)

- ▶ A third model of acids and bases, the Lewis model, defines a base as an electron pair donor and an acid as an electron pair acceptor. According to this definition, an acid does not have to contain hydrogen. A Lewis acid can be a compound with an empty orbital—or one that will rearrange to make an empty orbital—or a cation.

### Acid Rain (16.12)

- ▶ The combustion of fossil fuels produces oxides of sulfur and nitrogen, which react with oxygen and water to form sulfuric and nitric acids. These acids combine with rain to form acid rain.
- ▶ Acid rain corrodes human-made structures and damages aquatic environments and forests. Environmental legislation has helped stabilize the amount of acid rain being produced.

## Key Equations and Relationships

Note: In all of these equations  $[\text{H}^+]$  is interchangeable with  $[\text{H}_3\text{O}^+]$ .

Expression for the Acid Ionization Constant,  $K_a$  (16.4)

$$K_a = \frac{[\text{H}_3\text{O}^+][\text{A}^-]}{[\text{HA}]}$$

The Ion Product Constant for Water,  $K_w$  (16.5)

$$K_w = [\text{H}_3\text{O}^+][\text{OH}^-] = 1.0 \times 10^{-14} \text{ (at 25 °C)}$$

Expression for the pH Scale (16.5)

$$\text{pH} = -\log[\text{H}_3\text{O}^+]$$

Expression for the pOH Scale (16.5)

$$\text{pOH} = -\log[\text{OH}^-]$$

Relationship between pH and pOH (16.5)

$$\text{pH} + \text{pOH} = 14.00$$

Expression for the  $\text{p}K_a$  Scale (16.5)

$$\text{p}K_a = -\log K_a$$

Expression for Percent Ionization (16.6)

$$\begin{aligned} \text{Percent ionization} &= \frac{\text{concentration of ionized acid}}{\text{initial concentration of acid}} \times 100\% \\ &= \frac{[\text{H}_3\text{O}^+]_{\text{equil}}}{[\text{HA}]_{\text{init}}} \times 100\% \end{aligned}$$

Relationship between  $K_a$ ,  $K_b$ , and  $K_w$  (16.8)

$$K_a \times K_b = K_w$$

## Key Learning Outcomes

CHAPTER OBJECTIVES	ASSESSMENT
Identifying Brønsted–Lowry Acids and Bases and Their Conjugates ( <b>16.3</b> ) $\text{H}_2\text{SO}_4(\text{aq}) + \text{H}_2\text{O}(\text{l}) \longrightarrow \text{HSO}_4^-(\text{aq}) + \text{H}_3\text{O}^+(\text{aq})$ <div style="display: flex; justify-content: space-around; align-items: center; margin-top: 10px;"> <div style="text-align: center;">             Acid  </div> <div style="text-align: center;">             Base  </div> <div style="text-align: center;">             Conjugate base  </div> <div style="text-align: center;">             Conjugate acid  </div> </div>	Example 16.1 For Practice 16.1 Exercises 35, 36
Using $K_w$ in Calculations ( <b>16.5</b> )	Example 16.2 For Practice 16.2 Exercises 47, 48
Calculating pH from $[\text{H}_3\text{O}^+]$ or $[\text{OH}^-]$ ( <b>16.5</b> )	Examples 16.3, 16.4 For Practice 16.3, 16.4 Exercises 49–52
Finding the pH of a Weak Acid Solution ( <b>16.6</b> )	Examples 16.5, 16.6, 16.7 For Practice 16.5, 16.6, 16.7 Exercises 63–68
Finding the Acid Ionization Constant from pH ( <b>16.6</b> )	Example 16.8 For Practice 16.8 Exercises 69, 70
Finding the Percent Ionization of a Weak Acid ( <b>16.6</b> )	Example 16.9 For Practice 16.9 Exercises 71–74
Mixtures of Weak Acids ( <b>16.6</b> )	Example 16.10 For Practice 16.10 Exercises 79, 80
Finding the $[\text{OH}^-]$ and pH of a Strong Base Solution ( <b>16.7</b> )	Example 16.11 For Practice 16.11 Exercises 81, 82
Finding the $[\text{OH}^-]$ and pH of a Weak Base Solution ( <b>16.7</b> ) <div style="display: flex; justify-content: space-around; align-items: center; margin-top: 20px;"> <div style="text-align: center;">               Ammonia           </div> <div style="text-align: center;">               Methylamine           </div> <div style="text-align: center;">               Pyridine           </div> </div>	Example 16.12 For Practice 16.12 Exercises 89, 90
Determining Whether an Anion Is Basic or Neutral ( <b>16.8</b> )	Example 16.13 For Practice 16.13 Exercises 95, 96
Determining the pH of a Solution Containing an Anion Acting as a Base ( <b>16.8</b> )	Example 16.14 For Practice 16.14 Exercises 97, 98
Determining Whether a Cation Is Acidic or Neutral ( <b>16.8</b> )	Example 16.15 For Practice 16.15 Exercises 99, 100
Determining the Overall Acidity or Basicity of Salt Solutions ( <b>16.8</b> )	Example 16.16 For Practice 16.16 Exercises 101, 102
Finding the pH of a Polyprotic Acid Solution ( <b>16.9</b> )	Example 16.17 For Practice 16.17 Exercises 111, 112
Finding the $[\text{H}_3\text{O}^+]$ in Dilute $\text{H}_2\text{SO}_4$ Solutions ( <b>16.9</b> )	Example 16.18 For Practice 16.18 Exercise 115
Finding the Concentration of the Anions for a Weak Diprotic Acid Solution ( <b>16.9</b> )	Example 16.19 For Practice 16.19 Exercises 113, 114

## EXERCISES

### Review Questions

- What causes heartburn? What are some possible ways to alleviate heartburn?
- What are the general physical and chemical properties of acids? Of bases?
- What is a carboxylic acid? Give an example.
- What is the Arrhenius definition of an acid? Of a base?
- What is a hydronium ion? Does  $\text{H}^+$  exist in solution by itself?
- What is the Brønsted–Lowry definition of an acid? Of a base?
- Why is there more than one definition of acid–base behavior? Which definition is the right one?
- Describe amphoteric behavior and give an example.
- What is a conjugate acid–base pair? Provide an example.
- Explain the difference between a strong acid and a weak acid and list one example of each.

11. What are diprotic and triprotic acids? List an example of each.
12. Define the acid ionization constant and explain its significance.
13. Write an equation for the autoionization of water and an expression for the ion product constant for water ( $K_w$ ). What is the value of  $K_w$  at 25 °C?
14. What happens to the  $[\text{OH}^-]$  of a solution when the  $[\text{H}_3\text{O}^+]$  is increased? Decreased?
15. Define pH. What pH range is considered acidic? Basic? Neutral? (Assume 25 °C.)
16. Define pOH. What pOH range is considered acidic? Basic? Neutral? (Assume 25 °C.)
17. In most solutions containing a strong or weak acid, the autoionization of water can be neglected when calculating  $[\text{H}_3\text{O}^+]$ . Explain why this statement is valid.
18. When calculating  $[\text{H}_3\text{O}^+]$  for weak acid solutions, we can often use the  $x$  is *small* approximation. Explain the nature of this approximation and why it is valid.
19. What is the percent ionization of an acid? Explain what happens to the percent ionization of a weak acid as a function of the concentration of the weak acid solution.
20. In calculating  $[\text{H}_3\text{O}^+]$  for a mixture of a strong acid and weak acid, the weak acid can often be neglected. Explain why this statement is valid.
21. Write a generic equation showing how a weak base ionizes water.
22. How can you determine if an anion will act as a weak base? Write a generic equation showing the reaction by which an anion,  $\text{A}^-$ , acts as a weak base.
23. What is the relationship between the acid ionization constant for a weak acid ( $K_a$ ) and the base ionization constant for its conjugate base ( $K_b$ )?
24. What kinds of cations act as weak acids? List some examples.
25. When calculating the  $[\text{H}_3\text{O}^+]$  for a polyprotic acid, the second ionization step can often be neglected. Explain why this statement is valid.
26. For a weak diprotic acid  $\text{H}_2\text{X}$ , what is the relationship between  $[\text{X}^{2-}]$  and  $K_{a2}$ ? Under what conditions does this relationship exist?
27. For a binary acid,  $\text{H}-\text{Y}$ , which factors affect the relative ease with which the acid ionizes?
28. Which factors affect the relative acidity of an oxyacid?
29. What is the Lewis definition of an acid? Of a base?
30. What is a general characteristic of a Lewis acid? Of a Lewis base?
31. What is acid rain? What causes it, and where is the problem the greatest?
32. What are the main detrimental effects of acid rain? What is being done to address the problem of acid rain?

## Problems by Topic

### The Nature and Definitions of Acids and Base

33. Identify each substance as an acid or a base and write a chemical equation showing how it is an acid or a base according to the Arrhenius definition.
  - a.  $\text{HNO}_3(\text{aq})$
  - b.  $\text{NH}_4^+(\text{aq})$
  - c.  $\text{KOH}(\text{aq})$
  - d.  $\text{HC}_2\text{H}_3\text{O}_2(\text{aq})$
34. Identify each substance as an acid or a base and write a chemical equation showing how it is an acid or a base in aqueous solution according to the Arrhenius definition.
  - a.  $\text{NaOH}(\text{aq})$
  - b.  $\text{H}_2\text{SO}_4(\text{aq})$
  - c.  $\text{HBr}(\text{aq})$
  - d.  $\text{Sr}(\text{OH})_2(\text{aq})$
35. In each reaction, identify the Brønsted-Lowry acid, the Brønsted-Lowry base, the conjugate acid, and the conjugate base.
  - a.  $\text{H}_2\text{CO}_3(\text{aq}) + \text{H}_2\text{O}(\text{l}) \rightleftharpoons \text{H}_3\text{O}^+(\text{aq}) + \text{HCO}_3^-(\text{aq})$
  - b.  $\text{NH}_3(\text{aq}) + \text{H}_2\text{O}(\text{l}) \rightleftharpoons \text{NH}_4^+(\text{aq}) + \text{OH}^-(\text{aq})$
  - c.  $\text{HNO}_3(\text{aq}) + \text{H}_2\text{O}(\text{l}) \longrightarrow \text{H}_3\text{O}^+(\text{aq}) + \text{NO}_3^-(\text{aq})$
  - d.  $\text{C}_5\text{H}_5\text{N}(\text{aq}) + \text{H}_2\text{O}(\text{l}) \rightleftharpoons \text{C}_5\text{H}_5\text{NH}^+(\text{aq}) + \text{OH}^-(\text{aq})$
36. In each reaction, identify the Brønsted-Lowry acid, the Brønsted-Lowry base, the conjugate acid, and the conjugate base.
  - a.  $\text{HI}(\text{aq}) + \text{H}_2\text{O}(\text{l}) \longrightarrow \text{H}_3\text{O}^+(\text{aq}) + \text{I}^-(\text{aq})$
  - b.  $\text{CH}_3\text{NH}_2(\text{aq}) + \text{H}_2\text{O}(\text{l}) \rightleftharpoons \text{CH}_3\text{NH}_3^+(\text{aq}) + \text{OH}^-(\text{aq})$
  - c.  $\text{CO}_3^{2-}(\text{aq}) + \text{H}_2\text{O}(\text{l}) \rightleftharpoons \text{HCO}_3^-(\text{aq}) + \text{OH}^-(\text{aq})$
  - d.  $\text{HBr}(\text{aq}) + \text{H}_2\text{O}(\text{l}) \longrightarrow \text{H}_3\text{O}^+(\text{aq}) + \text{Br}^-(\text{aq})$
37. Write the formula for the conjugate base of each acid.
  - a.  $\text{HCl}$
  - b.  $\text{H}_2\text{SO}_3$
  - c.  $\text{HCHO}_2$
  - d.  $\text{HF}$
38. Write the formula for the conjugate acid of each base.
  - a.  $\text{NH}_3$
  - b.  $\text{ClO}_4^-$
  - c.  $\text{HSO}_4^-$
  - d.  $\text{CO}_3^{2-}$
39. Both  $\text{H}_2\text{O}$  and  $\text{H}_2\text{PO}_4^-$  are amphoteric. Write an equation to show how each substance can act as an acid and another equation to show how each can act as a base.
40. Both  $\text{HCO}_3^-$  and  $\text{HS}^-$  are amphoteric. Write an equation to show how each substance can act as an acid and another equation to show how each can act as a base.

### Acid Strength and $K_a$

41. Classify each acid as strong or weak. If the acid is weak, write an expression for the acid ionization constant ( $K_a$ ).
  - a.  $\text{HNO}_3$
  - b.  $\text{HCl}$
  - c.  $\text{HBr}$
  - d.  $\text{H}_2\text{SO}_3$
42. Classify each acid as strong or weak. If the acid is weak, write an expression for the acid ionization constant ( $K_a$ ).
  - a.  $\text{HF}$
  - b.  $\text{HCHO}_2$
  - c.  $\text{H}_2\text{SO}_4$
  - d.  $\text{H}_2\text{CO}_3$
43. The three diagrams represent three different solutions of the binary acid  $\text{HA}$ . Water molecules have been omitted for clarity, and hydronium ions ( $\text{H}_3\text{O}^+$ ) are represented by hydrogen ions ( $\text{H}^+$ ). Rank the acids in order of decreasing acid strength.

44. Rank the solutions in order of decreasing  $[\text{H}_3\text{O}^+]$ : 0.10 M  $\text{HCl}$ ; 0.10 M  $\text{HF}$ ; 0.10 M  $\text{HClO}$ ; 0.10 M  $\text{HC}_6\text{H}_5\text{O}$ .
45. Pick the stronger base from each pair.
  - a.  $\text{F}^-$  or  $\text{Cl}^-$
  - b.  $\text{NO}_2^-$  or  $\text{NO}_3^-$
  - c.  $\text{F}^-$  or  $\text{ClO}^-$
46. Pick the stronger base from each pair.
  - a.  $\text{ClO}_4^-$  or  $\text{ClO}_2^-$
  - b.  $\text{Cl}^-$  or  $\text{H}_2\text{O}$
  - c.  $\text{CN}^-$  or  $\text{ClO}^-$

## Autoionization of Water and pH

47. Calculate  $[\text{OH}^-]$  in each aqueous solution at 25 °C, and classify the solution as acidic or basic.
- a.  $[\text{H}_3\text{O}^+] = 1.2 \times 10^{-8} \text{ M}$       b.  $[\text{H}_3\text{O}^+] = 8.5 \times 10^{-5} \text{ M}$   
 c.  $[\text{H}_3\text{O}^+] = 3.5 \times 10^{-2} \text{ M}$
48. Calculate  $[\text{H}_3\text{O}^+]$  in each aqueous solution at 25 °C, and classify each solution as acidic or basic.
- a.  $[\text{OH}^-] = 1.1 \times 10^{-9} \text{ M}$       b.  $[\text{OH}^-] = 2.9 \times 10^{-2} \text{ M}$   
 c.  $[\text{OH}^-] = 6.9 \times 10^{-12} \text{ M}$
49. Calculate the pH and pOH of each solution at 25 °C.
- a.  $[\text{H}_3\text{O}^+] = 1.7 \times 10^{-8} \text{ M}$       b.  $[\text{H}_3\text{O}^+] = 1.0 \times 10^{-7} \text{ M}$   
 c.  $[\text{H}_3\text{O}^+] = 2.2 \times 10^{-6} \text{ M}$
50. Calculate  $[\text{H}_3\text{O}^+]$  and  $[\text{OH}^-]$  for each solution at 25 °C.
- a. pH = 8.55      b. pH = 11.23      c. pH = 2.87
51. Complete the table. (All solutions are at 25 °C.)

$[\text{H}_3\text{O}^+]$	$[\text{OH}^-]$	pH	Acidic or Basic
_____	_____	3.15	_____
$3.7 \times 10^{-9}$	_____	_____	_____
_____	_____	11.1	_____
_____	$1.6 \times 10^{-11}$	_____	_____

52. Complete the table. (All solutions are at 25 °C.)

$[\text{H}_3\text{O}^+]$	$[\text{OH}^-]$	pH	Acidic or Basic
$3.5 \times 10^{-3}$	_____	_____	_____
_____	$3.8 \times 10^{-7}$	_____	_____
$1.8 \times 10^{-9}$	_____	_____	_____
_____	_____	7.15	_____

53. Like all equilibrium constants, the value of  $K_w$  depends on temperature. At body temperature (37 °C),  $K_w = 2.4 \times 10^{-14}$ . What are the  $[\text{H}_3\text{O}^+]$  and pH of pure water at body temperature?
54. The value of  $K_w$  increases with increasing temperature. Is the autoionization of water endothermic or exothermic?
55. Calculate the pH of each acid solution. Explain how the resulting pH values demonstrate that the pH of an acid solution should carry as many digits to the right of the decimal place as the number of significant figures in the concentration of the solution.
- $[\text{H}_3\text{O}^+] = 0.044 \text{ M}$   
 $[\text{H}_3\text{O}^+] = 0.045 \text{ M}$   
 $[\text{H}_3\text{O}^+] = 0.046 \text{ M}$
56. Determine the concentration of  $\text{H}_3\text{O}^+$  to the correct number of significant figures in a solution with each pH. Describe how these calculations show the relationship between the number of digits to the right of the decimal place in pH and the number of significant figures in concentration.
- pH = 2.50  
 pH = 2.51  
 pH = 2.52

## Acid Solutions

57. For each strong acid solution, determine  $[\text{H}_3\text{O}^+]$ ,  $[\text{OH}^-]$ , and pH.
- a. 0.25 M HCl  
 b. 0.015 M  $\text{HNO}_3$   
 c. a solution that is 0.052 M in HBr and 0.020 M in  $\text{HNO}_3$   
 d. a solution that is 0.655%  $\text{HNO}_3$  by mass (assume a density of 1.01 g/mL for the solution)

58. Determine the pH of each solution.
- a. 0.048 M HI  
 b. 0.0895 M  $\text{HClO}_4$   
 c. a solution that is 0.045 M in  $\text{HClO}_4$  and 0.048 M in HCl  
 d. a solution that is 1.09% HCl by mass (assume a density of 1.01 g/mL for the solution)
59. What mass of HI must be present in 0.250 L of solution to obtain a solution with each pH value?
- a. pH = 1.25      b. pH = 1.75      c. pH = 2.85
60. What mass of  $\text{HClO}_4$  must be present in 0.500 L of solution to obtain a solution with each pH value?
- a. pH = 2.50      b. pH = 1.50      c. pH = 0.50
61. What is the pH of a solution in which 224 mL of  $\text{HCl(g)}$ , measured at 27.2 °C and 1.02 atm, is dissolved in 1.5 L of aqueous solution?
62. What volume of a concentrated HCl solution, which is 36.0% HCl by mass and has a density of 1.179 g/mL, should be used to make 5.00 L of an HCl solution with a pH of 1.8?
63. Determine the  $[\text{H}_3\text{O}^+]$  and pH of a 0.100 M solution of benzoic acid.
64. Determine the  $[\text{H}_3\text{O}^+]$  and pH of a 0.200 M solution of formic acid.
65. Determine the pH of an  $\text{HNO}_2$  solution of each concentration. In which cases can you *not* make the simplifying assumption that  $x$  is small?
- a. 0.500 M      b. 0.100 M      c. 0.0100 M
66. Determine the pH of an HF solution of each concentration. In which cases can you *not* make the simplifying assumption that  $x$  is small? ( $K_a$  for HF is  $6.8 \times 10^{-4}$ .)
- a. 0.250 M      b. 0.0500 M      c. 0.0250 M
67. If 15.0 mL of glacial acetic acid (pure  $\text{HC}_2\text{H}_3\text{O}_2$ ) is diluted to 1.50 L with water, what is the pH of the resulting solution? The density of glacial acetic acid is 1.05 g/mL.
68. Calculate the pH of a formic acid solution that contains 1.35% formic acid by mass. (Assume a density of 1.01 g/mL for the solution.)
69. A 0.185 M solution of a weak acid (HA) has a pH of 2.95. Calculate the acid ionization constant ( $K_a$ ) for the acid.
70. A 0.115 M solution of a weak acid (HA) has a pH of 3.29. Calculate the acid ionization constant ( $K_a$ ) for the acid.
71. Determine the percent ionization of a 0.125 M HCN solution.
72. Determine the percent ionization of a 0.225 M solution of benzoic acid.
73. Calculate the percent ionization of an acetic acid solution having the given concentration.
- a. 1.00 M      b. 0.500 M      c. 0.100 M      d. 0.0500 M
74. Calculate the percent ionization of a formic acid solution having the given concentration.
- a. 1.00 M      b. 0.500 M      c. 0.100 M      d. 0.0500 M
75. A 0.148 M solution of a monoprotic acid has a percent ionization of 1.55%. Determine the acid ionization constant ( $K_a$ ) for the acid.
76. A 0.085 M solution of a monoprotic acid has a percent ionization of 0.59%. Determine the acid ionization constant ( $K_a$ ) for the acid.
77. Find the pH and percent ionization of each HF solution. ( $K_a$  for HF is  $6.8 \times 10^{-4}$ .)
- a. 0.250 M HF      b. 0.100 M HF      c. 0.050 M HF
78. Find the pH and percent ionization of a 0.100 M solution of a weak monoprotic acid having the given  $K_a$  values.
- a.  $K_a = 1.0 \times 10^{-5}$       b.  $K_a = 1.0 \times 10^{-3}$       c.  $K_a = 1.0 \times 10^{-1}$

79. Find the pH of each mixture of acids.
- 0.115 M in HBr and 0.125 M in  $\text{HCHO}_2$
  - 0.150 M in  $\text{HNO}_2$  and 0.085 M in  $\text{HNO}_3$
  - 0.185 M in  $\text{HCHO}_2$  and 0.225 M in  $\text{HC}_2\text{H}_3\text{O}_2$
  - 0.050 M in acetic acid and 0.050 M in hydrocyanic acid
80. Find the pH of each mixture of acids.
- 0.075 M in  $\text{HNO}_3$  and 0.175 M in  $\text{HC}_7\text{H}_5\text{O}_2$
  - 0.020 M in HBr and 0.015 M in  $\text{HClO}_4$
  - 0.095 M in HF and 0.225 M in  $\text{HC}_6\text{H}_5\text{O}$
  - 0.100 M in formic acid and 0.050 M in hypochlorous acid

### Base Solutions

81. For each strong base solution, determine  $[\text{OH}^-]$ ,  $[\text{H}_3\text{O}^+]$ , pH, and pOH.
- 0.15 M NaOH
  - $1.5 \times 10^{-3}$  M  $\text{Ca}(\text{OH})_2$
  - $4.8 \times 10^{-4}$  M  $\text{Sr}(\text{OH})_2$
  - $8.7 \times 10^{-5}$  M KOH
82. For each strong base solution, determine  $[\text{OH}^-]$ ,  $[\text{H}_3\text{O}^+]$ , pH, and pOH.
- $8.77 \times 10^{-3}$  M LiOH
  - 0.0112 M  $\text{Ba}(\text{OH})_2$
  - $1.9 \times 10^{-4}$  M KOH
  - $5.0 \times 10^{-4}$  M  $\text{Ca}(\text{OH})_2$
83. Determine the pH of a solution that is 3.85% KOH by mass. Assume that the solution has density of 1.01 g/mL.
84. Determine the pH of a solution that is 1.55% NaOH by mass. Assume that the solution has density of 1.01 g/mL.
85. What volume of 0.855 M KOH solution is required to make 3.55 L of a solution with pH of 12.4?
86. What volume of a 15.0% by mass NaOH solution, which has a density of 1.116 g/mL, should be used to make 5.00 L of an NaOH solution with a pH of 10.8?
87. Write equations showing how each weak base ionizes water to form  $\text{OH}^-$ . Also write the corresponding expression for  $K_b$ .
- $\text{NH}_3$
  - $\text{HCO}_3^-$
  - $\text{CH}_3\text{NH}_2$
88. Write equations showing how each weak base ionizes water to form  $\text{OH}^-$ . Also write the corresponding expression for  $K_b$ .
- $\text{CO}_3^{2-}$
  - $\text{C}_6\text{H}_5\text{NH}_2$
  - $\text{C}_2\text{H}_5\text{NH}_2$
89. Determine the  $[\text{OH}^-]$ , pH, and pOH of a 0.15 M ammonia solution.
90. Determine the  $[\text{OH}^-]$ , pH, and pOH of a solution that is 0.125 M in  $\text{CO}_3^{2-}$ .
91. Caffeine ( $\text{C}_8\text{H}_{10}\text{N}_4\text{O}_2$ ) is a weak base with a  $pK_b$  of 10.4. Calculate the pH of a solution containing a caffeine concentration of 455 mg/L.
92. Amphetamine ( $\text{C}_9\text{H}_{13}\text{N}$ ) is a weak base with a  $pK_b$  of 4.2. Calculate the pH of a solution containing an amphetamine concentration of 225 mg/L.
93. Morphine is a weak base. A 0.150 M solution of morphine has a pH of 10.7. What is  $K_b$  for morphine?
94. A 0.135 M solution of a weak base has a pH of 11.23. Determine  $K_b$  for the base.

### Acid-Base Properties of Ions and Salts

95. Determine if each anion acts as a weak base in solution. For those anions that are basic, write an equation that shows how the anion acts as a base.
- $\text{Br}^-$
  - $\text{ClO}^-$
  - $\text{CN}^-$
  - $\text{Cl}^-$
96. Determine whether each anion is basic or neutral. For those anions that are basic, write an equation that shows how the anion acts as a base.
- $\text{C}_7\text{H}_5\text{O}_2^-$
  - $\text{I}^-$
  - $\text{NO}_3^-$
  - $\text{F}^-$
97. Determine the  $[\text{OH}^-]$  and pH of a solution that is 0.140 M in  $\text{F}^-$ .

98. Determine the  $[\text{OH}^-]$  and pH of a solution that is 0.250 M in  $\text{HCO}_3^-$ .
99. Determine whether each cation is acidic or pH-neutral. For those cations that are acidic, write an equation that shows how the cation acts as an acid.
- $\text{NH}_4^+$
  - $\text{Na}^+$
  - $\text{Co}^{3+}$
  - $\text{CH}_2\text{NH}_3^+$
100. Determine whether each cation is acidic or pH-neutral. For each cation that is acidic, write an equation that shows how the cation acts as an acid.
- $\text{Sr}^{2+}$
  - $\text{Mn}^{3+}$
  - $\text{C}_5\text{H}_5\text{NH}^+$
  - $\text{Li}^+$
101. Determine if each salt will form a solution that is acidic, basic, or pH-neutral.
- $\text{FeCl}_3$
  - NaF
  - $\text{CaBr}_2$
  - $\text{NH}_4\text{Br}$
  - $\text{C}_6\text{H}_5\text{NH}_3\text{NO}_2$
102. Determine if each salt will form a solution that is acidic, basic, or pH-neutral.
- $\text{Al}(\text{NO}_3)_3$
  - $\text{C}_2\text{H}_5\text{NH}_3\text{NO}_3$
  - $\text{K}_2\text{CO}_3$
  - RbI
  - $\text{NH}_4\text{ClO}$
103. Arrange the solutions in order of increasing acidity.
- $\text{NaCl}$ ,  $\text{NH}_4\text{Cl}$ ,  $\text{NaHCO}_3$ ,  $\text{NH}_4\text{ClO}_2$ ,  $\text{NaOH}$
104. Arrange the solutions in order of increasing basicity.
- $\text{CH}_3\text{NH}_3\text{Br}$ ,  $\text{KOH}$ ,  $\text{KBr}$ ,  $\text{KCN}$ ,  $\text{C}_5\text{H}_5\text{NHNO}_2$
105. Determine the pH of each solution.
- 0.10 M  $\text{NH}_4\text{Cl}$
  - 0.10 M  $\text{NaC}_2\text{H}_3\text{O}_2$
  - 0.10 M NaCl
106. Determine the pH of each solution.
- 0.20 M  $\text{KCHO}_2$
  - 0.20 M  $\text{CH}_3\text{NH}_3\text{I}$
  - 0.20 M KI
107. Calculate the concentration of all species in a 0.15 M KF solution.
108. Calculate the concentration of all species in a 0.225 M  $\text{C}_6\text{H}_5\text{NH}_3\text{Cl}$  solution.

### Polyprotic Acids

109. Write chemical equations and corresponding equilibrium expressions for each of the three ionization steps of phosphoric acid.
110. Write chemical equations and corresponding equilibrium expressions for each of the two ionization steps of carbonic acid.
111. Calculate the  $[\text{H}_3\text{O}^+]$  and pH of each polyprotic acid solution.
- 0.350 M  $\text{H}_3\text{PO}_4$
  - 0.350 M  $\text{H}_2\text{C}_2\text{O}_4$
112. Calculate the  $[\text{H}_3\text{O}^+]$  and pH of each polyprotic acid solution.
- 0.125 M  $\text{H}_2\text{CO}_3$
  - 0.125 M  $\text{H}_3\text{C}_6\text{H}_5\text{O}_7$
113. Calculate the concentration of all species in a 0.500 M solution of  $\text{H}_2\text{SO}_3$ .
114. Calculate the concentration of all species in a 0.155 M solution of  $\text{H}_2\text{CO}_3$ .
115. Calculate the  $[\text{H}_3\text{O}^+]$  and pH of each  $\text{H}_2\text{SO}_4$  solution. At approximately what concentration does the  $x$  is *small* approximation break down?
- 0.50 M
  - 0.10 M
  - 0.050 M
116. Consider a 0.10 M solution of a weak polyprotic acid ( $\text{H}_2\text{A}$ ) with the possible values of  $K_{a1}$  and  $K_{a2}$  given here.
- $K_{a1} = 1.0 \times 10^{-4}$ ;  $K_{a2} = 5.0 \times 10^{-5}$
  - $K_{a1} = 1.0 \times 10^{-4}$ ;  $K_{a2} = 1.0 \times 10^{-5}$
  - $K_{a1} = 1.0 \times 10^{-4}$ ;  $K_{a2} = 1.0 \times 10^{-6}$
- Calculate the contributions to  $[\text{H}_3\text{O}^+]$  from each ionization step. At what point can the contribution of the second step be neglected?

## Molecular Structure and Acid Strength

- 117.** Based on their molecular structure, pick the stronger acid from each pair of binary acids. Explain your choice.  
 a. HF and HCl      b. H<sub>2</sub>O or HF      c. H<sub>2</sub>Se or H<sub>2</sub>S
- 118.** Based on molecular structure, arrange the binary compounds in order of increasing acid strength. Explain your choice.  
 H<sub>2</sub>Te, HI, H<sub>2</sub>S, NaH
- 119.** Based on their molecular structure, pick the stronger acid from each pair of oxyacids. Explain your choice.  
 a. H<sub>2</sub>SO<sub>4</sub> or H<sub>2</sub>SO<sub>3</sub>  
 b. HClO<sub>2</sub> or HClO  
 c. HClO or HBrO  
 d. CCl<sub>3</sub>COOH or CH<sub>3</sub>COOH
- 120.** Based on molecular structure, arrange the oxyacids in order of increasing acid strength. Explain your choice.  
 HClO<sub>3</sub>, HIO<sub>3</sub>, HBrO<sub>3</sub>
- 121.** Which is a stronger base, S<sup>2-</sup> or Se<sup>2-</sup>? Explain.
- 122.** Which is a stronger base, PO<sub>4</sub><sup>3-</sup> or AsO<sub>4</sub><sup>3-</sup>? Explain.

## Lewis Acids and Bases

- 123.** Classify each species as either a Lewis acid or a Lewis base.  
 a. Fe<sup>3+</sup>      b. BH<sub>3</sub>  
 c. NH<sub>3</sub>      d. F<sup>-</sup>
- 124.** Classify each species as either a Lewis acid or a Lewis base.  
 a. BeCl<sub>2</sub>      b. OH<sup>-</sup>  
 c. B(OH)<sub>3</sub>      d. CN<sup>-</sup>
- 125.** Identify the Lewis acid and Lewis base from among the reactants in each equation.  
 a. Fe<sup>3+</sup>(aq) + 6 H<sub>2</sub>O(l) ⇌ Fe(H<sub>2</sub>O)<sub>6</sub><sup>3+</sup>(aq)  
 b. Zn<sup>2+</sup>(aq) + 4 NH<sub>3</sub>(aq) ⇌ Zn(NH<sub>3</sub>)<sub>4</sub><sup>2+</sup>(aq)  
 c. (CH<sub>3</sub>)<sub>3</sub>N(g) + BF<sub>3</sub>(g) ⇌ (CH<sub>3</sub>)<sub>3</sub>NBF<sub>3</sub>(s)
- 126.** Identify the Lewis acid and Lewis base from among the reactants in each equation.  
 a. Ag<sup>+</sup>(aq) + 2 NH<sub>3</sub>(aq) ⇌ Ag(NH<sub>3</sub>)<sub>2</sub><sup>+</sup>(aq)  
 b. AlBr<sub>3</sub> + NH<sub>3</sub> ⇌ H<sub>3</sub>NAlBr<sub>3</sub>  
 c. F<sup>-</sup>(aq) + BF<sub>3</sub>(aq) ⇌ BF<sub>4</sub><sup>-</sup>(aq)

## Cumulative Problems

- 127.** Based on these molecular views, determine whether each pictured acid is weak or strong.

- 128.** Based on these molecular views, determine whether each pictured base is weak or strong.

- 129.** The binding of oxygen by hemoglobin in the blood involves the equilibrium reaction:

In this equation, Hb is hemoglobin. The pH of normal human blood is highly controlled within a range of 7.35 to 7.45. Given the above equilibrium, why is this important? What would happen to the oxygen-carrying capacity of hemoglobin if blood became too acidic (a dangerous condition known as acidosis)?

- 130.** Carbon dioxide dissolves in water according to the equations:

Carbon dioxide levels in the atmosphere have increased about 20% over the last century. Given that Earth's oceans are exposed to atmospheric carbon dioxide, what effect might the increased CO<sub>2</sub> be having on the pH of the world's oceans? What effect might this change be having on the limestone structures (primarily CaCO<sub>3</sub>) of coral reefs and marine shells?

- 131.** People often take milk of magnesia to reduce the discomfort associated with acid stomach or heartburn. The recommended dose is 1 teaspoon, which contains  $4.00 \times 10^2$  mg of Mg(OH)<sub>2</sub>. What volume of an HCl solution with a pH of 1.3 can be neutralized by one dose of milk of magnesia? If the stomach contains  $2.00 \times 10^2$  mL of pH 1.3 solution, is all the acid neutralized? If not, what fraction is neutralized?

- 132.** Lakes that have been acidified by acid rain can be neutralized by liming, the addition of limestone ( $\text{CaCO}_3$ ). How much limestone (in kg) is required to completely neutralize a 4.3 billion liter lake with a pH of 5.5?

▲ Liming a lake.

- 133.** Acid rain over the Great Lakes has a pH of about 4.5. Calculate the  $[\text{H}_3\text{O}^+]$  of this rain and compare that value to the  $[\text{H}_3\text{O}^+]$  of rain over the West Coast that has a pH of 5.4. How many times more concentrated is the acid in rain over the Great Lakes?
- 134.** White wines tend to be more acidic than red wines. Find the  $[\text{H}_3\text{O}^+]$  in a Sauvignon Blanc with a pH of 3.23 and a Cabernet Sauvignon with a pH of 3.64. How many times more acidic is the Sauvignon Blanc?
- 135.** Common aspirin is acetylsalicylic acid, which has the structure shown here and a  $\text{p}K_a$  of 3.5.

Calculate the pH of a solution in which one normal adult dose of aspirin ( $6.5 \times 10^2$  mg) is dissolved in 8.0 ounces of water.

- 136.** The AIDS drug zalcitabine (also known as ddC) is a weak base with a  $\text{p}K_b$  of 9.8.  
What percentage of the base is protonated in an aqueous zalcitabine solution containing 565 mg/L?

## Challenge Problems

- 147.** A student mistakenly calculates the pH of a  $1.0 \times 10^{-7}$  M HI solution to be 7.0. Explain why the student is incorrect and calculate the correct pH.
- 148.** When 2.55 g of an unknown weak acid (HA) with a molar mass of 85.0 g/mol is dissolved in 250.0 g of water, the freezing point of the resulting solution is  $-0.257^\circ\text{C}$ . Calculate  $K_a$  for the unknown weak acid.
- 137.** Determine the pH of each solution.  
a. 0.0100 M  $\text{HClO}_4$       b. 0.115 M  $\text{HClO}_2$   
c. 0.045 M  $\text{Sr}(\text{OH})_2$       d. 0.0852 M KCN  
e. 0.155 M  $\text{NH}_4\text{Cl}$
- 138.** Determine the pH of each solution.  
a. 0.0650 M  $\text{HNO}_3$       b. 0.150 M  $\text{HNO}_2$   
c. 0.0195 M KOH      d. 0.245 M  $\text{CH}_3\text{NH}_3\text{I}$   
e. 0.318 M  $\text{KC}_6\text{H}_5\text{O}$
- 139.** Determine the pH of each two-component solution.  
a. 0.0550 M in HI and 0.00850 M in HF  
b. 0.112 M in NaCl and 0.0953 M in KF  
c. 0.132 M in  $\text{NH}_4\text{Cl}$  and 0.150 M  $\text{HNO}_3$   
d. 0.0887 M in sodium benzoate and 0.225 M in potassium bromide  
e. 0.0450 M in HCl and 0.0225 M in  $\text{HNO}_3$
- 140.** Determine the pH of each two-component solution.  
a. 0.050 M KOH and 0.015 M  $\text{Ba}(\text{OH})_2$   
b. 0.265 M  $\text{NH}_4\text{NO}_3$  and 0.102 M HCN  
c. 0.075 M RbOH and 0.100 M  $\text{NaHCO}_3$   
d. 0.088 M  $\text{HClO}_4$  and 0.022 M KOH  
e. 0.115 M NaClO and 0.0500 M KI
- 141.** Write net ionic equations for the reactions that take place when aqueous solutions of the following substances are mixed:  
a. sodium cyanide and nitric acid  
b. ammonium chloride and sodium hydroxide  
c. sodium cyanide and ammonium bromide  
d. potassium hydrogen sulfate and lithium acetate  
e. sodium hypochlorite and ammonia
- 142.** Morphine has the formula  $\text{C}_{17}\text{H}_{19}\text{NO}_3$ . It is a base and accepts one proton per molecule. It is isolated from opium. A 0.682-g sample of opium is found to require 8.92 mL of a 0.0116 M solution of sulfuric acid for neutralization. Assuming that morphine is the only acid or base present in opium, calculate the percent morphine in the sample of opium.
- 143.** The pH of a 1.00 M solution of urea, a weak organic base, is 7.050. Calculate the  $K_a$  of protonated urea.
- 144.** A solution is prepared by dissolving 0.10 mol of acetic acid and 0.10 mol of ammonium chloride in enough water to make 1.0 L of solution. Find the concentration of ammonia in the solution.
- 145.** Lactic acid is a weak acid found in milk. Its calcium salt is a source of calcium for growing animals. A saturated solution of this salt, which we can represent as  $\text{Ca}(\text{Lact})_2$ , has a  $[\text{Ca}^{2+}] = 0.26$  M and a pH = 8.78. Assuming the salt is completely dissociated, calculate the  $K_a$  of lactic acid.
- 146.** A solution of 0.23 mol of the chloride salt of protonated quinine ( $\text{QH}^+$ ), a weak organic base, in 1.0 L of solution has pH = 4.58. Find the  $K_b$  of quinine (Q).
- 149.** Calculate the pH of a solution that is 0.00115 M in HCl and 0.0100 M in  $\text{HClO}_2$ .
- 150.** To what volume should you dilute 1 L of a solution of a weak acid HA to reduce the  $[\text{H}^+]$  to one-half of that in the original solution?
- 151.** HA, a weak acid, with  $K_a = 1.0 \times 10^{-8}$ , also forms the ion  $\text{HA}_2^-$ . The reaction is  $\text{HA}(\text{aq}) + \text{A}^-(\text{aq}) \rightleftharpoons \text{HA}_2^-(\text{aq})$  and its  $K = 4.0$ . Calculate the  $[\text{H}^+]$ ,  $[\text{A}^-]$ , and  $[\text{HA}_2^-]$  in a 1.0 M solution of HA.

- 152.** Basicity in the gas phase can be defined as the proton affinity of the base, for example,  $\text{CH}_3\text{NH}_2(g) + \text{H}^+(g) \rightleftharpoons \text{CH}_3\text{NH}_3^+(g)$ . In the gas phase,  $(\text{CH}_3)_3\text{N}$  is more basic than  $\text{CH}_3\text{NH}_2$ , while in solution the reverse is true. Explain this observation.
- 153.** Calculate the pH of a solution prepared from 0.200 mol of  $\text{NH}_4\text{CN}$  and enough water to make 1.00 L of solution.
- 154.** To 1.0 L of a 0.30 M solution of  $\text{HClO}_2$  is added 0.20 mol of NaF. Calculate the  $[\text{HClO}_2]$  at equilibrium.

- 155.** A mixture of  $\text{Na}_2\text{CO}_3$  and  $\text{NaHCO}_3$  has a mass of 82.2 g. It is dissolved in 1.00 L of water, and the pH is found to be 9.95. Find the mass of  $\text{NaHCO}_3$  in the mixture.
- 156.** A mixture of NaCN and  $\text{NaHSO}_4$  consists of a total of 0.60 mol. When the mixture is dissolved in 1.0 L of water and comes to equilibrium, the pH is found to be 9.9. Find the amount of NaCN in the mixture.

## Conceptual Problems

- 157.** Without doing any calculations, determine which solution in each pair is more acidic.
- 0.0100 M in HCl and 0.0100 M in KOH
  - 0.0100 M in HF and 0.0100 M in KBr
  - 0.0100 M in  $\text{NH}_4\text{Cl}$  and 0.0100 M in  $\text{CH}_3\text{NH}_3\text{Br}$
  - 0.100 M in NaCN and 0.100 M in  $\text{CaCl}_2$
- 158.** Without doing any calculations, determine which solution in each pair is more basic.
- 0.100 M in NaClO and 0.100 M in NaF
  - 0.0100 M in KCl and 0.0100 M in  $\text{KClO}_2$

- 0.0100 M in  $\text{HNO}_3$  and 0.0100 M in NaOH
- 0.0100 M in  $\text{NH}_4\text{Cl}$  and 0.0100 M in HCN

- 159.** Rank the acids in order of increasing acid strength.  
 $\text{CH}_3\text{COOH}$   $\text{CH}_2\text{ClCOOH}$   $\text{CHCl}_2\text{COOH}$   $\text{CCl}_3\text{COOH}$
- 160.** Without using a calculator, determine the pH and pOH of each solution. Rank the solutions from most acidic to most basic.
- $1.0 \times 10^{-2} \text{ M HCl}$
  - $1.0 \times 10^{-4} \text{ M HCl}$
  - $1.0 \times 10^{-2} \text{ M NaOH}$
  - $1.0 \times 10^{-4} \text{ M NaOH}$

## Active Classroom Learning

### Questions for Group Work

Discuss these questions with the group and record your consensus answer.

- 161.** Without referring to the text, have each member of your group mention a different property of either an acid or a base, such as “Acids turn blue litmus paper red.” Record as many properties as your group can recall without the text.
- 162.** Have each group member make two flashcards with an acid or base on one side and its conjugate on the other side. Check each other's cards and quiz each other until each group member is proficient at identifying conjugate pairs.
- 163.** Answer the following in a complete sentence or two:
- How do you know if an acid is strong or weak?
  - How do you calculate the pH of a strong acid solution?

- How do you calculate the pH of a weak acid solution?
- If you know the  $K_a$  of an acid, how do you determine the  $K_b$  of its conjugate base?
- If you know  $[\text{OH}^-]$  for a solution, how do you determine  $[\text{H}_3\text{O}^+]$ ?

- 164.** Solve the following problem, taking turns in your group to explain how to do the next step: What is the pH when 5.3 g of sodium acetate,  $\text{NaC}_2\text{H}_3\text{O}_2$ , is dissolved in 100.0 mL of water? (The  $K_a$  of acetic acid,  $\text{HC}_2\text{H}_3\text{O}_2$ , is  $1.8 \times 10^{-5}$ .)
- 165.** Define each of the following with complete sentences, and provide an example chemical equation: an Arrhenius acid, a Brønsted–Lowry base, and a Lewis acid.

## Data Interpretation and Analysis

### Sulfur Dioxide in Wine

- 166.** Sulfur dioxide protects wine from spoiling; it acts as an antioxidant, a bactericide, and a preservative. Potassium or sodium metabisulfite, ( $\text{K}_2\text{S}_2\text{O}_5$  or  $\text{Na}_2\text{S}_2\text{O}_5$ ), is a good source of sulfur dioxide.  $\text{SO}_2$  exists in a pH-dependent equilibrium system:

In this equilibrium system,  $\text{SO}_2$  is called “molecular  $\text{SO}_2$ ”. In the  $\text{HSO}_3^-$  form, it is called “free  $\text{SO}_2$ ”. Only molecular  $\text{SO}_2$  is active as a preservative. The amount of molecular  $\text{SO}_2$  that is

available from a given amount of free  $\text{SO}_2$  is highly pH-dependent, which is one reason that winemakers carefully measure and adjust pH. The recommended amount of molecular  $\text{SO}_2$  in white wine is 0.8 ppm, and for red wine it is 0.5 ppm. The bisulfite ion ( $\text{HSO}_3^-$ ) or “free  $\text{SO}_2$ ” is measured in milligrams  $\text{SO}_2$  produced per L, or mg/L which is approximately equivalent to 1 ppm. Figure a► shows the recommended amount of free  $\text{SO}_2$  required to obtain the correct amount of molecular  $\text{SO}_2$  concentration as a function of pH in white wine and red wine.

pH	White Wine 0.8 ppm molecular SO <sub>2</sub>	Red Wine 0.5 ppm molecular SO <sub>2</sub>
3	13	8
3.05	15	9
3.1	16	10
3.15	19	12
3.2	21	13
3.25	23	15
3.3	26	16
3.35	29	18
3.4	32	20
3.45	37	23
3.5	40	25
3.55	46	29
3.6	50	31
3.65	57	36
3.7	63	39
3.75	72	45
3.8	79	49
3.85	91	57
3.9	99	62

**▲ FIGURE a** Amount of “free SO<sub>2</sub>” Required to Obtain the Correct Amount of Molecular SO<sub>2</sub> Concentration as a Function of pH in White and Red Wine.

Figure b► provides information in graph form about the concentration of free SO<sub>2</sub> required to maintain 0.8 ppm (0.8 mg/L) of molecular SO<sub>2</sub> in white wine at a given pH.

Use the information provided to answer the following questions:

- a. Write the Lewis structure of the metabisulfite, S<sub>2</sub>O<sub>5</sub><sup>2-</sup> anion, and sketch its VSEPR molecular shape. What is the molecular shape around each sulfur atom? (Hint: The S atoms are bonded to each other.)

- b. Write the equilibrium equation to represent how the metabisulfite anion, S<sub>2</sub>O<sub>5</sub><sup>2-</sup>, reacts with water to become the bisulfite anion.
- c. A batch of white wine has an initial concentration of free SO<sub>2</sub> of 22 ppm and pH of 3.70. How much sodium metabisulfite should be added to the wine (per liter) to achieve the proper amount of free SO<sub>2</sub>. Sodium metabisulfate is 67% free SO<sub>2</sub> by mass.
- d. How must the graph in Figure b change to represent the concentration of free SO<sub>2</sub> required to maintain 0.5 ppm (0.5 mg/L) of molecular SO<sub>2</sub> in red wine at a given pH? Should the bars shift upward, downward, or stay the same? Explain your answer.
- e. What concentration of free SO<sub>2</sub> must be present to protect red wine having a pH of 3.70?
- f. In general, white wines tend to be more acidic than red wines. What happens to the equilibrium species present in a sample of white wine when the pH drops from 4.0 to 3.0?

**Free SO<sub>2</sub> Concentration Required to Maintain 0.8 ppm Molecular SO<sub>2</sub>**

**▲ FIGURE b** Free SO<sub>2</sub> Required to Maintain 0.8 ppm (0.8 mg/L) of Molecular SO<sub>2</sub> in White Wine at a Given pH.

## Answers to Conceptual Connections

### Conjugate Acid–Base Pairs

- 16.1 (b)** H<sub>2</sub>SO<sub>4</sub> and H<sub>2</sub>SO<sub>3</sub> are both acids; this is not a conjugate acid–base pair.

### The Magnitude of the Acid Ionization Constant

- 16.2** HB has the largest *K*<sub>a</sub>.

### Relative Strengths of Weak Acids

- 16.3** HF is stronger because it has a larger acid ionization constant.

### pH and Acidity

- 16.4 (b)** As pH increases, acidity decreases.

### The *x* is small Approximation

- 16.5 (c)** The validity of the *x* is small approximation depends on both the value of the equilibrium constant and the initial concentration—the closer that these are to one another, the less likely the approximation is valid.

### Strong and Weak Acids

- 16.6 (a)** A weak acid solution is usually less than 5% dissociated. Since HCl is a strong acid, the 0.10 M solution is much more

acidic than either a weak acid with the same concentration or even a weak acid that is twice as concentrated.

### Percent Ionization

- 16.7** Solution (c) has the greatest percent ionization because percent ionization increases with decreasing weak acid concentration. Solution (b) has the lowest pH because the equilibrium H<sub>3</sub>O<sup>+</sup> concentration increases with increasing weak acid concentration.

### Judging Relative pH

- 16.8 (a)** A weak acid solution is usually less than 5% dissociated. Therefore, since HCl is the only strong acid, the 1.0 M solution is much more acidic than either a weak acid that is twice as concentrated or a combination of two weak acids with the same concentrations.

### Acid Strength and Molecular Structure

- 16.9 (a)** Since the carbon atom in (a) is bonded to another oxygen atom, which draws electron density away from the O—H bond (weakening and polarizing it), and the carbon atom in (b) is bonded only to other hydrogen atoms, the proton in structure (a) is more acidic.

## Aqueous Ionic Equilibrium

In the strictly scientific sense of the word, insolubility does not exist, and even those substances characterized by the most obstinate resistance to the solvent action of water may properly be designated as extraordinarily difficult of solution, not as insoluble.

—OTTO N. WITT (1853–1915)

**17.1 The Danger of Antifreeze 779**

**17.2 Buffers: Solutions That Resist pH Change 780**

**17.3 Buffer Effectiveness: Buffer Range and Buffer Capacity 791**

**17.4 Titrations and pH Curves 795**

**17.5 Solubility Equilibria and the Solubility Product Constant 809**

**17.6 Precipitation 815**

**17.7 Qualitative Chemical Analysis 818**

**17.8 Complex Ion Equilibria 821**

**KEY LEARNING OUTCOMES 827**

**W**e have already seen the importance of aqueous solutions, first in Chapters 4, 13, and 15, and most recently in Chapter 16 on acids and bases. We now turn our attention to two additional topics involving aqueous solutions: buffers (solutions that resist pH change) and solubility equilibria (the extent to which slightly soluble ionic compounds dissolve in water). Buffers are tremendously important in biology because nearly all physiological processes must occur within a narrow pH range. Solubility equilibria are related to the solubility rules that we discussed in Chapter 4. In this chapter, we find a more complicated picture: solids that we considered insoluble under the simple “solubility rules” are actually better described as being only very slightly soluble, as the chapter-opening quotation from Otto Witt suggests. Solubility equilibria are important in predicting not only solubility, but also precipitation reactions that might occur when aqueous solutions are mixed.

### 17.1 The Danger of Antifreeze

Every year, thousands of dogs and cats die from consuming a common household product: improperly stored or leaked antifreeze. Most types of auto antifreeze are aqueous solutions of ethylene glycol:

▲ Antifreeze is a dangerous poison that affects the blood's ability to carry oxygen.

Some brands of antifreeze use propylene glycol, which is less toxic than ethylene glycol.

Ethylene glycol has a somewhat sweet taste that can attract curious dogs and cats—and sometimes even young children, who are also vulnerable to this toxic compound. The first stage of ethylene glycol poisoning is a state resembling drunkenness. Because the compound is an alcohol, it affects the brain much as an alcoholic beverage would. Once ethylene glycol starts to be metabolized, however, a second and more deadly stage commences.

In the liver, ethylene glycol is oxidized to glycolic acid ( $\text{HOCH}_2\text{COOH}$ ), which enters the bloodstream. The acidity of blood is critically important and tightly regulated because many proteins only function in a narrow pH range. In human blood, for example, pH is held between 7.36 and 7.42. This nearly constant blood pH is maintained by *buffers*. We discuss buffers more carefully later in this chapter, but for now know that a buffer is a chemical system that resists pH changes by neutralizing added acid or base. An important buffer in blood is a mixture of carbonic acid ( $\text{H}_2\text{CO}_3$ ) and the bicarbonate ion ( $\text{HCO}_3^-$ ). The carbonic acid neutralizes added base:

The bicarbonate ion neutralizes added acid:

In this way, the carbonic acid and bicarbonate ion buffering system keeps blood pH nearly constant.

When the glycolic acid generated by antifreeze consumption first enters the bloodstream, the acid's tendency to lower blood pH is countered by the buffering action of the bicarbonate ion. However, if the quantities of consumed antifreeze are large enough, the glycolic acid overwhelms the capacity of the buffer (we discuss buffer capacity in Section 17.3), causing blood pH to drop to dangerously low levels.

Low blood pH results in *acidosis*, a condition in which the acid affects the equilibrium between hemoglobin (Hb) and oxygen:

The excess acid causes the equilibrium to shift to the left, reducing the blood's ability to carry oxygen. At this point, the cat or dog may begin hyperventilating in an effort to overcome the acidic blood's lowered oxygen-carrying capacity. If no treatment is administered, the animal will eventually go into a coma and die.

One treatment for ethylene glycol poisoning is the administration of ethyl alcohol (the alcohol found in alcoholic beverages). The two molecules are similar enough that the liver enzyme that catalyzes the metabolism of ethylene glycol also acts on ethyl alcohol, but the enzyme has a higher affinity for ethyl alcohol than for ethylene glycol. Consequently, the enzyme preferentially metabolizes ethyl alcohol, allowing the unmetabolized ethylene glycol to escape through the urine. If administered early, this treatment can save the life of a dog or cat that has consumed ethylene glycol.

## Buffers

### 17.2 Buffers: Solutions That Resist pH Change

Most solutions significantly change pH when an acid or base is added to them. As we have just learned, however, a **buffer** resists pH change by neutralizing added acid or added base. A buffer contains either:

1. significant amounts of a weak acid and its conjugate base or
2. significant amounts of a weak base and its conjugate acid.

For example, the buffer in blood is composed of carbonic acid ( $\text{H}_2\text{CO}_3$ ) and its conjugate base, the bicarbonate ion ( $\text{HCO}_3^-$ ). When additional base is added to a buffer, the weak acid reacts with the base, neutralizing it. When additional acid is added to a buffer, the conjugate base reacts with the acid, neutralizing it. In this way, a buffer can maintain a nearly constant pH.

## Formation of a Buffer

◀ **FIGURE 17.1 A Buffer Solution**

A buffer typically consists of a weak acid (which can neutralize added base) and its conjugate base (which can neutralize added acid).

A weak acid by itself, even though it partially ionizes to form some of its conjugate base, does not contain sufficient base to be a buffer. Similarly, a weak base by itself, even though it partially ionizes water to form some of its conjugate acid, does not contain sufficient acid to be a buffer. *A buffer must contain significant amounts of both a weak acid and its conjugate base (or vice versa).* Consider the simple buffer made by dissolving acetic acid ( $\text{HC}_2\text{H}_3\text{O}_2$ ) and sodium acetate ( $\text{NaC}_2\text{H}_3\text{O}_2$ ) in water (Figure 17.1 ▲).

Suppose, on one hand, that we add a strong base, such as  $\text{NaOH}$ , to this solution. The acetic acid neutralizes the base:

As long as the amount of added  $\text{NaOH}$  is less than the amount of  $\text{HC}_2\text{H}_3\text{O}_2$  in solution, the buffer neutralizes the added  $\text{NaOH}$  and the resulting pH change is small.

Suppose, on the other hand, that we add a strong acid, such as  $\text{HCl}$ , to the solution. In this case, the conjugate base,  $\text{NaC}_2\text{H}_3\text{O}_2$ , neutralizes the added  $\text{HCl}$ :

As long as the amount of added  $\text{HCl}$  is less than the amount of  $\text{NaC}_2\text{H}_3\text{O}_2$  in solution, the buffer neutralizes the added  $\text{HCl}$  and the resulting pH change is small.

**Summarizing Buffer Characteristics:**

- ▶ Buffers resist pH change.
- ▶ A buffer contains significant amounts of either (1) a weak acid and its conjugate base, or (2) a weak base and its conjugate acid.
- ▶ The acid neutralizes added base.
- ▶ The base neutralizes added acid.

$\text{C}_2\text{H}_3\text{O}_2^-$  is the conjugate base of  $\text{HC}_2\text{H}_3\text{O}_2$ .

**Buffers** Which solution is a buffer?

- (a) a solution that is 0.100 M in  $\text{HNO}_2$  and 0.100 M in  $\text{HCl}$
- (b) a solution that is 0.100 M in  $\text{HNO}_3$  and 0.100 M in  $\text{NaNO}_3$
- (c) a solution that is 0.100 M in  $\text{HNO}_2$  and 0.100 M in  $\text{NaCl}$
- (d) a solution that is 0.100 M in  $\text{HNO}_2$  and 0.100 M in  $\text{NaNO}_2$

Le Châtelier's principle is discussed in Section 15.9.

## SOLUTION

1. Write the balanced equation for the ionization of the acid and use it as a guide to prepare an ICE table showing the given concentrations of the acid and its conjugate base as the initial concentrations. Leave room in the table for the changes in concentrations and for the equilibrium concentrations.

	$[\text{HC}_2\text{H}_3\text{O}_2]$	$[\text{H}_3\text{O}^+]$	$[\text{C}_2\text{H}_3\text{O}_2^-]$
Initial	0.100	$\approx 0.00$	0.100
Change			
Equil			

2. Represent the change in the concentration of  $\text{H}_3\text{O}^+$  with the variable  $x$ . Express the changes in the concentrations of the other reactants and products in terms of  $x$ .

	$[\text{HC}_2\text{H}_3\text{O}_2]$	$[\text{H}_3\text{O}^+]$	$[\text{C}_2\text{H}_3\text{O}_2^-]$
Initial	0.100	$\approx 0.00$	0.100
Change	$-x$	$+x$	$+x$
Equil			

<p><b>3.</b> Sum each column to determine the equilibrium concentrations in terms of the initial concentrations and the variable <math>x</math>.</p>	$\text{HC}_2\text{H}_3\text{O}_2(aq) + \text{H}_2\text{O}(l) \rightleftharpoons \text{H}_3\text{O}^+(aq) + \text{C}_2\text{H}_3\text{O}_2^-(aq)$ <table><tr><th></th><th><math>[\text{HC}_2\text{H}_3\text{O}_2]</math></th><th><math>[\text{H}_3\text{O}^+]</math></th><th><math>[\text{C}_2\text{H}_3\text{O}_2^-]</math></th></tr><tr><td>Initial</td><td>0.100</td><td><math>\approx 0.00</math></td><td>0.100</td></tr><tr><td>Change</td><td><math>-x</math></td><td><math>+x</math></td><td><math>+x</math></td></tr><tr><td>Equil</td><td><math>0.100 - x</math></td><td><math>x</math></td><td><math>0.100 + x</math></td></tr></table>		$[\text{HC}_2\text{H}_3\text{O}_2]$	$[\text{H}_3\text{O}^+]$	$[\text{C}_2\text{H}_3\text{O}_2^-]$	Initial	0.100	$\approx 0.00$	0.100	Change	$-x$	$+x$	$+x$	Equil	$0.100 - x$	$x$	$0.100 + x$

## The Henderson–Hasselbalch Equation

We can derive an equation that relates the pH of a buffer solution to the initial concentration of the buffer components, thus simplifying the calculation of the pH of a buffer solution. Consider a buffer containing the generic weak acid HA and its conjugate base  $\text{A}^-$ . The acid ionizes as follows:

We derive an expression for the concentration of  $\text{H}_3\text{O}^+$  from the acid ionization equilibrium expression by solving the expression for  $[\text{H}_3\text{O}^+]$ :

$$K_a = \frac{[\text{H}_3\text{O}^+][\text{A}^-]}{[\text{HA}]}$$

$$[\text{H}_3\text{O}^+] = K_a \frac{[\text{HA}]}{[\text{A}^-]} \quad [17.1]$$

If we make the same  $x$  is *small* approximation that we make for weak acid or weak base equilibrium problems, we can consider the equilibrium concentrations of HA and  $\text{A}^-$  to be essentially identical to the initial concentrations of HA and  $\text{A}^-$  (see step 4 of Example 17.1). Therefore, to determine  $[\text{H}_3\text{O}^+]$  for any buffer solution, we multiply  $K_a$  by the ratio of

Recall that the variable  $x$  in a weak acid equilibrium problem represents the change in the initial acid concentration. The  $x$  is *small* approximation is valid because so little of the weak acid ionizes compared to its initial concentration.

the concentrations of the acid and the conjugate base. To find the  $[\text{H}_3\text{O}^+]$  of the buffer in Example 17.1 (a solution that is 0.100 M in  $\text{HC}_2\text{H}_3\text{O}_2$  and 0.100 M in  $\text{NaC}_2\text{H}_3\text{O}_2$ ), we substitute the concentrations of  $\text{HC}_2\text{H}_3\text{O}_2$  and  $\text{C}_2\text{H}_3\text{O}_2^-$  into Equation 17.1:

$$\begin{aligned} [\text{H}_3\text{O}^+] &= K_a \frac{[\text{HC}_2\text{H}_3\text{O}_2]}{[\text{C}_2\text{H}_3\text{O}_2^-]} \\ &= K_a \frac{0.100}{0.100} \\ &= K_a \end{aligned}$$

In this buffer solution, as in any in which the acid and conjugate base concentrations are equal,  $[\text{H}_3\text{O}^+]$  is equal to  $K_a$ .

We can derive an equation for the pH of a buffer by taking the negative logarithm of both sides of Equation 17.1:

$$[\text{H}_3\text{O}^+] = K_a \frac{[\text{HA}]}{[\text{A}^-]}$$

$$-\log[\text{H}_3\text{O}^+] = -\log\left(K_a \frac{[\text{HA}]}{[\text{A}^-]}\right)$$

$$-\log[\text{H}_3\text{O}^+] = -\log K_a - \log \frac{[\text{HA}]}{[\text{A}^-]} \quad [17.2]$$

We can rearrange Equation 17.2 to get:

$$-\log[\text{H}_3\text{O}^+] = -\log K_a + \log \frac{[\text{A}^-]}{[\text{HA}]}$$

Since  $\text{pH} = -\log[\text{H}_3\text{O}^+]$  and since  $\text{p}K_a = -\log K_a$ , we obtain the result:

$$\text{pH} = \text{p}K_a + \log \frac{[\text{A}^-]}{[\text{HA}]}$$

Since  $\text{A}^-$  is a weak base and HA is a weak acid, we can generalize the equation:

$$\text{pH} = \text{p}K_a + \log \frac{[\text{base}]}{[\text{acid}]} \quad [17.3]$$

where the base is the conjugate base of the acid or the acid is the conjugate acid of the base. This equation, known as the **Henderson–Hasselbalch equation**, allows us to quickly calculate the pH of a buffer solution from the initial concentrations of the buffer components *as long as the  $x$  is small approximation is valid*. In Example 17.2, we show how to find the pH of a buffer in two ways: in the left column we solve a common ion effect equilibrium problem using a method similar to the one we used in Example 17.1; in the right column we use the Henderson–Hasselbalch equation.

### Example 17.2 Calculating the pH of a Buffer Solution as an Equilibrium Problem and with the Henderson–Hasselbalch Equation

Calculate the pH of a buffer solution that is 0.050 M in benzoic acid ( $\text{HC}_7\text{H}_5\text{O}_2$ ) and 0.150 M in sodium benzoate ( $\text{NaC}_7\text{H}_5\text{O}_2$ ). For benzoic acid,  $K_a = 6.5 \times 10^{-5}$ .

#### SOLUTION

##### Equilibrium Approach

Write the balanced equation for the ionization of the acid and use it as a guide to prepare an ICE table.

##### Henderson–Hasselbalch Approach

To find the pH of this solution, determine which component is the acid and which is the base and substitute their concentrations into the Henderson–Hasselbalch equation to calculate pH.

	$[\text{HC}_7\text{H}_5\text{O}_2]$	$[\text{H}_3\text{O}^+]$	$[\text{C}_7\text{H}_5\text{O}_2^-]$
Initial	0.050	$\approx 0.00$	0.150
Change	$-x$	$+x$	$+x$
Equil	$0.050 - x$	$x$	$0.150 + x$

Substitute the expressions for the equilibrium concentrations into the expression for the acid ionization constant. Make the  $x$  is *small* approximation and solve for  $x$ .

$$K_a = \frac{[\text{H}_3\text{O}^+][\text{C}_7\text{H}_5\text{O}_2^-]}{[\text{HC}_7\text{H}_5\text{O}_2]}$$

$$= \frac{x(0.150 + x)}{0.050 - x} \quad (x \text{ is small})$$

$$6.5 \times 10^{-5} = \frac{x(0.150)}{0.050}$$

$$x = 2.2 \times 10^{-5}$$

Since  $[\text{H}_3\text{O}^+] = x$ , we calculate pH as follows:

$$\begin{aligned} \text{pH} &= -\log[\text{H}_3\text{O}^+] \\ &= -\log(2.2 \times 10^{-5}) \\ &= 4.66 \end{aligned}$$

$\text{HC}_7\text{H}_5\text{O}_2$  is the acid and  $\text{NaC}_7\text{H}_5\text{O}_2$  is the base. Therefore, we calculate the pH as follows:

$$\begin{aligned} \text{pH} &= \text{p}K_a + \log \frac{[\text{base}]}{[\text{acid}]} \\ &= -\log(6.5 \times 10^{-5}) + \log \frac{0.150}{0.050} \\ &= 4.187 + 0.477 \\ &= 4.66 \end{aligned}$$

Confirm that the  $x$  is *small* approximation is valid by calculating the ratio of  $x$  to the number it was subtracted from in the approximation. The ratio should be less than 0.05 (5%). (See Sections 15.8 and 16.6 to review the  $x$  is *small* approximation.)

$$\frac{2.2 \times 10^{-5}}{0.050} \times 100\% = 0.044\%$$

The approximation is valid.

Confirm that the  $x$  is *small* approximation is valid by calculating the  $[\text{H}_3\text{O}^+]$  from the pH. Since  $[\text{H}_3\text{O}^+]$  is formed by ionization of the acid, the calculated  $[\text{H}_3\text{O}^+]$  has to be less than 0.05 (or 5%) of the initial concentration of the acid in order for the  $x$  is *small* approximation to be valid.

$$\begin{aligned} \text{pH} &= 4.66 = -\log[\text{H}_3\text{O}^+] \\ [\text{H}_3\text{O}^+] &= 10^{-4.66} = 2.2 \times 10^{-5} \text{ M} \\ \frac{2.2 \times 10^{-5}}{0.050} \times 100\% &= 0.044\% \end{aligned}$$

The approximation is valid.

**FOR PRACTICE 17.2** Calculate the pH of a buffer solution that is 0.250 M in HCN and 0.170 M in KCN. For HCN,  $K_a = 4.9 \times 10^{-10}$  ( $\text{p}K_a = 9.31$ ). Use both the equilibrium approach and the Henderson–Hasselbalch approach.

You may be wondering how to decide whether to use the equilibrium approach or the Henderson–Hasselbalch equation when calculating the pH of buffer solutions. The answer depends on the specific problem. In cases where you can make the  $x$  is *small* approximation, the Henderson–Hasselbalch equation is adequate. However, as you can see from Example 17.2, checking the  $x$  is *small* approximation is not as convenient with the Henderson–Hasselbalch equation (because the approximation is implicit). Thus, the equilibrium approach, though lengthier, gives you a better sense of the important quantities in the problem and the nature of the approximation.

When first working buffer problems, use the equilibrium approach until you get a good sense for when the  $x$  is *small* approximation is adequate. Then, you can switch to the more streamlined approach in cases where the approximation applies (and only in those cases). In general, remember that the  $x$  is *small* approximation applies to problems in which both of the following are true: (a) the initial concentrations of acids (and/or bases) are not too dilute; and (b) the equilibrium constant is fairly small. Although the exact values depend on the details of the problem, for many buffer problems this means that the initial concentrations of acids and conjugate bases should be at least  $10^2$ – $10^3$  times greater than the equilibrium constant (depending on the required accuracy).

## CONCEPTUAL CONNECTION 17.2

**pH of Buffer Solutions** A buffer contains the weak acid HA and its conjugate base  $A^-$ . The weak acid has a  $pK_a$  of 4.82 and the buffer has a pH of 4.25. Which statement is true of the relative concentrations of the weak acid and conjugate base in the buffer?

- (a)  $[HA] > [A^-]$       (b)  $[HA] < [A^-]$       (c)  $[HA] = [A^-]$

Which buffer component would you add to change the pH of the buffer to 4.72?

## Calculating pH Changes in a Buffer Solution

When we add acid or base to a buffer, the buffer resists a pH change. Nonetheless, the pH does change by a small amount. Calculating the pH change requires breaking up the problem into two parts:

- 1. The stoichiometry calculation** in which we calculate how the addition changes the relative amounts of acid and conjugate base.
- 2. The equilibrium calculation** in which we calculate the pH based on the new amounts of acid and conjugate base.

We demonstrate this calculation with a 1.0-L buffer solution that is 0.100 M in the generic acid HA and 0.100 M in its conjugate base  $A^-$ . Since the concentrations of the weak acid and the conjugate base are equal, the pH of the buffer is equal to  $pK_a$ . Let's calculate the pH of the solution after we add 0.025 mol of strong acid ( $H^+$ ) (assuming that the change in volume from adding the acid is negligible).

### The Stoichiometry Calculation

As the added acid is neutralized, it converts a stoichiometric amount of the base into its conjugate acid through the neutralization reaction (Figure 17.3a►, on p. 788):

Neutralizing 0.025 mol of the strong acid ( $H^+$ ) requires 0.025 mol of the weak base ( $A^-$ ). Consequently, the amount of  $A^-$  *decreases* by 0.025 mol and the amount of HA *increases* by 0.025 mol (because of the 1:1:1 stoichiometry of the neutralization reaction). We can track these changes in tabular form as follows:

	$H^+(aq)$	+	$A^-(aq)$	$\longrightarrow$	$HA(aq)$
<b>Before addition</b>	$\approx 0.00$ mol		0.100 mol		0.100 mol
<b>Addition</b>	+0.025 mol		—		—
<b>After addition</b>	$\approx 0.00$ mol		0.075 mol		0.125 mol

*Notice that this table is not an ICE table.* This table simply tracks the stoichiometric changes that occur during the neutralization of the added acid. We write  $\approx 0.00$  mol for the amount of  $H^+$  because the amount is so small compared to the amounts of  $A^-$  and HA. (Remember that weak acids ionize only to a small extent and that the presence of the common ion further suppresses the ionization.) The amount of  $H^+$ , of course, is not *exactly* zero, as we can see by completing the equilibrium part of the calculation.

### The Equilibrium Calculation

We have just seen that adding a small amount of acid to a buffer is equivalent to changing the initial concentrations of the acid and conjugate base present in the buffer (in this case, since the volume is 1.0 L,  $[HA]$  increased from 0.100 M to 0.125 M and  $[A^-]$  decreased from 0.100 M to 0.075 M). Knowing these new initial concentrations, we can calculate the new pH in the same way that we calculate the pH of any buffer: either by working a full equilibrium problem or by using the Henderson-Hasselbalch equation (see Examples 17.1 and 17.2).

It is best to work with amounts in moles instead of concentrations when tracking these changes, as explained later in this chapter.

In this case, we work the full equilibrium problem. We begin by writing the balanced equation for the ionization of the acid and using it as a guide to prepare an ICE table. The initial concentrations for the ICE table are those that we calculated in the stoichiometry part of the calculation:

	[HA]	[H <sub>3</sub> O <sup>+</sup> ]	[A <sup>-</sup> ]
Initial	0.125	≈0.00	0.075
Change	-x	+x	+x
Equil	0.125 - x	x	0.075 + x

From stoichiometry calculation

We then substitute the expressions for the equilibrium concentrations into the expression for the acid ionization constant. As long as  $K_a$  is sufficiently small relative to the initial concentrations, we can make the  $x$  is *small* approximation and solve for  $x$ , which is equal to  $[\text{H}_3\text{O}^+]$ :

$$\begin{aligned} K_a &= \frac{[\text{H}_3\text{O}^+][\text{A}^-]}{[\text{HA}]} \\ &= \frac{x(0.075 + x)}{0.125 - x} \quad (x \text{ is small}) \\ K_a &= \frac{x(0.075)}{0.125} \\ x = [\text{H}_3\text{O}^+] &= K_a \frac{0.125}{0.075} \end{aligned}$$

Once we calculate  $[\text{H}_3\text{O}^+]$ , we can calculate the pH with the equation  $\text{pH} = -\log [\text{H}_3\text{O}^+]$ .

Notice that, since the expression for  $x$  contains a *ratio* of concentrations  $[\text{HA}]/[\text{A}^-]$ , the *amounts of acid and base in moles* may be substituted in place of concentration because, in a single buffer solution, the volume is the same for both the acid and the base. Therefore, the volumes cancel:

$$[\text{HA}]/[\text{A}^-] = \frac{\frac{n_{\text{HA}}}{V}}{\frac{n_{\text{A}^-}}{V}} = n_{\text{HA}}/n_{\text{A}^-}$$

The effect of adding a small amount of strong base to the buffer is exactly the opposite of adding acid. The added base converts a stoichiometric amount of the acid into its conjugate base through the neutralization reaction (Figure 17.3b, on the next page):

If we add 0.025 mol of  $\text{OH}^-$ , the amount of  $\text{A}^-$  goes *up* by 0.025 mol and the amount of HA goes *down* by 0.025 mol, as shown in the following table:

	$\text{OH}^-(aq)$	+	$\text{HA}(aq)$	→	$\text{H}_2\text{O}(l)$	+	$\text{A}^-(aq)$
<b>Before addition</b>	≈0.00 mol		0.100 mol				0.100 mol
<b>Addition</b>	+0.025 mol		—				—
<b>After addition</b>	≈0.00 mol		0.075 mol				0.125 mol

**When you calculate the pH of a buffer after adding small amounts of acid or base, remember the following:**

- Adding a small amount of strong acid to a buffer converts a stoichiometric amount of the base to the conjugate acid and decreases the pH of the buffer (adding acid decreases pH just as we would expect).
- Adding a small amount of strong base to a buffer converts a stoichiometric amount of the acid to the conjugate base and increases the pH of the buffer (adding base increases the pH just as we would expect).

The easiest way to remember these changes is relatively simple: adding acid creates more acid; adding base creates more base.

► **FIGURE 17.3** Buffering Action

(a) When an acid is added to a buffer, a stoichiometric amount of the weak base is converted to the conjugate acid.  
 (b) When a base is added to a buffer, a stoichiometric amount of the weak acid is converted to the conjugate base.

Example 17.3 and the For Practice Problems that follow it involve calculating pH changes in a buffer solution after small amounts of strong acid or strong base are added. As we have seen, these problems generally have two parts:

- Part I. Stoichiometry—use the stoichiometry of the neutralization equation to calculate the changes in the amounts (in moles) of the buffer components upon addition of the acid or base.
- Part II. Equilibrium—use the new amounts of buffer components to work an equilibrium problem to find pH. (For most buffers, this can also be done with the Henderson–Hasselbalch equation.)

CONCEPTUAL  
CONNECTION 17.3

**Buffering Action** Closely examine Figure 17.3▲. Which image best represents the amount of  $\text{OH}^-$  added to the buffer in part (b) of the figure?

**Example 17.3** Calculating the pH Change in a Buffer Solution after the Addition of a Small Amount of Strong Acid or Base

A 1.0-L buffer solution contains 0.100 mol  $\text{HC}_2\text{H}_3\text{O}_2$  and 0.100 mol  $\text{NaC}_2\text{H}_3\text{O}_2$ . The value of  $K_a$  for  $\text{HC}_2\text{H}_3\text{O}_2$  is  $1.8 \times 10^{-5}$ . Because the initial amounts of acid and conjugate base are equal, the pH of the buffer is equal to  $\text{p}K_a = -\log(1.8 \times 10^{-5}) = 4.74$ . Calculate the new pH after adding 0.010 mol of solid NaOH to the buffer. For comparison, calculate the pH after adding 0.010 mol of solid NaOH to 1.0 L of pure water. (Ignore any small changes in volume that might occur upon addition of the base.)

**SOLUTION**

Part I: Stoichiometry. The addition of the base converts a stoichiometric amount of acid to the conjugate base (adding base creates more base). Write an equation showing the neutralization reaction and then set up a table to track the changes.

	$\text{OH}^-(aq)$	+	$\text{HC}_2\text{H}_3\text{O}_2(aq)$	$\longrightarrow$	$\text{H}_2\text{O}(l)$	+	$\text{C}_2\text{H}_3\text{O}_2^-(aq)$
<b>Before addition</b>	$\approx 0.00$ mol		0.100 mol				0.100 mol
<b>Addition</b>	0.010 mol		—				—
<b>After addition</b>	$\approx 0.00$ mol		0.090 mol				0.110 mol

Part II: Equilibrium. Write the balanced equation for the ionization of the acid and use it as a guide to prepare an ICE table. Use the amounts of acid and conjugate base from part I as the initial amounts of acid and conjugate base in the ICE table.

	$[\text{HC}_2\text{H}_3\text{O}_2]$	$[\text{H}_3\text{O}^+]$	$[\text{C}_2\text{H}_3\text{O}_2^-]$
Initial	0.090	$\approx 0.00$	0.110
Change	$-x$	$+x$	$+x$
Equil	$0.090 - x$	$x$	$0.110 + x$

Substitute the expressions for the equilibrium concentrations of acid and conjugate base into the expression for the acid ionization constant. Make the  $x$  is *small* approximation and solve for  $x$ . Calculate the pH from the value of  $x$ , which is equal to  $[\text{H}_3\text{O}^+]$ .

$$\begin{aligned} K_a &= \frac{[\text{H}_3\text{O}^+][\text{C}_2\text{H}_3\text{O}_2^-]}{[\text{HC}_2\text{H}_3\text{O}_2]} \\ &= \frac{x(0.110 + x)}{0.090 - x} \quad (x \text{ is small}) \end{aligned}$$

$$1.8 \times 10^{-5} = \frac{x(0.110)}{0.090}$$

$$x = [\text{H}_3\text{O}^+] = 1.47 \times 10^{-5} \text{ M}$$

$$\begin{aligned} \text{pH} &= -\log[\text{H}_3\text{O}^+] \\ &= -\log(1.47 \times 10^{-5}) \\ &= 4.83 \end{aligned}$$

Confirm that the  $x$  is *small* approximation is valid by calculating the ratio of  $x$  to the smallest number it was subtracted from in the approximation. The ratio should be less than 0.05 (5%).

$$\frac{1.47 \times 10^{-5}}{0.090} \times 100\% = 0.016\%$$

The approximation is valid.

Part II: Equilibrium Alternative (using the Henderson–Hasselbalch equation). As long as the  $x$  is *small* approximation is valid, you can substitute the quantities of acid and conjugate base after the addition (from part I) into the Henderson–Hasselbalch equation and calculate the new pH.

$$\begin{aligned} \text{pH} &= \text{p}K_a + \log \frac{[\text{base}]}{[\text{acid}]} \\ &= -\log(1.8 \times 10^{-5}) + \log \frac{0.110}{0.090} \\ &= 4.74 + 0.087 \\ &= 4.83 \end{aligned}$$

The pH of 1.0 L of water after adding 0.010 mol of NaOH is calculated from the  $[\text{OH}^-]$ . For a strong base,  $[\text{OH}^-]$  is simply the number of moles of  $\text{OH}^-$  divided by the number of liters of solution.

$$\begin{aligned} [\text{OH}^-] &= \frac{0.010 \text{ mol}}{1.0 \text{ L}} = 0.010 \text{ M} \\ \text{pOH} &= -\log[\text{OH}^-] = -\log(0.010) \\ &= 2.00 \\ \text{pOH} + \text{pH} &= 14.00 \\ \text{pH} &= 14.00 - \text{pOH} \\ &= 14.00 - 2.00 \\ &= 12.00 \end{aligned}$$

**CHECK** Notice that the buffer solution changed from pH = 4.74 to pH = 4.83 upon addition of the base (a small fraction of a single pH unit). In contrast, the pure water changed from pH = 7.00 to pH = 12.00, five whole pH units (a factor of  $10^5$ ). Notice also that even the buffer solution got slightly more basic upon addition of a base, as we would expect. To check your answer, always make sure the pH goes in the direction you expect: adding base should make the solution more basic (higher pH); adding acid should make the solution more acidic (lower pH).

**FOR PRACTICE 17.3** Calculate the pH of the solution in Example 17.3 upon addition of 0.015 mol of NaOH to the original buffer.

**FOR MORE PRACTICE 17.3** Calculate the pH of the solution in Example 17.3 upon addition of 10.0 mL of 1.00 M HCl to the original buffer.

CONCEPTUAL  
CONNECTION 17.4

**Adding Acid or Base to a Buffer** A buffer contains equal amounts of a weak acid and its conjugate base and has a pH of 5.25. Which would be a reasonable value of buffer pH after the addition of a small amount of acid?

- (a) 4.15
- (b) 5.15
- (c) 5.35
- (d) 6.35

### Buffers Containing a Base and Its Conjugate Acid

So far, we have seen examples of buffers composed of an acid and its conjugate base (where the conjugate base is an ion). A buffer can also be composed of a base and its conjugate acid (where the conjugate acid is an ion). For example, a solution containing significant amounts of both  $\text{NH}_3$  and  $\text{NH}_4\text{Cl}$  acts as a buffer (Figure 17.4▼). The  $\text{NH}_3$  is a weak base that neutralizes small amounts of added acid, and the  $\text{NH}_4^+$  ion is the conjugate acid that neutralizes small amounts of added base.

We calculate the pH of a solution like this in the same way that we calculated the pH of a buffer containing a weak acid and its conjugate base. When using the Henderson–Hasselbalch equation, however, we must first calculate  $\text{p}K_a$  for the conjugate acid of the weak base. Recall from Section 16.8 that for a conjugate acid–base pair,  $K_a \times K_b = K_w$  and  $\text{p}K_a + \text{p}K_b = 14$ . Consequently, we can find  $\text{p}K_a$  of the conjugate acid by subtracting  $\text{p}K_b$  of the weak base from 14. Example 17.4 illustrates the procedure for calculating the pH of a buffer composed of a weak base and its conjugate acid.

**▲ FIGURE 17.4 Buffer Containing a Base** A buffer can also consist of a weak base and its conjugate acid.

**Example 17.4** Using the Henderson–Hasselbalch Equation to Calculate the pH of a Buffer Solution Composed of a Weak Base and Its Conjugate Acid

Use the Henderson–Hasselbalch equation to calculate the pH of a buffer solution that is 0.50 M in  $\text{NH}_3$  and 0.20 M in  $\text{NH}_4\text{Cl}$ . For ammonia,  $\text{p}K_b = 4.75$ .

**SOLUTION**

Since  $K_b$  for  $\text{NH}_3$  ( $1.76 \times 10^{-5}$ ) is much smaller than the initial concentrations in this problem, you can use the Henderson–Hasselbalch equation to calculate the pH of the buffer. First calculate  $\text{p}K_a$  from  $\text{p}K_b$ .

Then substitute the given quantities into the Henderson–Hasselbalch equation and calculate pH.

$$\text{p}K_a + \text{p}K_b = 14$$

$$\text{p}K_a = 14 - \text{p}K_b$$

$$= 14 - 4.75$$

$$= 9.25$$

$$\text{pH} = \text{p}K_a + \log \frac{[\text{base}]}{[\text{acid}]}$$

$$= 9.25 + \log \frac{0.50}{0.20}$$

$$= 9.25 + 0.40$$

$$= 9.65$$

**FOR PRACTICE 17.4** Calculate the pH of 1.0 L of the solution in Example 17.4 upon addition of 0.010 mol of solid NaOH to the original buffer solution.

**FOR MORE PRACTICE 17.4** Calculate the pH of 1.0 L of the solution in Example 17.4 upon addition of 30.0 mL of 1.0 M HCl to the original buffer solution.

## 17.3 Buffer Effectiveness: Buffer Range and Buffer Capacity

An effective buffer neutralizes small to moderate amounts of added acid or base. Recall from Section 17.1, however, that a buffer can be destroyed by the addition of too much acid or too much base. What factors influence the effectiveness of a buffer? In this section, we examine two such factors: *the relative amounts of the acid and conjugate base* and *the absolute concentrations of the acid and conjugate base*. We then define the *capacity of a buffer* (how much added acid or base it can effectively neutralize) and the *range of a buffer* (the pH range over which a particular acid and its conjugate base can be effective).

### Relative Amounts of Acid and Base

A buffer is most effective (most resistant to pH changes) when the concentrations of acid and conjugate base are equal. Let's explore this idea by considering the behavior of a generic buffer composed of HA and  $\text{A}^-$  for which  $\text{p}K_a = 5.00$  and calculating the percent change in pH upon addition of 0.010 mol of NaOH for two different 1.0-liter solutions of this buffer system. Both solutions have 0.20 mol of *total* acid and conjugate base. However, solution I has equal amounts of acid and conjugate base (0.10 mol of each), while solution II has much more acid than conjugate base (0.18 mol HA and 0.020 mol  $\text{A}^-$ ). We can calculate the initial pH values of each solution using the Henderson–Hasselbalch equation. Solution I has an initial pH of 5.00 and solution II has an initial pH of 4.05:

**Solution I: 0.10 mol HA and 0.10 mol A<sup>-</sup>;  
initial pH = 5.00**

	$\text{OH}^-(aq) + \text{HA}(aq) \longrightarrow \text{H}_2\text{O}(l) + \text{A}^-(aq)$		
<b>Before addition</b>	≈ 0.00 mol	0.100 mol	0.100 mol
<b>Addition</b>	0.010 mol	—	—
<b>After addition</b>	≈ 0.00 mol	0.090 mol	0.110 mol

$$\begin{aligned}
 \text{pH} &= \text{p}K_a + \log \frac{[\text{base}]}{[\text{acid}]} \\
 &= 5.00 + \log \frac{0.110}{0.090} \\
 &= 5.09 \\
 \% \text{ change} &= \frac{5.09 - 5.00}{5.00} \times 100\% \\
 &= 1.8\%
 \end{aligned}$$

**Solution II: 0.18 mol HA and 0.020 mol A<sup>-</sup>;  
initial pH = 4.05**

	$\text{OH}^-(aq) + \text{HA}(aq) \longrightarrow \text{H}_2\text{O}(l) + \text{A}^-(aq)$		
<b>Before addition</b>	≈ 0.00 mol	0.18 mol	0.020 mol
<b>Addition</b>	0.010 mol	—	—
<b>After addition</b>	≈ 0.00 mol	0.17 mol	0.030 mol

$$\begin{aligned}
 \text{pH} &= \text{p}K_a + \log \frac{[\text{base}]}{[\text{acid}]} \\
 &= 5.00 + \log \frac{0.030}{0.17} \\
 &= 4.25 \\
 \% \text{ change} &= \frac{4.25 - 4.05}{4.05} \times 100\% \\
 &= 4.9\%
 \end{aligned}$$

As you can see, the buffer with equal amounts of acid and conjugate base is more resistant to pH change and is therefore the more effective buffer. A buffer becomes less effective as the difference in the relative amounts of acid and conjugate base increases. As a guideline, we can say that an effective buffer must have a [base]/[acid] ratio in the range of 0.10 to 10. *In order for a buffer to be reasonably effective, the relative concentrations of acid and conjugate base should not differ by more than a factor of 10.*

## Absolute Concentrations of the Acid and Conjugate Base

*A buffer is most effective (most resistant to pH changes) when the concentrations of acid and conjugate base are high.* Let's explore this idea by again considering a generic buffer composed of HA and A<sup>-</sup> and a pK<sub>a</sub> of 5.00 and calculating the percent change in pH upon addition of 0.010 mol of NaOH for two 1.0-liter solutions of this buffer system. In this case, both the acid and the base in solution I are ten times more concentrated than the acid and base in solution II. Both solutions have equal relative amounts of acid and conjugate base and therefore have the same initial pH of 5.00:

**Solution I: 0.50 mol HA and 0.50 mol A<sup>-</sup>;  
initial pH = 5.00**

	$\text{OH}^-(aq) + \text{HA}(aq) \longrightarrow \text{H}_2\text{O}(l) + \text{A}^-(aq)$		
<b>Before addition</b>	≈ 0.00 mol	0.50 mol	0.50 mol
<b>Addition</b>	0.010 mol	—	—
<b>After addition</b>	≈ 0.00 mol	0.49 mol	0.51 mol

$$\begin{aligned}
 \text{pH} &= \text{p}K_a + \log \frac{[\text{base}]}{[\text{acid}]} \\
 &= 5.00 + \log \frac{0.51}{0.49} \\
 &= 5.02 \\
 \% \text{ change} &= \frac{5.02 - 5.00}{5.00} \times 100\% \\
 &= 0.4\%
 \end{aligned}$$

**Solution II: 0.050 mol HA and 0.050 mol A<sup>-</sup>;  
initial pH = 5.00**

	$\text{OH}^-(aq) + \text{HA}(aq) \longrightarrow \text{H}_2\text{O}(l) + \text{A}^-(aq)$		
<b>Before addition</b>	≈ 0.00 mol	0.050 mol	0.050 mol
<b>Addition</b>	0.010 mol	—	—
<b>After addition</b>	≈ 0.00 mol	0.040 mol	0.060 mol

$$\begin{aligned}
 \text{pH} &= \text{p}K_a + \log \frac{[\text{base}]}{[\text{acid}]} \\
 &= 5.00 + \log \frac{0.060}{0.040} \\
 &= 5.18 \\
 \% \text{ change} &= \frac{5.18 - 5.00}{5.00} \times 100\% \\
 &= 3.6\%
 \end{aligned}$$

As you can see, the buffer with greater amounts of acid and conjugate base is more resistant to pH changes and therefore is the more effective buffer. The more dilute the buffer components, the less effective the buffer.

## Buffer Range

In light of the guideline that the relative concentrations of acid and conjugate base should not differ by more than a factor of 10 in order for a buffer to be reasonably effective, we can calculate the pH range over which a particular acid and its conjugate base make an effective buffer. Because the pH of a buffer is given by the Henderson–Hasselbalch equation, we can calculate the outermost points of the effective range as follows:

*Lowest pH* for effective buffer occurs when the base is one-tenth as concentrated as the acid.

$$\begin{aligned}\text{pH} &= \text{p}K_a + \log \frac{[\text{base}]}{[\text{acid}]} \\ &= \text{p}K_a + \log 0.10 \\ &= \text{p}K_a - 1\end{aligned}$$

*Highest pH* for effective buffer occurs when the base is ten times as concentrated as the acid.

$$\begin{aligned}\text{pH} &= \text{p}K_a + \log \frac{[\text{base}]}{[\text{acid}]} \\ &= \text{p}K_a + \log 10 \\ &= \text{p}K_a + 1\end{aligned}$$

The effective range for a buffering system is one pH unit on either side of  $\text{p}K_a$ . For example, we can use a weak acid with a  $\text{p}K_a$  of 5.0 (and its conjugate base) to prepare a buffer in the range of 4.0–6.0. We can adjust the relative amounts of acid and conjugate base to achieve any pH within this range. As we noted earlier, however, the buffer would be most effective at pH 5.0 because the buffer components would be exactly equal at that pH. Example 17.5 demonstrates how to pick an acid/conjugate base system for a buffer and how to calculate the relative amounts of acid and conjugate base required for a desired pH.

▲ A concentrated buffer contains more of the weak acid and its conjugate base than a weak buffer does. It can therefore neutralize more added acid or added base.

### Example 17.5 Preparing a Buffer

Which acid would you choose to combine with its sodium salt to make a solution buffered at pH 4.25? For the best choice, calculate the ratio of the conjugate base to the acid required to attain the desired pH.

chlorous acid ( $\text{HClO}_2$ )  $\text{p}K_a = 1.95$     formic acid ( $\text{HCHO}_2$ )  $\text{p}K_a = 3.74$   
 nitrous acid ( $\text{HNO}_2$ )  $\text{p}K_a = 3.34$     hypochlorous acid ( $\text{HClO}$ )  $\text{p}K_a = 7.54$

#### SOLUTION

The best choice is formic acid because its  $\text{p}K_a$  lies closest to the desired pH. You can calculate the ratio of conjugate base ( $\text{CHO}_2^-$ ) to acid ( $\text{HCHO}_2$ ) required by using the Henderson–Hasselbalch equation as follows:

$$\begin{aligned}\text{pH} &= \text{p}K_a + \log \frac{[\text{base}]}{[\text{acid}]} \\ 4.25 &= 3.74 + \log \frac{[\text{base}]}{[\text{acid}]} \\ \log \frac{[\text{base}]}{[\text{acid}]} &= 4.25 - 3.74 \\ &= 0.51 \\ \frac{[\text{base}]}{[\text{acid}]} &= 10^{0.51} \\ &= 3.24\end{aligned}$$

**FOR PRACTICE 17.5** Which acid in Example 17.5 would you choose to create a buffer with  $\text{pH} = 7.35$ ? If you have 500.0 mL of a 0.10 M solution of the acid, what mass of the corresponding sodium salt of the conjugate base do you need to make the buffer?

## Chemistry AND Medicine

## Buffer Effectiveness in Human Blood

As we discussed in Section 17.1, blood contains several buffering systems, the most important of which consists of carbonic acid and the bicarbonate ion. The concentrations of these buffer components in normal blood plasma are  $[\text{HCO}_3^-] = 0.024 \text{ M}$  and  $[\text{H}_2\text{CO}_3] = 0.0012 \text{ M}$ . The  $\text{p}K_a$  for carbonic acid at body temperature is 6.1.

If we substitute these quantities into the Henderson–Hasselbalch equation, we can calculate the normal pH of blood:

$$\begin{aligned}\text{pH} &= \text{p}K_a + \log \frac{[\text{base}]}{[\text{acid}]} \\ &= 6.1 + \log \frac{[\text{HCO}_3^-]}{[\text{H}_2\text{CO}_3]} \\ &= 6.1 + \log \frac{0.024 \text{ M}}{0.0012 \text{ M}} \\ &= 7.4\end{aligned}$$

Normal blood has a pH of 7.4. Notice that the concentration of the bicarbonate ion is 20 times higher than the concentration of carbonic acid and the pH of the buffer is more than one pH unit away from  $\text{p}K_a$ . Why?

The higher bicarbonate ion concentration in blood makes the buffer capacity of blood greater for acid than for base, which is necessary because the products of metabolism that enter blood are mostly acidic. For example, when we exercise, our bodies produce lactic acid ( $\text{HC}_3\text{H}_5\text{O}_3$ ).

The lactic acid enters the bloodstream and must be neutralized. The bicarbonate ion neutralizes the lactic acid according to the equation:

An enzyme called carbonic anhydrase then catalyzes the conversion of carbonic acid into carbon dioxide and water:

We eliminate the carbon dioxide from our blood when we breathe. When large amounts of lactic acid are produced, we must breathe faster to keep up with the need to eliminate carbon dioxide. This is why we pant when we exert ourselves.

## QUESTION

A 70-kg person has a total blood volume of about 5.0 L. Given the carbonic acid and bicarbonate concentrations stated, what volume (in mL) of 6.0 M HCl can be neutralized by blood without the blood pH dropping below 7.0 (which would result in death)?

► Normal blood has a pH of 7.4.

## Buffer Capacity

**Buffer capacity** is the amount of acid or base that we can add to a buffer without causing a large change in pH. Given what we just learned about the absolute concentrations of acid and conjugate base in an effective buffer, we can conclude that the *buffer capacity increases with increasing absolute concentrations of the buffer components*. The more concentrated the weak acid and conjugate base that compose the buffer, the higher the buffer capacity. In addition, *overall buffer capacity increases as the relative concentrations of the buffer components become more similar to each other*. As the ratio of the buffer components gets closer to 1, the overall capacity of the buffer (the ability to neutralize added acid *and* added base) becomes greater. In some cases, however, a buffer that must neutralize primarily added acid (or primarily added base) may be overweighted in one of the buffer components, as shown in the *Chemistry and Medicine* box in this section.

CONCEPTUAL  
CONNECTION 17.5

**Buffer Capacity** A 1.0-L buffer solution is 0.10 M in HF and 0.050 M in NaF. Which action destroys the buffer?

- (a) adding 0.050 mol of HCl
- (b) adding 0.050 mol of NaOH
- (c) adding 0.050 mol of NaF
- (d) none of the above

## 17.4 Titrations and pH Curves

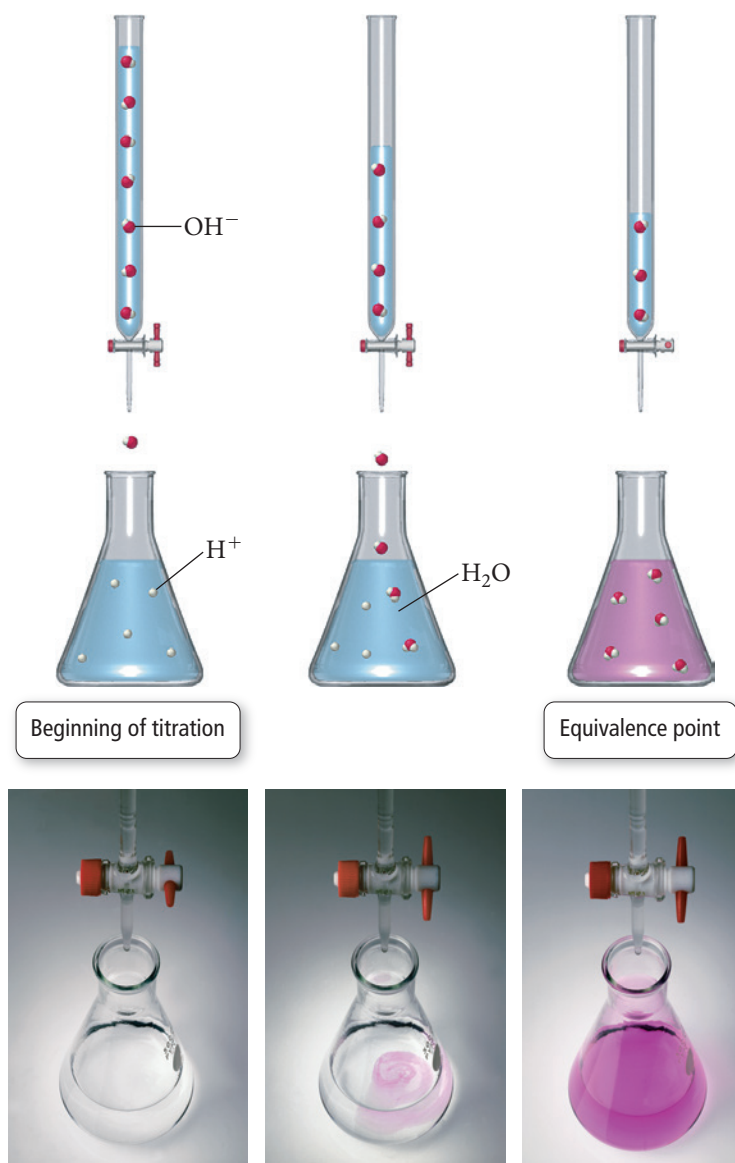

We first examined acid–base titrations in Section 4.8. In an **acid–base titration**, a basic (or acidic) solution of unknown concentration reacts with an acidic (or basic) solution of known concentration. The known solution is slowly added to the unknown one while the pH is monitored with either a pH meter or an **indicator** (a substance whose color depends on the pH). As the acid and base combine, they neutralize each other. At the **equivalence point**—the point in the titration when the number of moles of base is stoichiometrically equal to the number of moles of acid—the titration is complete. When the equivalence point is reached, neither reactant is in excess and the number of moles of the reactants are related by the reaction stoichiometry (Figure 17.5▼).

In this section, we examine acid–base titrations more closely, concentrating on the pH changes that occur during the titration. A plot of the pH of the solution during a titration is known as a *titration curve* or *pH curve*. Figure 17.6▼ is a pH curve for the titration of HCl with NaOH. Before any base is added to the solution, the pH is low (as we would expect for a solution of HCl). As the NaOH is added, the solution becomes less acidic because the NaOH begins to neutralize the HCl. The point of inflection in the

**The Titration of a Weak Acid and a Strong Base**

The equivalence point is so named because the number of moles of acid and base are stoichiometrically equivalent at this point.

▲ **FIGURE 17.5 Acid–Base Titration** As  $\text{OH}^-$  is added in a titration, it neutralizes the  $\text{H}^+$ , forming water. At the equivalence point, the titration is complete.

▲ **FIGURE 17.6 Titration Curve: Strong Acid + Strong Base** This curve represents the titration of 50.0 mL of 0.100 M HCl with 0.100 M NaOH.

middle of the curve is the equivalence point. Notice that the pH changes very quickly near the equivalence point (small amounts of added base cause large changes in pH). Beyond the equivalence point, the solution is basic because the HCl has been completely neutralized and excess base is being added to the solution. The exact shape of the pH curve depends on several factors, including the strength of the acid or base being titrated. Let's consider several combinations individually.

## The Titration of a Strong Acid with a Strong Base

Consider the titration of 25.0 mL of 0.100 M HCl with 0.100 M NaOH. We begin by calculating the volume of base required to reach the equivalence point and then the pH at several points during the titration.

### Volume of NaOH Required to Reach the Equivalence Point

During the titration, the added sodium hydroxide neutralizes the hydrochloric acid:

The equivalence point is reached when the number of moles of base added equals the number of moles of acid initially in solution. We calculate the amount of acid initially in solution from its volume and its concentration:

$$\text{Initial mol HCl} = 0.0250 \text{ L} \times \frac{0.100 \text{ mol}}{1 \text{ L}} = 0.00250 \text{ mol HCl}$$

The amount of NaOH that must be added is 0.00250 mol NaOH. We calculate the volume of NaOH required from its concentration:

$$\text{Volume NaOH solution} = 0.00250 \text{ mol} \times \frac{1 \text{ L}}{0.100 \text{ mol}} = 0.0250 \text{ L}$$

The equivalence point is reached when 25.0 mL of NaOH has been added. In this case, the concentrations of both solutions are identical, so the volume of NaOH solution required to reach the equivalence point is equal to the volume of the HCl solution that is being titrated.

### Initial pH (before Adding Any Base)

The initial pH of the solution is simply the pH of a 0.100 M HCl solution. Since HCl is a strong acid, the concentration of  $\text{H}_3\text{O}^+$  is also 0.100 M and the pH is 1.00:

$$\begin{aligned} \text{pH} &= -\log[\text{H}_3\text{O}^+] \\ &= -\log(0.100) \\ &= 1.00 \end{aligned}$$

### pH after Adding 5.00 mL NaOH

As NaOH is added to the solution, it neutralizes  $\text{H}_3\text{O}^+$ :

We calculate the amount of  $\text{H}_3\text{O}^+$  at any given point (before the equivalence point) by using the reaction stoichiometry—1 mol of NaOH neutralizes 1 mol of  $\text{H}_3\text{O}^+$ . The initial number of moles of  $\text{H}_3\text{O}^+$  (as just calculated) is 0.00250 mol. We calculate the number of moles of NaOH added at 5.00 mL by multiplying the added volume (in L) by the concentration of the NaOH solution:

$$\text{mol NaOH added} = 0.00500 \text{ L} \times \frac{0.100 \text{ mol}}{1 \text{ L}} = 0.000500 \text{ mol NaOH}$$

The addition of  $\text{OH}^-$  causes the amount of  $\text{H}_3\text{O}^+$  to decrease as shown in the following table:

	$\text{OH}^-(aq)$	+	$\text{H}_3\text{O}^+(aq)$	$\longrightarrow 2 \text{H}_2\text{O}(l)$
<b>Before addition</b>	$\approx 0.00 \text{ mol}$		0.00250 mol	
<b>Addition</b>	0.000500 mol		—	
<b>After addition</b>	$\approx 0.00 \text{ mol}$		0.00200 mol	

We calculate the  $\text{H}_3\text{O}^+$  concentration by dividing the number of moles of  $\text{H}_3\text{O}^+$  remaining by the *total volume* (initial volume plus added volume):

$$[\text{H}_3\text{O}^+] = \frac{0.00200 \text{ mol H}_3\text{O}^+}{0.0250 \text{ L} + 0.00500 \text{ L}} = 0.0667 \text{ M}$$

Initial volume
Added volume

The pH is therefore 1.18:

$$\begin{aligned}\text{pH} &= -\log 0.0667 \\ &= 1.18\end{aligned}$$

### pH after Adding 10.0, 15.0, and 20.0 mL NaOH

As more NaOH is added, it further neutralizes the  $\text{H}_3\text{O}^+$  in the solution. We calculate the pH at each of these points in the same way that we calculated the pH at the 5.00 mL point. The results are tabulated as follows:

Volume (mL)	pH
10.0	1.37
15.0	1.60
20.0	1.95

### pH after Adding 25.0 mL NaOH (Equivalence Point)

The pH at the equivalence point of a strong acid–strong base titration will always be 7.00 (at 25 °C). At the equivalence point, the strong base has completely neutralized the strong acid. The only source of hydronium ions then is the ionization of water. The  $[\text{H}_3\text{O}^+]$  at 25 °C from the ionization of water is  $1.00 \times 10^{-7} \text{ M}$  and the pH is 7.00.

### pH after Adding 30.00 mL NaOH

As NaOH is added beyond the equivalence point, it becomes the excess reagent. We calculate the amount of  $\text{OH}^-$  at any given point (past the equivalence point) by subtracting the initial amount of  $\text{H}_3\text{O}^+$  from the amount of added  $\text{OH}^-$ . The number of moles of  $\text{OH}^-$  added at 30.00 mL is:

$$\text{mol OH}^- \text{ added} = 0.0300 \text{ L} \times \frac{0.100 \text{ mol}}{1 \text{ L}} = 0.00300 \text{ mol OH}^-$$

The number of moles of  $\text{OH}^-$  remaining after neutralization is shown in the following table:

	$\text{OH}^-(\text{aq})$	$+$	$\text{H}_3\text{O}^+(\text{aq})$	$\longrightarrow$	$2 \text{ H}_2\text{O}(\text{l})$
<b>Before addition</b>	$\approx 0.00 \text{ mol}$		0.00250 mol		
<b>Addition</b>	0.00300 mol		—		
<b>After addition</b>	0.00050 mol		$\approx 0.00 \text{ mol}$		

We calculate the  $\text{OH}^-$  concentration by dividing the number of moles of  $\text{OH}^-$  remaining by the *total volume* (initial volume plus added volume):

$$[\text{OH}^-] = \frac{0.000500 \text{ mol OH}^-}{0.0250 \text{ L} + 0.0300 \text{ L}} = 0.00909 \text{ M}$$

We can then calculate the  $[\text{H}_3\text{O}^+]$  and pH:

$$\begin{aligned}[\text{H}_3\text{O}^+][\text{OH}^-] &= 10^{-14} \\ [\text{H}_3\text{O}^+] &= \frac{10^{-14}}{[\text{OH}^-]} = \frac{10^{-14}}{0.00909} \\ &= 1.10 \times 10^{-12} \text{ M} \\ \text{pH} &= -\log(1.10 \times 10^{-12}) \\ &= 11.96\end{aligned}$$

### pH after Adding 35.0, 40.0, and 50.0 mL NaOH

As more NaOH is added, it further increases the basicity of the solution. We calculate the pH at each of these points in the same way that we calculated the pH at the 30.00 mL point. The results are tabulated as follows:

Volume (mL)	pH
35.0	12.22
40.0	12.36
50.0	12.52

### The Overall pH Curve

The overall pH curve for the titration of a strong acid with a strong base has the characteristic S-shape we just plotted. The overall curve is as follows:

#### Summarizing the Titration of a Strong Acid with a Strong Base:

- ▶ The initial pH is simply the pH of the strong acid solution to be titrated.
- ▶ Before the equivalence point,  $\text{H}_3\text{O}^+$  is in excess. Calculate the  $[\text{H}_3\text{O}^+]$  by subtracting the number of moles of added  $\text{OH}^-$  from the initial number of moles of  $\text{H}_3\text{O}^+$  and dividing by the *total* volume.
- ▶ At the equivalence point, neither reactant is in excess and the  $\text{pH} = 7.00$ .
- ▶ Beyond the equivalence point,  $\text{OH}^-$  is in excess. Calculate the  $[\text{OH}^-]$  by subtracting the initial number of moles of  $\text{H}_3\text{O}^+$  from the number of moles of added  $\text{OH}^-$  and dividing by the *total* volume.

The pH curve for the titration of a strong base with a strong acid is shown in Figure 17.7. Calculating the points along this curve is very similar to calculating the points along the pH curve for the titration of a strong acid with a strong base. The main difference is that the curve starts basic and then becomes acidic after the equivalence point (instead of vice versa).

▶ **FIGURE 17.7 Titration Curve: Strong Base + Strong Acid** This curve represents the titration of 25.0 mL of 0.100 M NaOH with 0.100 M HCl.

**Example 17.6** Strong Acid–Strong Base Titration pH Curve

A 50.0-mL sample of 0.200 M sodium hydroxide is titrated with 0.200 M nitric acid. Calculate pH:

- (a) after adding 30.00 mL of  $\text{HNO}_3$       (b) at the equivalence point

**SOLUTION**

- (a) Begin by calculating the initial amount of NaOH (in moles) from the volume and molarity of the NaOH solution. Because NaOH is a strong base, it dissociates completely, so the amount of  $\text{OH}^-$  is equal to the amount of NaOH.

$$\begin{aligned}\text{moles NaOH} &= 0.0500 \text{ L} \times \frac{0.200 \text{ mol}}{1 \text{ L}} \\ &= 0.0100 \text{ mol} \\ \text{moles OH}^- &= 0.0100 \text{ mol}\end{aligned}$$

Calculate the amount of  $\text{HNO}_3$  (in moles) added at 30.0 mL from the molarity of the  $\text{HNO}_3$  solution.

$$\begin{aligned}\text{mol HNO}_3 \text{ added} &= 0.0300 \text{ L} \times \frac{0.200 \text{ mol}}{1 \text{ L}} \\ &= 0.00600 \text{ mol HNO}_3\end{aligned}$$

As  $\text{HNO}_3$  is added to the solution, it neutralizes some of the  $\text{OH}^-$ . Calculate the number of moles of  $\text{OH}^-$  remaining by setting up a table based on the neutralization reaction that shows the amount of  $\text{OH}^-$  before the addition, the amount of  $\text{H}_3\text{O}^+$  added, and the amounts left after the addition.

	$\text{OH}^-(aq)$	+	$\text{H}_3\text{O}^+(aq)$	$\longrightarrow$	$2 \text{H}_2\text{O}(l)$
<b>Before addition</b>	0.0100 mol		$\approx 0.00$ mol		
<b>Addition</b>	—		0.00600 mol		
<b>After addition</b>	0.0040 mol		0.00 mol		

Calculate the  $\text{OH}^-$  concentration by dividing the amount of  $\text{OH}^-$  remaining by the *total volume* (initial volume plus added volume).

$$\begin{aligned}[\text{OH}^-] &= \frac{0.0040 \text{ mol}}{0.0500 \text{ L} + 0.0300 \text{ L}} \\ &= 0.0500 \text{ M}\end{aligned}$$

Calculate the pOH from  $[\text{OH}^-]$ .

$$\begin{aligned}\text{pOH} &= -\log(0.0500) \\ &= 1.30\end{aligned}$$

Calculate the pH from the pOH using the equation  $\text{pH} + \text{pOH} = 14$ .

$$\begin{aligned}\text{pH} &= 14 - \text{pOH} \\ &= 14 - 1.30 \\ &= 12.70\end{aligned}$$

- (b) At the equivalence point, the strong base has completely neutralized the strong acid. The  $[\text{H}_3\text{O}^+]$  at 25 °C from the ionization of water is  $1.00 \times 10^{-7} \text{ M}$  and the pH is therefore 7.00.

$$\text{pH} = 7.00$$

**FOR PRACTICE 17.6** Calculate the pH in the titration in Example 17.6 after the addition of 60.0 mL of 0.200 M  $\text{HNO}_3$ .

**Titration Equivalence Point** The amount of strong acid in the flask shown here is to be titrated by a strong base. Which mark on the burette next to the flask indicates the amount of base required to reach the equivalence point?

- (a) A  
(b) B  
(c) C  
(d) D

CONCEPTUAL  
**CONNECTION 17.6**

## The Titration of a Weak Acid with a Strong Base

Consider the titration of 25.0 mL of 0.100 M  $\text{HCHO}_2$  with 0.100 M  $\text{NaOH}$ :

The concentrations and the volumes here are identical to those in our previous titration, in which we calculated the pH curve for the titration of a *strong* acid with a strong base. The only difference is that  $\text{HCHO}_2$  is a *weak* acid rather than a strong one. We begin by calculating the volume required to reach the equivalence point of the titration.

### Volume of NaOH Required to Reach the Equivalence Point

From the stoichiometry of the equation, we can see that the equivalence point occurs when the amount (in moles) of added base equals the amount (in moles) of acid initially in solution:

$$\text{Initial mol HCHO}_2 = 0.0250 \text{ L} \times \frac{0.100 \text{ mol}}{1 \text{ L}} = 0.00250 \text{ mol HCHO}_2$$

The amount of  $\text{NaOH}$  that must be added is 0.00250 mol  $\text{NaOH}$ . The volume of  $\text{NaOH}$  required is therefore:

$$\text{Volume NaOH solution} = 0.00250 \text{ mol} \times \frac{1 \text{ L}}{0.100 \text{ mol}} = 0.0250 \text{ L NaOH solution}$$

The equivalence point occurs when 25.0 mL of base has been added. Notice that the volume of  $\text{NaOH}$  required to reach the equivalence point for this weak acid is identical to that required for a strong acid. *The volume at the equivalence point in an acid–base titration does not depend on whether the acid being titrated is a strong acid or a weak acid; it depends only on the amount (in moles) of acid present in solution before the titration begins and on the concentration of the added base.*

### Initial pH (before Adding Any Base)

The initial pH of the solution is the pH of a 0.100 M  $\text{HCHO}_2$  solution. Since  $\text{HCHO}_2$  is a weak acid, we calculate the concentration of  $\text{H}_3\text{O}^+$  and the pH by doing an equilibrium problem for the ionization of  $\text{HCHO}_2$ . The procedure for solving weak acid ionization problems is given in Examples 16.5 and 16.6. We show a highly condensed calculation here ( $K_a$  for  $\text{HCHO}_2$  is  $1.8 \times 10^{-4}$ ):

	$[\text{HCHO}_2]$	$[\text{H}_3\text{O}^+]$	$[\text{CHO}_2^-]$
Initial	0.100	$\approx 0.00$	0.00
Change	$-x$	$+x$	$+x$
Equil	$0.100 - x$	$x$	$x$

$$K_a = \frac{[\text{H}_3\text{O}^+][\text{CHO}_2^-]}{[\text{HCHO}_2]}$$

$$= \frac{x^2}{0.100 - x} \quad (x \text{ is small})$$

$$1.8 \times 10^{-4} = \frac{x^2}{0.100}$$

$$x = 4.24 \times 10^{-3}$$

Therefore,  $[\text{H}_3\text{O}^+] = 4.24 \times 10^{-3} \text{ M}$ .

$$\text{pH} = -\log(4.24 \times 10^{-3})$$

$$= 2.37$$

Notice that the pH is initially at a higher value (less acidic) than it is for a strong acid of the same concentration, as we would expect because the acid is weak.

### pH after Adding 5.00 mL NaOH

When titrating a *weak acid* with a strong base, the added  $\text{NaOH}$  converts a stoichiometric amount of the acid into its conjugate base. As we calculated previously, 5.00 mL of the 0.100 M  $\text{NaOH}$  solution contains 0.000500 mol  $\text{OH}^-$ . When the 0.000500 mol  $\text{OH}^-$  is added to the

weak acid solution, the OH<sup>−</sup> reacts stoichiometrically with HCHO<sub>2</sub> causing the amount of HCHO<sub>2</sub> to *decrease* by 0.000500 mol and the amount of CHO<sub>2</sub><sup>−</sup> to *increase* by 0.000500 mol. This is very similar to what happens when we add strong base to a buffer, and it is summarized in the following table:

	OH <sup>−</sup> (aq)	+ HCHO <sub>2</sub> (aq)	→ H <sub>2</sub> O(l)	+ CHO <sub>2</sub> <sup>−</sup> (aq)
Before addition	≈ 0.00 mol	0.00250 mol	—	0.00 mol
Addition	0.000500 mol	—	—	—
After addition	≈ 0.00 mol	0.00200 mol	—	0.000500 mol

Notice that, after the addition, the solution contains significant amounts of both an acid (HCHO<sub>2</sub>) and its conjugate base (CHO<sub>2</sub><sup>−</sup>)—the solution is now a buffer. To calculate the pH of a buffer (when the *x* is *small* approximation applies as it does here), we can use the Henderson–Hasselbalch equation and pK<sub>a</sub> for HCHO<sub>2</sub> (which is 3.74):

$$\begin{aligned} \text{pH} &= \text{p}K_a + \log \frac{[\text{base}]}{[\text{acid}]} \\ &= 3.74 + \log \frac{0.000500}{0.00200} \\ &= 3.74 - 0.60 \\ &= 3.14 \end{aligned}$$

pH after Adding 10.0, 12.5, 15.0, and 20.0 mL NaOH

As more NaOH is added, it converts more HCHO<sub>2</sub> into CHO<sub>2</sub><sup>−</sup>. We calculate the relative amounts of HCHO<sub>2</sub> and CHO<sub>2</sub><sup>−</sup> at each of these volumes using the reaction stoichiometry and then calculate the pH of the resulting buffer using the Henderson–Hasselbalch equation (as we did for the pH at 5.00 mL). The amounts of HCHO<sub>2</sub> and CHO<sub>2</sub><sup>−</sup> (after addition of the OH<sup>−</sup>) at each volume and the corresponding values of pH are tabulated as follows:

Volume (mL)	mol HCHO <sub>2</sub>	mol CHO <sub>2</sub> <sup>−</sup>	pH
10.0	0.00150	0.00100	3.56
12.5	0.00125	0.00125	3.74
15.0	0.00100	0.00150	3.92
20.0	0.00050	0.00200	4.34

As the titration proceeds, more of the HCHO<sub>2</sub> is converted to the conjugate base (CHO<sub>2</sub><sup>−</sup>). Notice that an added NaOH volume of 12.5 mL corresponds to one-half of the equivalence point. At this volume, one-half of the initial amount of HCHO<sub>2</sub> has been converted to CHO<sub>2</sub><sup>−</sup>, resulting in *equal amounts of weak acid and conjugate base*. For any buffer in which the amounts of weak acid and conjugate base are equal, the pH = pK<sub>a</sub>:

$$\text{pH} = \text{p}K_a + \log \frac{[\text{base}]}{[\text{acid}]}$$

If [base] = [acid], then [base]/[acid] = 1.

$$\begin{aligned} \text{pH} &= \text{p}K_a + \log 1 \\ &= \text{p}K_a + 0 \\ &= \text{p}K_a \end{aligned}$$

pH after Adding 25.0 mL NaOH (Equivalence Point)

At the equivalence point, 0.00250 mol of OH<sup>−</sup> has been added and therefore all of the HCHO<sub>2</sub> has been converted into its conjugate base (CHO<sub>2</sub><sup>−</sup>) as summarized in the following table:

	OH <sup>−</sup> (aq)	+ HCHO <sub>2</sub> (aq)	→ H <sub>2</sub> O(l)	+ CHO <sub>2</sub> <sup>−</sup> (aq)
Before addition	≈ 0.00 mol	0.00250 mol	—	0.00 mol
Addition	0.00250 mol	—	—	—
After addition	≈ 0.00 mol	0.00 mol	—	0.00250 mol

Since pH = pK<sub>a</sub> halfway to the equivalence point, titrations can be used to measure the pK<sub>a</sub> of an acid.

The solution is no longer a buffer (it no longer contains significant amounts of both a weak acid and its conjugate base). Instead, the solution contains an ion ( $\text{CHO}_2^-$ ) acting as a weak base. We discussed how to calculate the pH of solutions such as this in Section 16.8 (see Example 16.14) by solving an equilibrium problem involving the ionization of water by the weak base ( $\text{CHO}_2^-$ ):

We calculate the initial concentration of  $\text{CHO}_2^-$  for the equilibrium problem by dividing the number of moles of  $\text{CHO}_2^-$  (0.00250 mol) by the *total* volume at the equivalence point (initial volume plus added volume):

$$[\text{CHO}_2^-] = \frac{\text{Moles } \text{CHO}_2^- \text{ at equivalence point}}{\text{Initial volume} + \text{Added volume at equivalence point}} = \frac{0.00250 \text{ mol}}{0.0250 \text{ L} + 0.0250 \text{ L}} = 0.0500 \text{ M}$$

We then proceed to solve the equilibrium problem as shown in condensed form as follows:

	$[\text{CHO}_2^-]$	$[\text{HCHO}_2]$	$[\text{OH}^-]$
Initial	0.0500	0.00	$\approx 0.00$
Change	$-x$	$+x$	$+x$
Equil	$0.0500 - x$	$x$	$x$

Before substituting into the expression for  $K_b$ , we find the value of  $K_b$  from  $K_a$  for formic acid ( $K_a = 1.8 \times 10^{-4}$ ) and  $K_w$ :

$$K_a \times K_b = K_w$$

$$K_b = \frac{K_w}{K_a} = \frac{1.0 \times 10^{-14}}{1.8 \times 10^{-4}} = 5.6 \times 10^{-11}$$

Then we substitute the equilibrium concentrations from the previous table into the expression for  $K_b$ :

$$K_b = \frac{[\text{HCHO}_2][\text{OH}^-]}{[\text{CHO}_2^-]}$$

$$= \frac{x^2}{0.0500 - x} \quad (x \text{ is small})$$

$$5.6 \times 10^{-11} = \frac{x^2}{0.0500}$$

$$x = 1.7 \times 10^{-6}$$

Remember that  $x$  represents the concentration of the hydroxide ion. We calculate  $[\text{H}_3\text{O}^+]$  and pH:

$$[\text{OH}^-] = 1.7 \times 10^{-6} \text{ M}$$

$$[\text{H}_3\text{O}^+][\text{OH}^-] = K_w = 1.0 \times 10^{-14}$$

$$[\text{H}_3\text{O}^+](1.7 \times 10^{-6}) = 1.0 \times 10^{-14}$$

$$[\text{H}_3\text{O}^+] = 5.9 \times 10^{-9} \text{ M}$$

$$\text{pH} = -\log[\text{H}_3\text{O}^+]$$

$$= -\log(5.9 \times 10^{-9})$$

$$= 8.23$$

Notice that the pH at the equivalence point is *not* neutral but basic. *The titration of a weak acid by a strong base always has a basic equivalence point* because, at the equivalence point, all of the acid has been converted into its conjugate base, resulting in a weakly basic solution.

### pH after Adding 30.00 mL NaOH

At this point in the titration, 0.00300 mol of  $\text{OH}^-$  has been added. NaOH has thus become the excess reagent as shown in the following table:

	$\text{OH}^-(aq)$	+	$\text{HCHO}_2(aq)$	$\longrightarrow$	$\text{H}_2\text{O}(l)$	+	$\text{CHO}_2^-(aq)$
<b>Before addition</b>	$\approx 0.00$ mol		0.00250 mol		—		0.00 mol
<b>Addition</b>	0.00300 mol		—		—		—
<b>After addition</b>	0.00050 mol		$\approx 0.00$ mol		—		0.00250 mol

The solution is now a mixture of a strong base (NaOH) and a weak base ( $\text{CHO}_2^-$ ). The strong base completely overwhelms the weak base, and we can calculate the pH by considering the strong base alone (as we did for the titration of a strong acid and a strong base). We calculate the  $\text{OH}^-$  concentration by dividing the amount of  $\text{OH}^-$  remaining by the *total volume* (initial volume plus added volume):

$$[\text{OH}^-] = \frac{0.00050 \text{ mol OH}^-}{0.0250 \text{ L} + 0.0300 \text{ L}} = 0.0091 \text{ M}$$

We can then calculate the  $[\text{H}_3\text{O}^+]$  and pH:

$$[\text{H}_3\text{O}^+][\text{OH}^-] = 10^{-14}$$

$$[\text{H}_3\text{O}^+] = \frac{10^{-14}}{[\text{OH}^-]} = \frac{10^{-14}}{0.0091} = 1.1 \times 10^{-12} \text{ M}$$

$$\text{pH} = -\log(1.10 \times 10^{-12})$$

$$= 11.96$$

### pH after Adding 35.0, 40.0, and 50.0 mL NaOH

As more NaOH is added, the basicity of the solution increases further. We calculate the pH at each of these volumes in the same way we calculated the pH at 30.00 mL of added NaOH. The results are tabulated as follows:

Volume (mL)	pH
35.0	12.22
40.0	12.36
50.0	12.52

### The Overall pH Curve

The overall pH curve for the titration of a weak acid with a strong base has a characteristic S-shape similar to that for the titration of a strong acid with a strong base. The main difference is that the equivalence point pH is basic (not neutral). Notice that calculating the pH in different regions throughout the titration involves working different kinds of acid-base problems, all of which we have encountered before.

**Summarizing Titration of a Weak Acid with a Strong Base:**

- ▶ The initial pH is that of the weak acid solution to be titrated. Calculate the pH by working an equilibrium problem (similar to Examples 16.5 and 16.6) using the concentration of the weak acid as the initial concentration.
- ▶ Between the initial pH and the equivalence point, the solution becomes a buffer. Use the reaction stoichiometry to calculate the amounts of each buffer component and then use the Henderson–Hasselbalch equation to calculate the pH (as in Example 17.3).
- ▶ Halfway to the equivalence point, the buffer components are exactly equal and  $\text{pH} = \text{p}K_a$ .
- ▶ At the equivalence point, the acid has all been converted into its conjugate base. Calculate the pH by working an equilibrium problem for the ionization of water by the ion acting as a weak base (similar to Example 16.14). (Calculate the concentration of the ion acting as a weak base by dividing the number of moles of the ion by the total volume at the equivalence point.)
- ▶ Beyond the equivalence point,  $\text{OH}^-$  is in excess. Ignore the weak base and calculate the  $[\text{OH}^-]$  by subtracting the initial number of moles of the weak acid from the number of moles of added  $\text{OH}^-$  and dividing by the *total* volume.

**Example 17.7 Weak Acid–Strong Base Titration pH Curve**

A 40.0-mL sample of 0.100 M  $\text{HNO}_2$  is titrated with 0.200 M KOH. Calculate:

- the volume required to reach the equivalence point
- the pH after adding 5.00 mL of KOH
- the pH at one-half the equivalence point

**SOLUTION**

- (a)** The equivalence point occurs when the amount (in moles) of added base equals the amount (in moles) of acid initially in the solution. Begin by calculating the amount (in moles) of acid initially in the solution. The amount (in moles) of KOH that must be added is equal to the amount of the weak acid.

Calculate the volume of KOH required from the number of moles of KOH and the molarity.

$$\begin{aligned}\text{mol HNO}_2 &= 0.0400 \cancel{\text{L}} \times \frac{0.100 \text{ mol}}{1 \cancel{\text{L}}} \\ &= 4.00 \times 10^{-3} \text{ mol} \\ \text{mol KOH required} &= 4.00 \times 10^{-3} \text{ mol}\end{aligned}$$

$$\begin{aligned}\text{volume KOH solution} &= 4.00 \times 10^{-3} \cancel{\text{mol}} \times \frac{1 \text{ L}}{0.200 \cancel{\text{mol}}} \\ &= 0.0200 \text{ L KOH solution} \\ &= 20.0 \text{ mL KOH solution}\end{aligned}$$

- (b)** Use the concentration of the KOH solution to calculate the amount (in moles) of  $\text{OH}^-$  in 5.00 mL of the solution.

Prepare a table showing the amounts of  $\text{HNO}_2$  and  $\text{NO}_2^-$  before and after the addition of 5.00 mL KOH. The addition of the KOH stoichiometrically reduces the concentration of  $\text{HNO}_2$  and increases the concentration of  $\text{NO}_2^-$ .

Since the solution now contains significant amounts of a weak acid and its conjugate base, use the Henderson–Hasselbalch equation and  $\text{p}K_a$  for  $\text{HNO}_2$  (which is 3.34) to calculate the pH of the solution.

$$\begin{aligned}\text{mol OH}^- &= 5.00 \times 10^{-3} \cancel{\text{L}} \times \frac{0.200 \text{ mol}}{1 \cancel{\text{L}}} \\ &= 1.00 \times 10^{-3} \text{ mol OH}^-\end{aligned}$$

	$\text{OH}^-(aq)$	+	$\text{HNO}_2(aq)$	$\longrightarrow$	$\text{H}_2\text{O}(l)$	+	$\text{NO}_2^-(aq)$
<b>Before addition</b>	$\approx 0.00 \text{ mol}$		$4.00 \times 10^{-3} \text{ mol}$		—		$0.00 \text{ mol}$
<b>Addition</b>	$1.00 \times 10^{-3} \text{ mol}$		—		—		—
<b>After addition</b>	$\approx 0.00 \text{ mol}$		$3.00 \times 10^{-3} \text{ mol}$		—		$1.00 \times 10^{-3} \text{ mol}$

$$\begin{aligned}\text{pH} &= \text{p}K_a + \log \frac{[\text{base}]}{[\text{acid}]} \\ &= 3.34 + \log \frac{1.00 \times 10^{-3}}{3.00 \times 10^{-3}} \\ &= 3.34 - 0.48 = 2.86\end{aligned}$$

- (c) At one-half the equivalence point, the amount of added base is exactly one-half the initial amount of acid. The base converts exactly half of the  $\text{HNO}_2$  into  $\text{NO}_2^-$ , resulting in equal amounts of the weak acid and its conjugate base. The pH is therefore equal to  $\text{p}K_a$ .

	$\text{OH}^-(\text{aq})$	+	$\text{HNO}_2(\text{aq}) \longrightarrow \text{H}_2\text{O}(\text{l}) + \text{NO}_2^-(\text{aq})$
<b>Before addition</b>	$\approx 0.00 \text{ mol}$		$4.00 \times 10^{-3} \text{ mol}$ — 0.00 mol
<b>Addition</b>	$2.00 \times 10^{-3} \text{ mol}$		— — —
<b>After addition</b>	$\approx 0.00 \text{ mol}$		$2.00 \times 10^{-3} \text{ mol}$ — $2.00 \times 10^{-3} \text{ mol}$

$$\text{pH} = \text{p}K_a + \log \frac{[\text{base}]}{[\text{acid}]}$$

$$= 3.34 + \log \frac{2.00 \times 10^{-3}}{2.00 \times 10^{-3}} = 3.34 + 0 = 3.34$$

**FOR PRACTICE 17.7** Determine the pH at the equivalence point for the titration of  $\text{HNO}_2$  and  $\text{KOH}$  in Example 17.7.

## The Titration of a Weak Base with a Strong Acid

The pH curve for the titration of a weak base with a strong acid is shown in Figure 17.8. Calculating the points along this curve is very similar to calculating the points along the pH curve for the titration of a weak acid with a strong base (which we just did). The main differences are that the curve starts basic and has an acidic equivalence point. We calculate the pH in the buffer region using  $\text{pH} = \text{p}K_a + \log \frac{[\text{base}]}{[\text{acid}]}$  where the  $\text{p}K_a$  corresponds to the conjugate acid of the base being titrated.

**The Half-Equivalence Point** What is the pH at the half-equivalence point in the titration of a weak base with a strong acid? The  $\text{p}K_b$  of the weak base is 8.75.

- (a) 8.75      (b) 7.0      (c) 5.25      (d) 4.37

CONCEPTUAL  
CONNECTION 17.7

## The Titration of a Polyprotic Acid

When a diprotic acid is titrated with a strong base, if  $K_{a1}$  and  $K_{a2}$  are sufficiently different, the pH curve will have two equivalence points. For example, Figure 17.9 shows the pH

**▲ FIGURE 17.8 Titration Curve: Weak Base with Strong Acid** This curve represents the titration of 0.100 M  $\text{NH}_3$  with 0.100 M  $\text{HCl}$ .

**▲ FIGURE 17.9 Titration Curve: Diprotic Acid with Strong Base** This curve represents the titration of 25.0 mL of 0.100 M  $\text{H}_2\text{SO}_3$  with 0.100 M  $\text{NaOH}$ .

curve for the titration of sulfurous acid ( $\text{H}_2\text{SO}_3$ ) with sodium hydroxide. Recall from Section 16.9 that sulfurous acid ionizes in two steps as follows:

The first equivalence point in the titration curve represents the titration of the first proton, whereas the second equivalence point represents the titration of the second proton. Notice that the volume required to reach the first equivalence point is identical to the volume required to reach the second point because the number of moles of  $\text{H}_2\text{SO}_3$  in the first step determines the number of moles of  $\text{HSO}_3^-$  in the second step.

## CONCEPTUAL CONNECTION 17.8

### Acid–Base Titrations

- Consider these three titrations:
- (i) the titration of 25.0 mL of a 0.100 M monoprotic weak acid with 0.100 M NaOH
  - (ii) the titration of 25.0 mL of a 0.100 M diprotic weak acid with 0.100 M NaOH
  - (iii) the titration of 25.0 mL of a 0.100 M strong acid with 0.100 M NaOH

Which statement is most likely to be true?

- (a) All three titrations have the same initial pH.
- (b) All three titrations have the same pH at their first equivalence points.
- (c) All three titrations require the same volume of NaOH to reach their first equivalence points.

### Indicators: pH-Dependent Colors

We can monitor the pH of a titration with either a pH meter or an indicator. The direct monitoring of pH with a meter yields data like the pH curves we have examined previously, allowing determination of the equivalence point from the pH curve itself, as shown in Figure 17.10. With an indicator, we rely on the point where the indicator changes color—called the **endpoint**—to determine the equivalence point, as shown

**▲ FIGURE 17.10 Monitoring the pH during a Titration** A pH meter monitors pH during titration. The inflection point in the resulting pH curve signifies the equivalence point.

## Using an Indicator

**FIGURE 17.11** Monitoring the Color Change during a Titration

Titration of 0.100 M  $\text{HC}_2\text{H}_3\text{O}_2$  with 0.100 M NaOH. The endpoint of a titration is signaled by a color change in an appropriate indicator (in this case, phenolphthalein).

in Figure 17.11▲. With the correct indicator, the endpoint of the titration (indicated by the color change) occurs at the equivalence point (when the amount of acid equals the amount of base).

An indicator is itself a weak organic acid that is a different color than its conjugate base. For example, phenolphthalein (whose structure is shown in Figure 17.12▼) is a common indicator whose acid form is colorless and conjugate base form is pink. If we let  $\text{HIn}$  represent the acid form of a generic indicator and  $\text{In}^-$  the conjugate base form, we have the following equilibrium:

Because its color is intense, only a small amount of indicator is required—an amount that will not affect the pH of the solution or the equivalence point of the neutralization reaction. When the  $[\text{H}_3\text{O}^+]$  changes during the titration, the equilibrium shifts in response. At low pH, the  $[\text{H}_3\text{O}^+]$  is high and the equilibrium lies far to the left, resulting in a solution of color 1. As the titration proceeds, the  $[\text{H}_3\text{O}^+]$  decreases, shifting the equilibrium to the right. Since the pH change is large near the equivalence point of the titration, there is a

## Phenolphthalein, a Common Indicator

**FIGURE 17.12** Phenolphthalein Phenolphthalein, a weakly acidic compound, is colorless. Its conjugate base is pink.

large change in  $[H_3O^+]$  near the equivalence point. Provided that the correct indicator is chosen, there will also be a correspondingly significant change in color. For the titration of a strong acid with a strong base, one drop of the base near the endpoint is usually enough to change the indicator from color 1 to color 2.

The color of a solution containing an indicator depends on the relative concentrations of  $HIn$  and  $In^-$ . As a useful guideline, we can assume the following:

If  $\frac{[In^-]}{[HIn]} = 1$ , the indicator solution will be intermediate in color.

If  $\frac{[In^-]}{[HIn]} > 10$ , the indicator solution will be the color of  $In^-$ .

If  $\frac{[In^-]}{[HIn]} < 0.1$ , the indicator solution will be the color of  $HIn$ .

From the Henderson-Hasselbalch equation, we can derive an expression for the ratio of  $[In^-]/[HIn]$ :

$$\begin{aligned} pH &= pK_a + \log \frac{[base]}{[acid]} \\ &= pK_a + \log \frac{[In^-]}{[HIn]} \\ \log \frac{[In^-]}{[HIn]} &= pH - pK_a \\ \frac{[In^-]}{[HIn]} &= 10^{(pH - pK_a)} \end{aligned}$$

Consider the following three pH values relative to  $pK_a$  and the corresponding colors of the indicator solution:

pH (relative to $pK_a$ )	$[In^-]/[HIn]$ ratio	Color of Indicator Solution
$pH = pK_a$	$\frac{[In^-]}{[HIn]} = 10^0 = 1$	Intermediate color
$pH = pK_a + 1$	$\frac{[In^-]}{[HIn]} = 10^1 = 10$	Color of $In^-$
$pH = pK_a - 1$	$\frac{[In^-]}{[HIn]} = 10^{-1} = 0.10$	Color of $HIn$

Indicator Color Change: Methyl Red

When the pH of the solution equals the  $pK_a$  of the indicator, the solution has an intermediate color. When the pH is 1 unit (or more) above  $pK_a$ , the indicator is the color of  $In^-$ , and when the pH is 1 unit (or more) below  $pK_a$ , the indicator is the color of  $HIn$ . As you can see, the indicator changes color within a range of two pH units centered at  $pK_a$  (Figure 17.13 ◀). Table 17.1 shows various indicators and their colors as a function of pH.

◀ **FIGURE 17.13** Indicator Color Change

An indicator (in this case, methyl red) generally changes color within a range of two pH units. (The pH for each solution is marked on its test tube.)

## 17.5 Solubility Equilibria and the Solubility Product Constant

Recall from Chapter 4 that a compound is considered *soluble* if it dissolves in water and *insoluble* if it does not. Recall also that, with the *solubility rules* in Table 4.1, we were able to classify ionic compounds simply as soluble or insoluble. Now we have the tools to examine *degrees* of solubility.

We can better understand the solubility of an ionic compound by applying the concept of equilibrium to the process of dissolution. For example, we can represent the dissolution of calcium fluoride in water as an equilibrium:

The equilibrium constant for a chemical equation representing the dissolution of an ionic compound is the **solubility product constant ( $K_{\text{sp}}$ )**. For  $\text{CaF}_2$ , the expression of the solubility product constant is:

$$K_{\text{sp}} = [\text{Ca}^{2+}][\text{F}^{-}]^2$$

Notice that, as we discussed in Section 15.5, solids are omitted from the equilibrium expression because the concentration of a solid is constant (it is determined by its density and does not change when more solid is added).

The value of  $K_{\text{sp}}$  is a measure of the solubility of a compound. Table 17.2 lists the values of  $K_{\text{sp}}$  for a number of ionic compounds. A more complete list can be found in Appendix IIC.

### $K_{\text{sp}}$ and Molar Solubility

Recall from Section 13.2 that the *solubility* of a compound is the quantity of the compound that dissolves in a certain amount of liquid. The **molar solubility** is the solubility in units of moles per liter (mol/L). We can calculate the molar solubility of a compound directly from  $K_{\text{sp}}$ .

Consider silver chloride:

**TABLE 17.2** Selected Solubility Product Constants ( $K_{sp}$ ) at 25 °C

Compound	Formula	$K_{sp}$	Compound	Formula	$K_{sp}$
Barium fluoride	BaF <sub>2</sub>	$2.45 \times 10^{-5}$	Lead(II) chloride	PbCl <sub>2</sub>	$1.17 \times 10^{-5}$
Barium sulfate	BaSO <sub>4</sub>	$1.07 \times 10^{-10}$	Lead(II) bromide	PbBr <sub>2</sub>	$4.67 \times 10^{-6}$
Calcium carbonate	CaCO <sub>3</sub>	$4.96 \times 10^{-9}$	Lead(II) sulfate	PbSO <sub>4</sub>	$1.82 \times 10^{-8}$
Calcium fluoride	CaF <sub>2</sub>	$1.46 \times 10^{-10}$	Lead(II) sulfide*	PbS	$9.04 \times 10^{-29}$
Calcium hydroxide	Ca(OH) <sub>2</sub>	$4.68 \times 10^{-6}$	Magnesium carbonate	MgCO <sub>3</sub>	$6.82 \times 10^{-6}$
Calcium sulfate	CaSO <sub>4</sub>	$7.10 \times 10^{-5}$	Magnesium hydroxide	Mg(OH) <sub>2</sub>	$2.06 \times 10^{-13}$
Copper(II) sulfide*	CuS	$1.27 \times 10^{-36}$	Silver chloride	AgCl	$1.77 \times 10^{-10}$
Iron(II) carbonate	FeCO <sub>3</sub>	$3.07 \times 10^{-11}$	Silver chromate	Ag <sub>2</sub> CrO <sub>4</sub>	$1.12 \times 10^{-12}$
Iron(II) hydroxide	Fe(OH) <sub>2</sub>	$4.87 \times 10^{-17}$	Silver bromide	AgBr	$5.35 \times 10^{-13}$
Iron(II) sulfide*	FeS	$3.72 \times 10^{-19}$	Silver iodide	AgI	$8.51 \times 10^{-17}$

\*Sulfide equilibrium is of the type:  $MS(s) + H_2O(l) \rightleftharpoons M^{2+}(aq) + HS^-(aq) + OH^-(aq)$

Notice that  $K_{sp}$  is *not* the molar solubility, but the solubility product constant. The solubility product constant has only one value at a given temperature. The solubility, however, can have different values in different kinds of solutions. For example, due to the common ion effect, the solubility of AgCl in pure water is different from its solubility in an NaCl solution, even though the solubility product constant is the same for both solutions. Notice also that the solubility of AgCl is directly related (by the reaction stoichiometry) to the amount of  $Ag^+$  or  $Cl^-$  present in solution when equilibrium is reached. Consequently, finding molar solubility from  $K_{sp}$  involves solving an equilibrium problem.

For AgCl, we set up an ICE table for the dissolution of AgCl into its ions in pure water:

	$[Ag^+]$	$[Cl^-]$
Initial	0.00	0.00
Change	+S	+S
Equil	S	S

Alternatively, the variable  $x$  can be used in place of  $S$ , as it was for other equilibrium calculations.

We let  $S$  represent the concentration of AgCl that dissolves (which is the molar solubility) and then represent the concentrations of the ions formed in terms of  $S$ . In this case, for every 1 mol of AgCl that dissolves, 1 mol of  $Ag^+$  and 1 mol of  $Cl^-$  are produced. Therefore, the concentrations of  $Ag^+$  or  $Cl^-$  present in solution are equal to  $S$ . Substituting the equilibrium concentrations of  $Ag^+$  and  $Cl^-$  into the expression for the solubility product constant, we get:

$$\begin{aligned} K_{sp} &= [Ag^+][Cl^-] \\ &= S \times S \\ &= S^2 \end{aligned}$$

Therefore,

$$\begin{aligned} S &= \sqrt{K_{sp}} \\ &= \sqrt{1.77 \times 10^{-10}} \\ &= 1.33 \times 10^{-5} M \end{aligned}$$

The molar solubility of AgCl is  $1.33 \times 10^{-5}$  mol per liter.

**Example 17.8** Calculating Molar Solubility from  $K_{sp}$ 

Calculate the molar solubility of  $\text{PbCl}_2$  in pure water.

**SOLUTION**

Begin by writing the reaction by which solid  $\text{PbCl}_2$  dissolves into its constituent aqueous ions and write the corresponding expression for  $K_{sp}$ .

Refer to the stoichiometry of the reaction and prepare an ICE table, showing the equilibrium concentrations of  $\text{Pb}^{2+}$  and  $\text{Cl}^{-}$  relative to  $S$ , the amount of  $\text{PbCl}_2$  that dissolves.

	$[\text{Pb}^{2+}]$	$[\text{Cl}^{-}]$
Initial	0.00	0.00
Change	+ $S$	+ $2S$
Equil	$S$	$2S$

Substitute the equilibrium expressions for  $[\text{Pb}^{2+}]$  and  $[\text{Cl}^{-}]$  from the previous step into the expression for  $K_{sp}$ .

$$K_{sp} = [\text{Pb}^{2+}][\text{Cl}^{-}]^2$$

$$= S(2S)^2 = 4S^3$$

Solve for  $S$  and substitute the numerical value of  $K_{sp}$  (from Table 17.2) to calculate  $S$ .

$$S = \sqrt[3]{\frac{K_{sp}}{4}}$$

$$S = \sqrt[3]{\frac{1.17 \times 10^{-5}}{4}} = 1.43 \times 10^{-2} \text{ M}$$

**FOR PRACTICE 17.8** Calculate the molar solubility of  $\text{Fe}(\text{OH})_2$  in pure water.

**Chemistry** IN YOUR DAY **Hard Water**

In many parts of the United States, significant concentrations of  $\text{CaCO}_3$  and  $\text{MgCO}_3$  dissolve into rainwater runoff as it flows through soils rich in these compounds. Water containing dissolved calcium and magnesium ions is known as *hard water*. Hard water is not a health hazard because both calcium and magnesium are part of a healthy diet. However, their presence in water can be a nuisance. Because of their relatively low solubility, hard water becomes saturated with  $\text{CaCO}_3$  and  $\text{MgCO}_3$  as it evaporates. If evaporation continues, some dissolved ions precipitate out as salts. These precipitates show up as scaly deposits on faucets, sinks, or cookware. Washing cars or dishes with hard water leaves spots of  $\text{CaCO}_3$  and  $\text{MgCO}_3$ .

Water can be softened with water softeners. These devices replace the  $\text{Ca}^{2+}$  and  $\text{Mg}^{2+}$  ions present in hard water with ions such as  $\text{K}^{+}$  or  $\text{Na}^{+}$ .

Since potassium and sodium salts are soluble, they do not form scaly deposits in the way that  $\text{Ca}^{2+}$  and  $\text{Mg}^{2+}$  ions do. However,

when sodium is used to soften drinking water, the resulting water is high in sodium content, a disadvantage to those who must control their sodium intake due to high blood pressure.

▲ The water in reservoirs where the soil is rich in limestone (calcium carbonate) contains  $\text{Ca}^{2+}$  ions. This so-called hard water contains dissolved  $\text{CaCO}_3$  and  $\text{MgCO}_3$ . When hard water evaporates, it can leave deposits of these salts on the shores of lakes and reservoirs (at left) and on plumbing fixtures (such as the pipe shown here).

**QUESTION**

Use the  $K_{sp}$  values from Table 17.2 to calculate the molar solubility of  $\text{CaCO}_3$  and  $\text{MgCO}_3$ . What mass of  $\text{CaCO}_3$  (in grams) is in 5 L of water that is saturated with  $\text{CaCO}_3$ ?

**Example 17.9** Calculating  $K_{sp}$  from Molar Solubility

The molar solubility of  $\text{Ag}_2\text{SO}_4$  in pure water is  $1.4 \times 10^{-2}$  M. Calculate  $K_{sp}$ .

**SOLUTION**

Begin by writing the reaction by which solid  $\text{Ag}_2\text{SO}_4$  dissolves into its constituent aqueous ions; then write the corresponding expression for  $K_{sp}$ .

Use an ICE table to define  $[\text{Ag}^+]$  and  $[\text{SO}_4^{2-}]$  in terms of  $S$ , the amount of  $\text{Ag}_2\text{SO}_4$  that dissolves.

	$[\text{Ag}^+]$	$[\text{SO}_4^{2-}]$
Initial	0.00	0.00
Change	+2S	+S
Equil	2S	S

Substitute the expressions for  $[\text{Ag}^+]$  and  $[\text{SO}_4^{2-}]$  from the previous step into the expression for  $K_{sp}$ . Substitute the given value of the molar solubility for  $S$  and calculate  $K_{sp}$ .

$$\begin{aligned} K_{sp} &= [\text{Ag}^+]^2[\text{SO}_4^{2-}] \\ &= (2S)^2S \\ &= 4S^3 \\ &= 4(1.4 \times 10^{-2})^3 \\ &= 1.1 \times 10^{-5} \end{aligned}$$

**FOR PRACTICE 17.9** The molar solubility of  $\text{AgBr}$  in pure water is  $7.3 \times 10^{-7}$  M. Calculate  $K_{sp}$ .

 **$K_{sp}$  and Relative Solubility**

As we have just seen, molar solubility and  $K_{sp}$  are related, and each can be calculated from the other; however, we cannot generally use the  $K_{sp}$  values of two different compounds to directly compare their relative solubilities.

For example, consider the following compounds, their  $K_{sp}$  values, and their molar solubilities:

Compound	$K_{sp}$	Solubility
$\text{Mg}(\text{OH})_2$	$2.06 \times 10^{-13}$	$3.72 \times 10^{-5}$ M
$\text{FeCO}_3$	$3.07 \times 10^{-11}$	$5.54 \times 10^{-6}$ M

Magnesium hydroxide has a smaller  $K_{sp}$  than iron(II) carbonate, but a higher molar solubility. Why? The relationship between  $K_{sp}$  and molar solubility depends on the stoichiometry of the dissociation reaction. Consequently, any direct comparison of  $K_{sp}$  values for different compounds can only be made if the compounds have the same dissociation stoichiometry.

Consider the following compounds with the same dissociation stoichiometry, their  $K_{sp}$  values, and their molar solubilities:

Compound	$K_{sp}$	Solubility
$\text{Mg}(\text{OH})_2$	$2.06 \times 10^{-13}$	$3.72 \times 10^{-5}$ M
$\text{CaF}_2$	$1.46 \times 10^{-10}$	$3.32 \times 10^{-4}$ M

In this case, magnesium hydroxide and calcium fluoride have the same dissociation stoichiometry (1 mol of each compound produces 3 mol of dissolved ions); therefore, the  $K_{sp}$  values can be directly compared as a measure of relative solubility.

**The Effect of a Common Ion on Solubility**

How is the solubility of an ionic compound affected when the compound is dissolved in a solution that already contains one of its ions? For example, what is the solubility

of  $\text{CaF}_2$  in a solution that is 0.100 M in NaF? We can determine the change in solubility by considering the common ion effect, which we first encountered in Section 17.2. We represent the dissociation of  $\text{CaF}_2$  in a 0.100 M NaF solution as shown in the right margin.

In accordance with Le Châtelier's principle, the presence of the  $\text{F}^-$  ion in solution causes the equilibrium to shift to the left (compared to its position in pure water), which means that less  $\text{CaF}_2$  dissolves—that is, its solubility is decreased.

**In general, the solubility of an ionic compound is lower in a solution containing a common ion than in pure water.**

We can calculate the exact value of the solubility by working an equilibrium problem in which the concentration of the common ion is accounted for in the initial conditions, as shown in Example 17.10.

### Example 17.10 Calculating Molar Solubility in the Presence of a Common Ion

What is the molar solubility of  $\text{CaF}_2$  in a solution containing 0.100 M NaF?

#### SOLUTION

Begin by writing the reaction by which solid  $\text{CaF}_2$  dissolves into its constituent aqueous ions. Write the corresponding expression for  $K_{\text{sp}}$ .

Use the stoichiometry of the reaction to prepare an ICE table showing the initial concentration of the common ion. Fill in the equilibrium concentrations of  $\text{Ca}^{2+}$  and  $\text{F}^-$  relative to  $S$ , the amount of  $\text{CaF}_2$  that dissolves.

	$[\text{Ca}^{2+}]$	$[\text{F}^-]$
Initial	0.00	0.100
Change	+ $S$	+ $2S$
Equil	$S$	$0.100 + 2S$

Substitute the equilibrium expressions for  $[\text{Ca}^{2+}]$  and  $[\text{F}^-]$  from the previous step into the expression for  $K_{\text{sp}}$ . Because  $K_{\text{sp}}$  is small, you can make the approximation that  $2S$  is much less than 0.100 and will therefore be insignificant when added to 0.100 (this is similar to the  $x$  is small approximation in equilibrium problems).

$$\begin{aligned} K_{\text{sp}} &= [\text{Ca}^{2+}][\text{F}^-]^2 \\ &= S(0.100 + 2S)^2 \quad (S \text{ is small}) \\ &= S(0.100)^2 \end{aligned}$$

Solve for  $S$  and substitute the numerical value of  $K_{\text{sp}}$  (from Table 17.2) to calculate  $S$ . Note that the calculated value of  $S$  is indeed small compared to 0.100; our approximation is valid.

$$\begin{aligned} K_{\text{sp}} &= S(0.100)^2 \\ S &= \frac{K_{\text{sp}}}{0.0100} = \frac{1.46 \times 10^{-10}}{0.0100} = 1.46 \times 10^{-8} \text{ M} \end{aligned}$$

For comparison, the molar solubility of  $\text{CaF}_2$  in pure water is  $3.32 \times 10^{-4}$  M, which means  $\text{CaF}_2$  is over 20,000 times more soluble in water than in the NaF solution. (Confirm this for yourself by calculating its solubility in pure water from the value of  $K_{\text{sp}}$ .)

**FOR PRACTICE 17.10** Calculate the molar solubility of  $\text{CaF}_2$  in a solution containing 0.250 M  $\text{Ca}(\text{NO}_3)_2$ .

### Common Ion Effect In which solution is $\text{BaSO}_4$ most soluble?

- (a) a solution that is 0.10 M in  $\text{BaNO}_3$
- (b) a solution that is 0.10 M in  $\text{Na}_2\text{SO}_4$
- (c) a solution that is 0.10 M in  $\text{NaNO}_3$

### CONCEPTUAL CONNECTION 17.9

## The Effect of pH on Solubility

The pH of a solution can affect the solubility of a compound in that solution. For example, consider the dissociation of  $\text{Mg}(\text{OH})_2$ , the active ingredient in milk of magnesia:

The solubility of this compound is highly dependent on the pH of the solution into which it dissolves. If the pH is high, then the concentration of  $\text{OH}^{-}$  in the solution is high. In accordance with the common ion effect, this shifts the equilibrium to the left, lowering the solubility:

If the pH is low, then the concentration of  $\text{H}_3\text{O}^{+}(aq)$  in the solution is high. As the  $\text{Mg}(\text{OH})_2$  dissolves, these  $\text{H}_3\text{O}^{+}$  ions neutralize the newly dissolved  $\text{OH}^{-}$  ions, driving the reaction to the right:

Consequently, the solubility of  $\text{Mg}(\text{OH})_2$  in an acidic solution is higher than in a pH-neutral or basic solution.

**In general, the solubility of an ionic compound with a strongly basic or weakly basic anion increases with increasing acidity (decreasing pH).**

Common basic anions include  $\text{OH}^{-}$ ,  $\text{S}^{2-}$ , and  $\text{CO}_3^{2-}$ . Therefore, hydroxides, sulfides, and carbonates are more soluble in acidic water than in pure water. Since rainwater is naturally acidic due to dissolved carbon dioxide, it can dissolve rocks high in limestone ( $\text{CaCO}_3$ ) as it flows through the ground. This process sometimes results in huge underground caverns such as those at Carlsbad Caverns National Park in New Mexico. Dripping water saturated in  $\text{CaCO}_3$  within the cave creates the dramatic mineral formations known as stalagmites and stalactites.

▲ Stalactites (which hang from the ceiling) and stalagmites (which grow up from the ground) form as calcium carbonate precipitates out of the water evaporating in underground caves.

### Example 17.11 The Effect of pH on Solubility

Determine whether each compound is more soluble in an acidic solution than it is in a neutral solution.

- (a)  $\text{BaF}_2$       (b)  $\text{AgI}$       (c)  $\text{Ca}(\text{OH})_2$

#### SOLUTION

- (a) The solubility of  $\text{BaF}_2$  is greater in an acidic solution than it is in a neutral solution because the  $\text{F}^{-}$  ion is a weak base. ( $\text{F}^{-}$  is the conjugate base of the weak acid  $\text{HF}$  and is therefore a weak base.)
- (b) The solubility of  $\text{AgI}$  is not greater in an acidic solution than it is in a neutral solution because the  $\text{I}^{-}$  is *not* a base. ( $\text{I}^{-}$  is the conjugate base of the *strong* acid  $\text{HI}$  and is therefore pH-neutral.)
- (c) The solubility of  $\text{Ca}(\text{OH})_2$  is greater in an acidic solution than it is in a neutral solution because the  $\text{OH}^{-}$  ion is a strong base.

**FOR PRACTICE 17.11** Which compound,  $\text{FeCO}_3$  or  $\text{PbBr}_2$ , is more soluble in acid than in base? Why?

## 17.6 Precipitation

In Chapter 4, we learned that a precipitation reaction can occur when we mix two solutions containing ionic compounds when one of the possible cross products—the combination of a cation from one solution and the anion from the other—is insoluble. In this chapter, however, we have seen that the terms *soluble* and *insoluble* are extremes in a continuous range of solubility—many compounds are slightly soluble, and even those that we categorize as insoluble in Chapter 4 actually have some limited degree of solubility (they have very small solubility product constants).

We can better understand precipitation reactions by revisiting a concept from Chapter 15—the reaction quotient ( $Q$ ). The reaction quotient for the reaction by which an ionic compound dissolves is the product of the concentrations of the ionic components raised to their stoichiometric coefficients. For example, consider the reaction by which  $\text{CaF}_2$  dissolves:

The reaction quotient for this reaction is:

$$Q = [\text{Ca}^{2+}][\text{F}^{-}]^2$$

The difference between  $Q$  and  $K_{\text{sp}}$  is that  $K_{\text{sp}}$  is the value of this product *at equilibrium only*, whereas  $Q$  is the value of the product under any conditions. We can therefore use the value of  $Q$  to compare a solution containing any concentrations of the component ions to a solution that is at equilibrium.

Consider a solution of calcium fluoride in which  $Q$  is less than  $K_{\text{sp}}$ . Recall from Chapter 15 that if  $Q$  is less than  $K_{\text{sp}}$ , the reaction will proceed to the right (toward products). Consequently, as long as solid  $\text{CaF}_2$  is present, the  $\text{CaF}_2$  will continue to dissolve. If all of the solid has already dissolved, the solution will simply remain as it is, containing less than the equilibrium amount of the dissolved ions. Such a solution is an *unsaturated solution*. If more solid is added to an unsaturated solution, it will dissolve, as long as  $Q$  remains less than  $K_{\text{sp}}$ .

Now consider a solution in which  $Q$  is exactly equal to  $K_{\text{sp}}$ . In this case, the reaction is at equilibrium and does not make progress in either direction. Such a solution most likely contains at least a small amount of the solid in equilibrium with its component ions. However, the amount of solid may be too small to be visible. Such a solution is a *saturated solution*.

Finally, consider a solution in which  $Q$  is greater than  $K_{\text{sp}}$ . In this case, the reaction proceeds to the left (toward the reactants) and solid calcium fluoride forms from the dissolved calcium and fluoride ions. In other words, the solid normally precipitates out of a solution in which  $Q$  is greater than  $K_{\text{sp}}$ . Under certain circumstances, however,  $Q$  can remain greater than  $K_{\text{sp}}$  for an unlimited period of time. Such a solution, called a *supersaturated solution*, is unstable and forms a precipitate when sufficiently disturbed. Figure 17.14► shows a supersaturated solution of sodium acetate. When a small seed crystal of solid sodium acetate is dropped into the solution, it triggers the precipitation reaction.

### Summarizing the Relationship of $Q$ and $K_{\text{sp}}$ in Solutions Containing an Ionic Compound:

- If  $Q < K_{\text{sp}}$ , the solution is unsaturated and more of the solid ionic compound can dissolve in the solution.
- If  $Q = K_{\text{sp}}$ , the solution is saturated. The solution is holding the equilibrium amount of the dissolved ions, and additional solid does not dissolve in the solution.
- If  $Q > K_{\text{sp}}$ , the solution is supersaturated. Under most circumstances, the excess solid precipitates out of a supersaturated solution.

▼ **FIGURE 17.14** Precipitation from a Supersaturated Solution

The excess solute in a supersaturated solution of sodium acetate precipitates out if a small sodium acetate crystal is added.

We can use  $Q$  to predict whether a precipitation reaction will occur upon the mixing of two solutions containing dissolved ionic compounds. For example, consider mixing a silver nitrate solution with a potassium iodide solution to form a mixture that is 0.010 M in  $\text{AgNO}_3$  and 0.015 M in  $\text{KI}$ . Will a precipitate form in the newly mixed solution? From Chapter 4 we know that one of the cross products,  $\text{KNO}_3$ , is soluble and will therefore not precipitate. The other cross product,  $\text{AgI}$ , *may* precipitate if the concentrations of  $\text{Ag}^+$  and  $\text{I}^-$  are high enough in the newly mixed solution: we can compare  $Q$  to  $K_{\text{sp}}$  to determine if a precipitate will form. For  $\text{AgI}$ ,  $K_{\text{sp}} = 8.51 \times 10^{-17}$ . For the newly mixed solution,  $[\text{Ag}^+] = 0.010 \text{ M}$  and  $[\text{I}^-] = 0.015 \text{ M}$ . We calculate  $Q$  as follows:

$$Q = [\text{Ag}^+][\text{I}^-] = (0.010)(0.015) = 1.5 \times 10^{-4}$$

The value of  $Q$  is much greater than  $K_{\text{sp}}$ ; therefore,  $\text{AgI}$  should precipitate out of the newly mixed solution.

### Example 17.12 Predicting Precipitation Reactions by Comparing $Q$ and $K_{\text{sp}}$

A solution containing lead(II) nitrate is mixed with one containing sodium bromide to form a solution that is 0.0150 M in  $\text{Pb}(\text{NO}_3)_2$  and 0.00350 M in  $\text{NaBr}$ . Does a precipitate form in the newly mixed solution?

#### SOLUTION

First, determine the possible cross products and their  $K_{\text{sp}}$  values (Table 17.2). Any cross products that are soluble do *not* precipitate (see Table 4.1).

Possible cross products:  
 $\text{NaNO}_3$  soluble  
 $\text{PbBr}_2$   $K_{\text{sp}} = 4.67 \times 10^{-6}$

Calculate  $Q$  and compare it to  $K_{\text{sp}}$ . A precipitate will only form if  $Q > K_{\text{sp}}$ .

$Q = [\text{Pb}^{2+}][\text{Br}^-]^2$   
 $= (0.0150)(0.00350)^2$   
 $= 1.84 \times 10^{-7}$   
 $Q < K_{\text{sp}}$ ; therefore no precipitate forms.

**FOR PRACTICE 17.12** If the original solutions in Example 17.12 are concentrated through evaporation and mixed again to form a solution that is 0.0600 M in  $\text{Pb}(\text{NO}_3)_2$  and 0.0158 M in  $\text{NaBr}$ , will a precipitate form in this newly mixed solution?

## Selective Precipitation

A solution may contain several different dissolved metal cations that can often be separated by **selective precipitation**, a process involving the addition of a reagent that forms a precipitate with one of the dissolved cations but not the others. For example, seawater contains dissolved magnesium and calcium cations with the concentrations  $[\text{Mg}^{2+}] = 0.059 \text{ M}$  and  $[\text{Ca}^{2+}] = 0.011 \text{ M}$ . We can separate these ions by adding a reagent that will precipitate one of the ions but not the other. From Table 17.2, we find that  $\text{Mg}(\text{OH})_2$  has a  $K_{\text{sp}}$  of  $2.06 \times 10^{-13}$  and that  $\text{Ca}(\text{OH})_2$  has a  $K_{\text{sp}}$  of  $4.68 \times 10^{-6}$ , indicating that the hydroxide ion forms a precipitate with magnesium at a much lower concentration than it does with calcium. Consequently, a soluble hydroxide—such as  $\text{KOH}$  or  $\text{NaOH}$ —is a good choice for the precipitating reagent. When we add an appropriate amount of  $\text{KOH}$  or  $\text{NaOH}$  to seawater, the hydroxide ion causes the precipitation of  $\text{Mg}(\text{OH})_2$  (the compound with the lowest  $K_{\text{sp}}$ ) but not  $\text{Ca}(\text{OH})_2$ . Calculations for this selective precipitation are shown in Examples 17.13 and 17.14. In these calculations, you compare  $Q$  to  $K_{\text{sp}}$  to determine the concentration that triggers precipitation.

The difference in  $K_{\text{sp}}$  values required for selective precipitation is a factor of at least  $10^3$ .

### Example 17.13 Finding the Minimum Required Reagent Concentration for Selective Precipitation

The magnesium and calcium ions present in seawater ( $[\text{Mg}^{2+}] = 0.059 \text{ M}$  and  $[\text{Ca}^{2+}] = 0.011 \text{ M}$ ) can be separated by selective precipitation with KOH. What minimum  $[\text{OH}^-]$  triggers the precipitation of the  $\text{Mg}^{2+}$  ion?

#### SOLUTION

The precipitation commences when the value of  $Q$  for the precipitating compound just equals the value of  $K_{\text{sp}}$ . Set the expression for  $Q$  for magnesium hydroxide equal to the value of  $K_{\text{sp}}$ , and solve for  $[\text{OH}^-]$ . This is the concentration above which  $\text{Mg}(\text{OH})_2$  precipitates.

$$\begin{aligned} Q &= [\text{Mg}^{2+}][\text{OH}^-]^2 \\ &= (0.059)[\text{OH}^-]^2 \end{aligned}$$

When  $Q = K_{\text{sp}}$ ,

$$(0.059)[\text{OH}^-]^2 = K_{\text{sp}} = 2.06 \times 10^{-13}$$

$$[\text{OH}^-]^2 = \frac{2.06 \times 10^{-13}}{0.059}$$

$$[\text{OH}^-] = 1.9 \times 10^{-6} \text{ M}$$

**FOR PRACTICE 17.13** If the concentration of  $\text{Mg}^{2+}$  in the previous solution was  $0.025 \text{ M}$ , what minimum  $[\text{OH}^-]$  triggers precipitation of the  $\text{Mg}^{2+}$  ion?

### Example 17.14 Finding the Concentrations of Ions Left in Solution after Selective Precipitation

You add potassium hydroxide to the solution in Example 17.13. When the  $[\text{OH}^-]$  reaches  $1.9 \times 10^{-6} \text{ M}$  (as you just calculated), magnesium hydroxide begins to precipitate out of solution. As you continue to add KOH, the magnesium hydroxide continues to precipitate. However, at some point, the  $[\text{OH}^-]$  becomes high enough to begin to precipitate the calcium ions as well. What is the concentration of  $\text{Mg}^{2+}$  when  $\text{Ca}^{2+}$  begins to precipitate?

#### SOLUTION

First, find the  $\text{OH}^-$  concentration at which  $\text{Ca}^{2+}$  begins to precipitate by writing the expression for  $Q$  for calcium hydroxide and substituting the concentration of  $\text{Ca}^{2+}$  from Example 17.13.

$$\begin{aligned} Q &= [\text{Ca}^{2+}][\text{OH}^-]^2 \\ &= (0.011)[\text{OH}^-]^2 \end{aligned}$$

Set the expression for  $Q$  equal to the value of  $K_{\text{sp}}$  for calcium hydroxide and solve for  $[\text{OH}^-]$ . This is the concentration above which  $\text{Ca}(\text{OH})_2$  precipitates.

$$\begin{aligned} \text{When } Q &= K_{\text{sp}}, \\ (0.011)[\text{OH}^-]^2 &= K_{\text{sp}} = 4.68 \times 10^{-6} \end{aligned}$$

$$[\text{OH}^-]^2 = \frac{4.68 \times 10^{-6}}{0.011}$$

$$[\text{OH}^-] = 2.06 \times 10^{-2} \text{ M}$$

Find the concentration of  $\text{Mg}^{2+}$  when  $\text{OH}^-$  reaches the concentration you just calculated by writing the expression for  $Q$  for magnesium hydroxide and substituting the concentration of  $\text{OH}^-$  that you just calculated. Then set the expression for  $Q$  equal to the value of  $K_{\text{sp}}$  for magnesium hydroxide and solve for  $[\text{Mg}^{2+}]$ . This is the concentration of  $\text{Mg}^{2+}$  that remains when  $\text{Ca}(\text{OH})_2$  begins to precipitate.

$$\begin{aligned} Q &= [\text{Mg}^{2+}][\text{OH}^-]^2 \\ &= [\text{Mg}^{2+}](2.06 \times 10^{-2})^2 \end{aligned}$$

When  $Q = K_{\text{sp}}$ ,

$$[\text{Mg}^{2+}](2.06 \times 10^{-2})^2 = K_{\text{sp}} = 2.06 \times 10^{-13}$$

$$[\text{Mg}^{2+}] = \frac{2.06 \times 10^{-13}}{(2.06 \times 10^{-2})^2}$$

$$[\text{Mg}^{2+}] = 4.9 \times 10^{-10} \text{ M}$$

—Continued on the next page

Continued—

As you can see from the results, the selective precipitation worked very well. The concentration of  $\text{Mg}^{2+}$  dropped from 0.059 M to  $4.9 \times 10^{-10}$  M before any calcium began to precipitate, which means that the process separated 99.99% of the magnesium out of the solution.

**FOR PRACTICE 17.14** A solution is 0.085 M in  $\text{Pb}^{2+}$  and 0.025 M in  $\text{Ag}^+$ . (a) If selective precipitation is to be achieved using NaCl, what minimum concentration of NaCl do you need to begin to precipitate the ion that precipitates first? (b) What is the concentration of each ion left in solution at the point where the second ion begins to precipitate?

## 17.7 Qualitative Chemical Analysis

Selective precipitation as discussed in Section 17.6 can be used in a systematic way to determine which metal ions are present in an unknown solution. This method is known as **qualitative analysis**. The word *qualitative* means *involving quality or kind*. Qualitative analysis involves finding the *kind* of ions present in the solution. This stands in contrast to **quantitative analysis**, which is concerned with quantity, or the amounts of substances in a solution or mixture.

In the past, qualitative analysis by selective precipitation was used extensively to determine the metals present in a sample. This process—dubbed *wet chemistry* because it involves the mixing of many aqueous solutions in the lab—has been replaced by more precise and less time-intensive instrumental techniques. Nonetheless, both for the sake of history and also because of the importance of the principles involved, we now examine a traditional qualitative analysis scheme. You may use such a scheme in your general chemistry laboratory as an exercise in qualitative analysis.

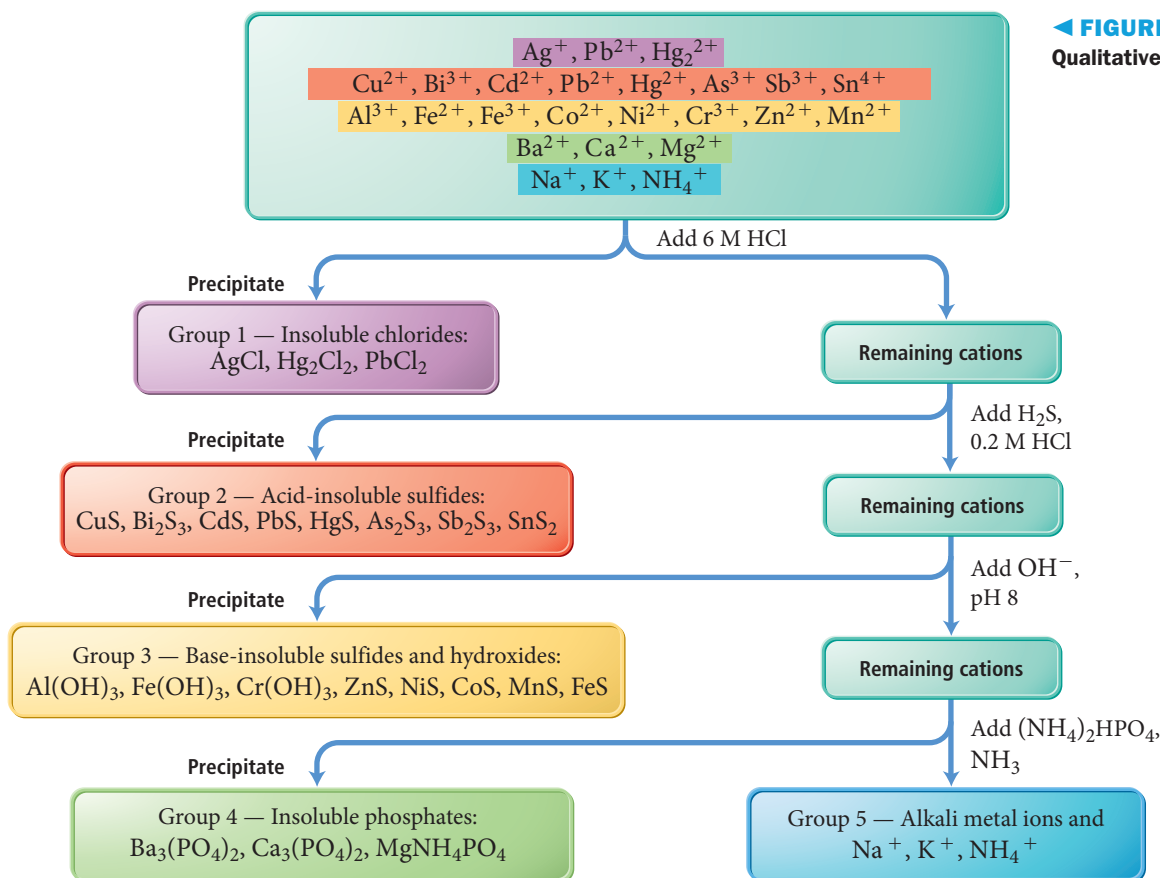

The basic idea behind qualitative analysis is straightforward. A sample containing a mixture of metal cations is subjected to the addition of several precipitating agents. At each step, some of the metal cations—those that form insoluble compounds with the precipitating agent—precipitate from the mixture and are separated out as solids. The remaining aqueous mixture is then subjected to the next precipitating agent, and so on (Figure 17.15▼).

**▲ FIGURE 17.15 Qualitative Analysis** In qualitative analysis, specific ions are precipitated successively by the addition of appropriate reagents.

Figure 17.16 is a diagram of a general qualitative analysis scheme. The scheme involves separating a mixture of the common ions into five groups by sequentially adding five different precipitating agents. After each precipitating agent is added, the mixture is put into a centrifuge to separate the solid from the liquid. The liquid is decanted for the next step, and the solid is set aside for subsequent analysis. We examine each group separately.

## Group 1: Insoluble Chlorides

In the first step, the aqueous mixture containing the metal cations is treated with 6 M HCl. Since most chlorides are soluble, the chloride ions *do not form* a precipitate with the majority of the cations in the mixture. However,  $\text{Ag}^+$ ,  $\text{Pb}^{2+}$ , and  $\text{Hg}_2^{2+}$  *do form* insoluble chlorides. So, if any of those metal cations are present, they precipitate out. The absence of a precipitate constitutes a negative test for  $\text{Ag}^+$ ,  $\text{Pb}^{2+}$ , and  $\text{Hg}_2^{2+}$ . If a precipitate forms, one or more of these ions is present. After the solid is separated from the liquid, the solution is ready for the next step.

## Group 2: Acid-Insoluble Sulfides

In the second step, the acidic aqueous mixture containing the remaining metal cations is treated with  $\text{H}_2\text{S}$ , a weak diprotic acid that dissociates in two steps:

The concentration of  $\text{S}^{2-}$  ions in an  $\text{H}_2\text{S}$  solution is pH-dependent. At low pH (high  $\text{H}^+$  concentration) the equilibria shift left, minimizing the amount of available  $\text{S}^{2-}$ . At high pH (low  $\text{H}^+$  concentration) the equilibria shift right, maximizing the amount of available  $\text{S}^{2-}$ . At this stage, the solution is acidic (from the addition of HCl in the previous step),

$(\text{NH}_4)_2\text{S}$     $\text{CdS}$     $\text{Sb}_2\text{S}_3$     $\text{PbS}$

and the concentration of  $\text{S}^{2-}$  in solution is relatively low. Only the most insoluble metal sulfides (those with the smallest  $K_{\text{sp}}$  values) precipitate under these conditions. These include  $\text{Hg}^{2+}$ ,  $\text{Cd}^{2+}$ ,  $\text{Bi}^{3+}$ ,  $\text{Cu}^{2+}$ ,  $\text{Sn}^{4+}$ ,  $\text{As}^{3+}$ ,  $\text{Pb}^{2+}$  and  $\text{Sb}^{3+}$ . If any of these metal cations are present, they precipitate out as sulfides. After the solid is separated from the liquid, the solution is ready for the next step.

### Group 3: Base-Insoluble Sulfides and Hydroxides

In the third step, additional base and  $\text{H}_2\text{S}$  are added to the acidic aqueous mixture containing the remaining metal cations. The added base reacts with acid, shifting the  $\text{H}_2\text{S}$  ionization equilibria to the right and creating a higher  $\text{S}^{2-}$  concentration. This causes the precipitation of those sulfides that were too soluble to precipitate out in the previous step but not soluble enough to prevent precipitation with the higher sulfide ion concentration. The ions that precipitate as sulfides at this point (if they are present) are  $\text{Fe}^{2+}$ ,  $\text{Co}^{2+}$ ,  $\text{Zn}^{2+}$ ,  $\text{Mn}^{2+}$ , and  $\text{Ni}^{2+}$ . In addition, the additional base causes  $\text{Cr}^{3+}$ ,  $\text{Fe}^{3+}$ , and  $\text{Al}^{3+}$  to precipitate as hydroxides. After the solid is separated from the liquid, the solution is ready for the next step.

### Group 4: Insoluble Phosphates

At this stage, all of the cations have precipitated except those belonging to the alkali metal family (group 1A in the periodic table) and the alkaline earth metal family (group 2A in the periodic table). The alkaline earth metal cations can be precipitated by adding  $(\text{NH}_4)_2\text{HPO}_4$  to the solution, causing  $\text{Mg}^{2+}$ ,  $\text{Ca}^{2+}$ , and  $\text{Ba}^{2+}$  to precipitate as metal phosphates, which are separated from the liquid.

### Group 5: Alkali Metals and $\text{NH}_4^+$

The only dissolved ions that the liquid decanted from the previous step can now contain are  $\text{Na}^+$ ,  $\text{K}^+$ , and  $\text{NH}_4^+$ . These cations do not form insoluble compounds with any anions and cannot be precipitated from the solution. Their presence can be determined, however, by other means. Sodium and potassium ions, for example, are usually identified through flame tests. The sodium ion produces a yellow-orange flame, and the potassium ion produces a violet flame, as shown in Figure 17.17.

By applying this procedure, nearly two dozen metal cations can be separated from a solution initially containing all of them. Each of the groups can be further analyzed to determine which specific ions are present. The procedures for these steps are found in many general chemistry laboratory manuals.

Sodium

Potassium

#### ► FIGURE 17.17 Flame Tests

The sodium ion produces a yellow-orange flame. The potassium ion produces a violet flame.

## 17.8 Complex Ion Equilibria

We have discussed several different types of equilibria so far, including acid–base equilibria and solubility equilibria. We now turn to equilibria of another type, which primarily involve transition metal ions in solution. Transition metal ions tend to be good electron acceptors (good Lewis acids). In aqueous solutions, water molecules can act as electron donors (Lewis bases) to hydrate transition metal ions. For example, silver ions are hydrated by water in solution to form  $\text{Ag}(\text{H}_2\text{O})_2^+(aq)$ . Chemists often write  $\text{Ag}^+(aq)$  as a shorthand notation for the hydrated silver ion, but the bare ion does not really exist by itself in solution.

Species such as  $\text{Ag}(\text{H}_2\text{O})_2^+$  are known as *complex ions*. A **complex ion** contains a central metal ion bound to one or more *ligands*. A **ligand** is a neutral molecule or ion that acts as a Lewis base with the central metal ion. In  $\text{Ag}(\text{H}_2\text{O})_2^+$ , water is the ligand. If a stronger Lewis base is put into a solution containing  $\text{Ag}(\text{H}_2\text{O})_2^+$ , the stronger Lewis base displaces the water in the complex ion. For example, ammonia reacts with  $\text{Ag}(\text{H}_2\text{O})_2^+$  according to the following reaction:

For simplicity, we often leave water out of the equation:

The equilibrium constant associated with the reaction for the formation of a complex ion, such as the one just shown, is called the **formation constant ( $K_f$ )**. The expression for  $K_f$  is determined by the law of mass action, like any equilibrium constant. For  $\text{Ag}(\text{NH}_3)_2^+$ , the expression for  $K_f$  is:

$$K_f = \frac{[\text{Ag}(\text{NH}_3)_2^+]}{[\text{Ag}^+][\text{NH}_3]^2}$$

Notice that the value of  $K_f$  for  $\text{Ag}(\text{NH}_3)_2^+$  is large, indicating that the formation of the complex ion is highly favored. Table 17.3 lists the formation constants for a number of common complex ions. You can see that, in general, values of  $K_f$  are very large, indicating that the formation of complex ions is highly favored in each case. Example 17.15 illustrates how to use  $K_f$  in calculations.

We cover complex ions in more detail in Chapter 25. Here, we focus on the equilibria associated with their formation.

**TABLE 17.3 Formation Constants of Selected Complex Ions in Water at 25 °C**

Complex Ion	$K_f$	Complex Ion	$K_f$
$\text{Ag}(\text{CN})_2^-$	$1 \times 10^{21}$	$\text{Cu}(\text{NH}_3)_4^{2+}$	$1.7 \times 10^{13}$
$\text{Ag}(\text{NH}_3)_2^+$	$1.7 \times 10^7$	$\text{Fe}(\text{CN})_6^{4-}$	$1.5 \times 10^{35}$
$\text{Ag}(\text{S}_2\text{O}_3)_2^{3-}$	$2.8 \times 10^{13}$	$\text{Fe}(\text{CN})_6^{3-}$	$2 \times 10^{43}$
$\text{AlF}_6^{3-}$	$7 \times 10^{19}$	$\text{Hg}(\text{CN})_4^{2-}$	$1.8 \times 10^{41}$
$\text{Al}(\text{OH})_4^-$	$3 \times 10^{33}$	$\text{HgCl}_4^{2-}$	$1.1 \times 10^{16}$
$\text{CdBr}_4^{2-}$	$5.5 \times 10^3$	$\text{HgI}_4^{2-}$	$2 \times 10^{30}$
$\text{CdI}_4^{2-}$	$2 \times 10^6$	$\text{Ni}(\text{NH}_3)_6^{2+}$	$2.0 \times 10^8$
$\text{Cd}(\text{CN})_4^{2-}$	$3 \times 10^{18}$	$\text{Pb}(\text{OH})_3^-$	$8 \times 10^{13}$
$\text{Co}(\text{NH}_3)_6^{3+}$	$2.3 \times 10^{33}$	$\text{Sn}(\text{OH})_3^-$	$3 \times 10^{25}$
$\text{Co}(\text{OH})_4^{2-}$	$5 \times 10^9$	$\text{Zn}(\text{CN})_4^{2-}$	$2.1 \times 10^{19}$
$\text{Co}(\text{SCN})_4^{2-}$	$1 \times 10^3$	$\text{Zn}(\text{NH}_3)_4^{2+}$	$2.8 \times 10^9$
$\text{Cr}(\text{OH})_4^-$	$8.0 \times 10^{29}$	$\text{Zn}(\text{OH})_4^{2-}$	$2 \times 10^{15}$
$\text{Cu}(\text{CN})_4^{2-}$	$1.0 \times 10^{25}$		

**Example 17.15** Complex Ion Equilibria

You mix a 200.0-mL sample of a solution that is  $1.5 \times 10^{-3}$  M in  $\text{Cu}(\text{NO}_3)_2$  with a 250.0-mL sample of a solution that is 0.20 M in  $\text{NH}_3$ . After the solution reaches equilibrium, what concentration of  $\text{Cu}^{2+}(\text{aq})$  remains?

**SOLUTION**

Write the balanced equation for the complex ion equilibrium that occurs and look up the value of  $K_f$  in Table 17.3. Since this is an equilibrium problem, you have to create an ICE table, which requires the initial concentrations of  $\text{Cu}^{2+}$  and  $\text{NH}_3$ . Calculate those concentrations from the given values.

$$K_f = 1.7 \times 10^{13}$$

$$[\text{Cu}^{2+}]_{\text{initial}} = \frac{0.200 \text{ L} \times \frac{1.5 \times 10^{-3} \text{ mol}}{\text{L}}}{0.200 \text{ L} + 0.250 \text{ L}} = 6.7 \times 10^{-4} \text{ M}$$

$$[\text{NH}_3]_{\text{initial}} = \frac{0.250 \text{ L} \times \frac{0.20 \text{ mol}}{1 \text{ L}}}{0.200 \text{ L} + 0.250 \text{ L}} = 0.11 \text{ M}$$

Construct an ICE table for the reaction and write down the initial concentrations of each species.

	$[\text{Cu}^{2+}]$	$[\text{NH}_3]$	$[\text{Cu}(\text{NH}_3)_4^{2+}]$
Initial	$6.7 \times 10^{-4}$	0.11	0.0
Change			
Equil			

Since the equilibrium constant is large and the concentration of ammonia is much larger than the concentration of  $\text{Cu}^{2+}$ , you can assume that the reaction will be driven to the right so that most of the  $\text{Cu}^{2+}$  is consumed. Unlike previous ICE tables, where you used  $x$  to represent the change in concentration in going to equilibrium, here you let  $x$  represent the small amount of  $\text{Cu}^{2+}$  that remains when equilibrium is reached.

	$[\text{Cu}^{2+}]$	$[\text{NH}_3]$	$[\text{Cu}(\text{NH}_3)_4^{2+}]$
Initial	$6.7 \times 10^{-4}$	0.11	0.0
Change	$\approx (-6.7 \times 10^{-4})$	$\approx 4(-6.7 \times 10^{-4})$	$\approx (+6.7 \times 10^{-4})$
Equil	$x$	0.11	$6.7 \times 10^{-4}$

Substitute the expressions for the equilibrium concentrations into the expression for  $K_f$  and solve for  $x$ .

$$\begin{aligned} K_f &= \frac{[\text{Cu}(\text{NH}_3)_4^{2+}]}{[\text{Cu}^{2+}][\text{NH}_3]^4} \\ &= \frac{6.7 \times 10^{-4}}{x(0.11)^4} \\ x &= \frac{6.7 \times 10^{-4}}{K_f(0.11)^4} \\ &= \frac{6.7 \times 10^{-4}}{1.7 \times 10^{13}(0.11)^4} \\ &= 2.7 \times 10^{-13} \end{aligned}$$

Confirm that  $x$  is indeed small compared to the initial concentration of the metal cation.

The remaining  $\text{Cu}^{2+}$  is very small because the formation constant is very large.

Since  $x = 2.7 \times 10^{-13} \ll 6.7 \times 10^{-4}$ , the approximation is valid. The remaining  $[\text{Cu}^{2+}] = 2.7 \times 10^{-13}$  M.

**FOR PRACTICE 17.15** You mix a 125.0-mL sample of a solution that is 0.0117 M in  $\text{NiCl}_2$  with a 175.0-mL sample of a solution that is 0.250 M in  $\text{NH}_3$ . After the solution reaches equilibrium, what concentration of  $\text{Ni}^{2+}(\text{aq})$  remains?

## The Effect of Complex Ion Equilibria on Solubility

Recall from Section 17.5 that the solubility of an ionic compound with a basic anion increases with increasing acidity because the acid reacts with the anion and drives the reaction to the right. Similarly, *the solubility of an ionic compound containing a metal cation that forms complex ions increases in the presence of Lewis bases that complex with the cation.* The most common Lewis bases that increase the solubility of metal cations are  $\text{NH}_3$ ,  $\text{CN}^-$ , and  $\text{OH}^-$ .

For example, silver chloride is only slightly soluble in pure water:

However, adding ammonia increases its solubility dramatically because, as we saw previously in this section, the ammonia forms a complex ion with the silver cations:

The large value of  $K_{\text{f}}$  significantly lowers the concentration of  $\text{Ag}^+(aq)$  in solution and therefore drives the dissolution of  $\text{AgCl}(s)$ . The two previous reactions can be added together:

As we learned in Section 15.3, the equilibrium constant for a reaction that is the sum of two other reactions is the product of the equilibrium constants for the two other reactions. Adding ammonia changes the equilibrium constant for the dissolution of  $\text{AgCl}(s)$  by a factor of  $3.0 \times 10^{-3} / 1.77 \times 10^{-10} = 1.7 \times 10^7$  (17 million), which makes the otherwise relatively insoluble  $\text{AgCl}(s)$  quite soluble, as shown in Figure 17.18 ▼.

### Complex Ion Formation

◀ **FIGURE 17.18** Complex Ion Formation Normally insoluble  $\text{AgCl}$  is made soluble by the addition of  $\text{NH}_3$ , which forms a complex ion with  $\text{Ag}^+$  and dissolves the  $\text{AgCl}$ .

## CONCEPTUAL CONNECTION 17.10

**Solubility and Complex Ion Equilibria** Which compound, when added to water, is most likely to increase the solubility of CuS?

- (a) NaCl      (b) KNO<sub>3</sub>      (c) NaCN      (d) MgBr<sub>2</sub>

### The Solubility of Amphoteric Metal Hydroxides

Many metal hydroxides are insoluble or only very slightly soluble in pH-neutral water. For example, Al(OH)<sub>3</sub> has  $K_{sp} = 1.3 \times 10^{-33}$ , which means that if we put Al(OH)<sub>3</sub> in water, the vast majority of it will settle to the bottom as an undissolved solid. All metal hydroxides, however, have a basic anion (OH<sup>−</sup>) and therefore become more soluble in acidic solutions (see the previous subsection and Section 17.5). The metal hydroxides become more soluble because they can act as bases and react with H<sub>3</sub>O<sup>+</sup>(aq). For example, Al(OH)<sub>3</sub> dissolves in acid according to the reaction:

Al(OH)<sub>3</sub> acts as a base in this reaction.

Interestingly, some metal hydroxides can also act as acids—they are *amphoteric*. The ability of an amphoteric metal hydroxide to act as an acid increases its solubility in basic solution. For example, Al(OH)<sub>3</sub>(s) dissolves in basic solution according to the reaction:

Al(OH)<sub>3</sub> acts as an acid in this reaction.

Al(OH)<sub>3</sub> is soluble at high pH and soluble at low pH but *insoluble* in a pH-neutral solution.

We can observe the whole range of the pH-dependent solubility behavior of Al<sup>3+</sup> by considering a hydrated aluminum ion in solution, beginning at an acidic pH. We know from Section 16.8 that Al<sup>3+</sup> in solution is inherently acidic because it complexes with water to form Al(H<sub>2</sub>O)<sub>6</sub><sup>3+</sup>(aq). The complex ion then acts as an acid by losing a proton from one of the complexed water molecules according to the reaction:

Addition of base to the solution drives the reaction to the right and continues to remove protons from complexed water molecules:

The result of removing three protons from Al(H<sub>2</sub>O)<sub>6</sub><sup>3+</sup>(aq) is the solid white precipitate Al(H<sub>2</sub>O)<sub>3</sub>(OH)<sub>3</sub>(s), which is more commonly written as Al(OH)<sub>3</sub>(s). The solution is now pH-neutral and the hydroxide is insoluble. Addition of more OH<sup>−</sup> makes the solution basic and dissolves the solid precipitate:

As the solution goes from acidic to neutral to basic, the solubility of Al<sup>3+</sup> changes accordingly, as illustrated in Figure 17.19.

The extent to which a metal hydroxide dissolves in both acid and base depends on the degree to which it is amphoteric. Cations that form amphoteric hydroxides include Al<sup>3+</sup>, Cr<sup>3+</sup>, Zn<sup>2+</sup>, Pb<sup>2+</sup>, and Sn<sup>2+</sup>. Other metal hydroxides, such as those of Ca<sup>2+</sup>, Fe<sup>2+</sup>, and Fe<sup>3+</sup>, are not amphoteric—they become soluble in acidic solutions, but not in basic ones.

Recall from Section 16.3 that a substance that can act as either an acid or a base is said to be amphoteric.

## pH-Dependent Solubility of an Amphoteric Hydroxide

▲ **FIGURE 17.19 Solubility of an Amphoteric Hydroxide**

Because aluminum hydroxide is amphoteric, its solubility is pH-dependent. At low pH, the formation of  $\text{Al}(\text{H}_2\text{O})_6^{3+}$  drives the dissolution. At neutral pH, insoluble  $\text{Al}(\text{OH})_3$  precipitates out of solution. At high pH, the formation of  $\text{Al}(\text{H}_2\text{O})_2(\text{OH})_4^-$  drives the dissolution.

## Self-Assessment Quiz

- Q1.** A buffer is 0.100 M in  $\text{NH}_4\text{Cl}$  and 0.100 M in  $\text{NH}_3$ . When a small amount of hydrobromic acid is added to this buffer, which buffer component neutralizes the added acid?
- $\text{NH}_4^+$
  - $\text{Cl}^-$
  - $\text{NH}_3$
  - None of the above (hydrobromic acid will not be neutralized by this buffer).
- Q2.** What is the pH of a buffer that is 0.120 M in formic acid ( $\text{HCHO}_2$ ) and 0.080 M in potassium formate ( $\text{KCHO}_2$ )? For formic acid,  $K_a = 1.8 \times 10^{-4}$ .
- 2.33
  - 3.57
  - 3.74
  - 3.91
- Q3.** A buffer with a pH of 9.85 contains  $\text{CH}_3\text{NH}_2$  and  $\text{CH}_3\text{NH}_3\text{Cl}$  in water. What can you conclude about the relative concentrations of  $\text{CH}_3\text{NH}_2$  and  $\text{CH}_3\text{NH}_3\text{Cl}$  in this buffer? For  $\text{CH}_3\text{NH}_2$ ,  $\text{p}K_b = 3.36$ .
- $\text{CH}_3\text{NH}_2 > \text{CH}_3\text{NH}_3\text{Cl}$
  - $\text{CH}_3\text{NH}_2 < \text{CH}_3\text{NH}_3\text{Cl}$
  - $\text{CH}_3\text{NH}_2 = \text{CH}_3\text{NH}_3\text{Cl}$
  - Nothing can be concluded about the relative concentrations of  $\text{CH}_3\text{NH}_2$  and  $\text{CH}_3\text{NH}_3\text{Cl}$ .
- Q4.** A 500.0-mL buffer solution is 0.10 M in benzoic acid and 0.10 M in sodium benzoate and has an initial pH of 4.19. What is the pH of the buffer upon addition of 0.010 mol of NaOH?
- 1.70
  - 4.01
  - 4.29
  - 4.37
- Q5.** Consider a buffer composed of the weak acid HA and its conjugate base  $\text{A}^-$ . Which pair of concentrations results in the most effective buffer?
- 0.10 M HA; 0.10 M  $\text{A}^-$
  - 0.50 M HA; 0.50 M  $\text{A}^-$
  - 0.90 M HA; 0.10 M  $\text{A}^-$
  - 0.10 M HA; 0.90 M  $\text{A}^-$
- Q6.** Which combination is the best choice to prepare a buffer with a pH of 9.0?
- $\text{NH}_3$ ;  $\text{NH}_4\text{Cl}$  ( $\text{p}K_b$  for  $\text{NH}_3$  is 4.75)
  - $\text{C}_5\text{H}_5\text{N}$ ;  $\text{C}_5\text{H}_5\text{NHCl}$  ( $\text{p}K_b$  for  $\text{C}_5\text{H}_5\text{N}$  is 8.76)
  - $\text{HNO}_2$ ;  $\text{NaNO}_2$  ( $\text{p}K_a$  for  $\text{HNO}_2$  is 3.33)
  - $\text{HCHO}_2$ ;  $\text{NaCHO}_2$  ( $\text{p}K_a$  for  $\text{HCHO}_2$  is 3.74)
- Q7.** A 25.0-mL sample of an unknown HBr solution is titrated with 0.100 M NaOH. The equivalence point is reached upon the addition of 18.88 mL of the base. What is the concentration of the HBr solution?
- 0.0755 M
  - 0.0376 M
  - 0.100 M
  - 0.00188 M
- Q8.** A 10.0-mL sample of 0.200 M hydrocyanic acid (HCN) is titrated with 0.0998 M NaOH. What is the pH at the equivalence point? For hydrocyanic acid,  $\text{p}K_a = 9.31$ .
- 7.00
  - 8.76
  - 9.31
  - 11.07
- Q9.** A 20.0-mL sample of 0.150 M ethylamine is titrated with 0.0981 M HCl. What is the pH after the addition of 5.0 mL of HCl? For ethylamine,  $\text{p}K_b = 3.25$ .
- 10.75
  - 11.04
  - 2.96
  - 11.46

Continued—

**Q10.** Three 15.0-mL acid samples—0.10 M HA, 0.10 M HB, and 0.10 M H<sub>2</sub>C—are all titrated with 0.100 M NaOH. If HA is a weak acid, HB is a strong acid, and H<sub>2</sub>C is a diprotic acid, which statement is true of all three titrations?

- All three titrations have the same pH at the first equivalence point.
- All three titrations have the same initial pH.
- All three titrations have the same final pH.
- All three titrations require the same volume of NaOH to reach the first equivalence point.

**Q11.** A weak unknown monoprotic acid is titrated with a strong base. The titration curve is shown. Find  $K_a$  for the unknown acid.

- $2.5 \times 10^{-3}$
- $3.2 \times 10^{-5}$
- $3.2 \times 10^{-7}$
- $2.5 \times 10^{-9}$

**Q12.** Calculate the molar solubility of lead(II) bromide (PbBr<sub>2</sub>). For lead(II) bromide,  $K_{sp} = 4.67 \times 10^{-6}$ .

- 0.00153 M
- 0.0105 M
- 0.0167 M
- 0.0211 M

**Q13.** Calculate the molar solubility of magnesium fluoride (MgF<sub>2</sub>) in a solution that is 0.250 M in NaF. For magnesium fluoride,  $K_{sp} = 5.16 \times 10^{-11}$ .

- $2.35 \times 10^{-4}$  M
- $2.06 \times 10^{-10}$  M
- $2.87 \times 10^{-5}$  M
- $8.26 \times 10^{-10}$  M

**Q14.** A solution is 0.025 M in Pb<sup>2+</sup>. What minimum concentration of Cl<sup>-</sup> is required to begin to precipitate PbCl<sub>2</sub>? For PbCl<sub>2</sub>,  $K_{sp} = 1.17 \times 10^{-5}$ .

- $1.17 \times 10^{-5}$  M
- 0.0108 M
- 0.0216 M
- $5.41 \times 10^{-4}$  M

**Q15.** Which compound is more soluble in an acidic solution than in a neutral solution?

- PbBr<sub>2</sub>
- CuCl
- AgI
- BaF<sub>2</sub>

Answers: 1. (c) 2. (b) 3. (b) 4. (d) 5. (b) 6. (a) 7. (a) 8. (d) 9. (d) 10. (d) 11. (b) 12. (b) 13. (d) 14. (c) 15. (d)

## Chapter 17 IN REVIEW

### Key Terms

#### Section 17.2

buffer (780)  
common ion effect (782)  
Henderson–Hasselbalch equation (784)

#### Section 17.3

buffer capacity (794)

#### Section 17.4

acid–base titration (795)

indicator (795)  
equivalence point (795)  
endpoint (806)

#### Section 17.5

solubility product constant ( $K_{sp}$ ) (809)  
molar solubility (809)

#### Section 17.6

selective precipitation (816)

#### Section 17.7

qualitative analysis (818)  
quantitative analysis (818)

#### Section 17.8

complex ion (821)  
ligand (821)  
formation constant ( $K_f$ ) (821)

### Key Concepts

#### The Danger of Antifreeze (17.1)

- Although buffers closely regulate the pH of mammalian blood, the capacity of these buffers to neutralize can be overwhelmed.
- Ethylene glycol, the main component of antifreeze, is metabolized by the liver into glycolic acid. The resulting acidity can exceed the buffering capacity of blood and cause acidosis, a serious condition that results in oxygen deprivation.

#### Buffers: Solutions That Resist pH Change (17.2)

- Buffers contain significant amounts of both a weak acid and its conjugate base (or a weak base and its conjugate acid), enabling the buffer to neutralize added acid or added base.
- Adding a small amount of acid to a buffer converts a stoichiometric amount of base to the conjugate acid. Adding a small amount of base to a buffer converts a stoichiometric amount of the acid to the conjugate base.

- ▶ We can determine the pH of a buffer solution by solving an equilibrium problem, focusing on the common ion effect, or by using the Henderson–Hasselbalch equation.

### Buffer Range and Buffer Capacity (17.3)

- ▶ A buffer works best when the amounts of acid and conjugate base it contains are large and approximately equal.
- ▶ If the relative amounts of acid and base in a buffer differ by more than a factor of 10, the ability of the buffer to neutralize added acid and added base diminishes. The maximum pH range at which a buffer is effective is one pH unit on either side of the acid's  $pK_a$ .

### Titration and pH Curves (17.4)

- ▶ A titration curve is a graph of the change in pH versus added volume of acid or base during a titration.
- ▶ This chapter examines three types of titration curves, representing three types of acid–base reactions: a strong acid with a strong base, a weak acid with a strong base (or vice versa), and a polyprotic acid with a strong base.
- ▶ The equivalence point of a titration can be made visible by an indicator, a compound that changes color over a specific pH range.

### Solubility Equilibria and the Solubility Product Constant (17.5)

- ▶ The solubility product constant ( $K_{sp}$ ) is an equilibrium constant for the dissolution of an ionic compound in water.
- ▶ We can determine the molar solubility of an ionic compound from  $K_{sp}$  and vice versa. Although the value of  $K_{sp}$  is constant at a given temperature, the solubility of an ionic substance can depend on other factors such as the presence of common ions and the pH of the solution.

### Precipitation (17.6)

- ▶ We can compare the magnitude of  $K_{sp}$  to the reaction quotient,  $Q$ , in order to determine the relative saturation of a solution.
- ▶ Substances with cations that have sufficiently different values of  $K_{sp}$  can be separated by selective precipitation, in which an added reagent forms a precipitate with one of the dissolved cations but not others.

### Qualitative Chemical Analysis (17.7)

- ▶ Qualitative analysis operates on the principle that a mixture of cations can be separated and analyzed based on the differences in the solubilities of their salts.
- ▶ In a classic qualitative analysis scheme, an unknown mixture of cations is sequentially treated with different reagents, each of which precipitates a known subgroup of cations.

### Complex Ion Equilibria (17.8)

- ▶ A complex ion contains a central metal ion coordinated to two or more ligands.
- ▶ The equilibrium constant for the formation of a complex ion is called a formation constant and is usually quite large.
- ▶ The solubility of an ionic compound containing a metal cation that forms complex ions increases in the presence of Lewis bases that complex with the cation because the formation of the complex ion drives the dissolution reaction to the right.
- ▶ All metal hydroxides become more soluble in the presence of acids, but amphoteric metal hydroxides also become more soluble in the presence of bases.

## Key Equations and Relationships

The Henderson–Hasselbalch Equation (17.2)

$$\text{pH} = \text{p}K_a + \log \frac{[\text{base}]}{[\text{acid}]}$$

Effective Buffer Range (17.3)

$$\text{pH} = \text{range} = \text{p}K_a \pm 1$$

The Relation between  $Q$  and  $K_{sp}$  (17.6)

If  $Q < K_{sp}$ , the solution is unsaturated. More of the solid ionic compound can dissolve in the solution.

If  $Q = K_{sp}$ , the solution is saturated. The solution is holding the equilibrium amount of the dissolved ions, and additional solid will not dissolve in the solution.

If  $Q > K_{sp}$ , the solution is supersaturated. Under most circumstances, the solid will precipitate out of a supersaturated solution.

## Key Learning Outcomes

CHAPTER OBJECTIVES	ASSESSMENT
Calculating the pH of a Buffer Solution (17.2)	Example 17.1 For Practice 17.1 For More Practice 17.1 Exercises 29, 30, 33, 34
Using the Henderson–Hasselbalch Equation to Calculate the pH of a Buffer Solution (17.2)	Example 17.2 For Practice 17.2 Exercises 37–42
Calculating the pH Change in a Buffer Solution after the Addition of a Small Amount of Strong Acid or Base (17.2)	Example 17.3 For Practice 17.3 For More Practice 17.3 Exercises 47–50
Using the Henderson–Hasselbalch Equation to Calculate the pH of a Buffer Solution Composed of a Weak Base and Its Conjugate Acid (17.2)	Example 17.4 For Practice 17.4 For More Practice 17.4 Exercises 37–42
Preparing a Buffer (17.3)	Example 17.5 For Practice 17.5 Exercises 57–58

## Strong Acid–Strong Base Titration pH Curve (17.4)

Example 17.6 For Practice 17.6 Exercises 67–70

## Weak Acid–Strong Base Titration pH Curve (17.4)

Example 17.7 For Practice 17.7 Exercises 65, 71–72, 75, 77–78

Calculating Molar Solubility from  $K_{sp}$  (17.5)

Example 17.8 For Practice 17.8 Exercises 87–88

Calculating  $K_{sp}$  from Molar Solubility (17.5)

Example 17.9 For Practice 17.9 Exercises 89–90, 92, 94

## Calculating Molar Solubility in the Presence of a Common Ion (17.5)

Example 17.10 For Practice 17.10 Exercises 95–96

## Determining the Effect of pH on Solubility (17.5)

Example 17.11 For Practice 17.11 Exercises 97–100

Predicting Precipitation Reactions by Comparing  $Q$  and  $K_{sp}$  (17.6)

Example 17.12 For Practice 17.12 Exercises 101–104

## Finding the Minimum Required Reagent Concentration for Selective Precipitation (17.6)

Example 17.13 For Practice 17.13 Exercises 105–106

## Finding the Concentrations of Ions Left in Solution after Selective Precipitation (17.6)

Example 17.14 For Practice 17.14 Exercises 107–108

## Working with Complex Ion Equilibria (17.8)

Example 17.15 For Practice 17.15 Exercises 109–112

## EXERCISES

## Review Questions

1. What is the pH range of human blood? How is human blood maintained in this pH range?
2. What is a buffer? How does a buffer work? How does it neutralize added acid? Added base?
3. What is the common ion effect?
4. What is the Henderson–Hasselbalch equation, and why is it useful?
5. What is the pH of a buffer solution when the concentrations of both buffer components (the weak acid and its conjugate base) are equal? What happens to the pH when the buffer contains more of the weak acid than the conjugate base? More of the conjugate base than the weak acid?

6. Suppose that a buffer contains equal amounts of a weak acid and its conjugate base. What happens to the relative amounts of the weak acid and conjugate base when a small amount of strong acid is added to the buffer? What happens when a small amount of strong base is added?
7. How do you use the Henderson–Hasselbalch equation to calculate the pH of a buffer containing a base and its conjugate acid? Specifically, how do you determine the correct value for  $pK_a$ ?
8. What factors influence the effectiveness of a buffer? What are the characteristics of an effective buffer?
9. What is the effective pH range of a buffer (relative to the  $pK_a$  of the weak acid component)?
10. Describe acid–base titration. What is the equivalence point?
11. The pH at the equivalence point of the titration of a strong acid with a strong base is 7.0. However, the pH at the equivalence point of the titration of a *weak* acid with a strong base is above 7.0. Explain.
12. The volume required to reach the equivalence point of an acid–base titration depends on the volume and concentration of the acid or base to be titrated and on the concentration of the acid or base used to do the titration. It does not, however, depend on whether or not the acid or base being titrated is strong or weak. Explain.
13. In the titration of a strong acid with a strong base, how do you calculate these quantities?
  - a. initial pH
  - b. pH before the equivalence point
  - c. pH at the equivalence point
  - d. pH beyond the equivalence point
14. In the titration of a weak acid with a strong base, how do you calculate these quantities?
  - a. initial pH
  - b. pH before the equivalence point
  - c. pH at one-half the equivalence point
  - d. pH at the equivalence point
  - e. pH beyond the equivalence point
15. The titration of a polyprotic acid with sufficiently different  $pK_a$ s displays two equivalence points. Why?
16. In the titration of a polyprotic acid, the volume required to reach the first equivalence point is identical to the volume required to reach the second one. Why?
17. What is the difference between the endpoint and the equivalence point in a titration?
18. What is an indicator? How can an indicator signal the equivalence point of a titration?
19. What is the solubility product constant? Write a general expression for the solubility constant of a compound with the general formula  $A_mX_n$ .
20. What is molar solubility? How can you obtain the molar solubility of a compound from  $K_{sp}$ ?
21. How does a common ion affect the solubility of a compound? More specifically, how is the solubility of a compound with the general formula  $AX$  different in a solution containing one of the common ions ( $A^+$  or  $X^-$ ) than it is in pure water? Explain.
22. How is the solubility of an ionic compound with a basic anion affected by pH? Explain.
23. For a given solution containing an ionic compound, what is the relationship between  $Q$ ,  $K_{sp}$ , and the relative saturation of the solution?
24. What is selective precipitation? Under which conditions does selective precipitation occur?
25. What is qualitative analysis? How does *qualitative* analysis differ from *quantitative* analysis?
26. What are the main groups in the general qualitative analysis scheme described in this chapter? Describe the steps and reagents necessary to identify each group.

## Problems by Topic

### The Common Ion Effect and Buffers

27. In which of these solutions will  $HNO_2$  ionize less than it does in pure water?
  - a. 0.10 M NaCl
  - b. 0.10 M  $KNO_3$
  - c. 0.10 M NaOH
  - d. 0.10 M  $NaNO_2$
28. A formic acid solution has a pH of 3.25. Which of these substances will raise the pH of the solution upon addition? Explain your answer.
 

a. HCl	b. NaBr
c. $NaCHO_2$	d. KCl
29. Solve an equilibrium problem (using an ICE table) to calculate the pH of each solution.
  - a. a solution that is 0.20 M in  $HCHO_2$  and 0.15 M in  $NaCHO_2$
  - b. a solution that is 0.16 M in  $NH_3$  and 0.22 M in  $NH_4Cl$
30. Solve an equilibrium problem (using an ICE table) to calculate the pH of each solution.
  - a. a solution that is 0.195 M in  $HC_2H_3O_2$  and 0.125 M in  $KC_2H_3O_2$
  - b. a solution that is 0.255 M in  $CH_3NH_2$  and 0.135 M in  $CH_3NH_3Br$
31. Calculate the percent ionization of a 0.15 M benzoic acid solution in pure water and in a solution containing 0.10 M sodium benzoate. Why does the percent ionization differ significantly in the two solutions?
32. Calculate the percent ionization of a 0.13 M formic acid solution in pure water and also in a solution containing 0.11 M potassium formate. Explain the difference in percent ionization in the two solutions.
33. Solve an equilibrium problem (using an ICE table) to calculate the pH of each solution.
  - a. 0.15 M HF
  - b. 0.15 M NaF
  - c. a mixture that is 0.15 M in HF and 0.15 M in NaF
34. Solve an equilibrium problem (using an ICE table) to calculate the pH of each solution.
  - a. 0.18 M  $CH_3NH_2$
  - b. 0.18 M  $CH_3NH_3Cl$
  - c. a mixture that is 0.18 M in  $CH_3NH_2$  and 0.18 M in  $CH_3NH_3Cl$
35. A buffer contains significant amounts of acetic acid and sodium acetate. Write equations showing how this buffer neutralizes added acid and added base.

36. A buffer contains significant amounts of ammonia and ammonium chloride. Write equations showing how this buffer neutralizes added acid and added base.
37. Use the Henderson–Hasselbalch equation to calculate the pH of each solution in Problem 29.
38. Use the Henderson–Hasselbalch equation to calculate the pH of each solution in Problem 30.
39. Use the Henderson–Hasselbalch equation to calculate the pH of each solution.
- a solution that is 0.135 M in HClO and 0.155 M in KClO
  - a solution that contains 1.05%  $\text{C}_2\text{H}_5\text{NH}_2$  by mass and 1.10%  $\text{C}_2\text{H}_5\text{NH}_3\text{Br}$  by mass
  - a solution that contains 10.0 g of  $\text{HC}_2\text{H}_3\text{O}_2$  and 10.0 g of  $\text{NaC}_2\text{H}_3\text{O}_2$  in 150.0 mL of solution
40. Use the Henderson–Hasselbalch equation to calculate the pH of each solution.
- a solution that is 0.145 M in propanoic acid and 0.115 M in potassium propanoate
  - a solution that contains 0.785%  $\text{C}_5\text{H}_5\text{N}$  by mass and 0.985%  $\text{C}_5\text{H}_5\text{NHCl}$  by mass
  - a solution that contains 15.0 g of HF and 25.0 g of NaF in 125 mL of solution
41. Calculate the pH of the solution that results from each mixture.
- 50.0 mL of 0.15 M  $\text{HCHO}_2$  with 75.0 mL of 0.13 M  $\text{NaCHO}_2$
  - 125.0 mL of 0.10 M  $\text{NH}_3$  with 250.0 mL of 0.10 M  $\text{NH}_4\text{Cl}$
42. Calculate the pH of the solution that results from each mixture.
- 150.0 mL of 0.25 M HF with 225.0 mL of 0.30 M NaF
  - 175.0 mL of 0.10 M  $\text{C}_2\text{H}_5\text{NH}_2$  with 275.0 mL of 0.20 M  $\text{C}_2\text{H}_5\text{NH}_3\text{Cl}$
43. Calculate the ratio of NaF to HF required to create a buffer with  $\text{pH} = 4.00$ .
44. Calculate the ratio of  $\text{CH}_3\text{NH}_2$  to  $\text{CH}_3\text{NH}_3\text{Cl}$  concentration required to create a buffer with  $\text{pH} = 10.24$ .
45. What mass of sodium benzoate should you add to 150.0 mL of a 0.15 M benzoic acid solution to obtain a buffer with a pH of 4.25? (Assume no volume change.)
46. What mass of ammonium chloride should you add to 2.55 L of a 0.155 M  $\text{NH}_3$  to obtain a buffer with a pH of 9.55? (Assume no volume change.)
47. A 250.0-mL buffer solution is 0.250 M in acetic acid and 0.250 M in sodium acetate.
- What is the initial pH of this solution?
  - What is the pH after addition of 0.0050 mol of HCl?
  - What is the pH after addition of 0.0050 mol of NaOH?
48. A 100.0-mL buffer solution is 0.175 M in HClO and 0.150 M in NaClO.
- What is the initial pH of this solution?
  - What is the pH after addition of 150.0 mg of HBr?
  - What is the pH after addition of 85.0 mg of NaOH?
49. For each solution, calculate the initial and final pH after adding 0.010 mol of HCl.
- 500.0 mL of pure water
  - 500.0 mL of a buffer solution that is 0.125 M in  $\text{HC}_2\text{H}_3\text{O}_2$  and 0.115 M in  $\text{NaC}_2\text{H}_3\text{O}_2$
  - 500.0 mL of a buffer solution that is 0.155 M in  $\text{C}_2\text{H}_5\text{NH}_2$  and 0.145 M in  $\text{C}_2\text{H}_5\text{NH}_3\text{Cl}$
50. For each solution, calculate the initial and final pH after adding 0.010 mol of NaOH.
- 250.0 mL of pure water
  - 250.0 mL of a buffer solution that is 0.195 M in  $\text{HCHO}_2$  and 0.275 M in  $\text{KCHO}_2$
  - 250.0 mL of a buffer solution that is 0.255 M in  $\text{CH}_3\text{CH}_2\text{NH}_2$  and 0.235 M in  $\text{CH}_3\text{CH}_2\text{NH}_3\text{Cl}$
51. A 350.0-mL buffer solution is 0.150 M in HF and 0.150 M in NaF. What mass of NaOH can this buffer neutralize before the pH rises above 4.00? If the same volume of the buffer were 0.350 M in HF and 0.350 M in NaF, what mass of NaOH could be handled before the pH rises above 4.00?
52. A 100.0-mL buffer solution is 0.100 M in  $\text{NH}_3$  and 0.125 M in  $\text{NH}_4\text{Br}$ . What mass of HCl can this buffer neutralize before the pH falls below 9.00? If the same volume of the buffer were 0.250 M in  $\text{NH}_3$  and 0.400 M in  $\text{NH}_4\text{Br}$ , what mass of HCl could be handled before the pH fell below 9.00?
53. Determine whether or not the mixing of each pair of solutions results in a buffer.
- 100.0 mL of 0.10 M  $\text{NH}_3$ ; 100.0 mL of 0.15 M  $\text{NH}_4\text{Cl}$
  - 50.0 mL of 0.10 M HCl; 35.0 mL of 0.150 M NaOH
  - 50.0 mL of 0.15 M HF; 20.0 mL of 0.15 M NaOH
  - 175.0 mL of 0.10 M  $\text{NH}_3$ ; 150.0 mL of 0.12 M NaOH
  - 125.0 mL of 0.15 M  $\text{NH}_3$ ; 150.0 mL of 0.20 M NaOH
54. Determine whether or not the mixing of each pair of solutions results in a buffer.
- 75.0 mL of 0.10 M HF; 55.0 mL of 0.15 M NaF
  - 150.0 mL of 0.10 M HF; 135.0 mL of 0.175 M HCl
  - 165.0 mL of 0.10 M HF; 135.0 mL of 0.050 M KOH
  - 125.0 mL of 0.15 M  $\text{CH}_3\text{NH}_2$ ; 120.0 mL of 0.25 M  $\text{CH}_3\text{NH}_3\text{Cl}$
  - 105.0 mL of 0.15 M  $\text{CH}_3\text{NH}_2$ ; 95.0 mL of 0.10 M HCl
55. Blood is buffered by carbonic acid and the bicarbonate ion. Normal blood plasma is 0.024 M in  $\text{HCO}_3^-$  and 0.0012 M  $\text{H}_2\text{CO}_3$  ( $\text{pK}_{\text{a}1}$  for  $\text{H}_2\text{CO}_3$  at body temperature is 6.1).
- What is the pH of blood plasma?
  - If the volume of blood in a normal adult is 5.0 L, what mass of HCl can be neutralized by the buffering system in blood before the pH falls below 7.0 (which would result in death)?
  - Given the volume from part (b), what mass of NaOH can be neutralized before the pH rises above 7.8?
56. The fluids within cells are buffered by  $\text{H}_2\text{PO}_4^-$  and  $\text{HPO}_4^{2-}$ .
- Calculate the ratio of  $\text{HPO}_4^{2-}$  to  $\text{H}_2\text{PO}_4^-$  required to maintain a pH of 7.1 within a cell.
  - Could a buffer system employing  $\text{H}_3\text{PO}_4$  as the weak acid and  $\text{H}_2\text{PO}_4^-$  as the weak base be used as a buffer system within cells? Explain.
57. Which buffer system is the best choice to create a buffer with  $\text{pH} = 7.20$ ? For the best system, calculate the ratio of the masses of the buffer components required to make the buffer.
- |   |                               |
|---|-------------------------------|
| $\text{HC}_2\text{H}_3\text{O}_2/\text{KC}_2\text{H}_3\text{O}_2$ | $\text{HClO}_2/\text{KClO}_2$ |
| $\text{NH}_3/\text{NH}_4\text{Cl}$                                | $\text{HClO}/\text{KClO}$     |
58. Which buffer system is the best choice to create a buffer with  $\text{pH} = 9.00$ ? For the best system, calculate the ratio of the masses of the buffer components required to make the buffer.
- |                                    |                             |
|------------------------------------|-----------------------------|
| $\text{HF}/\text{KF}$              | $\text{HNO}_2/\text{KNO}_2$ |
| $\text{NH}_3/\text{NH}_4\text{Cl}$ | $\text{HClO}/\text{KClO}$   |

59. A 500.0-mL buffer solution is 0.100 M in  $\text{HNO}_2$  and 0.150 M in  $\text{KNO}_2$ . Determine if each addition would exceed the capacity of the buffer to neutralize it.
- a. 250 mg NaOH                      b. 350 mg KOH  
c. 1.25 g HBr                         d. 1.35 g HI
60. A 1.0-L buffer solution is 0.125 M in  $\text{HNO}_2$  and 0.145 M in  $\text{NaNO}_2$ . Determine the concentrations of  $\text{HNO}_2$  and  $\text{NaNO}_2$  after the addition of each substance:
- a. 1.5 g HCl                      b. 1.5 g NaOH                      c. 1.5 g HI

### Titration, pH Curves, and Indicators

61. The graphs labeled (a) and (b) show the titration curves for two equal-volume samples of monoprotic acids, one weak and one strong. Both titrations were carried out with the same concentration of strong base.

(a)

(b)

- (i) What is the approximate pH at the equivalence point of each curve?
- (ii) Which graph corresponds to the titration of the strong acid and which one to the titration of the weak acid?
62. Two 25.0-mL samples, one 0.100 M HCl and the other 0.100 M HF, are titrated with 0.200 M KOH.
- a. What is the volume of added base at the equivalence point for each titration?
- b. Is the pH at the equivalence point for each titration acidic, basic, or neutral?
- c. Which titration curve has the lower initial pH?
- d. Sketch each titration curve.
63. Two 20.0-mL samples, one 0.200 M KOH and the other 0.200 M  $\text{CH}_3\text{NH}_2$ , are titrated with 0.100 M HI.
- a. What is the volume of added acid at the equivalence point for each titration?
- b. Is the pH at the equivalence point for each titration acidic, basic, or neutral?
- c. Which titration curve has the lower initial pH?
- d. Sketch each titration curve.
64. The graphs labeled (a) and (b) show the titration curves for two equal-volume samples of bases, one weak and one strong. Both titrations were carried out with the same concentration of strong acid.

(a)

(b)

- (i) What is the approximate pH at the equivalence point of each curve?
- (ii) Which graph corresponds to the titration of the strong base and which one to the weak base?

65. Consider the curve shown here for the titration of a weak monoprotic acid with a strong base and answer each question.

- a. What is the pH and what is the volume of added base at the equivalence point?
- b. At what volume of added base is the pH calculated by working an equilibrium problem based on the initial concentration and  $K_a$  of the weak acid?
- c. At what volume of added base does  $\text{pH} = \text{p}K_a$ ?
- d. At what volume of added base is the pH calculated by working an equilibrium problem based on the concentration and  $K_b$  of the conjugate base?
- e. Beyond what volume of added base is the pH calculated by focusing on the amount of excess strong base added?
66. Consider the curve shown here for the titration of a weak base with a strong acid and answer each question.

- a. What is the pH and what is the volume of added acid at the equivalence point?
- b. At what volume of added acid is the pH calculated by working an equilibrium problem based on the initial concentration and  $K_b$  of the weak base?
- c. At what volume of added acid does  $\text{pH} = 14 - \text{p}K_b$ ?
- d. At what volume of added acid is the pH calculated by working an equilibrium problem based on the concentration and  $K_a$  of the conjugate acid?
- e. Beyond what volume of added acid is the pH calculated by focusing on the amount of excess strong acid added?
67. Consider the titration of a 35.0-mL sample of 0.175 M HBr with 0.200 M KOH. Determine each quantity.
- a. the initial pH
- b. the volume of added base required to reach the equivalence point
- c. the pH at 10.0 mL of added base
- d. the pH at the equivalence point
- e. the pH after adding 5.0 mL of base beyond the equivalence point

68. A 20.0-mL sample of 0.125 M  $\text{HNO}_3$  is titrated with 0.150 M  $\text{NaOH}$ . Calculate the pH for at least five different points throughout the titration curve and sketch the curve. Indicate the volume at the equivalence point on your graph.

69. Consider the titration of a 25.0-mL sample of 0.115 M  $\text{RbOH}$  with 0.100 M  $\text{HCl}$ . Determine each quantity.

- the initial pH
- the volume of added acid required to reach the equivalence point
- the pH at 5.0 mL of added acid
- the pH at the equivalence point
- the pH after adding 5.0 mL of acid beyond the equivalence point

70. A 15.0-mL sample of 0.100 M  $\text{Ba}(\text{OH})_2$  is titrated with 0.125 M  $\text{HCl}$ . Calculate the pH for at least five different points throughout the titration curve and sketch the curve. Indicate the volume at the equivalence point on your graph.

71. Consider the titration of a 20.0-mL sample of 0.105 M  $\text{HC}_2\text{H}_3\text{O}_2$  with 0.125 M  $\text{NaOH}$ . Determine each quantity.

- the initial pH
- the volume of added base required to reach the equivalence point
- the pH at 5.0 mL of added base
- the pH at one-half of the equivalence point
- the pH at the equivalence point
- the pH after adding 5.0 mL of base beyond the equivalence point

72. A 30.0-mL sample of 0.165 M propanoic acid is titrated with 0.300 M  $\text{KOH}$ . Calculate the pH at each volume of added base: 0 mL, 5 mL, 10 mL, equivalence point, one-half equivalence point, 20 mL, 25 mL. Sketch the titration curve.

73. Consider the titration of a 25.0-mL sample of 0.175 M  $\text{CH}_3\text{NH}_2$  with 0.150 M  $\text{HBr}$ . Determine each quantity.

- the initial pH
- the volume of added acid required to reach the equivalence point
- the pH at 5.0 mL of added acid
- the pH at one-half of the equivalence point
- the pH at the equivalence point
- the pH after adding 5.0 mL of acid beyond the equivalence point

74. A 25.0-mL sample of 0.125 M pyridine is titrated with 0.100 M  $\text{HCl}$ . Calculate the pH at each volume of added acid: 0 mL, 10 mL, 20 mL, equivalence point, one-half equivalence point, 40 mL, 50 mL. Sketch the titration curve.

75. Consider the titration curves (labeled a and b) for two weak acids, both titrated with 0.100 M  $\text{NaOH}$ .

- Which acid solution is more concentrated?
- Which acid has the larger  $K_a$ ?

76. Consider the titration curves (labeled a and b) for two weak bases, both titrated with 0.100 M  $\text{HCl}$ .

- Which base solution is more concentrated?
- Which base has the larger  $K_b$ ?

77. A 0.229-g sample of an unknown monoprotic acid is titrated with 0.112 M  $\text{NaOH}$ . The resulting titration curve is shown here. Determine the molar mass and  $pK_a$  of the acid.

78. A 0.446-g sample of an unknown monoprotic acid is titrated with 0.105 M  $\text{KOH}$ . The resulting titration curve is shown here. Determine the molar mass and  $pK_a$  of the acid.

79. A 20.0-mL sample of 0.115 M sulfurous acid ( $\text{H}_2\text{SO}_3$ ) solution is titrated with 0.1014 M  $\text{KOH}$ . At what added volume of base solution does each equivalence point occur?

80. A 20.0-mL sample of a 0.125 M diprotic acid ( $\text{H}_2\text{A}$ ) solution is titrated with 0.1019 M  $\text{KOH}$ . The acid ionization constants for the acid are  $K_{a1} = 5.2 \times 10^{-5}$  and  $K_{a2} = 3.4 \times 10^{-10}$ . At what added volume of base does each equivalence point occur?

81. Methyl red has a  $pK_a$  of 5.0 and is red in its acid form and yellow in its basic form. If several drops of this indicator are placed in a 25.0-mL sample of 0.100 M  $\text{HCl}$ , what color will the solution appear? If 0.100 M  $\text{NaOH}$  is slowly added to the  $\text{HCl}$  sample, in what pH range will the indicator change color?

82. Phenolphthalein has a  $pK_a$  of 9.7. It is colorless in its acid form and pink in its basic form. For each of the values of pH, calculate  $[\text{In}^-]/[\text{HIn}]$  and predict the color of a phenolphthalein solution.

- $\text{pH} = 2.0$
- $\text{pH} = 5.0$
- $\text{pH} = 8.0$
- $\text{pH} = 11.0$

83. Referring to Table 17.1, pick an indicator for use in the titration of each acid with a strong base.
- HF
  - HCl
  - HCN
84. Referring to Table 17.1, pick an indicator for use in the titration of each base with a strong acid.
- $\text{CH}_3\text{NH}_2$
  - NaOH
  - $\text{C}_6\text{H}_5\text{NH}_2$

### Solubility Equilibria

85. Write balanced equations and expressions for  $K_{\text{sp}}$  for the dissolution of each ionic compound.
- $\text{BaSO}_4$
  - $\text{PbBr}_2$
  - $\text{Ag}_2\text{CrO}_4$
86. Write balanced equations and expressions for  $K_{\text{sp}}$  for the dissolution of each ionic compound.
- $\text{CaCO}_3$
  - $\text{PbCl}_2$
  - AgI
87. Refer to the  $K_{\text{sp}}$  values in Table 17.2 to calculate the molar solubility of each compound in pure water.
- AgBr
  - $\text{Mg}(\text{OH})_2$
  - $\text{CaF}_2$
88. Refer to the  $K_{\text{sp}}$  values in Table 17.2 to calculate the molar solubility of each compound in pure water.
- MX ( $K_{\text{sp}} = 1.27 \times 10^{-36}$ )
  - $\text{Ag}_2\text{CrO}_4$
  - $\text{Ca}(\text{OH})_2$
89. Use the given molar solubilities in pure water to calculate  $K_{\text{sp}}$  for each compound.
- MX; molar solubility  $= 3.27 \times 10^{-11} \text{ M}$
  - $\text{PbF}_2$ ; molar solubility  $= 5.63 \times 10^{-3} \text{ M}$
  - $\text{MgF}_2$ ; molar solubility  $= 2.65 \times 10^{-4} \text{ M}$
90. Use the given molar solubilities in pure water to calculate  $K_{\text{sp}}$  for each compound.
- $\text{BaCrO}_4$ ; molar solubility  $= 1.08 \times 10^{-5} \text{ M}$
  - $\text{Ag}_2\text{SO}_3$ ; molar solubility  $= 1.55 \times 10^{-5} \text{ M}$
  - $\text{Pd}(\text{SCN})_2$ ; molar solubility  $= 2.22 \times 10^{-8} \text{ M}$
91. Two compounds with general formulas AX and  $\text{AX}_2$  have  $K_{\text{sp}} = 1.5 \times 10^{-5}$ . Which of the two compounds has the higher molar solubility?
92. Consider the compounds with the generic formulas listed and their corresponding molar solubilities in pure water. Which compound has the smallest value of  $K_{\text{sp}}$ ?
- AX; molar solubility  $= 1.35 \times 10^{-4} \text{ M}$
  - $\text{AX}_2$ ; molar solubility  $= 2.25 \times 10^{-4} \text{ M}$
  - $\text{A}_2\text{X}$ ; molar solubility  $= 1.75 \times 10^{-4} \text{ M}$
93. Refer to the  $K_{\text{sp}}$  value from Table 17.2 to calculate the solubility of iron(II) hydroxide in pure water in grams per 100.0 mL of solution.
94. The solubility of copper(I) chloride is 3.91 mg per 100.0 mL of solution. Calculate  $K_{\text{sp}}$  for CuCl.
95. Calculate the molar solubility of barium fluoride in each liquid or solution.
- pure water
  - 0.10 M  $\text{Ba}(\text{NO}_3)_2$
  - 0.15 M NaF
96. Calculate the molar solubility of MX ( $K_{\text{sp}} = 1.27 \times 10^{-36}$ ) in each liquid or solution.
- pure water
  - 0.25 M  $\text{MCl}_2$
  - 0.20 M  $\text{Na}_2\text{X}$

97. Calculate the molar solubility of calcium hydroxide in a solution buffered at each pH.
- pH = 4
  - pH = 7
  - pH = 9
98. Calculate the solubility (in grams per  $1.00 \times 10^2 \text{ mL}$  of solution) of magnesium hydroxide in a solution buffered at pH = 10. How does this compare to the solubility of  $\text{Mg}(\text{OH})_2$  in pure water?
99. Determine if each compound is more soluble in acidic solution than it is in pure water. Explain.
- $\text{BaCO}_3$
  - CuS
  - AgCl
  - $\text{PbI}_2$
100. Determine if each compound is more soluble in acidic solution than it is in pure water. Explain.
- $\text{Hg}_2\text{Br}_2$
  - $\text{Mg}(\text{OH})_2$
  - $\text{CaCO}_3$
  - AgI

### Precipitation and Qualitative Analysis

101. A solution containing sodium fluoride is mixed with one containing calcium nitrate to form a solution that is 0.015 M in NaF and 0.010 M in  $\text{Ca}(\text{NO}_3)_2$ . Does a precipitate form in the mixed solution? If so, identify the precipitate.
102. A solution containing potassium bromide is mixed with one containing lead acetate to form a solution that is 0.013 M in KBr and 0.0035 M in  $\text{Pb}(\text{C}_2\text{H}_3\text{O}_2)_2$ . Does a precipitate form in the mixed solution? If so, identify the precipitate.
103. Predict whether a precipitate will form if you mix 75.0 mL of a NaOH solution with  $\text{pOH} = 2.58$  with 125.0 mL of a 0.018 M  $\text{MgCl}_2$  solution. Identify the precipitate, if any.
104. Predict whether a precipitate will form if you mix 175.0 mL of a 0.0055 M KCl solution with 145.0 mL of a 0.0015 M  $\text{AgNO}_3$  solution. Identify the precipitate, if any.
105. Potassium hydroxide is used to precipitate each of the cations from their respective solution. Determine the minimum concentration of KOH required for precipitation to begin in each case.
- 0.015 M  $\text{CaCl}_2$
  - 0.0025 M  $\text{Fe}(\text{NO}_3)_2$
  - 0.0018 M  $\text{MgBr}_2$
106. Determine the minimum concentration of the precipitating agent on the right to cause precipitation of the cation from the solution on the left.
- 0.035 M  $\text{Ba}(\text{NO}_3)_2$ ; NaF
  - 0.085 M  $\text{CaI}_2$ ;  $\text{K}_2\text{SO}_4$
  - 0.0018 M  $\text{AgNO}_3$ ; RbCl
107. A solution is 0.010 M in  $\text{Ba}^{2+}$  and 0.020 M in  $\text{Ca}^{2+}$ .
- If sodium sulfate is used to selectively precipitate one of the cations while leaving the other cation in solution, which cation will precipitate first? What minimum concentration of  $\text{Na}_2\text{SO}_4$  will trigger the precipitation of the cation that precipitates first?
  - What is the remaining concentration of the cation that precipitates first, when the other cation begins to precipitate?

- 108.** A solution is 0.022 M in  $\text{Fe}^{2+}$  and 0.014 M in  $\text{Mg}^{2+}$ .
- If potassium carbonate is used to selectively precipitate one of the cations while leaving the other cation in solution, which cation will precipitate first? What minimum concentration of  $\text{K}_2\text{CO}_3$  will trigger the precipitation of the cation that precipitates first?
  - What is the remaining concentration of the cation that precipitates first, when the other cation begins to precipitate?

### Complex Ion Equilibria

- 109.** A solution is made  $1.1 \times 10^{-3}$  M in  $\text{Zn}(\text{NO}_3)_2$  and 0.150 M in  $\text{NH}_3$ . After the solution reaches equilibrium, what concentration of  $\text{Zn}^{2+}(\text{aq})$  remains?

- 110.** A 120.0-mL sample of a solution that is  $2.8 \times 10^{-3}$  M in  $\text{AgNO}_3$  is mixed with a 225.0-mL sample of a solution that is 0.10 M in  $\text{NaCN}$ . After the solution reaches equilibrium, what concentration of  $\text{Ag}^+(\text{aq})$  remains?

- 111.** Use the appropriate values of  $K_{\text{sp}}$  and  $K_f$  to find the equilibrium constant for the reaction.

- 112.** Use the appropriate values of  $K_{\text{sp}}$  and  $K_f$  to find the equilibrium constant for the reaction.

## Cumulative Problems

- 113.** A 150.0-mL solution contains 2.05 g of sodium benzoate and 2.47 g of benzoic acid. Calculate the pH of the solution.

- 114.** A solution is made by combining 10.0 mL of 17.5 M acetic acid with 5.54 g of sodium acetate and diluting to a total volume of 1.50 L. Calculate the pH of the solution.

- 115.** A buffer is created by combining 150.0 mL of 0.25 M  $\text{HCHO}_2$  with 75.0 mL of 0.20 M  $\text{NaOH}$ . Determine the pH of the buffer.

- 116.** A buffer is created by combining 3.55 g of  $\text{NH}_3$  with 4.78 g of  $\text{HCl}$  and diluting to a total volume of 750.0 mL. Determine the pH of the buffer.

- 117.** A 1.0-L buffer solution initially contains 0.25 mol of  $\text{NH}_3$  and 0.25 mol of  $\text{NH}_4\text{Cl}$ . In order to adjust the buffer pH to 8.75, should you add  $\text{NaOH}$  or  $\text{HCl}$  to the buffer mixture? What mass of the correct reagent should you add?

- 118.** A 250.0-mL buffer solution initially contains 0.025 mol of  $\text{HCHO}_2$  and 0.025 mol of  $\text{NaCHO}_2$ . In order to adjust the buffer pH to 4.10, should you add  $\text{NaOH}$  or  $\text{HCl}$  to the buffer mixture? What mass of the correct reagent should you add?

- 119.** In analytical chemistry, bases used for titrations must often be standardized; that is, their concentration must be precisely determined. Standardization of sodium hydroxide solutions can be accomplished by titrating potassium hydrogen phthalate ( $\text{KHC}_8\text{H}_4\text{O}_4$ ), also known as KHP, with the  $\text{NaOH}$  solution to be standardized.

- Write an equation for the reaction between  $\text{NaOH}$  and KHP.
- The titration of 0.5527 g of KHP required 25.87 mL of an  $\text{NaOH}$  solution to reach the equivalence point. What is the concentration of the  $\text{NaOH}$  solution?

- 120.** A 0.5224-g sample of an unknown monoprotic acid was titrated with 0.0998 M  $\text{NaOH}$ . The equivalence point of the titration occurred at 23.82 mL. Determine the molar mass of the unknown acid.

- 121.** A 0.25-mol sample of a weak acid with an unknown  $\text{pK}_a$  was combined with 10.0 mL of 3.00 M  $\text{KOH}$ , and the resulting solution was diluted to 1.500 L. The measured pH of the solution was 3.85. What is the  $\text{pK}_a$  of the weak acid?

- 122.** A 5.55-g sample of a weak acid with  $K_a = 1.3 \times 10^{-4}$  was combined with 5.00 mL of 6.00 M  $\text{NaOH}$ , and the resulting solution was diluted to 750.0 mL. The measured pH of the solution was 4.25. What is the molar mass of the weak acid?

- 123.** A 0.552-g sample of ascorbic acid (vitamin C) was dissolved in water to a total volume of 20.0 mL and titrated with 0.1103 M

$\text{KOH}$ . The equivalence point occurred at 28.42 mL. The pH of the solution at 10.0 mL of added base was 3.72. From this data, determine the molar mass and  $K_a$  for vitamin C.

- 124.** Sketch the titration curve from Problem 123 by calculating the pH at the beginning of the titration, at one-half of the equivalence point, at the equivalence point, and at 5.0 mL beyond the equivalence point. Pick a suitable indicator for this titration from Table 17.1.

- 125.** One of the main components of hard water is  $\text{CaCO}_3$ . When hard water evaporates, some of the  $\text{CaCO}_3$  is left behind as a white mineral deposit. If a hard water solution is saturated with calcium carbonate, what volume of the solution has to evaporate to deposit  $1.00 \times 10^2$  mg of  $\text{CaCO}_3$ ?

- 126.** Gout—a condition that results in joint swelling and pain—is caused by the formation of sodium urate ( $\text{NaC}_5\text{H}_3\text{N}_4\text{O}_3$ ) crystals within tendons, cartilage, and ligaments. Sodium urate precipitates out of blood plasma when uric acid levels become abnormally high. This sometimes happens as a result of eating too many rich foods and consuming too much alcohol, which is why gout is sometimes referred to as the “disease of kings.” If the sodium concentration in blood plasma is 0.140 M, and  $K_{\text{sp}}$  for sodium urate is  $5.76 \times 10^{-8}$ , what minimum concentration of urate would result in precipitation?

- 127.** Pseudogout, a condition with symptoms similar to those of gout (see Problem 126), is caused by the formation of calcium diphosphate ( $\text{Ca}_2\text{P}_2\text{O}_7$ ) crystals within tendons, cartilage, and ligaments. Calcium diphosphate will precipitate out of blood plasma when diphosphate levels become abnormally high. If the calcium concentration in blood plasma is 9.2 mg/dL, and  $K_{\text{sp}}$  for calcium diphosphate is  $8.64 \times 10^{-13}$ , what minimum concentration of diphosphate results in precipitation?

- 128.** Calculate the solubility of silver chloride in a solution that is 0.100 M in  $\text{NH}_3$ .

- 129.** Calculate the solubility of  $\text{CuX}$  in a solution that is 0.150 M in  $\text{NaCN}$ .  $K_{\text{sp}}$  for  $\text{CuX}$  is  $1.27 \times 10^{-36}$ .

- 130.** Aniline, abbreviated  $\phi\text{NH}_2$ , where  $\phi$  is  $\text{C}_6\text{H}_5$ , is an important organic base used in the manufacture of dyes. It has  $K_b = 4.3 \times 10^{-10}$ . In a certain manufacturing process it is necessary to keep the concentration of  $\phi\text{NH}_3^+$  (aniline's conjugate acid, the anilinium ion) below  $1.0 \times 10^{-9}$  M in a solution that is 0.10 M in aniline. Find the concentration of  $\text{NaOH}$  required for this process.

- 131.** The  $K_b$  of hydroxylamine,  $\text{NH}_2\text{OH}$ , is  $1.10 \times 10^{-8}$ . A buffer solution is prepared by mixing 100.0 mL of a 0.36 M hydroxylamine solution with 50.0 mL of a 0.26 M HCl solution. Determine the pH of the resulting solution.
- 132.** A 0.867-g sample of an unknown acid requires 32.2 mL of a 0.182 M barium hydroxide solution for neutralization. Assuming the acid is diprotic, calculate the molar mass of the acid.
- 133.** A 25.0-mL volume of a sodium hydroxide solution requires 19.6 mL of a 0.189 M hydrochloric acid for neutralization. A 10.0-mL volume of a phosphoric acid solution requires 34.9 mL of the sodium hydroxide solution for complete neutralization. Calculate the concentration of the phosphoric acid solution.
- 134.** Find the mass of sodium formate that must be dissolved in 250.0  $\text{cm}^3$  of a 1.4 M solution of formic acid to prepare a buffer solution with  $\text{pH} = 3.36$ .
- 135.** What relative masses of dimethyl amine and dimethyl ammonium chloride do you need to prepare a buffer solution of  $\text{pH} = 10.43$ ?
- 136.** You are asked to prepare 2.0 L of a HCN/NaCN buffer that has a pH of 9.8 and an osmotic pressure of 1.35 atm at 298 K. What masses of HCN and NaCN should you use to prepare the buffer? (Assume complete dissociation of NaCN.)
- 137.** What should the molar concentrations of benzoic acid and sodium benzoate be in a solution that is buffered at a pH of 4.55 and has a freezing point of  $-2.0^\circ\text{C}$ ? (Assume complete dissociation of sodium benzoate and a density of 1.01 g/mL for the solution.)

## Challenge Problems

- 138.** Derive an equation similar to the Henderson–Hasselbalch equation for a buffer composed of a weak base and its conjugate acid. Instead of relating pH to  $\text{p}K_a$  and the relative concentrations of an acid and its conjugate base (as the Henderson–Hasselbalch equation does), the equation should relate pOH to  $\text{p}K_b$  and the relative concentrations of a base and its conjugate acid.
- 139.** Since soap and detergent action is hindered by hard water, laundry formulations usually include water softeners—called builders—designed to remove hard water ions (especially  $\text{Ca}^{2+}$  and  $\text{Mg}^{2+}$ ) from the water. A common builder used in North America is sodium carbonate. Suppose that the hard water used to do laundry contains 75 ppm  $\text{CaCO}_3$  and 55 ppm  $\text{MgCO}_3$  (by mass). What mass of  $\text{Na}_2\text{CO}_3$  is required to remove 90.0% of these ions from 10.0 L of laundry water?
- 140.** A 0.558-g sample of a diprotic acid with a molar mass of 255.8 g/mol is dissolved in water to a total volume of 25.0 mL. The solution is then titrated with a saturated calcium hydroxide solution.
- Assuming that the  $\text{p}K_a$  values for each ionization step are sufficiently different to see two equivalence points, determine the volume of added base for the first and second equivalence points.
  - The pH after adding 25.0 mL of the base is 3.82. Find the value of  $K_{a1}$ .
  - The pH after adding 20.0 mL past the first equivalence point is 8.25. Find the value of  $K_{a2}$ .
- 141.** When excess solid  $\text{Mg}(\text{OH})_2$  is shaken with 1.00 L of 1.0 M  $\text{NH}_4\text{Cl}$  solution, the resulting saturated solution has  $\text{pH} = 9.00$ . Calculate the  $K_{sp}$  of  $\text{Mg}(\text{OH})_2$ .
- 142.** What amount of solid NaOH must be added to 1.0 L of a 0.10 M  $\text{H}_2\text{CO}_3$  solution to produce a solution with  $[\text{H}^+] = 3.2 \times 10^{-11} \text{ M}$ ? There is no significant volume change as the result of the addition of the solid.
- 143.** Calculate the solubility of  $\text{Au}(\text{OH})_3$  in (a) water and (b) 1.0 M nitric acid solution ( $K_{sp} = 5.5 \times 10^{-46}$ ).
- 144.** Calculate the concentration of  $\Gamma^-$  in a solution obtained by shaking 0.10 M KI with an excess of  $\text{AgCl}(s)$ .
- 145.** What volume of 0.100 M sodium carbonate solution is required to precipitate 99% of the Mg from 1.00 L of 0.100 M magnesium nitrate solution?
- 146.** Find the solubility of CuI in 0.40 M HCN solution. The  $K_{sp}$  of CuI is  $1.1 \times 10^{-12}$  and the  $K_f$  for the  $\text{Cu}(\text{CN})_2^-$  complex ion is  $1 \times 10^{24}$ .
- 147.** Find the pH of a solution prepared from 1.0 L of a 0.10 M solution of  $\text{Ba}(\text{OH})_2$  and excess  $\text{Zn}(\text{OH})_2(s)$ . The  $K_{sp}$  of  $\text{Zn}(\text{OH})_2$  is  $3 \times 10^{-15}$  and the  $K_f$  of  $\text{Zn}(\text{OH})_4^{2-}$  is  $2 \times 10^{15}$ .
- 148.** What amount of HCl gas must be added to 1.00 L of a buffer solution that contains [acetic acid] = 2.0 M and [acetate] = 1.0 M in order to produce a solution with  $\text{pH} = 4.00$ ?

## Conceptual Problems

- 149.** Without doing any calculations, determine if  $\text{pH} = \text{p}K_a$ ,  $\text{pH} > \text{p}K_a$ , or  $\text{pH} < \text{p}K_a$ . Assume that HA is a weak monoprotic acid.
- 0.10 mol HA and 0.050 mol of  $\text{A}^-$  in 1.0 L of solution
  - 0.10 mol HA and 0.150 mol of  $\text{A}^-$  in 1.0 L of solution
  - 0.10 mol HA and 0.050 mol of  $\text{OH}^-$  in 1.0 L of solution
  - 0.10 mol HA and 0.075 mol of  $\text{OH}^-$  in 1.0 L of solution
- 150.** A buffer contains 0.10 mol of a weak acid and 0.20 mol of its conjugate base in 1.0 L of solution. Determine whether or not each addition exceeds the capacity of the buffer.
- adding 0.020 mol of NaOH
  - adding 0.020 mol of HCl
  - adding 0.10 mol of NaOH
  - adding 0.010 mol of HCl
- 151.** Consider three solutions:
- 0.10 M solution of a weak monoprotic acid
  - 0.10 M solution of strong monoprotic acid
  - 0.10 M solution of a weak diprotic acid
- Each solution is titrated with 0.15 M NaOH. Which quantity is the same for all three solutions?
- the volume required to reach the final equivalence point
  - the volume required to reach the first equivalence point
  - the pH at the first equivalence point
  - the pH at one-half the first equivalence point

- 152.** Two monoprotic acid solutions (A and B) are titrated with identical NaOH solutions. The volume to reach the equivalence point for solution A is twice the volume required to reach the equivalence point for solution B, and the pH at the equivalence point of solution A is higher than the pH at the equivalence point for solution B. Which statement is true?
- The acid in solution A is more concentrated than in solution B and is also a stronger acid than that in solution B.
  - The acid in solution A is less concentrated than in solution B and is also a weaker acid than that in solution B.

- The acid in solution A is more concentrated than in solution B and is also a weaker acid than that in solution B.
- The acid in solution A is less concentrated than in solution B and is also a stronger acid than that in solution B.

- 153.** Describe the solubility of  $\text{CaF}_2$  in each solution compared to its solubility in water.
- in a 0.10 M NaCl solution
  - in a 0.10 M NaF solution
  - in a 0.10 M HCl solution

- 154.** Why does the titration of a weak acid with a strong base always have a basic equivalence point?

### Active Classroom Learning

## Questions for Group Work

Discuss these questions with the group and record your consensus answer.

- 155.** Name a compound that you could add to a solution of each of the compounds to make a buffer. Explain your reasoning in complete sentences.
- acetic acid
  - sodium nitrite
  - ammonia
  - potassium formate
  - $\text{Na}_2\text{HPO}_4$  (two possible answers)
- 156.** Derive the Henderson–Hasselbalch equation as a group. Take turns having each group member write and explain the next step in the derivation.
- 157.** With group members acting as atoms or ions, act out the reaction that occurs when HCl is added to a buffer solution composed of  $\text{HC}_2\text{H}_3\text{O}_2$  and  $\text{NaC}_2\text{H}_3\text{O}_2$ . Write out a script for a narrator that describes the processes that occur, including how the buffer keeps the pH approximately the same even though a strong acid is added.

- 158.** A certain town gets its water from an underground aquifer that contains water in equilibrium with calcium carbonate limestone.
- What is the symbol for the equilibrium constant that describes calcium carbonate dissolving in water? What is the numerical value?
  - Calculate the molar solubility of calcium carbonate.
  - If an entire coffee cup of water (about 200 mL) evaporated on your desk over spring break, how many grams of calcium carbonate would be left behind?
  - If you wanted to clean out your coffee cup, would it be better to use an acidic or basic cleaning solution? Why?
- 159.** Have each group member look up the  $K_{\text{sp}}$  for a different compound. Calculate the molar solubility. Do the numerical values suggest that the compound is soluble or insoluble? Compare answers with the solubility rules from Chapter 4, and have each group member present his or her findings to the group.

## Data Interpretation and Analysis

### Buffers and Hydroponics

- 160.** Hydroponics is a method for growing plants in water with added nutrients and oxygen. No soil is used. A deviation from the optimal pH range of 5.5–6.5 can prevent a hydroponic plant from obtaining the necessary minerals and oxygen it needs to grow. To help maintain a pH of 5.5–6.5, growers use a citrate salt buffer system. Citric acid,  $\text{H}_3\text{C}_6\text{H}_5\text{O}_7$ , is a triprotic acid that has three carboxylic acid groups (Figure a ▽).

▲ **FIGURE a** Structure of Citric Acid.

Citric acid has three acid-dissociation constants shown here:

Use the information provided in the figures and equations to answer the following questions:

- Write a chemical equation that shows how citric acid reacts with a hydroxide ion.
- Which two of the citrate salts listed in Table a would you use to make a buffer with a pH range of 5.5–6.5? Explain.
- Show how your buffer system (from part b) reacts with incoming acid ( $\text{H}_3\text{O}^+$ ) and incoming base ( $\text{OH}^-$ ).
- Figure b represents a titration curve for citric acid ( $\text{H}_3\text{C}_6\text{H}_5\text{O}_7$ ) with a strong base. On the graph, indicate the buffer region involving the salts you chose in part b.
- To prepare a buffer with pH = 6.0, what is the proper ratio of the concentrations of the two citrate salts (from part b)? If the buffer must neutralize at least 0.010 M added acid, what should the minimum concentration be for each of the two buffer components?

Potassium Dihydrogen Citrate	Potassium Hydrogen Citrate	Potassium Citrate
$\text{KH}_2\text{C}_6\text{H}_5\text{O}_7$	$\text{K}_2\text{HC}_6\text{H}_5\text{O}_7$	$\text{K}_3\text{C}_6\text{H}_5\text{O}_7$

## Answers to Conceptual Connections

### Buffers

**17.1 (d)** Only this solution contains significant amounts of a weak acid and its conjugate base. (Remember that  $\text{HNO}_3$  is a strong acid, but  $\text{HNO}_2$  is a weak acid.)

### pH of Buffer Solutions

**17.2 (a)** Since the pH of the buffer is less than the  $\text{pK}_a$  of the acid, the buffer must contain more acid than base ( $[\text{HA}] > [\text{A}^-]$ ). In order to raise the pH of the buffer from 4.25 to 4.72, you must add more of the weak base (adding a base will make the buffer solution more basic).

### Buffering Action

**17.3 (a)** Since one HA molecule is converted to one ion of the conjugate base ( $\text{A}^-$  ion), one  $\text{OH}^-$  ion was added to the buffer solution.

### Adding Acid or Base to a Buffer

**17.4 (b)** Since acid is added to the buffer, the pH will become slightly lower (slightly more acidic). Answer (a) reflects too large a change in pH for a buffer, and answers (c) and (d) have the pH changing in the wrong direction.

### Buffer Capacity

**17.5 (a)** Adding 0.050 mol of HCl destroys the buffer because it will react with all of the NaF, leaving no conjugate base in the buffer mixture.

### Titration Equivalence Point

**17.6 (d)** Because the flask contains 7  $\text{H}^+$  ions, the equivalence point is reached when 7  $\text{OH}^-$  ions have been added.

### The Half-Equivalence Point

**17.7 (c)** The pH at the half-equivalence point is the  $\text{pK}_a$  of the conjugate acid, which is equal to  $14.00 - 8.75 = 5.25$ .

### Acid–Base Titrations

**17.8 (c)** Since the volumes and concentrations of all three acids are the same, the volume of NaOH required to reach the first equivalence point (and the only equivalence point for titrations i and iii) is the same for all three titrations.

### Common Ion Effect

**17.9 (c)** The sodium nitrate solution is the only one that has no common ion with barium sulfate. The other two solutions have common ions with barium sulfate; therefore, the solubility of barium sulfate is lower in these solutions.

### Solubility and Complex Ion Equilibria

**17.10 (c)** Only NaCN contains an anion ( $\text{CN}^-$ ) that forms a complex ion with  $\text{Cu}^{2+}$  [from Table 17.3 we can see that  $K_f = 1.0 \times 10^{25}$  for  $\text{Cu}(\text{CN})_4^{2-}$ ]. Therefore, the presence of  $\text{CN}^-$  will drive the dissolution reaction of CuS.

# Free Energy and Thermodynamics

Die Energie der Welt ist konstant. Die Entropie der Welt strebt einem Maximum zu.  
(The energy of the world is constant. The entropy of the world tends towards a maximum.)

**KEY LEARNING OUTCOMES** 878

Throughout this book, we have examined chemical and physical changes. We have studied how fast chemical changes occur (kinetics) and how to predict how far they will go (through the use of equilibrium constants). We have learned that acids neutralize bases and that gases expand to fill their containers. We now turn to the following question: why do these changes occur in the first place? What ultimately drives physical and chemical changes in matter? The answer may surprise you. The driving force behind chemical and physical change in the universe is a quantity called *entropy*, which is related to the dispersion (spreading out) of energy. Nature tends toward that state in which energy is spread out to the greatest extent possible. Although it does not seem obvious at first glance, the freezing of water below 0 °C, the dissolving of a solid into a solution, the neutralization of an acid by a base, and even the development of a person from an embryo all increase the entropy in the universe (they all result in greater energy dispersion). In our universe, entropy always increases.

▲ In this clever illusion, it seems that the water can perpetually flow through the canal. However, perpetual motion is forbidden under the laws of thermodynamics.

## 18.1 Nature's Heat Tax: You Can't Win and You Can't Break Even

Energy transactions are like gambling—you walk into the casino with your pockets full of cash and (if you keep gambling long enough) you walk out empty-handed. In the long run, you lose money in gambling because the casino takes a cut on each transaction. So it is with energy. Nature takes a cut—sometimes referred to as “nature’s heat tax”—on every energy transaction so that, in the end, energy is dissipated.

▲ A rechargeable battery always requires more energy to charge than the energy available for work during discharging because some energy is always lost to the surroundings during the charging/discharging cycle.

See the box entitled *Redheffer's Perpetual Motion Machine* in Section 6.3.

Recall from Chapter 6 that, according to the first law of thermodynamics, energy is conserved in chemical processes. When we burn gasoline to run a car, for example, the amount of energy produced by the chemical reaction does not vanish, nor does any new energy appear that was not present as potential energy (within the gasoline) before the combustion. Some of the energy from the combustion reaction goes toward driving the car forward (about 20%), and the rest is dissipated into the surroundings as heat (feel a car engine after a drive if you doubt this). The total energy given off by the combustion reaction exactly equals the sum of the amount of energy that goes to propel the car and the amount dissipated as heat—energy is conserved. In other words, when it comes to energy, we can't win; we cannot create energy that was not there to begin with.

The picture becomes more interesting, however, when we consider the second law of thermodynamics. The second law—which we examine in more detail throughout this chapter—implies that not only can we not win in an energy transaction, we cannot even break even. For example, consider a rechargeable battery. Suppose that when we use the fully charged battery for some application, the energy from the battery does 100 kJ of work. Recharging the battery to its original state will *necessarily* (according to the second law of thermodynamics) require *more than* 100 kJ of energy. Energy is not destroyed during the cycle of discharging and recharging the battery, but some energy must be lost to the surroundings in order for the process to occur at all. Nature imposes a heat tax, an unavoidable cut of every energy transaction.

The implications of the second law for energy use are significant. First of all, according to the second law, we cannot create a perpetual motion machine (a machine that perpetually moves *without any energy input*). If the machine is to be in motion, it must pay the heat tax with each cycle of its motion—over time, it will therefore run down and stop moving.

Second, in most energy transactions, not only is the heat tax lost to the surroundings, but additional energy is also lost as heat because real-world processes do not achieve the theoretically possible maximum efficiency (Figure 18.1◀). Consequently, the most efficient use of energy generally occurs with the smallest number of transactions. For example, heating your home with natural gas is generally cheaper and more efficient than heating it with electricity (Figure 18.2▶). When you heat your home with natural gas, there is only one energy transaction—you burn the gas and the heat from the reaction warms the house. When you heat your home with electricity, several transactions occur. Most electricity is generated from the combustion of fossil fuels; the heat from the burning fuel boils water to create steam. The steam then turns a turbine on a generator to create electricity. The electricity travels from the power plant to your home, and some of the energy is lost as heat during the trip. Finally, the electricity runs the heater that generates heat. With each transaction, energy is lost to the surroundings, resulting in a less efficient use of energy than if you had burned natural gas directly.

◀ **FIGURE 18.1 Energy Loss** In most energy transactions, some energy is lost to the surroundings, so each transaction is only fractionally efficient.

## CONCEPTUAL CONNECTION 18.1

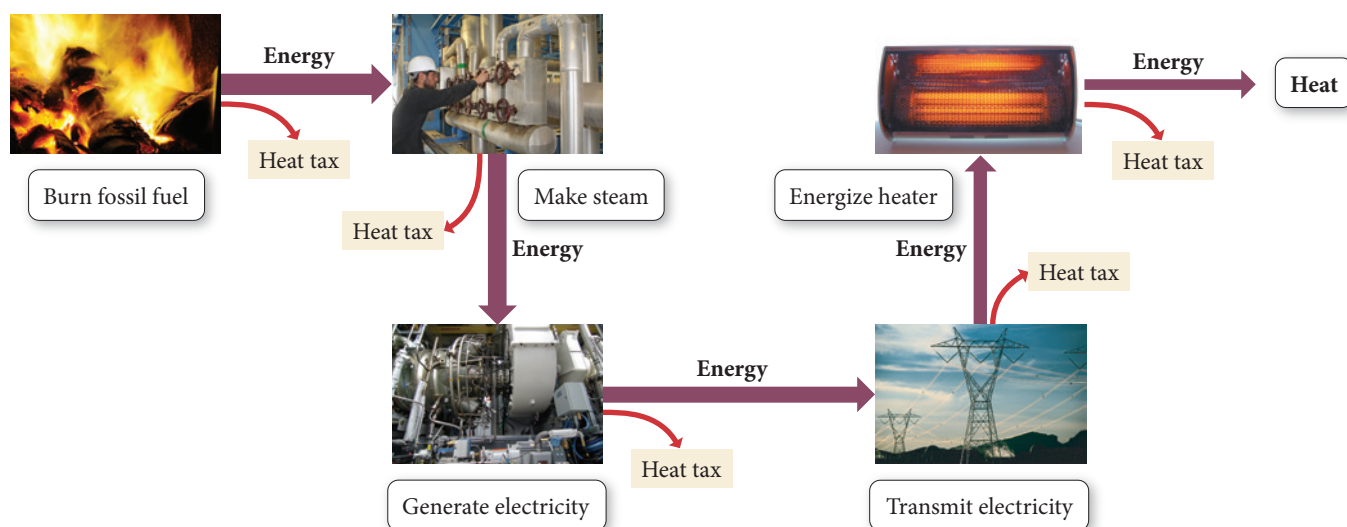

**Nature's Heat Tax and Diet** Advocates of a vegetarian diet argue that the amount of cropland required for one person to maintain a meat-based diet is about six to ten times greater than the amount required for the same person to maintain a vegetarian diet. Apply the concept of nature's heat tax to explain this assertion.

### Heating with Natural Gas

### Heating with Electricity

▲ **FIGURE 18.2 Heating with Gas versus Heating with Electricity** When natural gas heats a home, only a single energy transaction is involved, so the heat tax is minimized. When electricity is used to heat a home, a number of energy transactions are required, each of which involves some loss. The result is a much lower efficiency.

## 18.2 Spontaneous and Nonspontaneous Processes

A fundamental goal of thermodynamics is to predict *spontaneity*. For example, will rust spontaneously form when iron comes into contact with oxygen? Will water spontaneously decompose into hydrogen and oxygen? A **spontaneous process** is one that occurs *without ongoing outside intervention* (such as the performance of work by some external force). For example, when you drop a book in a gravitational field, it spontaneously drops to the floor. When you place a ball on a slope, it spontaneously rolls down the slope.

For simple mechanical systems, such as the dropping of a book or the rolling of a ball, predicting spontaneity is fairly intuitive. A mechanical system tends toward lowest potential energy, which is usually easy to see (at least in *simple* mechanical systems).

◀ Iron spontaneously rusts when it comes in contact with oxygen.

► **FIGURE 18.3 Mechanical Potential Energy and Chemical Potential** (a) Mechanical potential energy predicts the direction in which a mechanical system will spontaneously move. (b) We seek a chemical potential that predicts the direction in which a chemical system will spontaneously move.

However, the prediction of spontaneity for chemical systems is not so intuitively obvious. To make these predictions, we need to develop a criterion for the spontaneity of chemical systems. In other words, we need to develop a *chemical potential* that predicts the direction of a chemical system, much as mechanical potential energy predicts the direction of a mechanical system (Figure 18.3▲).

We must not confuse the *spontaneity* of a chemical reaction with the *speed* of a chemical reaction. In thermodynamics, we study the *spontaneity* of a reaction—the direction in which and extent to which a chemical reaction proceeds. In kinetics, we study the *speed* of the reaction—how fast a reaction takes place (Figure 18.4►). A reaction may be thermodynamically spontaneous but kinetically slow at a given temperature. For example, the conversion of diamond to graphite is thermodynamically spontaneous. But your diamonds will not become worthless anytime soon because the process is extremely slow kinetically. Although the rate of a spontaneous process can be increased by the use of a catalyst, a nonspontaneous process cannot be made spontaneous by the use of a catalyst. Catalysts affect only the rate of a reaction, not the spontaneity.

► Even though graphite is thermodynamically more stable than diamond, the conversion of diamond to graphite is kinetically so slow that it does not occur at any measurable rate.

One more observation about nonspontaneity—a nonspontaneous process is not *impossible*. For example, the extraction of iron metal from iron ore is a nonspontaneous process; it does not happen if the iron ore is left to itself, but that does not mean it is impossible. As we will see later in this chapter, a nonspontaneous process can be made spontaneous by coupling it to another process that is spontaneous or by supplying

◀ **FIGURE 18.4 Thermodynamics and**

**Kinetics** Thermodynamics deals with the relative chemical potentials of the reactants and products. It enables us to predict whether a reaction will be spontaneous and to calculate how much work it can do. Kinetics deals with the chemical potential of intermediate states and enables us to determine why a reaction is slow or fast.

energy from an external source. Iron can be separated from its ore if external energy is supplied, usually by means of another reaction (that is itself highly spontaneous).

## 18.3 Entropy and the Second Law of Thermodynamics

**Entropy and the Second Law of Thermodynamics**

The first candidate in our search for a chemical potential might be enthalpy, which we defined in Chapter 6. Perhaps, just as a mechanical system proceeds in the direction of lowest potential energy, so a chemical system might proceed in the direction of lowest enthalpy. If this were the case, all exothermic reactions would be spontaneous and all endothermic reactions would not. However, although *most* spontaneous processes are exothermic, some spontaneous processes are *endothermic*. For example, above 0 °C, ice spontaneously melts (an endothermic process). So enthalpy must not be the sole criterion for spontaneity.

We can learn more about the driving force behind chemical reactions by considering several processes (like ice melting) that involve an increase in enthalpy. The processes listed here are energetically uphill (they are endothermic), yet they occur spontaneously. What drives them?

- the melting of ice above 0 °C
- the evaporation of liquid water to gaseous water
- the dissolution of sodium chloride in water

Each of these processes is endothermic *and* spontaneous. Do they have anything in common? Notice that, in each process, disorder or randomness increases. In the melting of ice, the arrangement of the water molecules changes from a highly ordered one (in ice) to a somewhat disorderly one (in liquid water).

See Section 6.6 for the definition of enthalpy.

The use of the word *disorder* here is analogous to our macroscopic notions of disorder. The definition of molecular disorder, which is covered shortly, is very specific.

◀ When ice melts, the arrangement of water molecules changes from orderly to more disorderly.

During the evaporation of a liquid to a gas, the arrangement changes from a *somewhat* disorderly one (atoms or molecules in the liquid) to a *highly* disorderly one (atoms or molecules in the gas).

► When water evaporates, the arrangement of water molecules becomes still more disorderly.

In the dissolution of a salt into water, the arrangement again changes from an orderly one (in which the ions in the salt occupy regular positions in the crystal lattice) to a more disorderly one (in which the ions are randomly dispersed throughout the liquid water).

► When salt dissolves in water, the arrangement of the molecules and ions becomes more disorderly.

In all three of these processes, a quantity called *entropy*—related to disorder or randomness at the molecular level—increases.

## Entropy

We have hit upon the criterion for spontaneity in chemical systems: entropy. Informally, we can think of entropy as disorder or randomness. But the concept of disorder or randomness on the macroscopic scale—such as the messiness of a drawer—is only *analogous* to the concept of disorder or randomness on the molecular scale. Formally, **entropy**, abbreviated by the symbol  $S$ , has the following definition:

**Entropy ( $S$ ) is a thermodynamic function that increases with the number of *energetically equivalent* ways to arrange the components of a system to achieve a particular state.**

Austrian physicist, Ludwig Boltzmann (1844–1906) expressed this definition mathematically as:

$$S = k \ln W$$

where  $k$  is the Boltzmann constant (the gas constant divided by Avogadro's number,  $R/N_A = 1.38 \times 10^{-23} \text{ J/K}$ ) and  $W$  is the number of energetically equivalent ways to arrange the components of the system. Since  $W$  is unitless (it is simply a number), the units of entropy are joules per kelvin (J/K). We talk about the significance of the units shortly. As we can see from the equation, as  $W$  increases, entropy increases.

The key to understanding entropy is the quantity  $W$ . What does  $W$ —the number of energetically equivalent ways to arrange the components of the system—signify? Imagine a system of particles such as a fixed amount of an ideal gas. A given set of conditions ( $P$ ,  $V$ , and  $T$ ) defines the *state* (or *macrostate*) of the system. As long as these conditions remain constant, the energy of the system also remains constant. However, exactly where that energy is at any given instant is anything but constant.

At any one instant, a particular gas particle may have a good deal of kinetic energy. However, after a very short period of time, that particle may have very little kinetic energy (because it lost its energy through collisions with other particles). The exact internal energy distribution among the particles at any one instant is sometimes referred to as a *microstate*. We can think of a microstate as a snapshot of the system at a given instant in time. The next instant, the snapshot (the microstate) changes. However, the *macrostate*—defined by  $P$ ,  $V$ , and  $T$ —remains constant. A given macrostate can exist as a result of a large number of different microstates. In other words, the snapshot (or microstate) of a given macrostate is generally different from one moment to the next as the energy of the system is constantly redistributing itself among the particles of the system.

We can conceive of  $W$  in terms of microstates. The quantity,  $W$ , is the number of *possible* microstates that can result in a given macrostate. For example, suppose that we have two systems (call them System A and System B) and that each is composed of two particles (one blue and one red). Both systems have a total energy of 4 joules, but System A has only one energy level and System B has two:

Each system has the same total energy (4 J), but System A has only one possible microstate (the red and the blue particles both occupying the 2 J energy level) while System B has a second possible microstate:

In this second microstate for System B, the blue particle has 3 J and the red one has 1 J (as opposed to System B's first microstate, where the energy of the particles is switched). This second microstate is not possible for System A because it has only one energy level. For System A,  $W = 1$ , but for System B,  $W = 2$ . In other words, System B has more microstates that result in the same 4 J macrostate. Since  $W$  is larger for System B than for

▲ Boltzmann's equation is engraved on his tombstone.

System A, System B has greater *entropy*; it has more *energetically equivalent ways to arrange the components of the system*.

We can understand an important aspect of entropy by turning our attention to energy for a moment. The entropy of a state increases with the number of *energetically equivalent ways to arrange the components of the system to achieve that particular state*. This implies that *the state with the highest entropy also has the greatest dispersal of energy*. Returning to our previous example, the energy of System B is dispersed over two energy levels instead of being confined to just one. At the heart of entropy is the concept of energy dispersal or energy randomization. *A state in which a given amount of energy is more highly dispersed (or more highly randomized) has more entropy than a state in which the same energy is more highly concentrated*.

We have already alluded to the **second law of thermodynamics**; we now formally define it:

**For any spontaneous process, the entropy of the *universe* increases ( $\Delta S_{\text{univ}} > 0$ ).**

*The criterion for spontaneity is the entropy of the universe.* Processes that increase the entropy of the universe—those that result in greater dispersal or randomization of energy—occur spontaneously. Processes that decrease the entropy of the universe do not occur spontaneously.

Entropy, like enthalpy, is a *state function*—its value depends only on the state of the system, not on how the system arrived at that state. Therefore, for any process, *the change in entropy is the entropy of the final state minus the entropy of the initial state*:

$$\Delta S = S_{\text{final}} - S_{\text{initial}}$$

Entropy determines the direction of chemical and physical change. *A chemical system proceeds in a direction that increases the entropy of the universe*—it proceeds in a direction that has the largest number of *energetically equivalent ways to arrange its components*.

## The Entropy Change upon the Expansion of an Ideal Gas

To better understand this tendency, let us examine the expansion of an ideal gas into a vacuum (a spontaneous process with no associated change in enthalpy). Consider a flask containing an ideal gas that is connected to another, evacuated, flask by a tube equipped with a stopcock. When the stopcock is opened, the gas spontaneously expands into the evacuated flask. Since the gas is expanding into a vacuum, the pressure against which it expands is zero, and therefore the work ( $w = -P_{\text{ext}} \Delta V$ ) is also zero.

However, even though the total energy of the gas does not change during the expansion, the entropy does change. To picture this, consider a simplified system containing only four gas atoms:

When the stopcock is opened, several possible energetically equivalent final states may result, each with the four atoms distributed in a different way. For example, there could be three atoms in the flask on the left and one in the flask on the right, or vice versa. For simplicity, we consider only the possibilities shown in the figure in the left margin, which are state A, state B, and state C. Since the energy of any one atom is the same in either flask, and since the atoms do not interact, states A, B, and C are energetically equivalent.

Now we ask the following question for each state: how many microstates give rise to the same macrostate? To keep track of the microstates, we label the atoms 1–4. Although they have different numbered labels, since the atoms are all the same, there is externally

See the discussion of state functions in Section 6.3.

See the discussion of work done by an expanding gas in Section 6.4.

no difference between them. For states A and B, only one microstate results in the specified macrostate—atoms 1–4 on the left side or the right side, respectively:

For state C, however, six different possible microstates all result in the same macrostate (two atoms on each side):

This means that if the atoms are just randomly moving between the two flasks, the statistical probability of finding the atoms in state C is six times greater than the probability of finding the atoms in state A or state B. Consequently, even for a simple system consisting of only four atoms, the atoms are most likely to be found in state C. State C has the greatest entropy—it has the greatest number of energetically equivalent ways to distribute its components.

As the number of atoms increases, the number of microstates that leads to the atoms being equally distributed between the two flasks increases dramatically. For example, with 10 atoms, the number of microstates leading to an equal distribution of atoms between two flasks is 252 and with 20 atoms the number of microstates is 184,756. Yet, the number of microstates that leads to all of the atoms being only in the left flask (or all

In these drawings, the exact location of an atom within a flask is insignificant. The significant aspect is whether the atom is in the left flask or the right flask.

For  $n$  particles, the number of ways to put  $r$  particles in one flask and  $n - r$  particles in the other flask is  $n! / [(n - r)!r!]$ . For 10 atoms,  $n = 10$  and  $r = 5$ .

only in the right flask) does not increase—it is always only 1. In other words, the arrangement in which the atoms are equally distributed between the two flasks has a much larger number of possible microstates and therefore much greater entropy. The system thus tends toward that state.

The *change in entropy* in transitioning from a state in which all of the atoms are in the left flask to the state in which the atoms are evenly distributed between both flasks is *positive* because the final state has a greater entropy than the initial state:

$$\Delta S = S_{\text{final}} - S_{\text{initial}}$$

$\uparrow$   
 Entropy of state in  
 which atoms are  
 distributed between  
 both flasks

$\uparrow$   
 Entropy of state in  
 which atoms are all  
 in one flask

Since  $S_{\text{final}}$  is greater than  $S_{\text{initial}}$ ,  $\Delta S$  is positive and the process is spontaneous according to the second law. Notice that when the atoms are confined to one flask, their energy is also confined to that one flask; however, when the atoms are evenly distributed between both flasks, their energy is spread out over a greater volume. As the gas expands into the empty flask, energy is dispersed.

The second law explains many phenomena not explained by the first law. In Chapter 6, we learned that heat travels from a substance at higher temperature to one at lower temperature. For example, if we drop an ice cube into water, heat travels from the water to the ice cube—the water cools and the ice warms (and eventually melts). Why? The first law would not prohibit some heat from flowing the other way—from the ice to the water. The ice could lose 10 J of heat (cooling even more) and the water could gain 10 J of heat (warming even more). The first law of thermodynamics would not be violated by such a heat transfer. Imagine putting ice into water only to have the water get warmer as it absorbed thermal energy from the ice! It will never happen because heat transfer from cold to hot violates the second law of thermodynamics. According to the second law, energy is dispersed, not concentrated. The transfer of heat from a substance of higher temperature to one of lower temperature results in greater energy randomization—the energy that was concentrated in the hot substance becomes dispersed between the two substances. The second law accounts for this pervasive tendency.

## CONCEPTUAL CONNECTION 18.2

**Entropy** Consider these three changes in the possible distributions of six gaseous particles within three interconnected boxes. Which change has a positive  $\Delta S$ ?

## 18.4 Entropy Changes Associated with State Changes

The entropy of a sample of matter *increases* as it changes state from a solid to a liquid or from a liquid to a gas (Figure 18.5▶). We first consider this idea conceptually, and then we turn to actually calculating the value of  $\Delta S$  for this change. Recall that, in Chapter 6, we distinguished between a thermodynamic system and its surroundings. This distinction is useful in our discussion of entropy. For a change of state in a substance, we consider the substance to be the system. The surroundings are then the rest of the universe. Here, we

**FIGURE 18.5 Entropy and State Change** Entropy increases when matter changes from a solid to a liquid and from a liquid to a gas.

focus on the entropy of the *system* undergoing the change of state (not the surroundings, which we address in Section 18.5).

## Entropy and State Change: The Concept

We can informally think of the increase in entropy in going from a solid to a liquid or from a liquid to a gas by analogy with macroscopic disorder. The gaseous state is more disorderly than the liquid state, which is in turn more disorderly than the solid state. More formally, however, the differences in entropy are related to the number of energetically equivalent ways of arranging the particles in each state—there are more in the gas than in the liquid, and more in the liquid than in the solid.

A gas has more energetically equivalent configurations because it has more ways to distribute its energy than a solid. The energy in a molecular solid consists largely of the vibrations between its molecules. If the same substance is in its gaseous state, however, the energy can take the form of straight-line motions of the molecules (called translational energy) and rotations of the molecules (called rotational energy). In other words, when a solid vaporizes into a gas, there are new “places” to put energy (Figure 18.6▼). The gas thus has more possible microstates (more energetically equivalent configurations) than the solid and therefore a greater entropy.

**FIGURE 18.6 “Places” for Energy** In the solid state, energy is contained largely in the vibrations between molecules. In the gas state, energy can be contained in both the straight-line motion of molecules (translational energy) and the rotation of molecules (rotational energy).

### Additional “Places” for Energy

We can now predict the sign of  $\Delta S$  for processes involving changes of state (or phase). In general, entropy increases ( $\Delta S > 0$ ) for each of the following:

- the phase transition from a solid to a liquid
- the phase transition from a solid to a gas
- the phase transition from a liquid to a gas
- an increase in the number of moles of a gas during a chemical reaction

### Example 18.1 Predicting the Sign of Entropy Change

Predict the sign of  $\Delta S$  for each process.

- (a)  $\text{H}_2\text{O}(g) \longrightarrow \text{H}_2\text{O}(l)$   
 (b) Solid carbon dioxide sublimates.  
 (c)  $2 \text{N}_2\text{O}(g) \longrightarrow 2 \text{N}_2(g) + \text{O}_2(g)$

#### SOLUTION

- (a) Since a gas has a greater entropy than a liquid, the entropy decreases and  $\Delta S$  is negative.  
 (b) Since a solid has a lower entropy than a gas, the entropy increases and  $\Delta S$  is positive.  
 (c) Since the number of moles of gas increases, the entropy increases and  $\Delta S$  is positive.

**FOR PRACTICE 18.1** Predict the sign of  $\Delta S$  for each process.

- (a) the boiling of water  
 (b)  $\text{I}_2(g) \longrightarrow \text{I}_2(s)$   
 (c)  $\text{CaCO}_3(s) \longrightarrow \text{CaO}(s) + \text{CO}_2(g)$

## Entropy and State Changes: The Calculation

We have just seen how the entropy of system increases with the transition from a solid to a liquid to a gas. We can calculate the actual changes in entropy that occur in the system during these state transitions. Recall from Sections 11.5 and 11.6 that a change in state is accompanied by an exchange of heat between the system and surroundings. For example, melting and vaporization are endothermic (they absorb heat from the surroundings), while freezing and condensation are exothermic (they give off heat to the surroundings).

The definition of entropy that we introduced previously ( $S = k \ln W$ ) shows how entropy is related to the distribution of energy among the particles that compose matter. On a macroscopic scale, we can define the change in entropy that occurs when a system exchanges a quantity of heat ( $q$ ) with its surroundings at a constant temperature ( $T$ ) with the following equation:

$$\Delta S = \frac{q_{\text{rev}}}{T} \text{ (constant temperature)} \quad [18.1]$$

In this equation,  $\Delta S$  is the entropy change of the system,  $q_{\text{rev}}$  is the heat exchanged with the surroundings in a *reversible* process (more on this to come), and  $T$  is the temperature in K. The temperature must be constant throughout the change—the process must be *isothermal*. Let's address two important concepts related to this equation, the units of entropy and reversible processes.

### Units of Entropy

In Section 18.3 we saw that the units of entropy are J/K. We can now better understand these units. Entropy is a measure of energy dispersal per unit temperature and therefore has the units of energy (J) over temperature (K). For example, when a substance melts

(an endothermic process), it absorbs a certain amount of energy from the surroundings. That energy becomes dispersed into the system (as the substance changes state from a solid to a liquid) and the entropy of the substance increases. The change in entropy is related to the amount of energy the substance absorbs (units of J) divided by the temperature of the substance (units of K).

### Reversible Processes

A **reversible process** is one that reverses direction upon an infinitesimally small change in some property. The melting of ice when the ice and its surroundings are both at exactly 0 °C is an example of a reversible process. An infinitesimally small *removal* of heat reverses the melting and causes freezing instead. An infinitesimally small *addition* of heat causes the melting to resume. All reversible processes are in a constant state of equilibrium and represent highly idealized conditions. In contrast, the melting of ice that happens when we set an ice cube on a countertop at room temperature is *irreversible*. In this case, the countertop and the surrounding air are at 25.0 °C and an infinitesimally small removal of heat does not reverse the melting.

We can use Equation 18.1 to calculate the change in the entropy of a system that undergoes a state change. For example, when ice melts at its melting point, the heat exchanged with the surroundings is  $\Delta H_{\text{fus}}$  and the temperature is 273 K:

$$\begin{aligned} q_{\text{rev}} &= \Delta H_{\text{fus}} = 6.02 \text{ kJ/mol} \\ T &= 273 \text{ K} \end{aligned}$$

We substitute these quantities into Equation 18.1 to determine the change in entropy of the system when 1 mol of ice melts at its melting point:

$$\begin{aligned} \Delta S &= \frac{q_{\text{rev}}}{T} \\ &= \frac{(1 \text{ mol}) \frac{6.02 \times 10^3 \text{ J}}{\text{mol}}}{273 \text{ K}} \\ &= 22.1 \text{ J/K} \end{aligned}$$

The value of  $\Delta S$  is positive as we would expect for a transition from solid to liquid.

### Example 18.2 Calculating $\Delta S$ for a Change of State

Calculate the change in entropy that occurs in the system when 25.0 g of water condenses from a gas to a liquid at the normal boiling point of water (100.0 °C).

#### SOLUTION

Because the condensation is occurring at the boiling point of water and the temperature is constant, you can use Equation 18.1 to calculate the change in entropy of the system.

$$\Delta S = \frac{q_{\text{rev}}}{T}$$

Gather the necessary quantities. Look up the value of the enthalpy of vaporization for water at its boiling point in Table 11.7. The enthalpy of condensation is the same in value but opposite in sign.

$$\begin{aligned} \Delta H_{\text{vap}} &= 40.7 \text{ kJ/mol} \\ \Delta H_{\text{condensation}} &= -40.7 \text{ kJ/mol} \\ T(\text{K}) &= T(^{\circ}\text{C}) + 273.15 \\ &= 100.0 + 273.15 \\ &= 373.15 \text{ K} \end{aligned}$$

Calculate the temperature in K.

Substitute into Equation 18.1 to calculate the change in entropy for the system.

$$\begin{aligned} \Delta S &= \frac{q_{\text{rev}}}{T} \\ &= \frac{25.0 \text{ g} \times \frac{1 \text{ mol}}{18.02 \text{ g}} \times \left( \frac{-40.7 \times 10^3 \text{ J}}{\text{mol}} \right)}{373.15 \text{ K}} \\ &= -151 \text{ J/K} \end{aligned}$$

—Continued on the next page

Continued—

**CHECK** The answer has the correct units for entropy (J/K). The answer is negative as you would expect for the condensation of a gas to a liquid.

**FOR PRACTICE 18.2** Calculate the change in entropy that occurs in the system when 10.0 g of acetone ( $\text{C}_3\text{H}_6\text{O}$ ) vaporizes from a liquid to a gas at its normal boiling point (56.1 °C).

## 18.5 Heat Transfer and Changes in the Entropy of the Surroundings

We have now seen that the criterion for spontaneity is an increase in the entropy of the universe. However, you can probably think of several spontaneous processes in which entropy seems to decrease. For example, when water freezes at temperatures below 0 °C, the entropy of the water decreases, yet the process is spontaneous. Similarly, when water vapor in air condenses into fog on a cold night, the entropy of the water also decreases. Why are these processes spontaneous?

To answer this question, we must return to the second law: for any spontaneous process, the entropy of the universe increases ( $\Delta S_{\text{univ}} > 0$ ). Even though the entropy of the water decreases during freezing and condensation, the entropy of the universe must somehow increase in order for these processes to be spontaneous. If we define the water as the system, then  $\Delta S_{\text{sys}}$  is the entropy change for the water itself,  $\Delta S_{\text{surr}}$  is the entropy change for the surroundings, and  $\Delta S_{\text{univ}}$  is the entropy change for the universe. The entropy change for the universe is the sum of the entropy changes for the system and the surroundings:

$$\Delta S_{\text{univ}} = \Delta S_{\text{sys}} + \Delta S_{\text{surr}}$$

The second law states that the entropy of the universe must increase ( $\Delta S_{\text{univ}} > 0$ ) for a process to be spontaneous. The entropy of the system can decrease ( $\Delta S_{\text{sys}} < 0$ ) as long as the entropy of the surroundings increases by a greater amount ( $\Delta S_{\text{surr}} > -\Delta S_{\text{sys}}$ ), so that the overall entropy of the universe undergoes a net increase.

For liquid water freezing or water vapor condensing, we know that the change in entropy for the system ( $\Delta S_{\text{sys}}$ ) is negative as we discussed in Section 18.4. For  $\Delta S_{\text{univ}}$  to be positive, therefore,  $\Delta S_{\text{surr}}$  must be positive and greater in absolute value (or magnitude) than  $\Delta S_{\text{sys}}$  as shown graphically here:

But why does the freezing of ice or the condensation of water increase the entropy of the surroundings? Because both processes are *exothermic*: they give off heat to the surroundings. Because we think of entropy as the dispersal or randomization of energy, *the release of heat energy by the system disperses that energy into the surroundings, increasing the entropy of the surroundings*. The freezing of water below 0 °C and the condensation of water vapor on a cold night both increase the entropy of the universe because the heat given off to the surroundings increases the entropy of the surroundings to a sufficient degree to overcome the entropy decrease in the water.

Even though (as we saw earlier) enthalpy by itself cannot determine spontaneity, the increase in the entropy of the surroundings caused by the release of heat explains why exothermic processes are so often spontaneous.

**Summarizing Entropy Changes in the Surroundings:**

- ▶ An exothermic process increases the entropy of the surroundings.
- ▶ An endothermic process decreases the entropy of the surroundings.

**The Temperature Dependence of  $\Delta S_{\text{surr}}$** 

We have just seen how the freezing of water increases the entropy of the surroundings by dispersing heat energy into the surroundings. Yet we know that the freezing of water is not spontaneous at all temperatures. The freezing of water becomes *nonspontaneous* above 0 °C. Why? Because the magnitude of the increase in the entropy of the surroundings due to the dispersal of energy into the surroundings is *temperature dependent*.

The greater the temperature, the smaller the increase in entropy for a given amount of energy dispersed into the surroundings. Recall that the units of entropy are joules per kelvin: energy units divided by temperature units. As we have seen, *entropy is a measure of energy dispersal (joules) per unit temperature (kelvins)*. The higher the temperature, the lower the amount of entropy for a given amount of energy dispersed. We can understand the temperature dependence of entropy changes due to heat flow with a simple analogy. Imagine that you have \$1000 to give away. If you gave the \$1000 to a rich man, the impact on his net worth would be negligible (because he already has so much money). If you gave the same \$1000 to a poor man, however, his net worth would change substantially (because he has so little money). Similarly, if you disperse 1000 J of energy into surroundings that are hot, the entropy increase is small (because the impact of the 1000 J is small on surroundings that already contain a lot of energy). If you disperse the same 1000 J of energy into surroundings that are cold, however, the entropy increase is large (because the impact of the 1000 J is great on surroundings that contain little energy). For this same reason, the impact of the heat released to the surroundings by the freezing of water depends on the temperature of the surroundings—the higher the temperature, the smaller the impact.

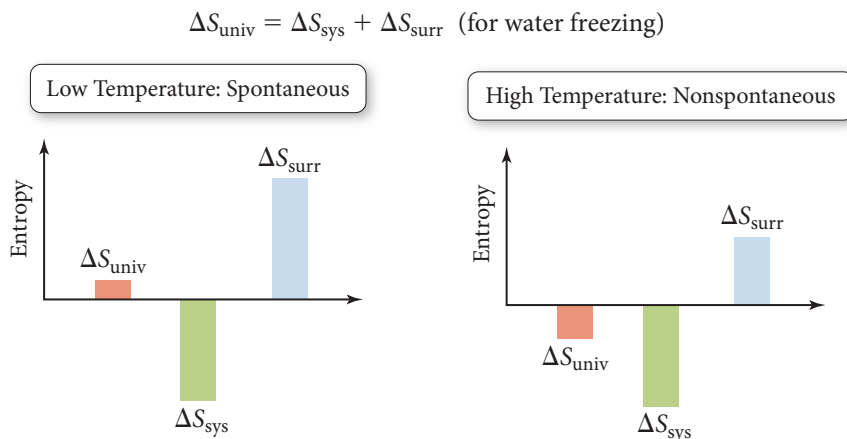

We can now understand why water spontaneously freezes at low temperature but not at high temperature. For the freezing of liquid water into ice, the change in entropy of the system is negative at all temperatures:

$$\Delta S_{\text{univ}} = \Delta S_{\text{sys}} + \Delta S_{\text{surr}}$$

$\Delta S_{\text{sys}}$   
Negative

$\Delta S_{\text{surr}}$   
Positive and large at low temperature  
Positive and small at high temperature

At low temperatures, on one hand, the decrease in entropy of the system is overcome by the large increase in the entropy of the surroundings (a positive quantity), resulting in a positive  $\Delta S_{\text{univ}}$  and a spontaneous process. At high temperatures, on the other hand, the decrease in entropy of the system is not overcome by the increase in entropy of the surroundings (because the magnitude of the positive  $\Delta S_{\text{surr}}$  is smaller at higher temperatures), resulting in a negative  $\Delta S_{\text{univ}}$ ; therefore, the freezing of water is not spontaneous at high temperature as shown graphically here:

## Quantifying Entropy Changes in the Surroundings

We have seen that when a system exchanges heat with the surroundings, it changes the entropy of the surroundings. In Section 18.4, we saw that, at constant temperature, we can use Equation 18.1 ( $\Delta S = q_{\text{rev}}/T$ ) to quantify the entropy change in the system. We can use the same expression to quantify entropy changes in the surroundings. In other words, the change in entropy of the surroundings depends on: (a) the amount of heat transferred into or out of the surroundings; and (b) the temperature of the surroundings.

Since the surroundings are usually an infinitely large bath at constant temperature, the heat transferred into or out of that bath under conditions of constant pressure (where only PV work is allowed) is simply  $-\Delta H_{\text{sys}}$ . The negative sign reflects that, according to the first law of thermodynamics, any heat leaving the system must go into the surroundings and vice versa ( $q_{\text{sys}} = -q_{\text{surr}}$ ). If we incorporate this idea into Equation 18.1, we get the following expression:

$$\Delta S_{\text{surr}} = \frac{-\Delta H_{\text{sys}}}{T} \quad (\text{constant } P, T) \quad [18.2]$$

For any chemical or physical process occurring at constant temperature and pressure, the entropy change of the surroundings is equal to the heat dispersed into or out of the surroundings ( $-\Delta H_{\text{sys}}$ ) divided by the temperature of the surroundings in kelvins. Notice that:

- A process that emits heat into the surroundings ( $\Delta H_{\text{sys}}$  negative) *increases* the entropy of the surroundings (positive  $\Delta S_{\text{surr}}$ ).
- A process that absorbs heat from the surroundings ( $\Delta H_{\text{sys}}$  positive) *decreases* the entropy of the surroundings (negative  $\Delta S_{\text{surr}}$ ).
- The magnitude of the change in entropy of the surroundings is proportional to the magnitude of  $\Delta H_{\text{sys}}$ .

Equation 18.1 gives us insight into why exothermic processes have a tendency to be spontaneous at low temperatures—they increase the entropy of the surroundings. As temperature increases, however, a given negative  $\Delta H_{\text{sys}}$  produces a smaller positive  $\Delta S_{\text{surr}}$ ; for this reason, exothermicity becomes less of a determining factor for spontaneity as temperature increases.

### Example 18.3 Calculating Entropy Changes in the Surroundings

Consider the combustion of propane gas:

- Calculate the entropy change in the surroundings when this reaction occurs at 25 °C.
- Determine the sign of the entropy change for the system.
- Determine the sign of the entropy change for the universe. Is the reaction spontaneous?

#### SOLUTION

- (a) The entropy change of the surroundings is given by Equation 18.2. Substitute the value of  $\Delta H_{\text{rxn}}$  and the temperature in kelvins and calculate  $\Delta S_{\text{surr}}$ .

$$\begin{aligned} T &= 273 + 25 = 298 \text{ K} \\ \Delta S_{\text{surr}} &= \frac{-\Delta H_{\text{rxn}}}{T} \\ &= \frac{-(-2044 \text{ kJ})}{298 \text{ K}} \\ &= +6.86 \text{ kJ/K} \\ &= +6.86 \times 10^3 \text{ J/K} \end{aligned}$$

- (b) Determine the number of moles of gas on each side of the reaction. An increase in the number of moles of gas implies a positive  $\Delta S_{\text{sys}}$ .

- (c) The change in entropy of the universe is the sum of the entropy changes of the system and the surroundings. If the entropy changes of the system and surroundings are both the same sign, the entropy change for the universe also has the same sign.

$$\Delta S_{\text{univ}} = \Delta S_{\text{sys}} + \Delta S_{\text{surr}}$$

Positive

Positive

Therefore,  $\Delta S_{\text{univ}}$  is positive and the reaction is spontaneous.

**FOR PRACTICE 18.3** Consider the reaction between nitrogen and oxygen gas to form dinitrogen monoxide:

- (a) Calculate the entropy change in the surroundings when this reaction occurs at 25 °C.  
 (b) Determine the sign of the entropy change for the system.  
 (c) Determine the sign of the entropy change for the universe. Is the reaction spontaneous?

**FOR MORE PRACTICE 18.3** For a reaction,  $\Delta H_{\text{rxn}} = -107 \text{ kJ}$  and  $\Delta S_{\text{rxn}} = 285 \text{ J/K}$ . At what temperature is the change in entropy for this reaction equal to the change in entropy for the surroundings?

**Entropy and Biological Systems** Do biological systems contradict the second law of thermodynamics? By taking energy from their surroundings and synthesizing large, complex biological molecules, plants and animals tend to concentrate energy, not disperse it. How can this be so?

### CONCEPTUAL CONNECTION 18.3

## 18.6 Gibbs Free Energy

Equation 18.2 establishes a relationship between the enthalpy change in a system and the entropy change in the surroundings. Recall that for any process the entropy change of the universe is the sum of the entropy change of the system and the entropy change of the surroundings:

$$\Delta S_{\text{univ}} = \Delta S_{\text{sys}} + \Delta S_{\text{surr}} \quad [18.3]$$

Combining Equation 18.3 with Equation 18.2 gives us the following relationship at constant temperature and pressure:

$$\Delta S_{\text{univ}} = \Delta S_{\text{sys}} - \frac{\Delta H_{\text{sys}}}{T} \quad [18.4]$$

Using Equation 18.4, we can calculate  $\Delta S_{\text{univ}}$  while focusing only on the *system*. If we multiply Equation 18.4 by  $-T$ , we arrive at the expression:

$$\begin{aligned} -T\Delta S_{\text{univ}} &= -T\Delta S_{\text{sys}} + T \frac{\Delta H_{\text{sys}}}{T} \\ &= \Delta H_{\text{sys}} - T\Delta S_{\text{sys}} \end{aligned} \quad [18.5]$$

If we drop the subscript *sys*—from now on  $\Delta H$  and  $\Delta S$  without subscripts mean  $\Delta H_{\text{sys}}$  and  $\Delta S_{\text{sys}}$ —we get the expression:

$$-T\Delta S_{\text{univ}} = \Delta H - T\Delta S \quad [18.6]$$

The right-hand side of Equation 18.6 represents the change in a thermodynamic function called *Gibbs free energy*. The formal definition of **Gibbs free energy (*G*)** is:

$$G = H - TS \quad [18.7]$$

where  $H$  is enthalpy,  $T$  is the temperature in kelvins, and  $S$  is entropy. The *change* in Gibbs free energy, symbolized by  $\Delta G$ , is expressed as follows (at constant temperature):

$$\Delta G = \Delta H - T\Delta S \quad [18.8]$$

If we combine Equations 18.6 and 18.8, we have an equation that makes clear the significance of  $\Delta G$ :

$$\Delta G = -T\Delta S_{\text{univ}} \quad (\text{constant } T, P) \quad [18.9]$$

The change in Gibbs free energy for a process occurring at constant temperature and pressure is proportional to the negative of  $\Delta S_{\text{univ}}$ . Since  $\Delta S_{\text{univ}}$  is a criterion for spontaneity,  $\Delta G$  is also a criterion for spontaneity (although opposite in sign). In fact, Gibbs free energy is also called *chemical potential* because it is analogous to mechanical potential energy discussed earlier. Just as mechanical systems tend toward lower potential energy, so chemical systems tend toward lower Gibbs free energy (toward lower chemical potential) (Figure 18.7▼).

► **FIGURE 18.7 Gibbs Free Energy** Gibbs free energy is also called chemical potential because it determines the direction of spontaneous change for chemical systems.

**Summarizing Gibbs Free Energy (at Constant Temperature and Pressure):**

- $\Delta G$  is proportional to the negative of  $\Delta S_{\text{univ}}$ .
- A decrease in Gibbs free energy ( $\Delta G < 0$ ) corresponds to a spontaneous process.
- An increase in Gibbs free energy ( $\Delta G > 0$ ) corresponds to a nonspontaneous process.

Notice that we can calculate changes in Gibbs free energy solely with reference to the system. So, to determine whether a process is spontaneous, we only have to find the change in *entropy* for the system ( $\Delta S$ ) and the change in *enthalpy* for the system ( $\Delta H$ ). We can then predict the spontaneity of the process at any temperature. In Chapter 6, we learned how to calculate changes in enthalpy ( $\Delta H$ ) for chemical reactions. In Section 18.7, we learn how to calculate changes in entropy ( $\Delta S$ ) for chemical reactions. We can then use those two quantities to calculate changes in free energy ( $\Delta G$ ) for chemical reactions and predict their spontaneity (Section 18.8). Before we move on to these topics, let's examine some examples that demonstrate how  $\Delta H$ ,  $\Delta S$ , and  $T$  affect the spontaneity of chemical processes.

**The Effect of  $\Delta H$ ,  $\Delta S$ , and  $T$  on Reaction Spontaneity**

**The Effect of  $\Delta H$ ,  $\Delta S$ , and  $T$  on Spontaneity**

**Case 1:  $\Delta H$  Negative,  $\Delta S$  Positive** If a reaction is exothermic ( $\Delta H < 0$ ), and if the change in entropy for the reaction is positive ( $\Delta S > 0$ ), then the change in free energy is negative at all temperatures and the reaction is spontaneous at all temperatures:

$$\Delta G = \Delta H - T \Delta S$$

↑

Negative at all temperatures

↑

Negative

↑

Positive

As an example, consider the dissociation of  $\text{N}_2\text{O}$ :

The change in *enthalpy* is negative—heat is emitted, increasing the entropy of the surroundings. The change in *entropy* for the reaction is positive, which means that the entropy of the system increases. (We can see that the change in entropy is positive from the balanced equation—the number of moles of gas increases.) Since the entropy of both the system and the surroundings increases, the entropy of the universe must also increase, making the reaction spontaneous at all temperatures.

Recall from Chapter 6 that  $\Delta H^\circ$  represents the standard enthalpy change. The definition of the standard state was first given in Section 6.9 and is summarized in Section 18.7.

**Case 2:  $\Delta H$  Positive,  $\Delta S$  Negative** If a reaction is endothermic ( $\Delta H > 0$ ), and if the change in entropy for the reaction is negative ( $\Delta S < 0$ ), then the change in free energy is positive at all temperatures and the reaction is nonspontaneous at all temperatures:

As an example, consider the formation of ozone from oxygen:

The change in *enthalpy* is positive—heat is therefore absorbed, *decreasing* the entropy of the surroundings. The change in *entropy* is negative, which means that the entropy of the system decreases. (We can see that the change in entropy is negative from the balanced equation—the number of moles of gas decreases.) Since the entropy of both the system and the surroundings decreases, the entropy of the universe must also decrease, making the reaction nonspontaneous at all temperatures.

**Case 3:  $\Delta H$  Negative,  $\Delta S$  Negative** If a reaction is exothermic ( $\Delta H < 0$ ), and if the change in entropy for the reaction is negative ( $\Delta S < 0$ ), then the sign of the change in free energy depends on temperature. The reaction is spontaneous at low temperature, but nonspontaneous at high temperature:

As an example, consider the freezing of liquid water to form ice:

The change in *enthalpy* is negative—heat is emitted, increasing the entropy of the surroundings. The change in *entropy* is negative, which means that the entropy of the system decreases. (We can see that the change in entropy is negative from the balanced equation—a liquid turns into a solid.)

Unlike the two previous cases, where the changes in *entropy* of the system and of the surroundings had the *same* sign, the changes here are *opposite* in sign. Therefore, the sign of the change in free energy depends on the relative magnitudes of the two changes. At a low enough temperature, the heat emitted into the surroundings causes a large entropy change in the surroundings, making the process spontaneous. At high temperature, the same amount of heat is dispersed into warmer surroundings, so the positive entropy change in the surroundings is smaller, resulting in a nonspontaneous process.

**Case 4:  $\Delta H$  Positive,  $\Delta S$  Positive** If a reaction is endothermic ( $\Delta H > 0$ ), and if the change in entropy for the reaction is positive ( $\Delta S > 0$ ), then the sign of the change

in free energy again depends on temperature. The reaction is nonspontaneous at low temperature but spontaneous at high temperature:

$$\Delta G = \Delta H - T \Delta S$$

Positive at low temperatures  
Negative at high temperatures
Positive
Positive

As an example, consider the vaporizing of liquid water to gaseous water:

The change in *enthalpy* is positive—heat is absorbed from the surroundings, so the entropy of the surroundings decreases. The change in *entropy* is positive, which means that the entropy of the system increases. (We can see that the change in entropy is positive from the balanced equation—a liquid turns into a gas.) The changes in entropy of the system and the surroundings again have opposite signs, only this time the entropy of the surroundings decreases while the entropy of the system increases. In cases such as this, high temperature favors spontaneity because the absorption of heat from the surroundings has less effect on the entropy of the surroundings as temperature increases.

Table 18.1 summarizes these effects. Notice that when  $\Delta H$  and  $\Delta S$  have opposite signs, the spontaneity of the reaction does not depend on temperature. *When  $\Delta H$  and  $\Delta S$  have the same sign, however, the spontaneity does depend on temperature.* The temperature at which the reaction changes from being spontaneous to being nonspontaneous (or vice versa) is the temperature at which  $\Delta G$  changes sign, which we can find by setting  $\Delta G = 0$  and solving for  $T$ , as shown in part b of Example 18.4.

**TABLE 18.1** The Effect of  $\Delta H$ ,  $\Delta S$ , and  $T$  on Spontaneity

$\Delta H$	$\Delta S$	Low Temperature	High Temperature	Example
–	+	Spontaneous ( $\Delta G < 0$ )	Spontaneous ( $\Delta G < 0$ )	$2 \text{ N}_2\text{O}(g) \longrightarrow 2 \text{ N}_2(g) + \text{O}_2(g)$
+	–	Nonspontaneous ( $\Delta G > 0$ )	Nonspontaneous ( $\Delta G > 0$ )	$3 \text{ O}_2(g) \longrightarrow 2 \text{ O}_3(g)$
–	–	Spontaneous ( $\Delta G < 0$ )	Nonspontaneous ( $\Delta G > 0$ )	$\text{H}_2\text{O}(l) \longrightarrow \text{H}_2\text{O}(s)$
+	+	Nonspontaneous ( $\Delta G > 0$ )	Spontaneous ( $\Delta G < 0$ )	$\text{H}_2\text{O}(l) \longrightarrow \text{H}_2\text{O}(g)$

### Example 18.4 Calculating Gibbs Free Energy Changes and Predicting Spontaneity from $\Delta H$ and $\Delta S$

Consider the reaction for the decomposition of carbon tetrachloride gas:

- (a) Calculate  $\Delta G$  at  $25^\circ\text{C}$  and determine whether the reaction is spontaneous.  
 (b) If the reaction is not spontaneous at  $25^\circ\text{C}$ , determine at what temperature (if any) the reaction becomes spontaneous.

#### SOLUTION

- (a) Use Equation 18.8 to calculate  $\Delta G$  from the given values of  $\Delta H$  and  $\Delta S$ . The temperature must be in kelvins. *Be sure to express both  $\Delta H$  and  $\Delta S$  in the same units (usually joules).*

$$\begin{aligned}
 T &= 273 + 25 = 298 \text{ K} \\
 \Delta G &= \Delta H - T \Delta S \\
 &= 95.7 \times 10^3 \text{ J} - (298 \text{ K})142.2 \text{ J/K} \\
 &= 95.7 \times 10^3 \text{ J} - 42.4 \times 10^3 \text{ J} \\
 &= +53.3 \times 10^3 \text{ J}
 \end{aligned}$$

The reaction is not spontaneous.

- (b) Since  $\Delta S$  is positive,  $\Delta G$  becomes more negative with increasing temperature. To determine the temperature at which the reaction becomes spontaneous, use Equation 18.8 to find the temperature at which  $\Delta G$  changes from positive to negative (set  $\Delta G = 0$  and solve for  $T$ ). The reaction is spontaneous above this temperature.

$$\begin{aligned}
 \Delta G &= \Delta H - T \Delta S \\
 0 &= 95.7 \times 10^3 \text{ J} - (T)142.2 \text{ J/K} \\
 T &= \frac{95.7 \times 10^3 \text{ J}}{142.2 \text{ J/K}} \\
 &= 673 \text{ K}
 \end{aligned}$$

**FOR PRACTICE 18.4** Consider the reaction:

Calculate  $\Delta G$  at 25 °C and determine whether the reaction is spontaneous. Does  $\Delta G$  become more negative or more positive as the temperature increases?

**$\Delta H$ ,  $\Delta S$ , and  $\Delta G$**  Which statement is true regarding the sublimation of dry ice (solid  $\text{CO}_2$ )?

- (a)  $\Delta H$  is positive,  $\Delta S$  is positive, and  $\Delta G$  is positive at low temperatures and negative at high temperatures.
- (b)  $\Delta H$  is negative,  $\Delta S$  is negative, and  $\Delta G$  is negative at low temperatures and positive at high temperatures.
- (c)  $\Delta H$  is negative,  $\Delta S$  is positive, and  $\Delta G$  is negative at all temperatures.
- (d)  $\Delta H$  is positive,  $\Delta S$  is negative, and  $\Delta G$  is positive at all temperatures.

## CONCEPTUAL CONNECTION 18.4

## 18.7 Entropy Changes in Chemical Reactions: Calculating $\Delta S_{\text{rxn}}^{\circ}$

Standard Molar Entropies

In Chapter 6, we learned how to calculate standard changes in enthalpy ( $\Delta H_{\text{rxn}}^{\circ}$ ) for chemical reactions. We now turn to calculating standard changes in *entropy* for chemical reactions.

### Defining Standard States and Standard Entropy Changes

Recall from Section 6.9 that the standard enthalpy change for a reaction ( $\Delta H_{\text{rxn}}^{\circ}$ ) is the change in enthalpy for a process in which all reactants and products are in their standard states. Recall also the definition of the standard state:

- *For a Gas:* The standard state for a gas is the pure gas at a pressure of exactly 1 atm.
- *For a Liquid or Solid:* The standard state for a liquid or solid is the pure substance in its most stable form at a pressure of 1 atm and at the temperature of interest (often taken to be 25 °C).
- *For a Substance in Solution:* The standard state for a substance in solution is a concentration of 1 M.

The standard state has recently been changed to a pressure of 1 bar, which is very close to 1 atm (1 atm = 1.013 bar). Both standards are now in common use.

We define the **standard entropy change for a reaction** ( $\Delta S_{\text{rxn}}^{\circ}$ ) as the change in *entropy* for a process in which all reactants and products are in their standard states. Since entropy is a function of state, the standard change in entropy is therefore the standard entropy of the products minus the standard entropy of the reactants:

$$\Delta S_{\text{rxn}}^{\circ} = S_{\text{products}}^{\circ} - S_{\text{reactants}}^{\circ}$$

But how do we find the standard entropies of the reactants and products? Recall from Chapter 6 that we defined *standard molar enthalpies of formation* ( $\Delta H_f^{\circ}$ ) to use in calculating  $\Delta H_{\text{rxn}}^{\circ}$ . We now need to define **standard molar entropies** ( $S^{\circ}$ ) to use in calculating  $\Delta S_{\text{rxn}}^{\circ}$ .

### Standard Molar Entropies ( $S^{\circ}$ ) and the Third Law of Thermodynamics

In Chapter 6, we defined a *relative* zero for enthalpy. To do this, we assigned a value of zero to the standard enthalpy of formation for an element in its standard state. This was necessary because absolute values of enthalpy cannot be determined. In other words, for

Perfect crystal at 0 K  
 $W = 1$      $S = 0$

**▲ FIGURE 18.8 Zero Entropy**  
A perfect crystal at 0 K has only one possible way to arrange its components.

enthalpy, there is no absolute zero against which to measure all other values; therefore, we always have to rely on enthalpy changes from an arbitrarily assigned standard (the elements in their standard states and most stable forms).

For entropy, however, *there is an absolute zero*. The absolute zero of entropy is established by the **third law of thermodynamics**, which states:

**The entropy of a perfect crystal at absolute zero (0 K) is zero.**

A perfect crystal at a temperature of absolute zero has only one possible way ( $W = 1$ ) to arrange its components (Figure 18.8). Based on Boltzmann’s definition of entropy ( $S = k \ln W$ ), its entropy is zero ( $S = k \ln 1 = 0$ ).

We can measure all entropy values against the absolute zero of entropy as defined by the third law. Table 18.2 lists values of standard entropies at 25 °C for selected substances. A more complete list is in Appendix IIB. Standard entropy values are listed in units of joules per mole per kelvin ( $\text{J/mol} \cdot \text{K}$ ). The units of mole in the denominator are required because *entropy is an extensive property*—it depends on the amount of the substance.

**TABLE 18.2** Standard Molar Entropy Values ( $S^\circ$ ) for Selected Substances at 298 K

Substance	$S^\circ (\text{J/mol} \cdot \text{K})$	Substance	$S^\circ (\text{J/mol} \cdot \text{K})$	Substance	$S^\circ (\text{J/mol} \cdot \text{K})$
<b>Gases</b>		<b>Liquids</b>		<b>Solids</b>	
$\text{H}_2(\text{g})$	130.7	$\text{H}_2\text{O}(\text{l})$	70.0	$\text{MgO}(\text{s})$	27.0
$\text{Ar}(\text{g})$	154.8	$\text{CH}_3\text{OH}(\text{l})$	126.8	$\text{Fe}(\text{s})$	27.3
$\text{CH}_4(\text{g})$	186.3	$\text{Br}_2(\text{l})$	152.2	$\text{Li}(\text{s})$	29.1
$\text{H}_2\text{O}(\text{g})$	188.8	$\text{C}_6\text{H}_6(\text{l})$	173.4	$\text{Cu}(\text{s})$	33.2
$\text{N}_2(\text{g})$	191.6			$\text{Na}(\text{s})$	51.3
$\text{NH}_3(\text{g})$	192.8			$\text{K}(\text{s})$	64.7
$\text{F}_2(\text{g})$	202.8			$\text{NaCl}(\text{s})$	72.1
$\text{O}_2(\text{g})$	205.2			$\text{CaCO}_3(\text{s})$	91.7
$\text{Cl}_2(\text{g})$	223.1			$\text{FeCl}_3(\text{s})$	142.3
$\text{C}_2\text{H}_4(\text{g})$	219.3				

At 25 °C, the standard entropy of any substance is the energy dispersed into one mole of that substance at 25 °C, which depends on the number of “places” to put energy within the substance. The factors that affect the number of “places” to put energy—and therefore the standard entropy—include the state of the substance, the molar mass of the substance, the particular allotrope, its molecular complexity, and its extent of dissolution. Let’s examine each of these separately.

**Relative Standard Entropies: Gases, Liquids, and Solids**

As we saw in Section 18.3, the entropy of a gas is generally greater than the entropy of a liquid, which is in turn greater than the entropy of a solid. We can see these trends in the tabulated values of standard entropies. For example, consider the relative standard entropies of liquid water and gaseous water at 25 °C:

$S^\circ (\text{J/mol} \cdot \text{K})$	
$\text{H}_2\text{O}(\text{l})$	70.0
$\text{H}_2\text{O}(\text{g})$	188.8

Gaseous water has a much greater standard entropy because, as we discussed in Section 18.3, it has more energetically equivalent ways to arrange its components, which in turn results in greater energy dispersal at 25 °C.

Some elements exist in two or more forms, called *allotropes*, within the same state.

**Relative Standard Entropies: Molar Mass**

Consider the standard entropies of the noble gases at 25 °C :

$S^{\circ}$ (J/mol·K)		
He(g)	126.2	
Ne(g)	146.1	
Ar(g)	154.8	
Kr(g)	163.8	
Xe(g)	169.4	

The more massive the noble gas, the greater its entropy at 25 °C. A complete explanation of why entropy increases with increasing molar mass is beyond the scope of this book. Briefly, the energy states associated with the motion of heavy atoms are more closely spaced than those of lighter atoms. The more closely spaced energy states allow for greater dispersal of energy at a given temperature and therefore greater entropy. This trend is true only for elements in the same state. (The effect of a state change—from a liquid to a gas, for example—is far greater than the effect of molar mass.)

**Relative Standard Entropies: Allotropes**

As mentioned previously, some elements can exist in two or more forms—called *allotropes*—in the same state of matter. For example, the allotropes of carbon include diamond and graphite—both solid forms of carbon. Because the arrangement of atoms within these forms is different, their standard molar entropies are different:

$S^{\circ}$ (J/mol·K)		
C(s, diamond)	2.4	
C(s, graphite)	5.7	

In diamond the atoms are constrained by chemical bonds in a highly restricted three-dimensional crystal structure. In graphite the atoms bond together in sheets, but the sheets have freedom to slide past each other. The less constrained structure of graphite results in more “places” to put energy and therefore greater entropy compared to diamond.

**Relative Standard Entropies: Molecular Complexity**

For a given state of matter, entropy generally increases with increasing molecular complexity. For example, consider the standard entropies of argon and nitrogen monoxide gas:

	Molar Mass (g/mol)	$S^\circ$ (J/mol · K)
Ar(g)	39.948	154.8
NO(g)	30.006	210.8

Ar has a greater molar mass than NO, yet it has less entropy at 25 °C. Why? Molecules generally have more “places” to put energy than do atoms. In a gaseous sample of argon, on one hand, the only form that energy can take is the translational motion of the atoms. In a gaseous sample of NO, on the other hand, energy can take the form of translational motion, rotational motion, and (at high enough temperatures) vibrational motions of the molecules (Figure 18.9▼). Therefore, for a given state, molecules generally have a greater entropy than free atoms.

► **FIGURE 18.9** “Places” for Energy in Gaseous NO Energy can be contained in translational motion, rotational motion, and (at high enough temperatures) vibrational motion.

Similarly, more complex molecules generally have more entropy than simpler ones. For example, consider the standard entropies of carbon monoxide and ethene gas:

	Molar Mass (g/mol)	$S^\circ$ (J/mol · K)
CO(g)	28.01	197.7
C <sub>2</sub> H <sub>4</sub> (g)	28.05	219.3

These two substances have nearly the same molar mass, but the greater complexity of C<sub>2</sub>H<sub>4</sub> results in a greater molar entropy. When molecular complexity and molar mass both increase (as is often the case), molar entropy also increases, as demonstrated by the oxides of nitrogen:

	$S^\circ$ (J/mol · K)
NO(g)	210.8
NO <sub>2</sub> (g)	240.1
N <sub>2</sub> O <sub>4</sub> (g)	304.4

The increasing molecular complexity as we move down this list, as well as the increasing molar mass, results in more “places” to put energy and therefore greater entropy.

**Relative Standard Entropies: Dissolution**

The dissolution of a crystalline solid into solution usually results in an increase in entropy. For example, consider the standard entropies of solid and aqueous potassium chlorate:

	$S^\circ$ (J/mol · K)
KClO <sub>3</sub> (s)	143.1
KClO <sub>3</sub> (aq)	265.7

When solid potassium chlorate dissolves in water, the energy that was concentrated within the crystal becomes dispersed throughout the entire solution. The greater energy dispersal results in greater entropy.

The standard entropies for aqueous solutions are for the solution in its standard state, which is defined as having a concentration of 1 M.

## CONCEPTUAL CONNECTION 18.5

**Standard Entropies** Arrange these gases in order of increasing standard molar entropy:  $\text{SO}_3$ , Kr,  $\text{Cl}_2$ .

### Calculating the Standard Entropy Change ( $\Delta S^\circ_{\text{rxn}}$ ) for a Reaction

Since entropy is a state function, and since standard entropies for many common substances are tabulated, we can calculate the standard entropy change for a chemical reaction by calculating the difference in entropy between the products and the reactants. More specifically,

**To calculate  $\Delta S^\circ_{\text{rxn}}$ , subtract the standard entropies of the reactants multiplied by their stoichiometric coefficients from the standard entropies of the products multiplied by their stoichiometric coefficients. In the form of an equation:**

$$\Delta S^\circ_{\text{rxn}} = \sum n_p S^\circ(\text{products}) - \sum n_r S^\circ(\text{reactants}) \quad [18.10]$$

In Equation 18.10,  $n_p$  represents the stoichiometric coefficients of the products,  $n_r$  represents the stoichiometric coefficients of the reactants, and  $S^\circ$  represents the standard entropies. Keep in mind when using this equation that, *unlike enthalpies of formation, which are zero for elements in their standard states, standard entropies are always nonzero at 25 °C*. Example 18.5 demonstrates the application of Equation 18.10.

#### Example 18.5 Calculating Standard Entropy Changes ( $\Delta S^\circ_{\text{rxn}}$ )

Calculate  $\Delta S^\circ_{\text{rxn}}$  for the balanced chemical equation:

#### SOLUTION

Begin by looking up the standard entropy for each reactant and product in Appendix IIB. Always note the correct state—(g), (l), (aq), or (s)—for each reactant and product.

Reactant or product	$S^\circ$ (in J/mol · K)
$\text{NH}_3(\text{g})$	192.8
$\text{O}_2(\text{g})$	205.2
$\text{NO}(\text{g})$	210.8
$\text{H}_2\text{O}(\text{g})$	188.8

Calculate  $\Delta S^\circ_{\text{rxn}}$  by substituting the appropriate values into Equation 18.10. Remember to include the stoichiometric coefficients in your calculation.

$$\begin{aligned} \Delta S^\circ_{\text{rxn}} &= \sum n_p S^\circ(\text{products}) - \sum n_r S^\circ(\text{reactants}) \\ &= [4(S^\circ_{\text{NO}(\text{g})}) + 6(S^\circ_{\text{H}_2\text{O}(\text{g})})] - [4(S^\circ_{\text{NH}_3(\text{g})}) + 5(S^\circ_{\text{O}_2(\text{g})})] \\ &= [4(210.8 \text{ J/K}) + 6(188.8 \text{ J/K})] - [4(192.8 \text{ J/K}) + 5(205.2 \text{ J/K})] \\ &= 1976.0 \text{ J/K} - 1797.2 \text{ J/K} = 178.8 \text{ J/K} \end{aligned}$$

**CHECK** Notice that  $\Delta S^\circ_{\text{rxn}}$  is positive, as you would expect for a reaction in which the number of moles of gas increases.

**FOR PRACTICE 18.5** Calculate  $\Delta S^\circ_{\text{rxn}}$  for the balanced chemical equation:

## 18.8 Free Energy Changes in Chemical Reactions: Calculating $\Delta G^\circ_{\text{rxn}}$

In the previous section, we learned how to calculate the standard change in entropy for a chemical reaction ( $\Delta S^\circ_{\text{rxn}}$ ). However, the criterion for spontaneity at standard conditions is the **standard change in free energy ( $\Delta G^\circ_{\text{rxn}}$ )**. In this section, we examine three methods to calculate the standard change in free energy for a reaction ( $\Delta G^\circ_{\text{rxn}}$ ). In the

first method, we calculate  $\Delta H_{\text{rxn}}^\circ$  and  $\Delta S_{\text{rxn}}^\circ$  from tabulated values of  $\Delta H_f^\circ$  and  $S^\circ$ , and then use the relationship  $\Delta G_{\text{rxn}}^\circ = \Delta H_{\text{rxn}}^\circ - T\Delta S_{\text{rxn}}^\circ$  to calculate  $\Delta G_{\text{rxn}}^\circ$ . In the second method, we use tabulated values of free energies of formation to calculate  $\Delta G_{\text{rxn}}^\circ$  directly. In the third method, we determine the free energy change for a stepwise reaction from the free energy changes of each of the steps. At the end of this section, we discuss what is “free” about free energy. Remember that  $\Delta G_{\text{rxn}}^\circ$  is extremely useful because it tells us about the spontaneity of a process at standard conditions. The more negative  $\Delta G_{\text{rxn}}^\circ$  is, the more spontaneous the process (the further it will go toward products to reach equilibrium).

### Calculating Standard Free Energy Changes with

$$\Delta G_{\text{rxn}}^\circ = \Delta H_{\text{rxn}}^\circ - T\Delta S_{\text{rxn}}^\circ$$

In Chapter 6 (Section 6.9), we used tabulated values of standard enthalpies of formation to calculate  $\Delta H_{\text{rxn}}^\circ$ . In the previous section of this chapter, we used tabulated values of standard entropies to calculate  $\Delta S_{\text{rxn}}^\circ$ . We can use these calculated values of  $\Delta H_{\text{rxn}}^\circ$  and  $\Delta S_{\text{rxn}}^\circ$  to determine the standard free energy change for a reaction by using the equation:

$$\Delta G_{\text{rxn}}^\circ = \Delta H_{\text{rxn}}^\circ - T\Delta S_{\text{rxn}}^\circ \quad [18.11]$$

Since tabulated values of standard enthalpies of formation ( $\Delta H_f^\circ$ ) and standard entropies ( $S^\circ$ ) are usually applicable at 25 °C, the equation should (strictly speaking) be valid only when  $T = 298 \text{ K}$  (25 °C). However, the changes in  $\Delta H_{\text{rxn}}^\circ$  and  $\Delta S_{\text{rxn}}^\circ$  over a limited temperature range are small when compared to the changes in the value of the temperature itself. Therefore, we can use Equation 18.11 to estimate changes in free energy at temperatures other than 25 °C.

#### Example 18.6 Calculating the Standard Change in Free Energy for a Reaction Using $\Delta G_{\text{rxn}}^\circ = \Delta H_{\text{rxn}}^\circ - T\Delta S_{\text{rxn}}^\circ$

One of the possible initial steps in the formation of acid rain is the oxidation of the pollutant  $\text{SO}_2$  to  $\text{SO}_3$  by the reaction:

Calculate  $\Delta G_{\text{rxn}}^\circ$  at 25 °C and determine whether the reaction is spontaneous.

#### SOLUTION

Begin by looking up (in Appendix IIB) the standard enthalpy of formation and the standard entropy for each reactant and product.

Reactant or product	$\Delta H_f^\circ (\text{kJ/mol})$	$S^\circ (\text{J/mol} \cdot \text{K})$
$\text{SO}_2(\text{g})$	-296.8	248.2
$\text{O}_2(\text{g})$	0	205.2
$\text{SO}_3(\text{g})$	-395.7	256.8

Calculate  $\Delta H_{\text{rxn}}^\circ$  using Equation 6.15.

$$\begin{aligned} \Delta H_{\text{rxn}}^\circ &= \sum n_p \Delta H_f^\circ (\text{products}) - \sum n_r \Delta H_f^\circ (\text{reactants}) \\ &= [\Delta H_f^\circ \text{SO}_3(\text{g})] - [\Delta H_f^\circ \text{SO}_2(\text{g}) + \frac{1}{2}(\Delta H_f^\circ \text{O}_2(\text{g}))] \\ &= -395.7 \text{ kJ} - (-296.8 \text{ kJ} + 0.0 \text{ kJ}) = -98.9 \text{ kJ} \end{aligned}$$

Calculate  $\Delta S_{\text{rxn}}^\circ$  using Equation 18.10.

$$\begin{aligned} \Delta S_{\text{rxn}}^\circ &= \sum n_p S^\circ (\text{products}) - \sum n_r S^\circ (\text{reactants}) \\ &= [S_{\text{SO}_3(\text{g})}^\circ] - [S_{\text{SO}_2(\text{g})}^\circ + \frac{1}{2}(S_{\text{O}_2(\text{g})}^\circ)] \\ &= 256.8 \text{ J/K} - [248.2 \text{ J/K} + \frac{1}{2}(205.2 \text{ J/K})] = -94.0 \text{ J/K} \end{aligned}$$

Calculate  $\Delta G_{\text{rxn}}^\circ$  using the calculated values of  $\Delta H_{\text{rxn}}^\circ$  and  $\Delta S_{\text{rxn}}^\circ$  and Equation 18.11. Convert the temperature to kelvins.

$$\begin{aligned} T &= 25 + 273 = 298 \text{ K} \\ \Delta G_{\text{rxn}}^\circ &= \Delta H_{\text{rxn}}^\circ - T\Delta S_{\text{rxn}}^\circ \\ &= -98.9 \times 10^3 \text{ J} - 298 \text{ K}(-94.0 \text{ J/K}) \\ &= -70.9 \times 10^3 \text{ J} = -70.9 \text{ kJ} \end{aligned}$$

The reaction is spontaneous at this temperature because  $\Delta G_{\text{rxn}}^\circ$  is negative.

**FOR PRACTICE 18.6** Consider the oxidation of NO to  $\text{NO}_2$ :

Calculate  $\Delta G_{\text{rxn}}^\circ$  at 25 °C and determine whether the reaction is spontaneous at standard conditions.

**Example 18.7** Estimating the Standard Change in Free Energy for a Reaction at a Temperature Other Than 25 °C Using  $\Delta G_{\text{rxn}}^\circ = \Delta H_{\text{rxn}}^\circ - T\Delta S_{\text{rxn}}^\circ$ 

For the reaction in Example 18.6, estimate the value of  $\Delta G_{\text{rxn}}^\circ$  at 125 °C. Is the reaction more or less spontaneous at this elevated temperature; that is, is the value of  $\Delta G_{\text{rxn}}^\circ$  more negative (more spontaneous) or more positive (less spontaneous)?

**SOLUTION**

Estimate  $\Delta G_{\text{rxn}}^\circ$  at the new temperature using the calculated values of  $\Delta H_{\text{rxn}}^\circ$  and  $\Delta S_{\text{rxn}}^\circ$  from Example 18.6. For  $T$ , convert the given temperature to kelvins. Make sure to use the same units for  $\Delta H_{\text{rxn}}^\circ$  and  $\Delta S_{\text{rxn}}^\circ$  (usually joules).

$$\begin{aligned} T &= 125 + 273 = 398 \text{ K} \\ \Delta G_{\text{rxn}}^\circ &= \Delta H_{\text{rxn}}^\circ - T\Delta S_{\text{rxn}}^\circ \\ &= -98.9 \times 10^3 \text{ J} - 398 \text{ K} (-94.0 \text{ J/K}) \\ &= -61.5 \times 10^3 \text{ J} \\ &= -61.5 \text{ kJ} \end{aligned}$$

Since the value of  $\Delta G_{\text{rxn}}^\circ$  at this elevated temperature is less negative (or more positive) than the value of  $\Delta G_{\text{rxn}}^\circ$  at 25 °C (which is  $-70.9 \text{ kJ}$ ), the reaction is less spontaneous.

**FOR PRACTICE 18.7** For the reaction in For Practice 18.6, calculate the value of  $\Delta G_{\text{rxn}}^\circ$  at  $-55^\circ\text{C}$ . Is the reaction more spontaneous (more negative  $\Delta G_{\text{rxn}}^\circ$ ) or less spontaneous (more positive  $\Delta G_{\text{rxn}}^\circ$ ) at the lower temperature?

## Calculating $\Delta G_{\text{rxn}}^\circ$ with Tabulated Values of Free Energies of Formation

Because  $\Delta G_{\text{rxn}}^\circ$  is the *change* in free energy for a chemical reaction—the difference in free energy between the products and the reactants—and because free energy is a state function, we can calculate  $\Delta G_{\text{rxn}}^\circ$  by subtracting the free energies of the reactants of the reaction from the free energies of the products of the reaction. Also, since we are interested only in *changes* in free energy (and not in absolute values of free energy), we are free to define the *zero* of free energy as conveniently as possible. By analogy with our definition of enthalpies of formation, we define the **free energy of formation ( $\Delta G_f^\circ$ )** as follows:

**The free energy of formation ( $\Delta G_f^\circ$ ) is the change in free energy when 1 mol of a compound in its standard state forms from its constituent elements in their standard states. The free energy of formation of pure elements in their standard states is zero.**

We can measure all changes in free energy relative to pure elements in their standard states. To calculate  $\Delta G_{\text{rxn}}^\circ$ , we subtract the free energies of formation of the reactants multiplied by their stoichiometric coefficients from the free energies of formation of the products multiplied by their stoichiometric coefficients. In the form of an equation:

$$\Delta G_{\text{rxn}}^\circ = \sum n_p \Delta G_f^\circ(\text{products}) - \sum n_r \Delta G_f^\circ(\text{reactants}) \quad [18.12]$$

In Equation 18.12,  $n_p$  represents the stoichiometric coefficients of the products,  $n_r$  represents the stoichiometric coefficients of the reactants, and  $\Delta G_f^\circ$  represents the standard free energies of formation.

Table 18.3 lists  $\Delta G_f^\circ$  values for selected substances. You can find a more complete list in Appendix IIB. Notice that, by definition, *elements* have standard free energies of formation of zero. Notice also that most *compounds* have negative standard free energies of formation. This means that those compounds spontaneously form from their elements in their standard states. Compounds with positive free energies of formation do not spontaneously form from their elements and are therefore less common.

Example 18.8 demonstrates the calculation of  $\Delta G_{\text{rxn}}^\circ$  from  $\Delta G_f^\circ$  values. This method of calculating  $\Delta G_{\text{rxn}}^\circ$  works only at the temperature for which the free energies of formation are tabulated, namely, 25 °C. To estimate  $\Delta G_{\text{rxn}}^\circ$  at other temperatures we must use  $\Delta G_{\text{rxn}}^\circ = \Delta H_{\text{rxn}}^\circ - T\Delta S_{\text{rxn}}^\circ$ , as demonstrated previously.

**TABLE 18.3** Standard Molar Free Energies of Formation  $\Delta G_f^\circ$  for Selected Substances at 298 K

Substance	$\Delta G_f^\circ$ (kJ/mol)	Substance	$\Delta G_f^\circ$ (kJ/mol)
H <sub>2</sub> (g)	0	CH <sub>4</sub> (g)	-50.5
O <sub>2</sub> (g)	0	H <sub>2</sub> O(g)	-228.6
N <sub>2</sub> (g)	0	H <sub>2</sub> O(l)	-237.1
C(s, graphite)	0	NH <sub>3</sub> (g)	-16.4
C(s, diamond)	2.900	NO(g)	+87.6
CO(g)	-137.2	NO <sub>2</sub> (g)	+51.3
CO <sub>2</sub> (g)	-394.4	NaCl(s)	-384.1

**Example 18.8** Calculating  $\Delta G_{\text{rxn}}^\circ$  from Standard Free Energies of Formation

Ozone in the lower atmosphere is a pollutant that can form by the following reaction involving the oxidation of unburned hydrocarbons:

Use the standard free energies of formation to determine  $\Delta G_{\text{rxn}}^\circ$  for this reaction at 25 °C.

**SOLUTION**

Begin by looking up (in Appendix IIB) the standard free energies of formation for each reactant and product. Remember that the standard free energy of formation of a pure element in its standard state is zero.

Reactant or product	$\Delta G_f^\circ$ (in kJ/mol)
CH <sub>4</sub> (g)	-50.5
O <sub>2</sub> (g)	0.0
CO <sub>2</sub> (g)	-394.4
H <sub>2</sub> O(g)	-228.6
O <sub>3</sub> (g)	163.2

Calculate  $\Delta G_{\text{rxn}}^\circ$  by substituting into Equation 18.12.

$$\begin{aligned}
 \Delta G_{\text{rxn}}^\circ &= \sum n_p \Delta G_f^\circ(\text{products}) - \sum n_r \Delta G_f^\circ(\text{reactants}) \\
 &= [\Delta G_{\text{f}, \text{CO}_2(\text{g})}^\circ + 2(\Delta G_{\text{f}, \text{H}_2\text{O}(\text{g})}^\circ) + 4(\Delta G_{\text{f}, \text{O}_3(\text{g})}^\circ)] - [\Delta G_{\text{f}, \text{CH}_4(\text{g})}^\circ + 8(\Delta G_{\text{f}, \text{O}_2(\text{g})}^\circ)] \\
 &= [-394.4 \text{ kJ} + 2(-228.6 \text{ kJ}) + 4(163.2 \text{ kJ})] - [-50.5 \text{ kJ} + 8(0.0 \text{ kJ})] \\
 &= -198.8 \text{ kJ} + 50.5 \text{ kJ} \\
 &= -148.3 \text{ kJ}
 \end{aligned}$$

**FOR PRACTICE 18.8** One of the reactions that occurs within a catalytic converter in the exhaust pipe of a car is the simultaneous oxidation of carbon monoxide and reduction of NO (both of which are harmful pollutants):

Use standard free energies of formation to determine  $\Delta G_{\text{rxn}}^\circ$  for this reaction at 25 °C. Is the reaction spontaneous at standard conditions?

**FOR MORE PRACTICE 18.8** In For Practice 18.8, you calculated  $\Delta G_{\text{rxn}}^\circ$  for the simultaneous oxidation of carbon monoxide and reduction of NO using standard free energies of formation. Calculate  $\Delta G_{\text{rxn}}^\circ$  for that reaction again at 25 °C, only this time use  $\Delta G_{\text{rxn}}^\circ = \Delta H_{\text{rxn}}^\circ - T\Delta S_{\text{rxn}}^\circ$ . How do the two values compare? Use your results to calculate  $\Delta G_{\text{rxn}}^\circ$  at 500.0 K and explain why you could not calculate  $\Delta G_{\text{rxn}}^\circ$  at 500.0 K using tabulated standard free energies of formation.

## Chemistry IN YOUR DAY

## Making a Nonspontaneous Process Spontaneous

A process that is nonspontaneous can be made spontaneous by coupling it with another process that is highly spontaneous. For example, hydrogen gas is a potential future fuel because it can be used in a fuel cell (a type of battery in which the reactants are constantly supplied—see Chapter 19) to generate electricity. The main problem with switching to hydrogen is securing a source. Where can we get the huge amounts of hydrogen gas that would be needed to meet our world's energy needs?

Earth's oceans and lakes, of course, contain vast amounts of hydrogen. But that hydrogen is locked up in water molecules, and the decomposition of water into hydrogen and oxygen has a positive  $\Delta G_{\text{rxn}}^{\circ}$  and is therefore nonspontaneous:

To obtain hydrogen from water, we need to find another reaction with a highly negative  $\Delta G_{\text{rxn}}^{\circ}$  that can couple with the decomposition reaction to give an overall reaction with a negative  $\Delta G_{\text{rxn}}^{\circ}$ . For example, the oxidation of carbon monoxide to carbon dioxide has a large negative  $\Delta G_{\text{rxn}}^{\circ}$  and is highly spontaneous:

If we add the two reactions together, we get a negative  $\Delta G_{\text{rxn}}^{\circ}$ :

The reaction between water and carbon monoxide is thus a spontaneous way to generate hydrogen gas.

The coupling of nonspontaneous reactions with highly spontaneous ones is also important in biological systems. The synthesis reactions that create the complex biological molecules (such as proteins and DNA) needed by living organisms, for example, are themselves nonspontaneous. Living systems grow and reproduce by coupling these nonspontaneous reactions to highly spontaneous ones. The main spontaneous reaction that ultimately drives the nonspontaneous ones is the metabolism of food. The oxidation of glucose, for example, is highly spontaneous:

Spontaneous reactions such as these ultimately drive the nonspontaneous reactions necessary to sustain life.

## Calculating $\Delta G_{\text{rxn}}^{\circ}$ for a Stepwise Reaction from the Changes in Free Energy for Each of the Steps

Recall from Section 6.8 that because enthalpy is a state function, we can calculate  $\Delta H_{\text{rxn}}^{\circ}$  for a stepwise reaction from the sum of the changes in enthalpy for each step (according to Hess's law). Since free energy is also a state function, the same relationships that we covered in Chapter 6 for enthalpy also apply to free energy:

1. If a chemical equation is multiplied by some factor, then  $\Delta G_{\text{rxn}}$  is also multiplied by the same factor.
2. If a chemical equation is reversed, then  $\Delta G_{\text{rxn}}$  changes sign.
3. If a chemical equation can be expressed as the sum of a series of steps, then  $\Delta G_{\text{rxn}}$  for the overall equation is the sum of the free energies of reactions for each step.

Example 18.9 illustrates the use of these relationships to calculate  $\Delta G_{\text{rxn}}^{\circ}$  for a stepwise reaction.

### Example 18.9 Calculating $\Delta G_{\text{rxn}}^{\circ}$ for a Stepwise Reaction

Find  $\Delta G_{\text{rxn}}^{\circ}$  for the reaction:

Use the following reactions with known  $\Delta G_{\text{rxn}}^{\circ}$  values:

—Continued on the next page

Continued—

**SOLUTION**

To work this problem, you need to manipulate the given reactions with known values of  $\Delta G^\circ_{\text{rxn}}$  in such a way as to get the reactants of interest on the left, the products of interest on the right, and other species to cancel.

Since the first reaction has  $\text{C}_3\text{H}_8$  as a reactant, and the reaction of interest has  $\text{C}_3\text{H}_8$  as a product, reverse the first reaction and change the sign of  $\Delta G^\circ_{\text{rxn}}$ .

The second reaction has C as a reactant and  $\text{CO}_2$  as a product, as required in the reaction of interest. However, the coefficient for C is 1, and in the reaction of interest, the coefficient for C is 3. Therefore, multiply this equation and its  $\Delta G^\circ_{\text{rxn}}$  by 3.

In the third reaction  $\text{H}_2(\text{g})$  is a reactant, as required. However, the coefficient for  $\text{H}_2$  is 2, and in the reaction of interest, the coefficient for  $\text{H}_2$  is 4. Multiply this reaction and its  $\Delta G^\circ_{\text{rxn}}$  by 2.

Lastly, rewrite the three reactions after multiplying through by the indicated factors and show how they sum to the reaction of interest.  $\Delta G^\circ_{\text{rxn}}$  for the reaction of interest is then the sum of the  $\Delta G^\circ$ 's for the steps.

**FOR PRACTICE 18.9**

Find  $\Delta G^\circ_{\text{rxn}}$  for the reaction:

Use the following reactions with known  $\Delta G^\circ_{\text{rxn}}$  values:

**▲ FIGURE 18.10 Free Energy**

Although the reaction produces 74.6 kJ of heat, only a maximum of 50.5 kJ is available to do work. The rest of the energy is lost to the surroundings.

**Why Free Energy Is “Free”**

We often want to use the energy released by a chemical reaction to do work. For example, in an automobile engine, we use the energy released by the combustion of gasoline to move the car forward. The change in free energy of a chemical reaction represents the maximum amount of energy available, or *free*, to do work (if  $\Delta G^\circ_{\text{rxn}}$  is negative).

For many reactions, the change in free energy is less than the change in enthalpy for the reaction. Consider the reaction between carbon and hydrogen occurring at 25 °C :

The reaction is exothermic and gives off 74.6 kJ of heat energy. However, the maximum amount of energy available for useful work is only 50.5 kJ (Figure 18.10). Why? We can see that the change in entropy of the *system* is negative. Nevertheless, the reaction is spontaneous. This is possible only if some of the emitted heat goes to increase the entropy of the surroundings by an amount sufficient to make the change in entropy of the *universe* positive. The amount of energy available to do work (the free energy) is what remains after accounting for the heat that must be lost to the surroundings.

## Reversible Process

**▲ FIGURE 18.11 A Reversible Process** In a reversible process, the free energy is drawn out in infinitesimally small increments that exactly match the amount of energy that the process is producing in that increment. In this case, grains of sand are removed one at a time, resulting in a series of small expansions in which the weight of sand almost exactly matches the pressure of the expanding gas. This process is close to reversible—each sand grain would need to have an infinitesimally small mass for the process to be fully reversible.

The change in free energy for a chemical reaction represents a *theoretical limit* as to how much work can be done by the reaction. In a *real* reaction, the amount of energy available to do work is even *less* than  $\Delta G_{\text{rxn}}^{\circ}$  because additional energy is lost to the surroundings as heat. The only reactions that reach the theoretical limit are reversible reactions (see Section 18.4 for the definition of reversible processes). A reversible chemical reaction occurs infinitesimally slowly, and the free energy is drawn out in infinitesimally small increments that exactly match the amount of energy that the reaction is producing during that increment (Figure 18.11▲).

All real reactions are irreversible and therefore do not achieve the theoretical limit of available free energy. Let's return to the discharging battery from the opening section of this chapter as an example of this concept. A battery contains chemical reactants configured in such a way that, upon spontaneous reaction, they produce an electrical current. We can harness the free energy released by the reaction to do work. For example, an electric motor can be wired to the battery. Flowing electrical current makes the motor turn (Figure 18.12►).

Because of the resistance in the wire, the flowing electrical current also produces some heat, which is lost to the surroundings and is not available to do work. The amount of free energy lost as heat can be decreased by slowing down the rate of current flow. The slower the rate of current flow, the less free energy is lost as heat and the more is available to do work. However, only in the theoretical case of infinitesimally slow current flow is the maximum amount of work (equal to  $\Delta G_{\text{rxn}}^{\circ}$ ) done. Any real rate of current flow results in some loss of energy as heat. This lost energy is the “heat tax” that we discussed in the opening section of this chapter.

Recharging the battery necessarily requires more energy than is obtained as work because some of the energy is lost as heat. In other words, during discharging and recharging, the battery has gone through a cycle in which it returns to its original (charged) state. However, the surroundings have gained some heat during the process, and the entropy of the surroundings has increased (which makes the process spontaneous). Any real (or irreversible) cyclical process such as this suffers the same fate—the system may return to its original state, but the surroundings do not, resulting in the permanent dispersal of energy to the surroundings.

If the change in free energy of a chemical reaction is positive, then  $\Delta G_{\text{rxn}}^{\circ}$  represents *the minimum amount of energy required to make the reaction occur*. Again,  $\Delta G_{\text{rxn}}^{\circ}$  represents a theoretical limit. Making a real nonspontaneous reaction occur always requires more energy than the theoretical limit.

Applying the definition of reversibility from Section 18.4, a reversible chemical reaction is one that changes direction upon an infinitesimally small change in a variable (such as temperature or pressure) related to the reaction.

**▲ FIGURE 18.12 Energy Loss in a Battery** When current is drawn from a battery to do work, some energy is lost as heat due to resistance in the wire. Consequently, the quantity of energy required to recharge the battery will be more than the quantity of work done.

## 18.9 Free Energy Changes for Nonstandard States: The Relationship between $\Delta G^\circ_{\text{rxn}}$ and $\Delta G_{\text{rxn}}$

We have learned how to calculate the *standard* free energy change for a reaction ( $\Delta G^\circ_{\text{rxn}}$ ). However, the standard free energy change applies only to a very narrow set of conditions, namely, those conditions in which the reactants and products are in their standard states.

### Standard versus Nonstandard States

Consider the standard free energy change for the evaporation of liquid water to gaseous water:

The standard free energy change for this process is positive, so the process is nonspontaneous. But you know that if you spill water onto the floor under ordinary conditions, it spontaneously evaporates. Why? *Because under ordinary conditions the reactants and products are not in their standard states* and  $\Delta G^\circ_{\text{rxn}}$  applies only when the reactants and product are in their standard states, sometimes called *standard conditions*. For a gas (such as the water vapor in the reaction just given), the standard state is that the pure gas is present at a partial pressure of 1 atmosphere. In a flask containing liquid water and water vapor in its standard state ( $P_{\text{H}_2\text{O}} = 1 \text{ atm}$ ) at  $25^\circ\text{C}$  the water does not vaporize. In fact, since  $\Delta G^\circ_{\text{rxn}}$  is negative for the reverse reaction, the reaction spontaneously occurs in reverse—water vapor condenses.

In open air under ordinary circumstances, the partial pressure of water vapor is much less than 1 atm. The state of the water vapor is not its standard state, and therefore the value of  $\Delta G^\circ_{\text{rxn}}$  does not apply. For the nonstandard state, we must calculate  $\Delta G_{\text{rxn}}$  (as opposed to  $\Delta G^\circ_{\text{rxn}}$ ) to predict spontaneity.

▲ Spilled water spontaneously evaporates even though  $\Delta G^\circ$  for the vaporization of water is positive. Why?

### The Free Energy Change of a Reaction under Nonstandard Conditions

We can calculate the **free energy change of a reaction under nonstandard conditions** ( $\Delta G_{\text{rxn}}$ ) from  $\Delta G^\circ_{\text{rxn}}$  using the relationship:

$$\Delta G_{\text{rxn}} = \Delta G^\circ_{\text{rxn}} + RT \ln Q \quad [18.13]$$

where  $Q$  is the reaction quotient (defined in Section 15.7),  $T$  is the temperature in kelvins, and  $R$  is the gas constant in the appropriate units ( $8.314 \text{ J/mol} \cdot \text{K}$ ).

In Equation 18.13 and all subsequent thermodynamic equations, we use  $Q_p$  for reactions involving gases, and we use  $Q_c$  for reactions involving substances dissolved in solution. We can demonstrate the use of this equation by applying it to the liquid-vapor water equilibrium under several different conditions, as shown in Figure 18.13►. Note that by the law of mass action, for this equilibrium,  $Q = P_{\text{H}_2\text{O}}$  (where the pressure is expressed in atmospheres):

#### Standard Conditions

Under standard conditions,  $P_{\text{H}_2\text{O}} = 1 \text{ atm}$  and therefore  $Q = 1$ . Substituting, we get the expression:

$$\begin{aligned} \Delta G_{\text{rxn}} &= \Delta G^\circ_{\text{rxn}} + RT \ln Q \\ &= +8.59 \text{ kJ/mol} + RT \ln(1) \\ &= +8.59 \text{ kJ/mol} \end{aligned}$$

**▲ FIGURE 18.13 Free Energy versus Pressure for Water** The free energy change for the vaporization of water is a function of pressure.

Under standard conditions,  $Q$  is always equal to 1, and since  $\ln(1) = 0$ , the value of  $\Delta G_{\text{rxn}}$  is therefore equal to  $\Delta G_{\text{rxn}}^{\circ}$ , as expected. For the liquid-vapor water equilibrium, because  $\Delta G_{\text{rxn}}^{\circ} > 0$ , the reaction is not spontaneous in the forward direction but is spontaneous in the reverse direction. As stated previously, under standard conditions water vapor condenses into liquid water.

### Equilibrium Conditions

At 25.00 °C, liquid water is in equilibrium with water vapor at a pressure of 0.0313 atm; therefore,  $Q = K_p = 0.0313$ . Substituting:

$$\begin{aligned}
 \Delta G_{\text{rxn}} &= \Delta G_{\text{rxn}}^{\circ} + RT \ln(0.0313) \\
 &= +8.59 \text{ kJ/mol} + 8.314 \frac{\text{J}}{\text{mol} \cdot \text{K}} (298.15 \text{ K}) \ln(0.0313) \\
 &= +8.59 \text{ kJ/mol} + (-8.59 \times 10^3 \text{ J/mol}) \\
 &= +8.59 \text{ kJ/mol} - 8.59 \text{ kJ/mol} \\
 &= 0
 \end{aligned}$$

Under equilibrium conditions, the value of  $RT \ln Q$  is always equal in magnitude but opposite in sign to the value of  $\Delta G_{\text{rxn}}^{\circ}$ . Therefore, the value of  $\Delta G_{\text{rxn}}$  is zero. Because  $\Delta G_{\text{rxn}} = 0$ , the reaction is not spontaneous in either direction, as expected for a reaction at equilibrium.

A water partial pressure of  $5.00 \times 10^{-3}$  atm corresponds to a relative humidity of 16% at 25 °C.

### Other Nonstandard Conditions

To calculate the value of  $\Delta G_{\text{rxn}}$  under any other set of nonstandard conditions, calculate  $Q$  and substitute the value into Equation 18.13. For example, the partial pressure of water vapor in the air on a dry (nonhumid) day is  $5.00 \times 10^{-3}$  atm, so  $Q = 5.00 \times 10^{-3}$ . Substituting:

$$\begin{aligned}\Delta G_{\text{rxn}} &= \Delta G_{\text{rxn}}^{\circ} + RT \ln (5.00 \times 10^{-3}) \\ &= +8.59 \text{ kJ/mol} + 8.314 \frac{\text{J}}{\text{mol} \cdot \text{K}} (298 \text{ K}) \ln(5.00 \times 10^{-3}) \\ &= +8.59 \text{ kJ/mol} + (-13.1 \times 10^3 \text{ J/mol}) \\ &= +8.59 \text{ kJ/mol} - 13.1 \text{ kJ/mol} \\ &= -4.5 \text{ kJ/mol}\end{aligned}$$

Under these conditions, the value of  $\Delta G_{\text{rxn}} < 0$ , so the reaction is spontaneous in the forward direction, consistent with our experience of water evaporating when spilled on the floor.

### Example 18.10 Calculating $\Delta G_{\text{rxn}}$ under Nonstandard Conditions

Consider the reaction at 298 K:

Calculate  $\Delta G_{\text{rxn}}$  under these conditions:

$$P_{\text{NO}} = 0.100 \text{ atm}; \quad P_{\text{O}_2} = 0.100 \text{ atm}; \quad P_{\text{NO}_2} = 2.00 \text{ atm}$$

Is the reaction more or less spontaneous under these conditions than under standard conditions?

#### SOLUTION

Use the law of mass action to calculate  $Q$ .

$$Q = \frac{(P_{\text{NO}_2})^2}{(P_{\text{NO}})^2 P_{\text{O}_2}} = \frac{(2.00)^2}{(0.100)^2 (0.100)} = 4.00 \times 10^3$$

Substitute  $Q$ ,  $T$ , and  $\Delta G_{\text{rxn}}^{\circ}$  into Equation 18.13 to calculate  $\Delta G_{\text{rxn}}$ . (Since the units of  $R$  include joules, write  $\Delta G_{\text{rxn}}^{\circ}$  in joules.)

$$\begin{aligned}\Delta G_{\text{rxn}} &= \Delta G_{\text{rxn}}^{\circ} + RT \ln Q \\ &= -71.2 \times 10^3 \text{ J} + 8.314 \frac{\text{J}}{\text{mol} \cdot \text{K}} (298 \text{ K}) \ln(4.00 \times 10^3) \\ &= -71.2 \times 10^3 \text{ J} + 20.5 \times 10^3 \text{ J} \\ &= -50.7 \times 10^3 \text{ J} \\ &= -50.7 \text{ kJ}\end{aligned}$$

The reaction is spontaneous under these conditions, but less spontaneous than it would be under standard conditions (because  $\Delta G_{\text{rxn}}$  is less negative than  $\Delta G_{\text{rxn}}^{\circ}$ ).

**CHECK** The calculated result is consistent with what you would expect based on Le Châtelier's principle; increasing the concentration of the products and decreasing the concentration of the reactants relative to standard conditions should make the reaction less spontaneous than it was under standard conditions.

**FOR PRACTICE 18.10** Consider the reaction at 298 K:

Calculate  $\Delta G_{\text{rxn}}$  under these conditions:

$$P_{\text{H}_2\text{S}} = 2.00 \text{ atm}; \quad P_{\text{SO}_2} = 1.50 \text{ atm}; \quad P_{\text{H}_2\text{O}} = 0.0100 \text{ atm}$$

Is the reaction more or less spontaneous under these conditions than under standard conditions?

## CONCEPTUAL CONNECTION 18.6

**Free Energy Changes and Le Châtelier's Principle** According to Le Châtelier's principle and the dependence of free energy on reactant and product concentrations, which statement is true? (Assume that both reactants and products are gaseous.)

- (a) A high concentration of reactants relative to products results in a more spontaneous reaction than one in which the reactants and products are in their standard states.
- (b) A high concentration of products relative to reactants results in a more spontaneous reaction than one in which the reactants and products are in their standard states.
- (c) A reaction in which the reactants are in standard states, but in which no products have formed, has a  $\Delta G_{\text{rxn}}$  that is more positive than  $\Delta G_{\text{rxn}}^{\circ}$ .

## 18.10 Free Energy and Equilibrium: Relating $\Delta G_{\text{rxn}}^{\circ}$ to the Equilibrium Constant ( $K$ )

We have discussed throughout this chapter that  $\Delta G_{\text{rxn}}^{\circ}$  determines the spontaneity of a reaction when the reactants and products are in their standard states. In Chapter 15, we learned that the equilibrium constant ( $K$ ) determines how far a reaction goes toward products, a measure of spontaneity. Therefore, as you might expect, the standard free energy change of a reaction and the equilibrium constant are related—the equilibrium constant becomes larger as the standard free energy change becomes more negative. In other words, if, on the one hand, the reactants in a particular reaction undergo a large *negative* free energy change as they become products, then the reaction has a large equilibrium constant, with products strongly favored at equilibrium. If, on the other hand, the reactants in a particular reaction undergo a large *positive* free energy change as they become products, then the reaction has a small equilibrium constant, with reactants strongly favored at equilibrium.

### The Relationship between $\Delta G_{\text{rxn}}^{\circ}$ and $K$

We can derive a relationship between  $\Delta G_{\text{rxn}}^{\circ}$  and  $K$  from Equation 18.13. We know that at equilibrium  $Q = K$  and  $\Delta G_{\text{rxn}} = 0$ . Making these substitutions:

$$\begin{aligned}\Delta G_{\text{rxn}} &= \Delta G_{\text{rxn}}^{\circ} + RT \ln Q \\ 0 &= \Delta G_{\text{rxn}}^{\circ} + RT \ln K \\ \Delta G_{\text{rxn}}^{\circ} &= -RT \ln K\end{aligned}\quad [18.14]$$

In Equation 18.14 and all subsequent thermodynamic equations, we use  $K_p$  for reactions involving gases, and we use  $K_c$  for reactions involving substances dissolved in solution.

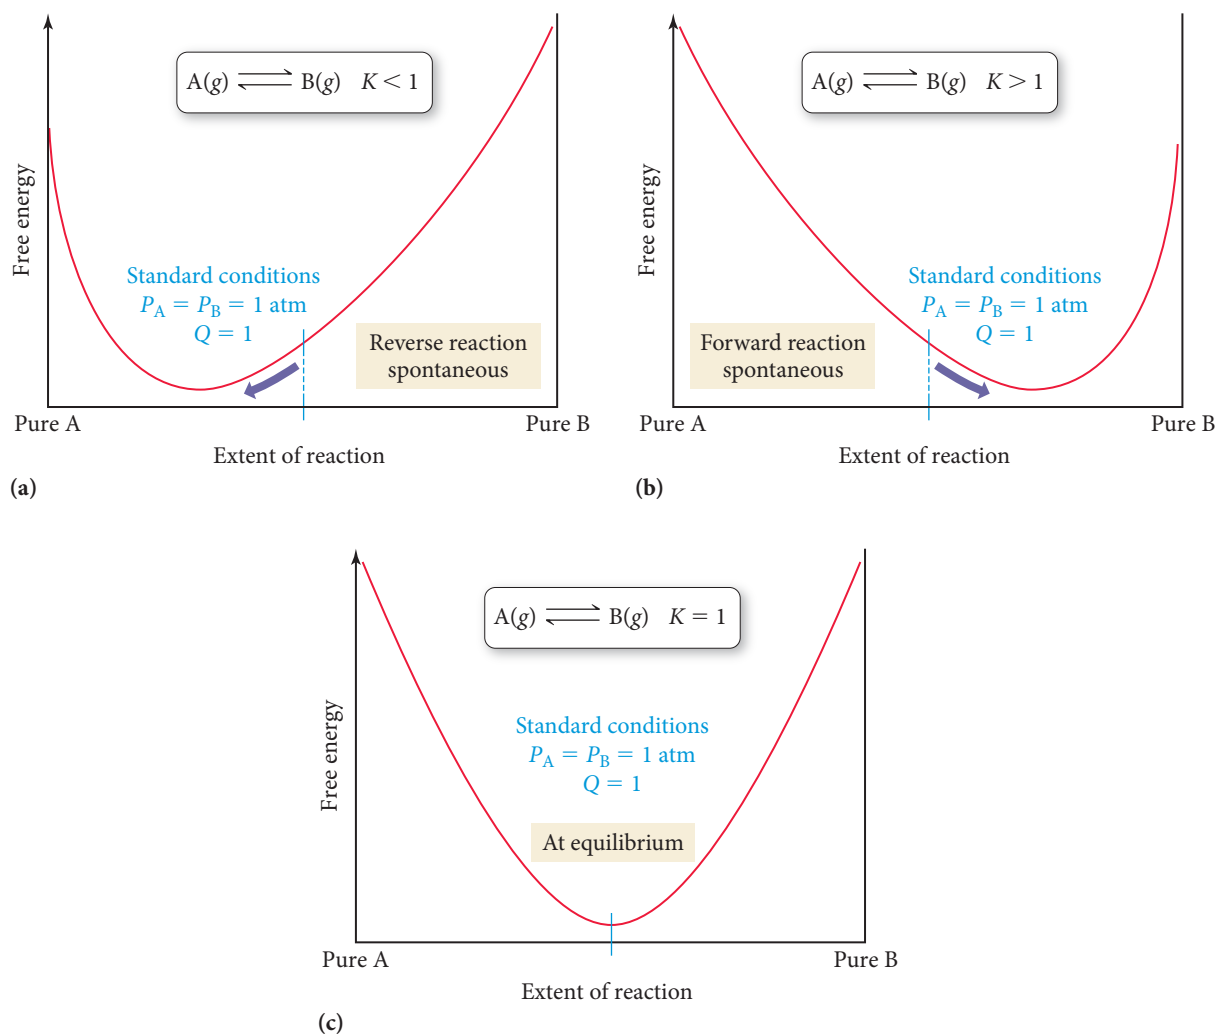

We can better understand the relationship between  $\Delta G_{\text{rxn}}^{\circ}$  and  $K$  by considering the following ranges of values for  $K$ , as summarized in Figure 18.14►:

- When  $K < 1$ ,  $\ln K$  is negative and  $\Delta G_{\text{rxn}}^{\circ}$  is positive. Under standard conditions (when  $Q = 1$ ) the reaction is spontaneous in the reverse direction.
- When  $K > 1$ ,  $\ln K$  is positive and  $\Delta G_{\text{rxn}}^{\circ}$  is negative. Under standard conditions (when  $Q = 1$ ) the reaction is spontaneous in the forward direction.
- When  $K = 1$ ,  $\ln K$  is zero and  $\Delta G_{\text{rxn}}^{\circ}$  is zero. The reaction happens to be at equilibrium under standard conditions.

The relationship between  $\Delta G_{\text{rxn}}^{\circ}$  and  $K$  is logarithmic—small changes in  $\Delta G_{\text{rxn}}^{\circ}$  have a large effect on  $K$ .

## Free Energy and the Equilibrium Constant

**▲ FIGURE 18.14 Free Energy and the Equilibrium Constant** (a) Free energy curve for a reaction with a small equilibrium constant. (b) Free energy curve for a reaction with a large equilibrium constant. (c) Free energy curve for a reaction in which  $K = 1$ .

### Example 18.11 The Equilibrium Constant and $\Delta G^\circ_{\text{rxn}}$

Use tabulated free energies of formation to calculate the equilibrium constant for the reaction at 298 K:

#### SOLUTION

Look up (in Appendix IIB) the standard free energies of formation for each reactant and product.

Reactant or product	$\Delta G_f^\circ$ (in kJ/mol)
$\text{N}_2\text{O}_4(g)$	99.8
$\text{NO}_2(g)$	51.3

Calculate  $\Delta G^\circ_{\text{rxn}}$  by substituting into Equation 18.12.

$$\begin{aligned}
 \Delta G^\circ_{\text{rxn}} &= \sum n_p \Delta G_f^\circ (\text{products}) - \sum n_r \Delta G_f^\circ (\text{reactants}) \\
 &= 2[\Delta G_f^\circ, \text{NO}_2(g)] - \Delta G_f^\circ, \text{N}_2\text{O}_4(g) \\
 &= 2(51.3 \text{ kJ}) - 99.8 \text{ kJ} \\
 &= 2.8 \text{ kJ}
 \end{aligned}$$

Calculate  $K$  from  $\Delta G_{\text{rxn}}^{\circ}$  by solving Equation 18.14 for  $K$  and substituting the values of  $\Delta G_{\text{rxn}}^{\circ}$  and temperature.

$$\begin{aligned}\Delta G_{\text{rxn}}^{\circ} &= -RT \ln K \\ \ln K &= \frac{-\Delta G_{\text{rxn}}^{\circ}}{RT} \\ &= \frac{-2.8 \times 10^3 \text{ J/mol}}{8.314 \frac{\text{J}}{\text{mol} \cdot \text{K}} (298 \text{ K})} \\ &= -1.13 \\ K &= e^{-1.13} \\ &= 0.32\end{aligned}$$

**FOR PRACTICE 18.11** Calculate  $\Delta G_{\text{rxn}}^{\circ}$  at 298 K for the reaction:

**$K$  and  $\Delta G_{\text{rxn}}^{\circ}$**  The reaction  $\text{A}(\text{g}) \rightleftharpoons \text{B}(\text{g})$  has an equilibrium constant that is less than one. What can you conclude about  $\Delta G_{\text{rxn}}^{\circ}$  for the reaction?

- (a)  $\Delta G_{\text{rxn}}^{\circ} = 0$       (b)  $\Delta G_{\text{rxn}}^{\circ} < 0$       (c)  $\Delta G_{\text{rxn}}^{\circ} > 0$

### CONCEPTUAL CONNECTION 18.7

**The Conditions of Spontaneity** A reaction is spontaneous under a certain set of conditions. Select all equations that *must be true* for this reaction under these conditions:

$\Delta G_{\text{rxn}} < 0$ ,  $\Delta G_{\text{rxn}} > 0$ ,  $\Delta G_{\text{rxn}} = 0$ ,  $\Delta G_{\text{rxn}}^{\circ} < 0$ ,  $\Delta G_{\text{rxn}}^{\circ} > 0$ ,  $\Delta G_{\text{rxn}}^{\circ} = 0$ ,  $\Delta H_{\text{rxn}} < 0$ ,  $\Delta H_{\text{rxn}} > 0$ ,  $\Delta H_{\text{rxn}} = 0$ ,  $\Delta S_{\text{rxn}} < 0$ ,  $\Delta S_{\text{rxn}} > 0$ ,  $\Delta S_{\text{rxn}} = 0$ ,  $Q = K$ ,  $Q < K$ ,  $Q > K$

### CONCEPTUAL CONNECTION 18.8

## The Temperature Dependence of the Equilibrium Constant

We now have an equation that relates the standard free energy change for a reaction ( $\Delta G_{\text{rxn}}^{\circ}$ ) to the equilibrium constant for a reaction ( $K$ ):

$$\Delta G_{\text{rxn}}^{\circ} = -RT \ln K \quad [18.15]$$

We also have an equation for how the free energy change for a reaction ( $\Delta G_{\text{rxn}}^{\circ}$ ) depends on temperature ( $T$ ):

$$\Delta G_{\text{rxn}}^{\circ} = \Delta H_{\text{rxn}}^{\circ} - T \Delta S_{\text{rxn}}^{\circ} \quad [18.16]$$

We can combine these two equations to obtain an equation for how the equilibrium constant depends on temperature. Combining Equations 18.15 and 18.16, we arrive at:

$$-RT \ln K = \Delta H_{\text{rxn}}^{\circ} - T \Delta S_{\text{rxn}}^{\circ} \quad [18.17]$$

We can then divide both sides of Equation 18.17 by the quantity  $RT$ :

$$-\ln K = \frac{\Delta H_{\text{rxn}}^{\circ}}{RT} - \frac{T \Delta S_{\text{rxn}}^{\circ}}{RT}$$

Canceling and rearranging, we get this important result:

$$\ln K = -\frac{\Delta H_{\text{rxn}}^{\circ}}{R} \left( \frac{1}{T} \right) + \frac{\Delta S_{\text{rxn}}^{\circ}}{R} \quad [18.18]$$

$$y = mx + b$$

Equation 18.18 is in the form of a straight line. A plot of the natural log of the equilibrium constant ( $\ln K$ ) versus the inverse of the temperature in kelvins ( $1/T$ ) yields a straight line with a slope of  $-\Delta H_{\text{rxn}}^{\circ}/R$  and a  $y$ -intercept of  $\Delta S_{\text{rxn}}^{\circ}/R$ . Such a plot is useful for obtaining thermodynamic data (namely,  $\Delta H_{\text{rxn}}^{\circ}$  and  $\Delta S_{\text{rxn}}^{\circ}$ ) from measurements of  $K$  as a function of temperature. However, since  $\Delta H_{\text{rxn}}^{\circ}$  and  $\Delta S_{\text{rxn}}^{\circ}$  can themselves be slightly temperature dependent, this analysis works only over a relatively limited temperature range.

The equation can also be expressed in a two-point form:

$$\ln \frac{K_2}{K_1} = -\frac{\Delta H_{\text{rxn}}^{\circ}}{R} \left( \frac{1}{T_2} - \frac{1}{T_1} \right) \quad [18.19]$$

We can use this equation to find  $\Delta H_{\text{rxn}}^{\circ}$  from a measurement of the equilibrium constant at two different temperatures or to find the equilibrium constant at some other temperature if we know the equilibrium constant at a given temperature and  $\Delta H_{\text{rxn}}^{\circ}$ .

## Self-Assessment Quiz

**Q1.** Which reaction is most likely to have a positive  $\Delta S_{\text{sys}}$ ?

- a)  $\text{SiO}_2(\text{s}) + 3 \text{C}(\text{s}) \longrightarrow \text{SiC}(\text{s}) + 2 \text{CO}(\text{g})$
- b)  $6 \text{CO}_2(\text{g}) + 6 \text{H}_2\text{O}(\text{g}) \longrightarrow \text{C}_6\text{H}_{12}\text{O}_6(\text{s}) + 6 \text{O}_2(\text{g})$
- c)  $\text{CO}(\text{g}) + \text{Cl}_2(\text{g}) \longrightarrow \text{COCl}_2(\text{g})$
- d)  $3 \text{NO}_2(\text{g}) + \text{H}_2\text{O}(\text{l}) \longrightarrow 2 \text{HNO}_3(\text{l}) + \text{NO}(\text{g})$

**Q2.** The sign of  $\Delta H_{\text{rxn}}$  and  $\Delta S_{\text{rxn}}$  for several different reactions are given. In which case is the reaction spontaneous at all temperatures?

- a)  $\Delta H_{\text{rxn}} < 0$ ;  $\Delta S_{\text{rxn}} < 0$
- b)  $\Delta H_{\text{rxn}} > 0$ ;  $\Delta S_{\text{rxn}} > 0$
- c)  $\Delta H_{\text{rxn}} < 0$ ;  $\Delta S_{\text{rxn}} > 0$
- d)  $\Delta H_{\text{rxn}} > 0$ ;  $\Delta S_{\text{rxn}} < 0$

**Q3.** Arrange the gases— $\text{F}_2$ , Ar, and  $\text{CH}_3\text{F}$ —in order of increasing standard entropy ( $S^{\circ}$ ) at 298 K.

- a)  $\text{F}_2 < \text{Ar} < \text{CH}_3\text{F}$
- b)  $\text{CH}_3\text{F} < \text{F}_2 < \text{Ar}$
- c)  $\text{CH}_3\text{F} < \text{Ar} < \text{F}_2$
- d)  $\text{Ar} < \text{F}_2 < \text{CH}_3\text{F}$

**Q4.** Calculate the change in entropy that occurs in the system when 1.00 mol of methanol ( $\text{CH}_3\text{OH}$ ) vaporizes from a liquid to a gas at its boiling point ( $64.6^{\circ}\text{C}$ ). For methanol,  $\Delta H_{\text{vap}} = 35.21 \text{ kJ/mol}$ .

- a)  $104 \text{ J/K}$
- b)  $-104 \text{ J/K}$
- c)  $545 \text{ J/K}$
- d)  $-545 \text{ J/K}$

**Q5.** A reaction has a  $\Delta H_{\text{rxn}} = 54.2 \text{ kJ}$ . Calculate the change in entropy for the surroundings ( $\Delta S_{\text{sur}}$ ) for the reaction at  $25.0^{\circ}\text{C}$ . (Assume constant pressure and temperature.)

- a)  $2.17 \times 10^3 \text{ J/K}$
- b)  $-2.17 \times 10^3 \text{ J/K}$
- c)  $-182 \text{ J/K}$
- d)  $182 \text{ J/K}$

**Q6.** A reaction has  $\Delta H_{\text{rxn}}^{\circ} = -255 \text{ kJ}$  and  $\Delta S_{\text{rxn}}^{\circ} = 211 \text{ J/K}$ . Calculate  $\Delta G_{\text{rxn}}^{\circ}$  at  $55^{\circ}\text{C}$ .

- a)  $11.9 \times 10^3 \text{ kJ}$
- b)  $69.5 \times 10^3 \text{ kJ}$
- c)  $-267 \text{ kJ}$
- d)  $-324 \text{ kJ}$

**Q7.** Use standard entropies to calculate  $\Delta S_{\text{rxn}}^{\circ}$  for the balanced chemical equation:

Substance	$S^{\circ} (\text{J/mol} \cdot \text{K})$
$\text{POCl}_3(\text{l})$	222.5
$\text{POCl}_3(\text{g})$	325.5
$\text{PCl}_3(\text{l})$	217.1
$\text{PCl}_3(\text{g})$	311.8
$\text{O}_2(\text{g})$	205.2

- a)  $-194.4 \text{ J/K}$
- b)  $-199.8 \text{ J/K}$
- c)  $10.8 \text{ J/K}$
- d)  $1084.4 \text{ J/K}$

**Q8.** Use standard free energies of formation to calculate  $\Delta G_{\text{rxn}}^{\circ}$  for the balanced chemical equation:

Substance	$\Delta G_{\text{rxn}}^{\circ} (\text{kJ/mol})$
$\text{N}_2\text{O}(\text{g})$	103.7
$\text{MgO}(\text{s})$	-569.3

- a)  $673.0 \text{ kJ}$
- b)  $-673.0 \text{ kJ}$
- c)  $-465.6 \text{ kJ}$
- d)  $465.6 \text{ kJ}$

**Q9.** Find  $\Delta G_{\text{rxn}}^{\circ}$  for the reaction  $2 \text{A} + \text{B} \longrightarrow 2 \text{C}$  from the given data.

- a)  $-401 \text{ kJ}$
- b)  $509 \text{ kJ}$
- c)  $401 \text{ kJ}$
- d)  $-509 \text{ kJ}$

**Q10.** The given reaction has a  $\Delta G_{\text{rxn}}^{\circ} = 9.4 \text{ kJ}$  at  $25^{\circ}\text{C}$ . Find  $\Delta G_{\text{rxn}}$  when  $P_{\text{NO}_2} = 0.115 \text{ atm}$  and  $P_{\text{NO}} = 9.7 \text{ atm}$  at  $25^{\circ}\text{C}$ .

- a)  $-12.3 \text{ kJ}$
- b)  $21.7 \times 10^3 \text{ kJ}$
- c)  $31.1 \text{ kJ}$
- d)  $18.8 \text{ kJ}$

**Q11.** The reaction  $\text{A}(\text{g}) \rightleftharpoons \text{B}(\text{g})$  has an equilibrium constant of  $K_p = 2.3 \times 10^{-5}$ . What can you conclude about the sign of  $\Delta G_{\text{rxn}}^{\circ}$  for the reaction?

- a)  $\Delta G_{\text{rxn}}^{\circ} = 0$
- b)  $\Delta G_{\text{rxn}}^{\circ}$  is negative
- c)  $\Delta G_{\text{rxn}}^{\circ}$  is positive
- d) Nothing can be concluded about the sign of  $\Delta G_{\text{rxn}}^{\circ}$  for the reaction.

**Q12.** A reaction has an equilibrium constant of  $K_p = 0.018$  at  $25^{\circ}\text{C}$ . Find  $\Delta G_{\text{rxn}}^{\circ}$  for the reaction at this temperature.

- a)  $-835 \text{ J}$
- b)  $-4.32 \text{ kJ}$
- c)  $-9.95 \text{ kJ}$
- d)  $9.95 \text{ kJ}$

**Q13.** Which distribution of six particles into three interconnected boxes has the highest entropy?

- Q14.** Which process results in the increase in entropy of the universe?
- the cooling of a hot cup of coffee in room temperature air
  - the evaporation of water from a desk at room temperature
  - the melting of snow above 0 °C
  - all of the above

- Q15.** Under which set of conditions is  $\Delta G_{\text{rxn}}$  for the reaction  $A(g) \longrightarrow B(g)$  most likely to be negative?

- $P_A = 10.0 \text{ atm}$ ;  $P_B = 10.0 \text{ atm}$
- $P_A = 10.0 \text{ atm}$ ;  $P_B = 0.010 \text{ atm}$
- $P_A = 0.010 \text{ atm}$ ;  $P_B = 10.0 \text{ atm}$
- $P_A = 0.010 \text{ atm}$ ;  $P_B = 0.010 \text{ atm}$

- Q16.** Which statement is true for the freezing of liquid water below 0 °C?

- $\Delta H$  is positive;  $\Delta S$  is negative;  $\Delta G$  is negative
- $\Delta H$  is negative;  $\Delta S$  is negative;  $\Delta G$  is negative
- $\Delta H$  is positive;  $\Delta S$  is positive;  $\Delta G$  is positive
- $\Delta H$  is positive;  $\Delta S$  is negative;  $\Delta G$  is positive

Answers: 1. (a) 2. (c) 3. (d) 4. (a) 5. (c) 6. (d) 7. (a) 8. (b) 9. (d) 10. (c) 11. (c) 12. (d) 13. (b) 14. (d) 15. (b) 16. (b) 17. (a)

## Chapter 18 IN REVIEW

### Key Terms

#### Section 18.2

spontaneous process (841)

#### Section 18.3

entropy ( $S$ ) (844)

second law of thermodynamics (846)

#### Section 18.4

reversible process (851)

#### Section 18.6

Gibbs free energy ( $G$ ) (855)

#### Section 18.7

standard entropy change for a reaction

( $\Delta S_{\text{rxn}}^\circ$ ) (859)

standard molar entropies ( $S^\circ$ ) (859)

third law of thermodynamics (860)

#### Section 18.8

standard free energy change ( $\Delta G_{\text{rxn}}^\circ$ ) (863)

free energy of formation ( $\Delta G_f^\circ$ ) (865)

#### Section 18.9

free energy change of a reaction under

nonstandard conditions ( $\Delta G_{\text{rxn}}$ ) (870)

### Key Concepts

#### Nature's Heat Tax: You Can't Win and You Can't Break Even (18.1)

- The first law of thermodynamics states that energy can be neither created nor destroyed.
- According to the second law of thermodynamics, in every energy transaction, some energy is lost to the surroundings; this lost energy is nature's heat tax.

#### Spontaneous and Nonspontaneous Processes (18.2)

- Both spontaneous and nonspontaneous processes can occur, but only spontaneous processes can take place without outside intervention.
- Thermodynamics is the study of the *spontaneity* of reactions, *not* to be confused with kinetics, the study of the *rate* of reactions.

#### Entropy and the Second Law of Thermodynamics (18.3)

- The second law of thermodynamics states that for *any* spontaneous process, the entropy of the universe increases.
- Entropy ( $S$ ) is proportional to the number of energetically equivalent ways in which the components of a system can be arranged and is a measure of energy dispersal per unit temperature.

#### The Entropy Changes Associated with Changes of State (18.4)

- The entropy of a substance increases as it changes state from a solid to a liquid and when it changes from a liquid to a gas.

- The change in entropy for a system undergoing a reversible change in state is  $\Delta S = q_{\text{rev}}/T$ .

#### Heat Transfer and Changes in the Entropy of the Surroundings (18.5)

- For a process to be spontaneous, the total entropy of the universe (system plus surroundings) must increase.
- The entropy of the surroundings increases when the change in *enthalpy* of the system ( $\Delta H_{\text{sys}}$ ) is negative (i.e., for exothermic reactions).
- The change in entropy of the surroundings for a given  $\Delta H_{\text{sys}}$  depends inversely on temperature—the greater the temperature, the smaller the magnitude of  $\Delta S_{\text{surr}}$ .

#### Gibbs Free Energy (18.6)

- Gibbs free energy,  $G$ , is a thermodynamic function that is proportional to the negative of the change in the entropy of the universe. A negative  $\Delta G$  represents a spontaneous reaction and a positive  $\Delta G$  represents a nonspontaneous reaction.
- We can calculate the value of  $\Delta G$  for a reaction from the values of  $\Delta H$  and  $\Delta S$  for the *system* using the equation  $\Delta G = \Delta H - T\Delta S$ .

#### Entropy Changes in Chemical Reactions: Calculating $\Delta S_{\text{rxn}}^\circ$ (18.7)

- We calculate the standard change in entropy for a reaction similarly to the way we calculate the standard change in enthalpy

for a reaction: by subtracting the sum of the standard entropies of the reactants multiplied by their stoichiometric coefficients from the sum of the standard entropies of the products multiplied by their stoichiometric coefficients.

- ▶ Standard entropies are *absolute*; an entropy of zero is established by the third law of thermodynamics as the entropy of a perfect crystal at absolute zero.
- ▶ The entropy of a substance at a given temperature depends on factors that affect the number of energetically equivalent arrangements of the substance; these include the state, size, and molecular complexity of the substance.

### Free Energy Changes in Chemical Reactions: Calculating $\Delta G^\circ_{\text{rxn}}$ (18.8)

- ▶ There are three ways to calculate  $\Delta G^\circ_{\text{rxn}}$ : (1) from  $\Delta H^\circ$  and  $\Delta S^\circ$ , (2) from free energies of formation (only at 25 °C), and (3) from the  $\Delta G^\circ$ 's of reactions that sum to the reaction of interest.
- ▶ The magnitude of a negative  $\Delta G^\circ_{\text{rxn}}$  represents the theoretical amount of energy available to do work, while a positive  $\Delta G^\circ_{\text{rxn}}$

represents the minimum amount of energy required to make a nonspontaneous process occur.

### Free Energy Changes for Nonstandard States: The Relationship between $\Delta G^\circ_{\text{rxn}}$ and $\Delta G_{\text{rxn}}$ (18.9)

- ▶ The value of  $\Delta G^\circ_{\text{rxn}}$  applies only to standard conditions, and most real conditions are not standard.
- ▶ Under nonstandard conditions, we can calculate  $\Delta G_{\text{rxn}}$  from the equation  $\Delta G_{\text{rxn}} = \Delta G^\circ_{\text{rxn}} + RT \ln Q$ .

### Free Energy and Equilibrium: Relating $\Delta G^\circ_{\text{rxn}}$ to the Equilibrium Constant ( $K$ ) (18.10)

- ▶ Under standard conditions, the free energy change for a reaction is directly proportional to the negative of the natural log of the equilibrium constant,  $K$ ; the more negative the free energy change (*i.e.*, the more spontaneous the reaction), the larger the equilibrium constant.
- ▶ We can use the temperature dependence of  $\Delta G^\circ_{\text{rxn}}$ , as given by  $\Delta G^\circ = \Delta H^\circ - T\Delta S^\circ$ , to derive an expression for the temperature dependence of the equilibrium constant.

## Key Equations and Relationships

The Definition of Entropy (18.3)

$$S = k \ln W \quad k = 1.38 \times 10^{-23} \text{ J/K}$$

Change in Entropy (18.3, 18.4)

$$\Delta S = S_{\text{final}} - S_{\text{initial}}$$

$$\Delta S = q_{\text{rev}}/T \quad (\text{Isothermal, reversible process})$$

Change in the Entropy of the Universe (18.5)

$$\Delta S_{\text{univ}} = \Delta S_{\text{sys}} + \Delta S_{\text{surr}}$$

Change in the Entropy of the Surroundings (18.5)

$$\Delta S_{\text{surr}} = \frac{-\Delta H_{\text{sys}}}{T} \quad (\text{constant } T, P)$$

Change in Gibbs Free Energy (18.6)

$$\Delta G = \Delta H - T\Delta S$$

The Relationship between Spontaneity and  $\Delta H$ ,  $\Delta S$ , and  $T$  (18.6)

$\Delta H$	$\Delta S$	Low Temperature	High Temperature
–	+	Spontaneous	Spontaneous
+	–	Nonspontaneous	Nonspontaneous
–	–	Spontaneous	Nonspontaneous
+	+	Nonspontaneous	Spontaneous

Standard Change in Entropy (18.7)

$$\Delta S^\circ_{\text{rxn}} = \sum n_p S^\circ(\text{products}) - \sum n_r S^\circ(\text{reactants})$$

Methods for Calculating the Free Energy of Formation ( $\Delta G^\circ_{\text{rxn}}$ ) (18.8)

1.  $\Delta G^\circ_{\text{rxn}} = \Delta H^\circ_{\text{rxn}} - T\Delta S^\circ_{\text{rxn}}$
2.  $\Delta G^\circ_{\text{rxn}} = \sum n_p \Delta G^\circ_f(\text{products}) - \sum n_r \Delta G^\circ_f(\text{reactants})$
3.  $\Delta G^\circ_{\text{rxn(overall)}} = \Delta G^\circ_{\text{rxn(step 1)}} + \Delta G^\circ_{\text{rxn(step 2)}} + \Delta G^\circ_{\text{rxn(step 3)}} + \dots$

The Relationship between  $\Delta G^\circ_{\text{rxn}}$  and  $\Delta G_{\text{rxn}}$  (18.9)

$$\Delta G_{\text{rxn}} = \Delta G^\circ_{\text{rxn}} + RT \ln Q \quad R = 8.314 \text{ J/mol} \cdot \text{K}$$

The Relationship between  $\Delta G^\circ_{\text{rxn}}$  and  $K$  (18.10)

$$\Delta G^\circ_{\text{rxn}} = -RT \ln K$$

The Temperature Dependence of the Equilibrium Constant (18.10)

$$\ln K = -\frac{\Delta H^\circ_{\text{rxn}}}{R} \left( \frac{1}{T} \right) + \frac{\Delta S^\circ_{\text{rxn}}}{R}$$

$$\ln \frac{K_2}{K_1} = -\frac{\Delta H^\circ_{\text{rxn}}}{R} \left( \frac{1}{T_2} - \frac{1}{T_1} \right)$$

## Key Learning Outcomes

CHAPTER OBJECTIVES	ASSESSMENT
Predicting the Sign of Entropy Change (18.4)	Example 18.1 For Practice 18.1 Exercises 27–28, 35–38, 41–42
Calculating $\Delta S$ for a Change of State (18.4)	Example 18.2 For Practice 18.2 Exercises 31–34
Calculating Entropy Changes in the Surroundings (18.4)	Example 18.3 For Practice 18.3 For More Practice 18.3 Exercises 39–42

$$\Delta S_{\text{univ}} = \Delta S_{\text{sys}} + \Delta S_{\text{surr}}$$

Positive
Positive

Calculating Gibbs Free Energy Changes and Predicting Spontaneity from $\Delta H$ and $\Delta S$ ( <b>18.6</b> )	Example 18.4 For Practice 18.4 Exercises 43–48
Computing Standard Entropy Changes ( $\Delta S_{\text{rxn}}^\circ$ ) ( <b>18.7</b> )	Example 18.5 For Practice 18.5 Exercises 55–58
<div>Perfect crystal at 0 K <math>W = 1 \quad S = 0</math></div> 	
Calculating the Standard Change in Free Energy for a Reaction using $\Delta G_{\text{rxn}}^\circ = \Delta H_{\text{rxn}}^\circ - T\Delta S_{\text{rxn}}^\circ$ ( <b>18.8</b> )	Examples 18.6, 18.7 For Practice 18.6, 18.7 Exercises 59–62, 65–66
Calculating $\Delta G_{\text{rxn}}^\circ$ from Standard Free Energies of Formation ( <b>18.8</b> )	Example 18.8 For Practice 18.8 For More Practice 18.8 Exercises 63–64
Determining $\Delta G_{\text{rxn}}^\circ$ for a Stepwise Reaction ( <b>18.8</b> )	Example 18.9 For Practice 18.9 Exercises 67–68
Calculating $\Delta G_{\text{rxn}}$ under Nonstandard Conditions ( <b>18.9</b> )	Example 18.10 For Practice 18.10 Exercises 69–72, 75–76
Relating the Equilibrium Constant and $\Delta G_{\text{rxn}}^\circ$ ( <b>18.9</b> )	Example 18.11 For Practice 18.11 Exercises 73–74, 77–78

## EXERCISES

### Review Questions

- What is the first law of thermodynamics, and how does it relate to energy use?
- What is nature's heat tax, and how does it relate to energy use?
- What is a perpetual motion machine? Can such a machine exist given the laws of thermodynamics?
- Is it more efficient to heat your home with a natural gas furnace or an electric furnace? Explain.
- What is a spontaneous process? Provide an example.
- Explain the difference between the spontaneity of a reaction (which depends on thermodynamics) and the speed at which the reaction occurs (which depends on kinetics). Can a catalyst make a nonspontaneous reaction spontaneous?
- What is the precise definition of entropy? What is the significance of entropy being a state function?
- Why does the entropy of a gas increase when it expands into a vacuum?
- Explain the difference between macrostates (external arrangements of particles) and microstates (internal arrangements of particles).
- Based on its fundamental definition, explain why entropy is a measure of energy dispersion.
- State the second law of thermodynamics. How does the second law explain why heat travels from a substance at higher temperature to one at lower temperature?
- What happens to the entropy of a sample of matter when it changes state from a solid to a liquid? From a liquid to a gas?
- Explain why water spontaneously freezes to form ice below  $0^\circ\text{C}$  even though the entropy of the water decreases during the state transition. Why is the freezing of water not spontaneous above  $0^\circ\text{C}$ ?
- Why do exothermic processes tend to be spontaneous at low temperatures? Why does their tendency toward spontaneity decrease with increasing temperature?
- What is the significance of the change in Gibbs free energy ( $\Delta G$ ) for a reaction?
- Predict the spontaneity of a reaction (and the temperature dependence of the spontaneity) for each possible combination of signs for  $\Delta H$  and  $\Delta S$  (for the system).
  - $\Delta H$  negative,  $\Delta S$  positive
  - $\Delta H$  positive,  $\Delta S$  negative
  - $\Delta H$  negative,  $\Delta S$  negative
  - $\Delta H$  positive,  $\Delta S$  positive
- State the third law of thermodynamics and explain its significance.
- Why is the standard entropy of a substance in the gas state greater than its standard entropy in the liquid state?
- How does the standard entropy of a substance depend on its molar mass? On its molecular complexity?
- How can you calculate the standard entropy change for a reaction from tables of standard entropies?
- What are three different methods to calculate  $\Delta G^\circ$  for a reaction? Which method would you choose to calculate  $\Delta G^\circ$  for a reaction at a temperature other than  $25^\circ\text{C}$ ?
- Why is free energy "free"?
- Explain the difference between  $\Delta G^\circ$  and  $\Delta G$ .
- Why does water spilled on the floor evaporate even though  $\Delta G^\circ$  for the evaporation process is positive at room temperature?
- How do you calculate the change in free energy for a reaction under nonstandard conditions?
- How does the value of  $\Delta G^\circ$  for a reaction relate to the equilibrium constant for the reaction? What does a negative  $\Delta G^\circ$  for a reaction imply about  $K$  for the reaction? A positive  $\Delta G^\circ$ ?

## Problems by Topic

### Entropy, the Second Law of Thermodynamics, and the Direction of Spontaneous Change

27. Which of these processes is spontaneous?
- the combustion of natural gas
  - the extraction of iron metal from iron ore
  - a hot drink cooling to room temperature
  - drawing heat energy from the ocean's surface to power a ship
28. Which of these processes are nonspontaneous? Are the nonspontaneous processes impossible?
- a bike going up a hill
  - a meteor falling to Earth
  - obtaining hydrogen gas from liquid water
  - a ball rolling down a hill
29. Two systems, each composed of two particles represented by circles, have 20 J of total energy. Which system, A or B, has the greater entropy? Why?

30. Two systems, each composed of three particles represented by circles, have 30 J of total energy. How many energetically equivalent ways can you distribute the particles in each system? Which system has greater entropy?

31. Calculate the change in entropy that occurs in the system when 1.00 mole of isopropyl alcohol ( $\text{C}_3\text{H}_8\text{O}$ ) melts at its melting point ( $-89.5^\circ\text{C}$ ). See Table 11.9 for heats of fusion.
32. Calculate the change in entropy that occurs in the system when 1.00 mole of diethyl ether ( $\text{C}_4\text{H}_{10}\text{O}$ ) condenses from a gas to a liquid at its normal boiling point ( $34.6^\circ\text{C}$ ). See Table 11.7 for heats of vaporization.
33. Calculate the change in entropy that occurs in the system when 45.0 g of acetone ( $\text{C}_3\text{H}_6\text{O}$ ) freezes at its melting point ( $-94.8^\circ\text{C}$ ). See Table 11.9 for heats of fusion.
34. Calculate the change in entropy that occurs in the system when 55.0 g of water vaporizes from a liquid to a gas at its boiling point ( $100.0^\circ\text{C}$ ). See Table 11.7 for heats of vaporization.
35. Without doing any calculations, determine the sign of  $\Delta S_{\text{sys}}$  for each chemical reaction.
- $2 \text{KClO}_3(\text{s}) \longrightarrow 2 \text{KCl}(\text{s}) + 3 \text{O}_2(\text{g})$
  - $\text{CH}_2=\text{CH}_2(\text{g}) + \text{H}_2(\text{g}) \longrightarrow \text{CH}_3\text{CH}_3(\text{g})$
  - $\text{Na}(\text{s}) + 1/2 \text{Cl}_2(\text{g}) \longrightarrow \text{NaCl}(\text{s})$
  - $\text{N}_2(\text{g}) + 3 \text{H}_2(\text{g}) \longrightarrow 2 \text{NH}_3(\text{g})$

36. Without doing any calculations, determine the sign of  $\Delta S_{\text{sys}}$  for each chemical reaction.

37. Without doing any calculations, determine the signs of  $\Delta S_{\text{sys}}$  and  $\Delta S_{\text{surr}}$  for each chemical reaction. In addition, predict under what temperatures (all temperatures, low temperatures, or high temperatures), if any, the reaction is spontaneous.

38. Without doing any calculations, determine the signs of  $\Delta S_{\text{sys}}$  and  $\Delta S_{\text{surr}}$  for each chemical reaction. In addition, predict under what temperatures (all temperatures, low temperatures, or high temperatures), if any, the reaction is spontaneous.

39. Calculate  $\Delta S_{\text{surr}}$  at the indicated temperature for each reaction.

40. A reaction has  $\Delta H_{\text{rxn}}^\circ = -112 \text{ kJ}$  and  $\Delta S_{\text{rxn}}^\circ = 354 \text{ J/K}$ . At what temperature is the change in entropy for the reaction equal to the change in entropy for the surroundings?

41. Given the values of  $\Delta H_{\text{rxn}}^\circ$ ,  $\Delta S_{\text{rxn}}^\circ$ , and  $T$ , determine  $\Delta S_{\text{univ}}$  and predict whether or not each reaction is spontaneous. (Assume that all reactants and products are in their standard states.)

42. Given the values of  $\Delta H_{\text{rxn}}^\circ$ ,  $\Delta S_{\text{rxn}}^\circ$ , and  $T$ , determine  $\Delta S_{\text{univ}}$  and predict whether or not each reaction is spontaneous. (Assume that all reactants and products are in their standard states.)

### Standard Entropy Changes and Gibbs Free Energy

43. Calculate the change in Gibbs free energy for each of the sets of  $\Delta H_{\text{rxn}}^\circ$ ,  $\Delta S_{\text{rxn}}^\circ$ , and  $T$  given in Problem 41. Predict whether or not each reaction is spontaneous at the temperature indicated. (Assume that all reactants and products are in their standard states.)

44. Calculate the change in Gibbs free energy for each of the sets of  $\Delta H_{\text{rxn}}^\circ$ ,  $\Delta S_{\text{rxn}}^\circ$ , and  $T$  given in Problem 42. Predict whether or not each reaction is spontaneous at the temperature indicated. (Assume that all reactants and products are in their standard states.)

45. Calculate the free energy change for this reaction at 25 °C. Is the reaction spontaneous? (Assume that all reactants and products are in their standard states.)

46. Calculate the free energy change for this reaction at 25 °C. Is the reaction spontaneous? (Assume that all reactants and products are in their standard states.)

47. Fill in the blanks in the table. Both  $\Delta H$  and  $\Delta S$  refer to the system.

$\Delta H$	$\Delta S$	$\Delta G$	Low Temperature	High Temperature
–	+	–	Spontaneous	_____
–	–	Temperature dependent	_____	_____
+	+	_____	_____	Spontaneous
_____	–	_____	Nonspontaneous	Nonspontaneous

48. Predict the conditions (high temperature, low temperature, all temperatures, or no temperatures) under which each reaction is spontaneous.

- $\text{H}_2\text{O}(\text{g}) \longrightarrow \text{H}_2\text{O}(\text{l})$
- $\text{CO}_2(\text{s}) \longrightarrow \text{CO}_2(\text{g})$
- $\text{H}_2(\text{g}) \longrightarrow 2 \text{H}(\text{g})$
- $2 \text{NO}_2(\text{g}) \longrightarrow 2 \text{NO}(\text{g}) + \text{O}_2(\text{g})$  (endothermic)

49. How does the molar entropy of a substance change with increasing temperature?

50. What is the molar entropy of a pure crystal at 0 K? What is the significance of the answer to this question?

51. For each pair of substances, choose the one that you expect to have the higher standard molar entropy ( $S^\circ$ ) at 25 °C. Explain your choices.

- $\text{CO}(\text{g}); \text{CO}_2(\text{g})$
- $\text{CH}_3\text{OH}(\text{l}); \text{CH}_3\text{OH}(\text{g})$
- $\text{Ar}(\text{g}); \text{CO}_2(\text{g})$
- $\text{CH}_4(\text{g}); \text{SiH}_4(\text{g})$
- $\text{NO}_2(\text{g}); \text{CH}_3\text{CH}_2\text{CH}_3(\text{g})$
- $\text{NaBr}(\text{s}); \text{NaBr}(\text{aq})$

52. For each pair of substances, choose the one that you expect to have the higher standard molar entropy ( $S^\circ$ ) at 25 °C. Explain your choices.

- $\text{NaNO}_3(\text{s}); \text{NaNO}_3(\text{aq})$
- $\text{CH}_4(\text{g}); \text{CH}_3\text{CH}_3(\text{g})$
- $\text{Br}_2(\text{l}); \text{Br}_2(\text{g})$
- $\text{Br}_2(\text{g}); \text{F}_2(\text{g})$
- $\text{PCl}_3(\text{g}); \text{PCl}_5(\text{g})$
- $\text{CH}_3\text{CH}_2\text{CH}_2\text{CH}_3(\text{g}); \text{SO}_2(\text{g})$

53. Rank each set of substances in order of increasing standard molar entropy ( $S^\circ$ ). Explain your reasoning.

- $\text{NH}_3(\text{g}); \text{Ne}(\text{g}); \text{SO}_2(\text{g}); \text{CH}_3\text{CH}_2\text{OH}(\text{g}); \text{He}(\text{g})$
- $\text{H}_2\text{O}(\text{s}); \text{H}_2\text{O}(\text{l}); \text{H}_2\text{O}(\text{g})$
- $\text{CH}_4(\text{g}); \text{CF}_4(\text{g}); \text{CCl}_4(\text{g})$

54. Rank each set of substances in order of increasing standard molar entropy ( $S^\circ$ ). Explain your reasoning.

- $\text{I}_2(\text{g}); \text{F}_2(\text{g}); \text{Br}_2(\text{g}); \text{Cl}_2(\text{g})$
- $\text{H}_2\text{O}(\text{g}); \text{H}_2\text{O}_2(\text{g}); \text{H}_2\text{S}(\text{g})$
- $\text{C}(\text{s, graphite}); \text{C}(\text{s, diamond}); \text{C}(\text{s, amorphous})$

55. Use data from Appendix IIB to calculate  $\Delta S_{\text{rxn}}^\circ$  for each of the reactions. In each case, try to rationalize the sign of  $\Delta S_{\text{rxn}}^\circ$ .

- $\text{C}_2\text{H}_4(\text{g}) + \text{H}_2(\text{g}) \longrightarrow \text{C}_2\text{H}_6(\text{g})$
- $\text{C}(\text{s}) + \text{H}_2\text{O}(\text{g}) \longrightarrow \text{CO}(\text{g}) + \text{H}_2(\text{g})$
- $\text{CO}(\text{g}) + \text{H}_2\text{O}(\text{g}) \longrightarrow \text{H}_2(\text{g}) + \text{CO}_2(\text{g})$
- $2 \text{H}_2\text{S}(\text{g}) + 3 \text{O}_2(\text{g}) \longrightarrow 2 \text{H}_2\text{O}(\text{l}) + 2 \text{SO}_2(\text{g})$

56. Use data from Appendix IIB to calculate  $\Delta S_{\text{rxn}}^\circ$  for each of the reactions. In each case, try to rationalize the sign of  $\Delta S_{\text{rxn}}^\circ$ .

- $3 \text{NO}_2(\text{g}) + \text{H}_2\text{O}(\text{l}) \longrightarrow 2 \text{HNO}_3(\text{aq}) + \text{NO}(\text{g})$
- $\text{Cr}_2\text{O}_3(\text{s}) + 3 \text{CO}(\text{g}) \longrightarrow 2 \text{Cr}(\text{s}) + 3 \text{CO}_2(\text{g})$
- $\text{SO}_2(\text{g}) + \frac{1}{2} \text{O}_2(\text{g}) \longrightarrow \text{SO}_3(\text{g})$
- $\text{N}_2\text{O}_4(\text{g}) + 4 \text{H}_2(\text{g}) \longrightarrow \text{N}_2(\text{g}) + 4 \text{H}_2\text{O}(\text{g})$

57. Find  $\Delta S^\circ$  for the formation of  $\text{CH}_2\text{Cl}_2(\text{g})$  from its gaseous elements in their standard states. Rationalize the sign of  $\Delta S^\circ$ .

58. Find  $\Delta S^\circ$  for the reaction between nitrogen gas and fluorine gas to form nitrogen trifluoride gas. Rationalize the sign of  $\Delta S^\circ$ .

59. Methanol ( $\text{CH}_3\text{OH}$ ) burns in oxygen to form carbon dioxide and water. Write a balanced equation for the combustion of liquid methanol and calculate  $\Delta H_{\text{rxn}}^\circ$ ,  $\Delta S_{\text{rxn}}^\circ$ , and  $\Delta G_{\text{rxn}}^\circ$  at 25 °C. Is the combustion of methanol spontaneous?

60. In photosynthesis, plants form glucose ( $\text{C}_6\text{H}_{12}\text{O}_6$ ) and oxygen from carbon dioxide and water. Write a balanced equation for photosynthesis and calculate  $\Delta H_{\text{rxn}}^\circ$ ,  $\Delta S_{\text{rxn}}^\circ$ , and  $\Delta G_{\text{rxn}}^\circ$  at 25 °C. Is photosynthesis spontaneous?

61. For each reaction, calculate  $\Delta H_{\text{rxn}}^\circ$ ,  $\Delta S_{\text{rxn}}^\circ$ , and  $\Delta G_{\text{rxn}}^\circ$  at 25 °C and state whether or not the reaction is spontaneous. If the reaction is not spontaneous, would a change in temperature make it spontaneous? If so, should the temperature be raised or lowered from 25 °C?

- $\text{N}_2\text{O}_4(\text{g}) \longrightarrow 2 \text{NO}_2(\text{g})$
- $\text{NH}_4\text{Cl}(\text{s}) \longrightarrow \text{HCl}(\text{g}) + \text{NH}_3(\text{g})$
- $3 \text{H}_2(\text{g}) + \text{Fe}_2\text{O}_3(\text{s}) \longrightarrow 2 \text{Fe}(\text{s}) + 3 \text{H}_2\text{O}(\text{g})$
- $\text{N}_2(\text{g}) + 3 \text{H}_2(\text{g}) \longrightarrow 2 \text{NH}_3(\text{g})$

62. For each reaction, calculate  $\Delta H_{\text{rxn}}^\circ$ ,  $\Delta S_{\text{rxn}}^\circ$ , and  $\Delta G_{\text{rxn}}^\circ$  at 25 °C and state whether or not the reaction is spontaneous. If the reaction is not spontaneous, would a change in temperature make it spontaneous? If so, should the temperature be raised or lowered from 25 °C?

- $2 \text{CH}_4(\text{g}) \longrightarrow \text{C}_2\text{H}_6(\text{g}) + \text{H}_2(\text{g})$
- $2 \text{NH}_3(\text{g}) \longrightarrow \text{N}_2\text{H}_4(\text{g}) + \text{H}_2(\text{g})$
- $\text{N}_2(\text{g}) + \text{O}_2(\text{g}) \longrightarrow 2 \text{NO}(\text{g})$
- $2 \text{KClO}_3(\text{s}) \longrightarrow 2 \text{KCl}(\text{s}) + 3 \text{O}_2(\text{g})$

63. Use standard free energies of formation to calculate  $\Delta G^\circ$  at 25 °C for each reaction in Problem 61. How do the values of  $\Delta G^\circ$  calculated this way compare to those calculated from  $\Delta H^\circ$  and  $\Delta S^\circ$ ? Which of the two methods could be used to determine how  $\Delta G^\circ$  changes with temperature?

64. Use standard free energies of formation to calculate  $\Delta G^\circ$  at 25 °C for each reaction in Problem 62. How well do the values of  $\Delta G^\circ$  calculated this way compare to those calculated from  $\Delta H^\circ$  and  $\Delta S^\circ$ ? Which of the two methods could be used to determine how  $\Delta G^\circ$  changes with temperature?

65. Consider the reaction:

Estimate  $\Delta G^\circ$  for this reaction at each temperature and predict whether or not the reaction is spontaneous. (Assume that  $\Delta H^\circ$  and  $\Delta S^\circ$  do not change too much within the given temperature range.)

- 298 K
- 715 K
- 855 K

66. Consider the reaction:

Estimate  $\Delta G^\circ$  for this reaction at each temperature and predict whether or not the reaction is spontaneous. (Assume that  $\Delta H^\circ$  and  $\Delta S^\circ$  do not change too much within the given temperature range.)

- 298 K
- 1055 K
- 1455 K

67. Determine
- $\Delta G^\circ$
- for the reaction:

Use the following reactions with known  $\Delta G_{\text{rxn}}^\circ$  values:

68. Calculate
- $\Delta G_{\text{rxn}}^\circ$
- for the reaction:

Use the following reactions and given  $\Delta G_{\text{rxn}}^\circ$  values:

### Free Energy Changes, Nonstandard Conditions, and the Equilibrium Constant

69. Consider the sublimation of iodine at 25.0 °C:

- Find  $\Delta G_{\text{rxn}}^\circ$  at 25.0 °C.
  - Find  $\Delta G_{\text{rxn}}$  at 25.0 °C under the following nonstandard conditions:
    - $P_{\text{I}_2} = 1.00 \text{ mmHg}$
    - $P_{\text{I}_2} = 0.100 \text{ mmHg}$
  - Explain why iodine spontaneously sublimates in open air at 25.0 °C.
70. Consider the evaporation of methanol at 25.0 °C:
- $$\text{CH}_3\text{OH}(\text{l}) \longrightarrow \text{CH}_3\text{OH}(\text{g})$$
- Find  $\Delta G_{\text{r}}^\circ$  at 25.0 °C.
  - Find  $\Delta G_{\text{r}}$  at 25.0 °C under the following nonstandard conditions:
    - $P_{\text{CH}_3\text{OH}} = 150.0 \text{ mmHg}$
    - $P_{\text{CH}_3\text{OH}} = 100.0 \text{ mmHg}$
    - $P_{\text{CH}_3\text{OH}} = 10.0 \text{ mmHg}$
  - Explain why methanol spontaneously evaporates in open air at 25.0 °C.

71. Consider the reaction:

Calculate  $\Delta G$  for this reaction at 25 °C under the following conditions:

- $P_{\text{CH}_3\text{OH}} = 0.855 \text{ atm}$
- $P_{\text{CO}} = 0.125 \text{ atm}$
- $P_{\text{H}_2} = 0.183 \text{ atm}$

72. Consider the reaction:

Calculate  $\Delta G$  for this reaction at 25 °C under the following conditions:

- $P_{\text{CO}_2} = 0.112 \text{ atm}$
- $P_{\text{CCl}_4} = 0.174 \text{ atm}$
- $P_{\text{COCl}_2} = 0.744 \text{ atm}$

73. Use data from Appendix IIB to calculate the equilibrium constants at 25 °C for each reaction.

- $2 \text{CO}(\text{g}) + \text{O}_2(\text{g}) \rightleftharpoons 2 \text{CO}_2(\text{g})$
- $2 \text{H}_2\text{S}(\text{g}) \rightleftharpoons 2 \text{H}_2(\text{g}) + \text{S}_2(\text{g})$

74. Use data from Appendix IIB to calculate the equilibrium constants at 25 °C for each reaction.
- $\Delta G_{\text{f}}^\circ$
- for
- $\text{BrCl}(\text{g})$
- is
- $-1.0 \text{ kJ/mol}$
- .

- $2 \text{NO}_2(\text{g}) \rightleftharpoons \text{N}_2\text{O}_4(\text{g})$
- $\text{Br}_2(\text{g}) + \text{Cl}_2(\text{g}) \rightleftharpoons 2 \text{BrCl}(\text{g})$

75. Consider the reaction:

$$K_{\text{p}} = 2.26 \times 10^4 \text{ at } 25^\circ\text{C}$$

Calculate  $\Delta G_{\text{rxn}}$  for the reaction at 25 °C under each of the following conditions:

- standard conditions
- at equilibrium
- $P_{\text{CH}_3\text{OH}} = 1.0 \text{ atm}$ ;  $P_{\text{CO}} = P_{\text{H}_2} = 0.010 \text{ atm}$

76. Consider the reaction:

$$K_{\text{p}} = 81.9 \text{ at } 25^\circ\text{C}$$

Calculate  $\Delta G_{\text{rxn}}$  for the reaction at 25 °C under each of the following conditions:

- standard conditions
- at equilibrium
- $P_{\text{ICl}} = 2.55 \text{ atm}$ ;  $P_{\text{I}_2} = 0.325 \text{ atm}$ ;  $P_{\text{Cl}_2} = 0.221 \text{ atm}$

77. Estimate the value of the equilibrium constant at 525 K for each reaction in Problem 73.

78. Estimate the value of the equilibrium constant at 655 K for each reaction in Problem 74. (
- $\Delta H_{\text{f}}^\circ$
- for
- $\text{BrCl}$
- is
- $14.6 \text{ kJ/mol}$
- .)

79. Consider the reaction:

The following data show the equilibrium constant for this reaction measured at several different temperatures. Use the data to find  $\Delta H_{\text{rxn}}^\circ$  and  $\Delta S_{\text{rxn}}^\circ$  for the reaction.

Temperature	$K_{\text{p}}$
150 K	$1.4 \times 10^{-6}$
175 K	$4.6 \times 10^{-4}$
200 K	$3.6 \times 10^{-2}$
225 K	1.1
250 K	15.5

80. Consider the reaction:

The following data show the equilibrium constant for this reaction measured at several different temperatures. Use the data to find  $\Delta H_{\text{rxn}}^\circ$  and  $\Delta S_{\text{rxn}}^\circ$  for the reaction.

Temperature	$K_{\text{p}}$
170 K	$3.8 \times 10^{-3}$
180 K	0.34
190 K	18.4
200 K	681

81. The change in enthalpy (
- $\Delta H_{\text{rxn}}^\circ$
- ) for a reaction is
- $-25.8 \text{ kJ/mol}$
- . The equilibrium constant for the reaction is
- $1.4 \times 10^3$
- at 298 K. What is the equilibrium constant for the reaction at 655 K?

82. A reaction has an equilibrium constant of
- $8.5 \times 10^3$
- at 298 K. At 755 K, the equilibrium constant is 0.65. Find
- $\Delta H_{\text{rxn}}^\circ$
- for the reaction.

## Cumulative Problems

83. Determine the sign of  $\Delta S_{\text{sys}}$  for each process.

- water boiling
- water freezing
- 

84. Determine the sign of  $\Delta S_{\text{sys}}$  for each process.

- dry ice subliming
- dew forming
- 

85. Our atmosphere is composed primarily of nitrogen and oxygen, which coexist at 25 °C without reacting to any significant extent. However, the two gases can react to form nitrogen monoxide according to the reaction:

- Calculate  $\Delta G^\circ$  and  $K_p$  for this reaction at 298 K. Is the reaction spontaneous?
  - Estimate  $\Delta G^\circ$  at 2000 K. Does the reaction become more spontaneous as temperature increases?
86. Nitrogen dioxide, a pollutant in the atmosphere, can combine with water to form nitric acid. One of the possible reactions is shown here. Calculate  $\Delta G^\circ$  and  $K_p$  for this reaction at 25 °C and comment on the spontaneity of the reaction.

87. Ethene ( $\text{C}_2\text{H}_4$ ) can be halogenated by the reaction:

where  $\text{X}_2$  can be  $\text{Cl}_2$ ,  $\text{Br}_2$ , or  $\text{I}_2$ . Use the thermodynamic data given to calculate  $\Delta H^\circ$ ,  $\Delta S^\circ$ ,  $\Delta G^\circ$ , and  $K_p$  for the halogenation reaction by each of the three halogens at 25 °C. Which reaction is most spontaneous? Least spontaneous? What is the main factor responsible for the difference in the spontaneity of the three reactions? Does higher temperature make the reactions more spontaneous or less spontaneous?

Compound	$\Delta H_f^\circ$ (kJ/mol)	$S^\circ$ (J/mol · K)
$\text{C}_2\text{H}_4\text{Cl}_2(\text{g})$	-129.7	308.0
$\text{C}_2\text{H}_4\text{Br}_2(\text{g})$	+38.3	330.6
$\text{C}_2\text{H}_4\text{I}_2(\text{g})$	+66.5	347.8

88.  $\text{H}_2$  reacts with the halogens ( $\text{X}_2$ ) according to the reaction:

where  $\text{X}_2$  can be  $\text{Cl}_2$ ,  $\text{Br}_2$ , or  $\text{I}_2$ . Use the thermodynamic data in Appendix IIB to calculate  $\Delta H^\circ$ ,  $\Delta S^\circ$ ,  $\Delta G^\circ$ , and  $K_p$  for the reaction between hydrogen and each of the three halogens. Which reaction is most spontaneous? Least spontaneous? What is the main factor responsible for the difference in the spontaneity of the three reactions? Does higher temperature make the reactions more spontaneous or less spontaneous?

89. Consider this reaction occurring at 298 K:

- Show that the reaction is not spontaneous under standard conditions by calculating  $\Delta G_{\text{rxn}}^\circ$ .
- If a reaction mixture contains only  $\text{N}_2\text{O}$  and  $\text{NO}_2$  at partial pressures of 1.0 atm each, the reaction will be spontaneous until some NO forms in the mixture. What maximum partial pressure of NO builds up before the reaction ceases to be spontaneous?
- Can the reaction be made more spontaneous by an increase or decrease in temperature? If so, what temperature is required to make the reaction spontaneous under standard conditions?

90. Consider this reaction occurring at 298 K:

- Show that the reaction is not spontaneous under standard conditions by calculating  $\Delta G_{\text{rxn}}^\circ$ .
- If  $\text{BaCO}_3$  is placed in an evacuated flask, what is the partial pressure of  $\text{CO}_2$  when the reaction reaches equilibrium?
- Can the reaction be made more spontaneous by an increase or decrease in temperature? If so, at what temperature is the partial pressure of carbon dioxide 1.0 atm?

91. Living organisms use energy from the metabolism of food to create an energy-rich molecule called adenosine triphosphate (ATP). The ATP acts as an energy source for a variety of reactions that the living organism must carry out to survive. ATP provides energy through its hydrolysis, which can be symbolized as follows:

where ADP represents adenosine diphosphate and  $\text{P}_i$  represents an inorganic phosphate group (such as  $\text{HPO}_4^{2-}$ ).

- Calculate the equilibrium constant,  $K$ , for the given reaction at 298 K.
  - The free energy obtained from the oxidation (reaction with oxygen) of glucose ( $\text{C}_6\text{H}_{12}\text{O}_6$ ) to form carbon dioxide and water can be used to re-form ATP by driving the given reaction in reverse. Calculate the standard free energy change for the oxidation of glucose and estimate the maximum number of moles of ATP that can be formed by the oxidation of one mole of glucose.
92. The standard free energy change for the hydrolysis of ATP was given in Problem 91. In a particular cell, the concentrations of ATP, ADP, and  $\text{P}_i$  are 0.0031 M, 0.0014 M, and 0.0048 M, respectively. Calculate the free energy change for the hydrolysis of ATP under these conditions. (Assume a temperature of 298 K.)

93. These reactions are important in catalytic converters in automobiles. Calculate  $\Delta G^\circ$  for each at 298 K. Predict the effect of increasing temperature on the magnitude of  $\Delta G^\circ$ .

- $2 \text{CO}(\text{g}) + 2 \text{NO}(\text{g}) \longrightarrow \text{N}_2(\text{g}) + 2 \text{CO}_2(\text{g})$
- $5 \text{H}_2(\text{g}) + 2 \text{NO}(\text{g}) \longrightarrow 2 \text{NH}_3(\text{g}) + 2 \text{H}_2\text{O}(\text{g})$
- $2 \text{H}_2(\text{g}) + 2 \text{NO}(\text{g}) \longrightarrow \text{N}_2(\text{g}) + 2 \text{H}_2\text{O}(\text{g})$
- $2 \text{NH}_3(\text{g}) + 2 \text{O}_2(\text{g}) \longrightarrow \text{N}_2\text{O}(\text{g}) + 3 \text{H}_2\text{O}(\text{g})$

94. Calculate  $\Delta G^\circ$  at 298 K for these reactions and predict the effect on  $\Delta G^\circ$  of lowering the temperature.

- $\text{NH}_3(\text{g}) + \text{HBr}(\text{g}) \longrightarrow \text{NH}_4\text{Br}(\text{s})$
- $\text{CaCO}_3(\text{s}) \longrightarrow \text{CaO}(\text{s}) + \text{CO}_2(\text{g})$
- $\text{CH}_4(\text{g}) + 3 \text{Cl}_2(\text{g}) \longrightarrow \text{CHCl}_3(\text{g}) + 3 \text{HCl}(\text{g})$   
( $\Delta G_f^\circ$  for  $\text{CHCl}_3(\text{g})$  is -70.4 kJ/mol.)

95. All the oxides of nitrogen have positive values of  $\Delta G_f^\circ$  at 298 K, but only one common oxide of nitrogen has a positive  $\Delta S_f^\circ$ . Identify that oxide of nitrogen without reference to thermodynamic data and explain.
96. The values of  $\Delta G_f^\circ$  for the hydrogen halides become less negative with increasing atomic number. The  $\Delta G_f^\circ$  of HI is slightly positive. However, the trend in  $\Delta S_f^\circ$  is to become more positive with increasing atomic number. Explain.
97. Consider the reaction  $X_2(g) \longrightarrow 2 X(g)$ . When a vessel initially containing 755 torr of  $X_2$  comes to equilibrium at 298 K, the equilibrium partial pressure of X is 103 torr. The same reaction is repeated with an initial partial pressure of  $X_2$  at 755 K; the equilibrium partial pressure of X is 532 torr. Find  $\Delta H^\circ$  for the reaction.
98. Dinitrogen tetroxide decomposes to nitrogen dioxide:

At 298 K, a reaction vessel initially contains 0.100 atm of  $N_2O_4$ . When equilibrium is reached, 58% of the  $N_2O_4$  has decomposed to  $NO_2$ . What percentage of  $N_2O_4$  decomposes at 388 K? Assume that the initial pressure of  $N_2O_4$  is the same (0.100 atm).

99. Indicate and explain the sign of  $\Delta S_{univ}$  for each process.
- $2 H_2(g) + O_2(g) \longrightarrow 2 H_2O(l)$  at 298 K
  - the electrolysis of  $H_2O(l)$  to  $H_2(g)$  and  $O_2(g)$  at 298 K
  - the growth of an oak tree from a little acorn
100. The Haber process is very important for agriculture because it converts  $N_2(g)$  from the atmosphere into bound nitrogen, which can be taken up and used by plants. The Haber process reaction is  $N_2(g) + 3 H_2(g) \rightleftharpoons 2 NH_3(g)$ . The reaction is exothermic but is carried out at relatively high temperatures. Why?
101. A metal salt with the formula  $MCl_2$  crystallizes from water to form a solid with the composition  $MCl_2 \cdot 6 H_2O$ . The equilibrium vapor pressure of water above this solid at 298 K is 18.3 mmHg. What is the value of  $\Delta G$  for the reaction  $MCl_2 \cdot 6 H_2O(s) \rightleftharpoons MCl_2(s) + 6 H_2O(g)$  when the pressure of water vapor is 18.3 mmHg? When the pressure of water vapor is 760 mmHg?
102. The solubility of  $AgCl(s)$  in water at 25 °C is  $1.33 \times 10^{-5} \text{ mol/L}$  and its  $\Delta H^\circ$  of solution is 65.7 kJ/mol. What is its solubility at 50.0 °C?

## Challenge Problems

103. Review the box in this chapter entitled Chemistry in Your Day: Making a Nonspontaneous Process Spontaneous. The hydrolysis of ATP, shown in Problem 91, is often used to drive nonspontaneous processes—such as muscle contraction and protein synthesis—in living organisms. The nonspontaneous process to be driven must be coupled to the ATP hydrolysis reaction. For example, suppose the nonspontaneous process is  $A + B \longrightarrow AB$  ( $\Delta G^\circ$  positive). The coupling of a nonspontaneous reaction such as this one to the hydrolysis of ATP is often accomplished by the mechanism:

As long as  $\Delta G_{rxn}$  for the nonspontaneous reaction is less than 30.5 kJ, the reaction can be made spontaneous by coupling in this way to the hydrolysis of ATP. Suppose that ATP is to drive the reaction between glutamate and ammonia to form glutamine:

- a. Calculate  $K$  for the reaction between glutamate and ammonia. (The standard free energy change for the reaction is +14.2 kJ/mol. Assume a temperature of 298 K.)

- b. Write a set of reactions such as those given showing how the glutamate and ammonia reaction can couple with the hydrolysis of ATP. What is  $\Delta G_{rxn}^\circ$  and  $K$  for the coupled reaction?
104. Calculate the entropy of each state and rank the states in order of increasing entropy.

105. Suppose we redefine the standard state as  $P = 2 \text{ atm}$ . Find the new standard  $\Delta G_f^\circ$  values of each substance.
- $HCl(g)$
  - $N_2O(g)$
  - $H(g)$
- Explain the results in terms of the relative entropies of reactants and products of each reaction.

**106.** The  $\Delta G$  for the freezing of  $\text{H}_2\text{O}(l)$  at  $-10^\circ\text{C}$  is  $-210\text{ J/mol}$ , and the heat of fusion of ice at this temperature is  $5610\text{ J/mol}$ . Find the entropy change of the universe when 1 mol of water freezes at  $-10^\circ\text{C}$ .

**107.** Consider the reaction that occurs during the Haber process:

The equilibrium constant is  $3.9 \times 10^5$  at 300 K and  $1.2 \times 10^{-1}$  at 500 K. Calculate  $\Delta H_{\text{rxn}}^\circ$  and  $\Delta S_{\text{rxn}}^\circ$  for this reaction.

**108.** The salt ammonium nitrate can follow three modes of decomposition: (a) to  $\text{HNO}_3(g)$  and  $\text{NH}_3(g)$ , (b) to  $\text{N}_2\text{O}(g)$  and  $\text{H}_2\text{O}(g)$ , and (c) to  $\text{N}_2(g)$ ,  $\text{O}_2(g)$ , and  $\text{H}_2\text{O}(g)$ . Calculate  $\Delta G_{\text{rxn}}^\circ$  for each mode of decomposition at 298 K. Explain in light of these results how it is still possible to use ammonium nitrate as a fertilizer and the precautions that should be taken when it is used.

**109.** Given the data, calculate  $\Delta S_{\text{vap}}$  for each of the first four liquids. ( $\Delta S_{\text{vap}} = \Delta H_{\text{vap}}/T$ , where  $T$  is in K)

Compound	Name	BP ( $^\circ\text{C}$ )	$\Delta H_{\text{vap}}$ (kJ/mol) at BP
$\text{C}_4\text{H}_{10}\text{O}$	Diethyl ether	34.6	26.5
$\text{C}_3\text{H}_6\text{O}$	Acetone	56.1	29.1
$\text{C}_6\text{H}_6\text{O}$	Benzene	79.8	30.8
$\text{CHCl}_3$	Chloroform	60.8	29.4
$\text{C}_2\text{H}_5\text{OH}$	Ethanol	77.8	38.6
$\text{H}_2\text{O}$	Water	100	40.7

All four values should be close to each other. Predict whether the last two liquids in the table have  $\Delta S_{\text{vap}}$  in this same range. If not, predict whether it is larger or smaller and explain. Verify your prediction.

## Conceptual Problems

**110.** Which is more efficient, a butane lighter or an electric lighter (such as the ones traditionally found on the dashboard of automobiles)? Explain.

**111.** Which statement is true?

- A spontaneous reaction is always a fast reaction.
- A spontaneous reaction is always a slow reaction.
- The spontaneity of a reaction is not necessarily related to the speed of a reaction.

**112.** Which process is necessarily driven by an increase in the entropy of the surroundings?

- the condensation of water
- the sublimation of dry ice
- the freezing of water

**113.** Consider the changes in the distribution of nine particles into three interconnected boxes shown here. Which has the most negative  $\Delta S$ ?

**114.** Which statement is true?

- A reaction in which the entropy of the system increases can be spontaneous only if it is exothermic.
- A reaction in which the entropy of the system increases can be spontaneous only if it is endothermic.
- A reaction in which the entropy of the system decreases can be spontaneous only if it is exothermic.

**115.** Which process is spontaneous at 298 K?

- $\text{H}_2\text{O}(l) \longrightarrow \text{H}_2\text{O}(g, 1\text{ atm})$
- $\text{H}_2\text{O}(l) \longrightarrow \text{H}_2\text{O}(g, 0.10\text{ atm})$
- $\text{H}_2\text{O}(l) \longrightarrow \text{H}_2\text{O}(g, 0.010\text{ atm})$

**116.** The free energy change of the reaction  $\text{A}(g) \longrightarrow \text{B}(g)$  is zero under certain conditions. The *standard* free energy change of the reaction is  $-42.5\text{ kJ}$ . Which statement must be true about the reaction?

- The concentration of the product is greater than the concentration of the reactant.
- The reaction is at equilibrium.
- The concentration of the reactant is greater than the concentration of the product.

**117.** The reaction  $\text{A}(g) \rightleftharpoons \text{B}(g)$  has an equilibrium constant of 5.8 and under certain conditions has  $Q = 336$ . What can you conclude about the sign of  $\Delta G_{\text{rxn}}^\circ$  and  $\Delta G_{\text{rxn}}$  for this reaction under these conditions?

## Active Classroom Learning

### Questions for Group Work

Discuss these questions with the group and record your consensus answer.

**118.** Imagine that you roll two dice. Write down all the possible rolls that sum to 2. Write all the possible rolls that sum to 12. Write all the possible rolls that sum to 7. Which configuration has the greatest entropy: 2, 12, or 7?

**119.** If you roll 1 million dice, what will be the average of all the dice? If there is a room with 1 million dice and they all have a 1 on the top face, and there is an earthquake strong enough to roll dice around, what is the likelihood that after the earthquake all the top faces will sum to 1 million? To 6 million? How does this thought experiment illustrate the second law of thermodynamics?

- 120.** Not all processes in which the system increases in entropy are spontaneous. How can this observation be consistent with the second law? Provide an example and explain your answer in complete sentences.
- 121.** Have each group member look up  $\Delta H_f^\circ$  and  $S^\circ$  for one substance in the reaction:  $3 \text{O}_2(\text{g}) + 6 \text{H}_2(\text{g}) + 6 \text{C}(\text{s, graphite}) \longrightarrow \text{C}_6\text{H}_{12}\text{O}_6(\text{s, glucose})$ . What is  $\Delta H^\circ$  for this reaction? What is  $\Delta S^\circ$ ?

When is  $\Delta H_f^\circ$  for a substance equal to zero? When is  $S^\circ$  for a substance equal to zero?

- 122.** Calculate  $\Delta G^\circ$  at 25 °C for the reaction in the previous question. Is this reaction spontaneous under standard conditions? How do you know? What is the determining factor: the change in energy or the change in entropy or both? Explain.

## Data Interpretation and Analysis

### Thermodynamic Functions for Borax

- 123.** Borax (sodium tetraboratedecahydrate), a mineral found in dry lakebeds in California, is used as a preservative and in the manufacturing of soap and glass. By determining the  $K_{\text{sp}}$  of borax at different temperatures, we can determine  $\Delta H^\circ$ ,  $\Delta S^\circ$ , and  $\Delta G^\circ$  for the dissolution of borax:

The relationship:

$$\ln(K_{\text{sp}}) = \frac{-\Delta H^\circ}{RT} + \frac{\Delta S^\circ}{R}$$

has the form of a linear equation  $y = mx + b$ , where  $y$  is the  $\ln K_{\text{sp}}$  and  $x$  is  $1/T$  ( $T$  in Kelvin). The slope is equal to  $-\Delta H^\circ/R$ , and the  $y$  intercept is  $\Delta S^\circ/R$ , where  $R$  is the gas constant, 8.314 J/K mol. Determining  $K_{\text{sp}}$  at several different temperatures allows us to plot a graph of  $\ln K$  versus  $1/T$  as shown in Figure a.

**▲ FIGURE a** Plot of  $\ln K_{\text{sp}}$  versus  $1/T$  (Units of Temperature in Kelvin).

Knowing the values of  $\Delta H^\circ$  and  $\Delta S^\circ$  at a specific temperature allows the calculation of the change in Gibbs free energy for the reaction  $\Delta G^\circ = \Delta H^\circ - T \Delta S^\circ$ .

Table a lists  $K_{\text{sp}}$  values for the dissolution of borax at several different temperatures (°C).

Temperature (°C)	$K_{\text{sp}}$
40.0	0.041
45.0	0.083
50.0	0.264
55.0	0.486
60.0	0.552

**TABLE a**  $K_{\text{sp}}$  Values for Dissolution of Borax

Use the information provided in the figure and table to do the following:

- Plot a graph of  $\ln K_{\text{sp}}$  versus  $1/T$  ( $T$  in Kelvin).
- Determine  $\Delta H^\circ$ . Is this process endothermic or exothermic?
- Determine  $\Delta S^\circ$ .
- Determine  $\Delta G^\circ$  at 298 K.
- Sketch a graph of  $\ln K$  versus  $1/T$  for an exothermic process.

## Answers to Conceptual Connections

### Nature's Heat Tax and Diet

**18.1** A person subsisting on a vegetarian diet eats fruits and vegetables, metabolizing the energy-containing molecules of these foods directly. A person subsisting on a meat-based diet eats the meat of animals such as cows and metabolizes energy-containing molecules that were part of the animals. Beef cattle synthesize their energy-containing molecules from compounds that they obtain by eating and digesting plants. Since breaking down and resynthesizing biological molecules requires energy—and since the cattle also need to extract some of the energy from their food to live—a meat-based diet necessitates additional energy transactions in the overall process of obtaining energy for life. Due to nature's heat tax, the meat-based diet is less efficient than the vegetarian diet.

### Entropy

**18.2 (a)** The more spread out the particles are between the three boxes, the greater the entropy. Therefore, the entropy change is positive only in scheme (a).

### Entropy and Biological Systems

**18.3** Biological systems do not violate the second law of thermodynamics. The key to understanding this concept is realizing that entropy changes in the system can be negative as long as the entropy change of the universe is positive. Biological systems can decrease their own entropy, but only at the expense of creating more entropy in the surroundings (which they do primarily by emitting the heat they generate by their metabolic processes). Thus, for any biological process,  $\Delta S_{\text{univ}}$  is positive.

### $\Delta H$ , $\Delta S$ , and $\Delta G$

**18.4 (a)** Sublimation is endothermic (it requires energy to overcome the intermolecular forces that hold solid carbon dioxide together), so  $\Delta H$  is positive. The number of moles of gas increases when the solid turns into a gas, so the entropy of the carbon dioxide increases and  $\Delta S$  is positive. Since  $\Delta G = \Delta H - T\Delta S$ ,  $\Delta G$  is positive at low temperature and negative at high temperature.

### Standard Entropies

**18.5**  $\text{Kr} < \text{Cl}_2 < \text{SO}_3$ . Because krypton is a monoatomic gas, it has the least entropy. Because  $\text{SO}_3$  is the most complex molecule, it has the most entropy. The molar masses of the three gases vary slightly, but not enough to overcome the differences in molecular complexity.

### Free Energy Changes and Le Châtelier's Principle

**18.6 (a)** A high concentration of reactants relative to products will lead to  $Q < 1$ , making the term  $RT \ln Q$  in Equation 18.14 negative.  $\Delta G_{\text{rxn}}$  is more negative than  $\Delta G_{\text{rxn}}^\circ$  and the reaction is more spontaneous.

### $K$ and $\Delta G_{\text{rxn}}^\circ$

**18.7 (c)** Since the equilibrium constant is less than 1, the reaction proceeds toward reactants under standard conditions (when  $Q = 1$ ). Therefore,  $\Delta G_{\text{rxn}}^\circ$  is positive.

### The Conditions of Spontaneity

**18.8**  $\Delta G_{\text{rxn}} < 0$ ,  $Q < K$

# Electrochemistry

**One day sir, you may tax it.**

—MICHAEL FARADAY (1791–1867)

[In response to Mr. Gladstone, the British Chancellor of the Exchequer, when asked about the practical worth of electricity.]

**KEY LEARNING OUTCOMES 930**

This chapter's opening quote from Michael Faraday illustrates an important aspect of basic research (research for the sake of understanding how nature works). The Chancellor of the Exchequer (the British cabinet minister responsible for all financial matters) wanted to know how Michael Faraday's apparently esoteric investigations of electricity would ever be useful to the empire. Faraday responded in a way that the chancellor would understand—he pointed out the eventual financial payoff. Today electricity is a fundamental form of energy, powering our entire economy. Although basic research does not always lead to useful applications, much of the technology our society relies on has grown out of basic research. The history of modern science shows that we must first understand nature (the goal of basic research) before we can harness its power. In this chapter, we discuss oxidation–reduction reactions (first introduced in Chapter 4) and how we can exploit them to generate electricity. The applications range from the batteries that power flashlights to the fuel cells that may one day power our homes and automobiles.

▲ The smartphone shown here is powered by a hydrogen–oxygen fuel cell, a device that generates electricity from the reaction between hydrogen and oxygen to form water.

## 19.1 Pulling the Plug on the Power Grid

The power grid distributes centrally generated electricity throughout the country to homes and businesses. When you turn on a light or electrical appliance, electricity flows from the grid through the wires in your home to the light or appliance. The electrical energy is converted into light within the lightbulb or into work within the appliance. The average U.S. household consumes about 1000 kilowatt-hours (kWh) of electricity per month. The local electrical utility monitors your electricity use and bills you for it.

The kilowatt-hour is a unit of energy first introduced in Section 6.2.

▲ The energy produced by this fuel cell can power an entire house.

▲ The Toyota Mirai is the first mass-produced fuel-cell vehicle that runs on hydrogen gas and produces only water as exhaust.

In the future, you may have the option of disconnecting from the power grid. Several innovative companies are developing small, fuel-cell power plants—each no bigger than a refrigerator—to sit next to homes and quietly generate enough electricity to meet each household's power needs. The heat produced by a fuel cell's operation can be recaptured and used to heat water or the space within the home, eliminating the need for a hot-water heater or a furnace. Similar fuel cells can also power cars. Fuel cells are highly efficient and, although obstacles to their development and use must yet be overcome, one day they may supply a majority of our power while producing less pollution than fossil fuel combustion.

Fuel cells are based on oxidation–reduction reactions (see Section 4.9). The most common type of fuel cell—the hydrogen–oxygen fuel cell—is based on the reaction between hydrogen and oxygen:

In this reaction, hydrogen and oxygen form covalent bonds with one another. Recall that, according to the Lewis theory, a single covalent bond is a shared electron pair. However, since oxygen is more electronegative than hydrogen, the electron pair in a hydrogen–oxygen bond is not *equally* shared: oxygen gets the larger portion (see Section 9.6). In effect, oxygen has more electrons in  $\text{H}_2\text{O}$  than it does in elemental  $\text{O}_2$ —oxygen has gained electrons in the reaction and has therefore been reduced.

In a reaction between hydrogen and oxygen, oxygen atoms gain electrons directly from hydrogen atoms. In a hydrogen–oxygen fuel cell, this same redox reaction occurs, but the hydrogen and oxygen are separated, forcing electrons to travel through an external wire to get from hydrogen to oxygen. The moving electrons constitute an electrical current. In this way, a fuel cell employs the electron-gaining tendency of oxygen and the electron-losing tendency of hydrogen to force electrons to move through a wire to create the electricity that can provide power for a home or an electric automobile. Smaller fuel cells can also replace batteries and be used to power consumer electronics such as laptop computers, smartphones, and MP3 players. The generation of electricity from spontaneous redox reactions (such as those that occur in a fuel cell) and the use of electricity to drive nonspontaneous redox reactions (such as those that occur in gold or silver plating) are examples of electrochemistry, the subject of this chapter.

## 19.2 Balancing Oxidation–Reduction Equations

Recall from Section 4.9 that *oxidation* is the loss of electrons, and *reduction* is the gain of electrons. Recall also that we can identify oxidation–reduction reactions through changes in oxidation states: *oxidation corresponds to an increase in oxidation state, and reduction corresponds to a decrease in oxidation state*. For example, consider the following reaction between calcium and water:

Because calcium increases in oxidation state from 0 to +2, it is oxidized. Because hydrogen decreases in oxidation state from +1 to 0, it is reduced.

Balancing redox reactions can be more complicated than balancing other types of reactions because both the mass (or number of each type of atom) and the *charge* must be balanced. We can balance redox reactions occurring in aqueous solutions with a special procedure called the *half-reaction method of balancing*. In this procedure, we break down the overall equation into two half-reactions: one for oxidation and one for reduction. We then balance the half-reactions individually and add them together. The steps differ slightly for reactions occurring in acidic and in basic solution. Examples 19.1 and 19.2 demonstrate the method for an acidic solution, and Example 19.3 demonstrates the method for a basic solution.

Review Section 4.9 on assigning oxidation states.

## Procedure for...

## Half-Reaction Method of Balancing Aqueous Redox Equations in Acidic Solution

## GENERAL PROCEDURE

**Step 1** Assign oxidation states to all atoms and identify the substances being oxidized and reduced.

**Step 2** Separate the overall reaction into two half-reactions: one for oxidation and one for reduction.

**Step 3** Balance each half-reaction with respect to mass in the following order:

- Balance all elements other than H and O.
- Balance O by adding  $\text{H}_2\text{O}$ .
- Balance H by adding  $\text{H}^+$ .

**Step 4** Balance each half-reaction with respect to charge by adding electrons. (Make the sum of the charges on both sides of the equation equal by adding as many electrons as necessary.)

**Step 5** Make the number of electrons in both half-reactions equal by multiplying one or both half-reactions by a small whole number.

**Step 6** Add the two half-reactions together, canceling electrons and other species as necessary.

## Example 19.1

## Half-Reaction Method of Balancing Aqueous Redox Equations in Acidic Solution

Balance the redox equation:

All elements are balanced, so proceed to the next step.

## Example 19.2

## Half-Reaction Method of Balancing Aqueous Redox Equations in Acidic Solution

Balance the redox equation:

All elements other than H and O are balanced, so proceed to balance H and O.

—Continued on the next page

—Continued

<b>Step 7</b> Verify that the reaction is balanced with respect to both mass and charge.	<table><tr><th>Reactants</th><th>Products</th></tr><tr><td>2 Al</td><td>2 Al</td></tr><tr><td>3 Cu</td><td>3 Cu</td></tr><tr><td>+6 charge</td><td>+6 charge</td></tr></table>	Reactants	Products	2 Al	2 Al	3 Cu	3 Cu	+6 charge	+6 charge	<table><tr><th>Reactants</th><th>Products</th></tr><tr><td>5 Fe</td><td>5 Fe</td></tr><tr><td>8 H</td><td>8 H</td></tr><tr><td>1 Mn</td><td>1 Mn</td></tr><tr><td>4 O</td><td>4 O</td></tr><tr><td>+17 charge</td><td>+17 charge</td></tr></table>	Reactants	Products	5 Fe	5 Fe	8 H	8 H	1 Mn	1 Mn	4 O	4 O	+17 charge	+17 charge

<b>FOR PRACTICE 19.1</b> Balance the redox reaction in acidic solution: $\text{H}^+(aq) + \text{Cr}(s) \longrightarrow \text{H}_2(g) + \text{Cr}^{2+}(aq)$	<b>FOR PRACTICE 19.2</b> Balance the redox reaction in acidic solution: $\text{Cu}(s) + \text{NO}_3^-(aq) \longrightarrow \text{Cu}^{2+}(aq) + \text{NO}_2(g)$																					

When a redox reaction occurs in basic solution, we balance the reaction in a similar manner, except that we add an additional step to neutralize any  $\text{H}^+$  with  $\text{OH}^-$ . The  $\text{H}^+$  and the  $\text{OH}^-$  combine to form  $\text{H}_2\text{O}$  as shown in Example 19.3.

### Example 19.3 Balancing Redox Reactions Occurring in Basic Solution

Balance the equation occurring in basic solution:

#### SOLUTION

To balance redox reactions occurring in basic solution, follow the half-reaction method outlined in Examples 19.1 and 19.2, but add an extra step to neutralize the acid with  $\text{OH}^-$  as shown in step 3.

<b>1.</b> Assign oxidation states.	
<b>2.</b> Separate the overall reaction into two half-reactions.	<b>Oxidation:</b> $\text{I}^-(aq) \longrightarrow \text{I}_2(aq)$ <b>Reduction:</b> $\text{MnO}_4^-(aq) \longrightarrow \text{MnO}_2(s)$
<b>3.</b> Balance each half-reaction with respect to mass. <ul style="list-style-type: none"> <li>Balance all elements other than H and O.</li> <li>Balance O by adding <math>\text{H}_2\text{O}</math>.</li> <li>Balance H by adding <math>\text{H}^+</math>.</li> <li>Neutralize <math>\text{H}^+</math> by adding enough <math>\text{OH}^-</math> to neutralize each <math>\text{H}^+</math>. Add the same number of <math>\text{OH}^-</math> ions to each side of the equation.</li> </ul>	$\begin{cases} 2 \text{I}^-(aq) \longrightarrow \text{I}_2(aq) \\ \text{MnO}_4^-(aq) \longrightarrow \text{MnO}_2(s) \end{cases}$ $\begin{cases} 2 \text{I}^-(aq) \longrightarrow \text{I}_2(aq) \\ \text{MnO}_4^-(aq) \longrightarrow \text{MnO}_2(s) + 2 \text{H}_2\text{O}(l) \end{cases}$ $\begin{cases} 2 \text{I}^-(aq) \longrightarrow \text{I}_2(aq) \\ 4 \text{H}^+(aq) + \text{MnO}_4^-(aq) \longrightarrow \text{MnO}_2(s) + 2 \text{H}_2\text{O}(l) \end{cases}$ $\begin{cases} 2 \text{I}^-(aq) \longrightarrow \text{I}_2(aq) \\ 4 \text{H}^+(aq) + 4 \text{OH}^-(aq) + \text{MnO}_4^-(aq) \longrightarrow \text{MnO}_2(s) + 2 \text{H}_2\text{O}(l) + 4 \text{OH}^-(aq) \end{cases}$ $\underbrace{4 \text{H}^+(aq) + 4 \text{OH}^-(aq)}_{4 \text{H}_2\text{O}(l)}$

4. Balance each half-reaction with respect to charge.	$2 \text{I}^-(aq) \longrightarrow \text{I}_2(aq) + 2 \text{e}^-$ $4 \text{H}_2\text{O}(l) + \text{MnO}_4^-(aq) + 3 \text{e}^- \longrightarrow \text{MnO}_2(s) + 2 \text{H}_2\text{O}(l) + 4 \text{OH}^-(aq)$												
5. Make the number of electrons in both half-reactions equal.	$3[2 \text{I}^-(aq) \longrightarrow \text{I}_2(aq) + 2 \text{e}^-]$ $6 \text{I}^-(aq) \longrightarrow 3 \text{I}_2(aq) + 6 \text{e}^-$ $2[4 \text{H}_2\text{O}(l) + \text{MnO}_4^-(aq) + 3 \text{e}^- \longrightarrow \text{MnO}_2(s) + 2 \text{H}_2\text{O}(l) + 4 \text{OH}^-(aq)]$ $8 \text{H}_2\text{O}(l) + 2 \text{MnO}_4^-(aq) + 6 \text{e}^- \longrightarrow 2 \text{MnO}_2(s) + 4 \text{H}_2\text{O}(l) + 8 \text{OH}^-(aq)$												
6. Add the half-reactions together.	$6 \text{I}^-(aq) \longrightarrow 3 \text{I}_2(aq) + 6 \text{e}^-$ $4 \text{H}_2\text{O}(l) + 2 \text{MnO}_4^-(aq) + 6 \text{e}^- \longrightarrow 2 \text{MnO}_2(s) + 4 \text{H}_2\text{O}(l) + 8 \text{OH}^-(aq)$ <hr/> $6 \text{I}^-(aq) + 4 \text{H}_2\text{O}(l) + 2 \text{MnO}_4^-(aq) \longrightarrow 3 \text{I}_2(aq) + 2 \text{MnO}_2(s) + 8 \text{OH}^-(aq)$												
7. **FOR PRACTICE 19.3** Balance the following redox reaction occurring in basic solution:

$$\text{ClO}^-(aq) + \text{Cr}(\text{OH})_4^-(aq) \longrightarrow \text{CrO}_4^{2-}(aq) + \text{Cl}^-(aq)$$

## 19.3 Voltaic (or Galvanic) Cells: Generating Electricity from Spontaneous Chemical Reactions

**Electrical current** is the flow of electric charge. Electrons flowing through a wire or ions flowing through a solution both constitute electrical current. Since redox reactions involve the transfer of electrons from one substance to another, these reactions have the potential to generate electrical current as we discussed in Section 19.1.

For example, consider the spontaneous redox reaction:

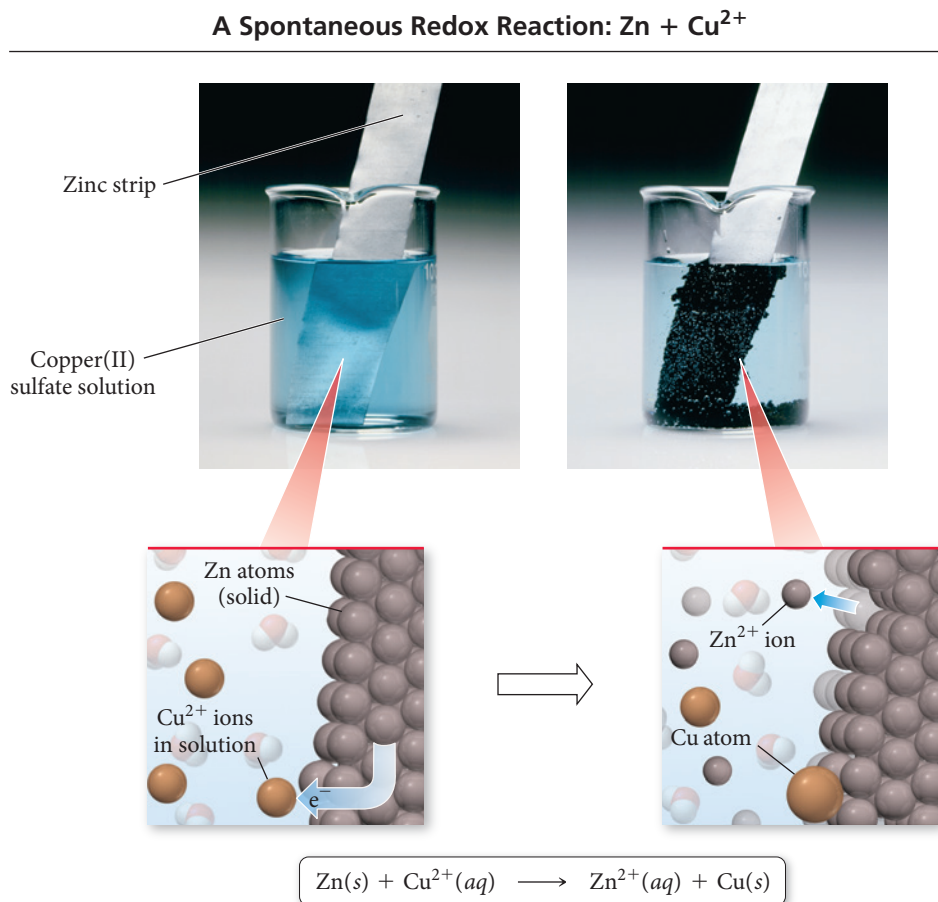

When Zn metal is placed in a  $\text{Cu}^{2+}$  solution, the greater tendency of zinc to lose electrons results in Zn being oxidized and  $\text{Cu}^{2+}$  being reduced. Electrons are transferred directly from the Zn to the  $\text{Cu}^{2+}$  (Figure 19.1, on the next page). Although the actual process is more complicated, we can imagine that—on the atomic scale—a zinc atom within the zinc metal transfers two electrons to a copper ion in solution. The zinc atom then becomes a zinc ion dissolved in the solution. The copper ion accepts the two electrons and is deposited on the zinc as solid copper.

Suppose we were to separate the zinc atoms and copper ions and force the electron transfer to occur another way—not directly from the zinc atom to the copper ion, but through a wire connecting the two half-reactions. The flowing electrons would constitute an electrical current and could be used to do electrical work.

► **FIGURE 19.1** A Spontaneous Oxidation–Reduction Reaction

When zinc is immersed in a solution containing copper ions, the zinc atoms transfer electrons to the copper ions. The zinc atoms are oxidized and dissolve in the solution. The copper ions are reduced and are deposited on the electrode.

## The Voltaic Cell

The generation of electricity through redox reactions is carried out in a device called an **electrochemical cell**. A **voltaic (or galvanic) cell** is an electrochemical cell that *produces* electrical current from a *spontaneous* chemical reaction. A second type of electrochemical cell, called an **electrolytic cell**, *consumes* electrical current to drive a *nonspontaneous* chemical reaction. We discuss voltaic cells in this section and electrolytic cells in Section 19.8.

In the voltaic cell in Figure 19.2►, a solid strip of zinc is placed in a  $\text{Zn}(\text{NO}_3)_2$  solution to form a **half-cell**. A solid strip of copper placed in a  $\text{Cu}(\text{NO}_3)_2$  solution forms a second half-cell. The strips act as **electrodes**, conductive surfaces through which electrons can enter or leave the half-cells. Each metal strip reaches equilibrium with its ions in solution according to these half-reactions:

However, the position of these equilibria is not the same for both metals. As we have just seen, the zinc has a greater tendency to ionize than the copper, so the zinc half-reaction lies further to the right. As a result, the zinc electrode becomes negatively charged relative to the copper electrode.

If the two half-cells are connected by a wire running from the zinc—through a light-bulb or other electrical device—to the copper, electrons spontaneously flow from the zinc electrode (which is more negatively charged, and therefore, repels electrons) to the copper electrode. As the electrons flow away from the zinc electrode, the  $\text{Zn}/\text{Zn}^{2+}$  equilibrium shifts to the right (according to Le Châtelier's principle) and oxidation occurs. As electrons flow to the copper electrode, the  $\text{Cu}/\text{Cu}^{2+}$  equilibrium shifts to the left, and reduction occurs. The flowing electrons constitute an electrical current that lights the bulb.

The *continual* flow of electrical current in a voltaic cell requires a pathway by which counterions can flow to neutralize charge buildup; this is discussed later.

The idea that one electrode in a voltaic cell becomes more negatively charged relative to the other electrode due to differences in ionization tendencies is central to understanding how a voltaic cell works.

## A Voltaic Cell

**▲ FIGURE 19.2 A Voltaic Cell** The tendency of zinc to transfer electrons to copper results in a flow of electrons through the wire that lights the bulb. The movement of electrons from the zinc anode to the copper cathode creates a positive charge buildup at the zinc half-cell and a negative charge buildup at the copper half-cell. The flow of ions within the salt bridge neutralizes this charge buildup, allowing the reaction to continue.

## Current and Potential Difference

We can understand electrical current and why it flows by analogy with water current in a stream (Figure 19.3▶). The *rate of electrons flowing* through a wire is analogous to the *rate of water moving* through a stream. Electrical current is measured in units of **amperes (A)**, also called amps. One ampere represents the flow of one coulomb (a measure of electrical charge) per second:

$$1 \text{ A} = 1 \text{ C/s}$$

Because an electron has a charge of  $1.602 \times 10^{-19} \text{ C}$ , 1 A corresponds to the flow of  $6.242 \times 10^{18}$  electrons per second.

The *driving force* for electrical current is analogous to the driving force for water current. Water current is driven by a difference in gravitational potential energy (caused by a gravitational field). Streams flow downhill, from higher to lower potential energy. Electrical current is also driven by a difference in potential energy (caused by an electric field resulting from the charge difference on the two electrodes) called **potential difference**. *Potential difference is a measure of the difference in potential energy (usually in joules) per unit of charge (coulombs)*. The SI unit of potential difference is the **volt (V)**, which is equal to one joule per coulomb:

$$1 \text{ V} = 1 \text{ J/C}$$

In other words, a potential difference of one volt indicates that a charge of one coulomb experiences an energy difference of one joule between the two electrodes.

A large potential difference corresponds to a large difference in charge between the two electrodes, and therefore, a strong tendency for electron flow (analogous to a steeply descending streambed). Potential difference, since it gives rise to the force that results in the motion of electrons, is also referred to as **electromotive force (emf)**.

The ampere is often abbreviated as *amp*.

**▲ FIGURE 19.3 An Analogy for Electrical Current** Just as water flows downhill in response to a difference in gravitational potential energy, electrons flow through a conductor in response to an electrical potential difference, creating an electrical current.

In a voltaic cell, the potential difference between the two electrodes is the **cell potential** ( $E_{\text{cell}}$ ) or **cell emf**. The cell potential depends on the relative tendencies of the reactants to undergo oxidation and reduction. Combining the oxidation of a substance with a strong tendency to undergo oxidation and the reduction of a substance with a strong tendency to undergo reduction produces a large difference in charge between the two electrodes, and therefore, a high positive cell potential.

In general, cell potential also depends on the concentrations of the reactants and products in the cell and the temperature (which we will assume to be 25 °C unless otherwise noted). Under standard conditions (1 M concentration for reactants in solution and 1 atm pressure for gaseous reactants), the cell potential is called the **standard cell potential** ( $E_{\text{cell}}^{\circ}$ ) or **standard emf**. For example, the standard cell potential in the zinc and copper cell described previously is 1.10 volts:

If the zinc is replaced with nickel (which has a lower tendency to be oxidized) the cell potential is lower:

The cell potential is a measure of the overall tendency of the redox reaction to occur spontaneously—the lower the cell potential, the lower the tendency to occur. A negative cell potential indicates that the forward reaction is not spontaneous.

## Anode, Cathode, and Salt Bridge

In all electrochemical cells, we call the electrode where oxidation occurs the **anode** and the electrode where reduction occurs the **cathode**. In a voltaic cell, the anode is the more negatively charged electrode, and we label it with a negative (−) sign. The cathode of a voltaic cell is the more positively charged electrode, and we label it with a (+) sign. Electrons flow from the anode to the cathode (from negative to positive) through the wires connecting the electrodes.

As electrons flow out of the anode, positive ions ( $\text{Zn}^{2+}$  in the preceding example) form in the oxidation half-cell, resulting in a buildup of *positive charge* in the *solution*. As electrons flow into the cathode, positive ions ( $\text{Cu}^{2+}$  in the preceding example) are reduced at the reduction half-cell, resulting in a buildup of *negative charge* in the *solution*.

If the movement of electrons from anode to cathode were the only flow of charge, the buildup of the opposite charge in the solution would stop electron flow almost immediately. The cell needs a pathway by which counterions can flow between the half-cells without the solutions in the half-cells totally mixing. One such pathway is a **salt bridge**, an inverted, U-shaped tube that contains a strong electrolyte such as  $\text{KNO}_3$  and connects the two half-cells (see Figure 19.2). The electrolyte is usually suspended in a gel and held within the tube by permeable stoppers. The salt bridge allows a flow of ions that neutralizes the charge buildup in the solution. *The negative ions within the salt bridge flow to neutralize the accumulation of positive charge at the anode, and the positive ions flow to neutralize the accumulation of negative charge at the cathode.* In other words, the salt bridge completes the circuit, allowing electrical current to flow.

Note that the anode and cathode need not actually be negatively and positively charged, respectively. The anode is the electrode with the relatively *more* negative (or less positive) charge.

## CONCEPTUAL CONNECTION 19.1

**Voltaic Cells** In a voltaic cell, electrons flow:

- from the more negatively charged electrode to the more positively charged electrode.
- from the more positively charged electrode to the more negatively charged electrode.
- from lower potential energy to higher potential energy.

## Electrochemical Cell Notation

We represent electrochemical cells with a compact notation called a *cell diagram* or *line notation*. For example, we represent the electrochemical cell discussed previously in which Zn is oxidized to  $\text{Zn}^{2+}$  and  $\text{Cu}^{2+}$  is reduced to Cu as follows:

In this representation,

- the oxidation half-reaction is on the left and the reduction is on the right. A double vertical line, indicating the salt bridge, separates the two half-reactions.
- substances in different phases are separated by a single vertical line, which represents the boundary between the phases.
- for some redox reactions, the reactants and products of one or both of the half-reactions may be in the same phase. In these cases (which we explain further next), we separate the reactants and products from each other with a comma in the line diagram. Such cells use an inert electrode, such as platinum (Pt) or graphite, as the anode or cathode (or both).

Consider the redox reaction in which  $\text{Fe(s)}$  is oxidized and  $\text{MnO}_4^-(\text{aq})$  is reduced:

The half-reactions for this overall reaction are:

Notice that in the reduction half-reaction the principal species are all in the aqueous phase. In this case, the electron transfer needs an electrode on which to occur. An inert platinum electrode is employed, and the electron transfer takes place at its surface. Using line notation, we represent the electrochemical cell corresponding to the above reaction as:

The Pt(s) on the far right indicates that an inert platinum electrode acts as the cathode in this reaction, as depicted in Figure 19.4 ▼.

### Inert Platinum Electrode

◀ **FIGURE 19.4 Inert Platinum Electrode** When the participants in a half-reaction are all in the aqueous phase, a conductive surface is needed for electron transfer to take place. In such cases an inert electrode of graphite or platinum is often used. In this electrochemical cell, an iron strip acts as the anode and a platinum strip acts as the cathode. Iron is oxidized at the anode, and  $\text{MnO}_4^-$  is reduced at the cathode.

## Standard Electrode Potentials

## 19.4 Standard Electrode Potentials

▲ **FIGURE 19.5** An Analogy for Electrode Potential

As we have just seen, the standard cell potential ( $E_{\text{cell}}^{\circ}$ ) for an electrochemical cell depends on the specific half-reactions occurring in the half-cells and is a measure of the potential energy difference (per unit charge) between the two electrodes. We can think of the electrode in each half-cell as having its own individual potential, called the **standard electrode potential**. The overall standard cell potential ( $E_{\text{cell}}^{\circ}$ ) is the difference between the two standard electrode potentials.

We can better understand this idea with an analogy. Consider two water tanks with different water levels connected by a common pipe, as shown in Figure 19.5 ◀. The water in each tank has its own level and corresponding potential energy. When the tanks are connected, water flows from the tank with the higher level (higher potential energy) to the tank with a lower water level (lower potential energy). Similarly, each half-cell in an electrochemical cell has its own charge and corresponding electrode potential. *When the cells are connected, electrons flow from the electrode with more negative charge (greater potential energy) to the electrode with more positive charge (less potential energy).*

One limitation of this analogy is that, unlike the water level in a tank, we cannot measure the electrode potential in a half-cell directly—we can only measure the overall potential that occurs when two half-cells are combined in a whole cell. However, we can arbitrarily assign a potential of zero to the electrode in a *particular* type of half-cell and then measure all other electrode potentials relative to that zero.

The half-cell electrode that is normally chosen to have a potential of zero is the **standard hydrogen electrode (SHE)**. This half-cell consists of an inert platinum electrode immersed in 1 M HCl with hydrogen gas at 1 atm bubbling through the solution, as shown in Figure 19.6 ▼. When the SHE acts as the cathode, the following half-reaction occurs:

If we connect the standard hydrogen electrode to an electrode in another half-cell of interest, we can measure the potential difference (or voltage) between the two electrodes. Because we assigned the standard hydrogen electrode zero voltage, we can now determine the electrode potential of the other half-cell.

For example, consider the electrochemical cell in Figure 19.7 ►. In this electrochemical cell, Zn is oxidized to  $\text{Zn}^{2+}$  and  $\text{H}^{+}$  is reduced to  $\text{H}_2$  under standard conditions (all solutions are 1 M in concentration, and all gases are 1 atm in pressure) and at 25 °C.

### Standard Hydrogen Electrode (SHE)

► **FIGURE 19.6** The Standard Hydrogen Electrode We arbitrarily assign the standard hydrogen electrode (SHE) an electrode potential of zero. All other electrode potentials are then measured relative to the SHE.

## Measuring Half-Cell Potential with the SHE

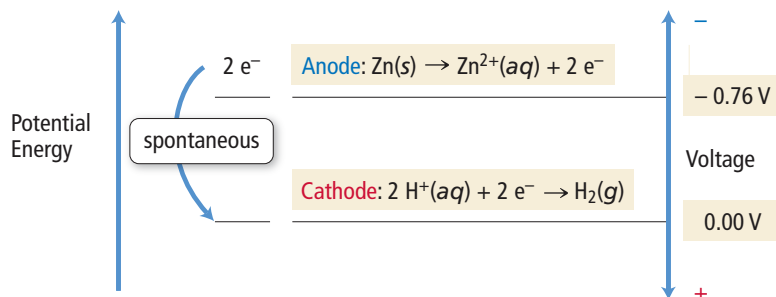

**▲ FIGURE 19.7 Measuring Electrode Potential** Because the electrode potential of the SHE is zero, the electrode potential for the oxidation of Zn is equal to the cell potential.

Electrons travel from the anode (where oxidation occurs) to the cathode (where reduction occurs), so we define  $E_{\text{cell}}^\circ$  as the difference in voltage between the cathode (final state) and the anode (initial state):

$$E_{\text{cell}}^\circ = E_{\text{final}}^\circ - E_{\text{initial}}^\circ = E_{\text{cathode}}^\circ - E_{\text{anode}}^\circ$$

The measured cell potential for this cell is +0.76 V. The anode (in this case, Zn/Zn<sup>2+</sup>) is at a more negative voltage (higher potential energy) than the cathode (in this case, the SHE). Therefore, electrons spontaneously flow from the anode to the cathode. We can diagram the potential energy and the voltage as follows:

Referring back to our water tank analogy, the zinc half-cell is like the water tank with the higher water level, and electrons therefore flow from the zinc electrode to the standard hydrogen electrode.

Because we assigned the SHE a potential of zero (0.00 V), we can determine the electrode potential for the Zn/Zn<sup>2+</sup> half-cell (the anode) from the measured cell potential ( $E_{\text{cell}}^\circ$ ):

$$E_{\text{cell}}^\circ = E_{\text{cathode}}^\circ - E_{\text{anode}}^\circ$$

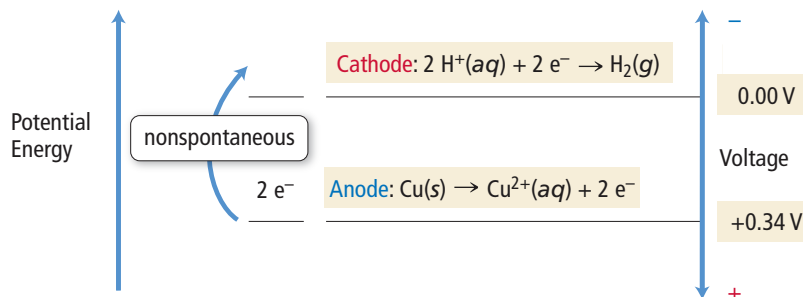

$$0.76\text{ V} = 0.00\text{ V} - E_{\text{anode}}^\circ$$

$$E_{\text{anode}}^\circ = -0.76\text{ V}$$

The potential for the Zn/Zn<sup>2+</sup> electrode is *negative*. The negative potential indicates that an electron at the Zn/Zn<sup>2+</sup> electrode has greater potential energy than it does at the SHE. Remember that the more negative the electrode potential is, the greater the potential energy of an electron at that electrode (because negative charge repels electrons).

What happens if we connect an electrode in which the electron has *more positive* potential (than the standard hydrogen electrode) to the standard hydrogen electrode? That electrode would then have a more *positive* voltage (lower potential energy for an electron).

For example, suppose we connect the standard hydrogen electrode to a Cu electrode immersed in a 1 M  $\text{Cu}^{2+}$  solution. The measured cell potential for this cell is  $-0.34$  V. The anode (defined as  $\text{Cu}/\text{Cu}^{2+}$ ) is at a more positive voltage (lower potential energy) than the cathode (the SHE). Therefore, electrons will *not* spontaneously flow from the anode to the cathode. We can diagram the potential energy and the voltage of this cell as follows:

The copper half-cell is like the water tank with the lower water level, and electrons *do not* spontaneously flow from the copper electrode to the standard hydrogen electrode.

We can again determine the electrode potential for the  $\text{Cu}/\text{Cu}^{2+}$  half-cell (the anode) from the measured cell potential:

$$E_{\text{cell}}^{\circ} = E_{\text{cathode}}^{\circ} - E_{\text{anode}}^{\circ}$$

$$-0.34 \text{ V} = 0.00 \text{ V} - E_{\text{anode}}^{\circ}$$

$$E_{\text{anode}}^{\circ} = +0.34 \text{ V}$$

The potential for the  $\text{Cu}/\text{Cu}^{2+}$  electrode is *positive*. The positive potential indicates that an electron at the  $\text{Cu}/\text{Cu}^{2+}$  electrode has *lower* potential energy than it does at the SHE. The more positive the electrode potential, the lower the potential energy of an electron at that electrode (because positive charge attracts electrons).

By convention, standard electrode potentials are written for *reduction* half-reactions. We write the standard electrode potentials for the two half-reactions just discussed as:

We can see that the  $\text{Cu}/\text{Cu}^{2+}$  electrode is positive relative to the SHE (and therefore, tends to draw electrons *away* from the SHE) and that the  $\text{Zn}/\text{Zn}^{2+}$  electrode is negative relative to the SHE (and therefore, tends to repel electrons toward the SHE). Table 19.1 lists the standard electrode potentials for a number of common half-reactions.

#### Summarizing Standard Electrode Potentials:

- ▶ The electrode potential of the standard hydrogen electrode (SHE) is exactly zero.
- ▶ The electrode in any half-cell with a greater tendency to undergo reduction is positively charged relative to the SHE, and therefore, has a positive  $E^{\circ}$ .
- ▶ The electrode in any half-cell with a lesser tendency to undergo reduction (or greater tendency to undergo oxidation) is negatively charged relative to the SHE, and therefore, has a negative  $E^{\circ}$ .
- ▶ The cell potential of any electrochemical cell ( $E_{\text{cell}}^{\circ}$ ) is the difference between the electrode potentials of the cathode and the anode ( $E_{\text{cell}}^{\circ} = E_{\text{cat}}^{\circ} - E_{\text{an}}^{\circ}$ ).
- ▶  $E_{\text{cell}}^{\circ}$  is positive for spontaneous reactions and negative for nonspontaneous reactions.

Multiplying a half-reaction by some constant to balance a redox reaction does not affect the value of  $E^{\circ}$  for the half-reaction.

	$\text{Al}^{3+}(\text{aq}) + 3 \text{e}^- \longrightarrow \text{Al}(\text{s})$	-1.66	
	$\text{Mg}^{2+}(\text{aq}) + 2 \text{e}^- \longrightarrow \text{Mg}(\text{s})$	-2.37	
	$\text{Na}^+(\text{aq}) + \text{e}^- \longrightarrow \text{Na}(\text{s})$	-2.71	
	$\text{Ca}^{2+}(\text{aq}) + 2 \text{e}^- \longrightarrow \text{Ca}(\text{s})$	-2.76	
	$\text{Ba}^{2+}(\text{aq}) + 2 \text{e}^- \longrightarrow \text{Ba}(\text{s})$	-2.90	
	$\text{K}^+(\text{aq}) + \text{e}^- \longrightarrow \text{K}(\text{s})$	-2.92	
	$\text{Li}^+(\text{aq}) + \text{e}^- \longrightarrow \text{Li}(\text{s})$	-3.04	

Example 19.4 illustrates how to calculate the potential of an electrochemical cell from the standard electrode potentials of the half-reactions.

### Example 19.4 Calculating Standard Potentials for Electrochemical Cells from Standard Electrode Potentials of the Half-Reactions

Use tabulated standard electrode potentials to calculate the standard cell potential for the following reaction occurring in an electrochemical cell at 25 °C. (The equation is balanced.)

#### SOLUTION

Begin by separating the reaction into oxidation and reduction half-reactions. (In this case, you can readily see that Al(s) is oxidized. In cases where it is not so apparent, you may want to assign oxidation states to determine the correct half-reactions.)

Look up the standard electrode potentials for each half-reaction in Table 19.1. Add the half-cell reactions together to obtain the overall redox equation. Calculate the standard cell potential by subtracting the electrode potential of the anode from the electrode potential of the cathode.

**Oxidation**

**(Anode):**

**Reduction**

**(Cathode):**

$$\begin{aligned} E_{\text{cell}}^\circ &= E_{\text{cat}}^\circ - E_{\text{an}}^\circ \\ &= 0.96 \text{ V} - (-1.66 \text{ V}) \\ &= 2.62 \text{ V} \end{aligned}$$

**FOR PRACTICE 19.4** Use tabulated standard electrode potentials to calculate the standard cell potential for the following reaction occurring in an electrochemical cell at 25 °C. (The equation is balanced.)

### CONCEPTUAL CONNECTION 19.2

#### Standard Electrode Potentials

An electrode has a negative electrode potential. Which statement is correct regarding the potential energy of an electron at this electrode?

- (a) An electron at this electrode has a lower potential energy than it has at a standard hydrogen electrode.
- (b) An electron at this electrode has a higher potential energy than it has at a standard hydrogen electrode.
- (c) An electron at this electrode has the same potential energy as it has at a standard hydrogen electrode.

### Predicting the Spontaneous Direction of an Oxidation–Reduction Reaction

To determine the spontaneous direction of an oxidation–reduction reaction, we examine the electrode potentials of the two relevant half-reactions in Table 19.1. The half-reaction with the more *negative* electrode potential tends to lose electrons, and

therefore, undergo oxidation. (Remember that negative charge repels electrons.) The half-reaction having the more *positive* electrode potential tends to gain electrons, and therefore, undergo reduction. (Remember that positive charge attracts electrons.)

For example, consider the two reduction half-reactions:

Because the manganese half-reaction has a more negative electrode potential, it repels electrons and proceeds in the reverse direction (oxidation). Because the nickel half-reaction has the more positive (or less negative) electrode potential, it attracts electrons and proceeds in the forward direction.

We can confirm this by calculating the standard electrode potential for manganese acting as the anode (oxidation) and nickel acting as the cathode (reduction):

**Oxidation (Anode):**

**Reduction (Cathode):**

$$\begin{aligned} \text{Ni}^{2+}(\text{aq}) + \text{Mn}(\text{s}) &\longrightarrow \text{Ni}(\text{s}) + \text{Mn}^{2+}(\text{aq}) & E_{\text{cell}}^{\circ} &= E_{\text{cat}}^{\circ} - E_{\text{an}}^{\circ} \\ & & &= -0.23\text{ V} - (-1.18\text{ V}) \\ & & &= 0.95\text{ V} \end{aligned}$$

The overall cell potential is positive, indicating a spontaneous reaction. Consider the electrochemical cell corresponding to this spontaneous redox reaction in Figure 19.8. We draw the manganese half-cell on the left as the anode and the nickel half-cell on the right as the cathode. Electrons flow from the anode to the cathode.

Another way to predict the spontaneity of a redox reaction is to note the relative positions of the two half-reactions in Table 19.1. The table lists half-reactions in order of *decreasing* electrode potential, so the half-reactions near the top of the table—those having large *positive* electrode potentials—attract electrons, and therefore, tend to occur in the forward direction. Half-reactions near the bottom of the table—those having large *negative* electrode potentials—repel electrons, and therefore, tend to occur in the reverse direction. In other words, as we move down Table 19.1, the half-reactions become less likely to occur in the forward direction and more likely to occur in the reverse direction. As a result, *any reduction half-reaction listed is spontaneous when paired with the reverse of a half-reaction that appears below it in Table 19.1.*

For example, if we return to our two previous half-reactions involving manganese and nickel, we can see that the manganese half-reaction is below the nickel half-reaction in Table 19.1:

Therefore, the nickel reaction occurs in the forward direction (reduction) and the manganese reaction occurs in the reverse direction (oxidation).

**FIGURE 19.8 Mn/Ni<sup>2+</sup> Electrochemical Cell** The reduction of Mn<sup>2+</sup> is listed below the reduction of Ni<sup>2+</sup> in Table 19.1, so the reduction of Ni<sup>2+</sup> is spontaneous when paired with the oxidation of Mn.

Recall from Section 4.9 that an *oxidizing agent* causes the oxidation of another substance (and is itself reduced) and that a *reducing agent* causes the reduction of another substance (and is itself oxidized).

### Summarizing the Prediction of Spontaneous Direction for Redox Reactions:

- ▶ The half-reaction with the more *positive* electrode potential attracts electrons more strongly and undergoes reduction. (Substances listed at the top of Table 19.1 tend to undergo reduction; they are good oxidizing agents.)
- ▶ The half-reaction with the more *negative* electrode potential repels electrons more strongly and undergoes oxidation. (Substances listed near the bottom of Table 19.1 tend to undergo oxidation; they are good reducing agents.)
- ▶ Any reduction reaction in Table 19.1 is spontaneous when paired with the *reverse* of any of the reactions listed below it on the table.

### Example 19.5 Predicting Spontaneous Redox Reactions and Sketching Electrochemical Cells

Without calculating  $E^\circ_{\text{cell}}$ , predict whether each of the redox reactions is spontaneous. If the reaction is spontaneous as written, make a sketch of the electrochemical cell in which the reaction could occur. If the reaction is not spontaneous as written, write an equation for the spontaneous direction in which the reaction would occur and sketch the electrochemical cell in which the spontaneous reaction would occur. In your sketches, make sure to label the anode (which should be drawn on the left), the cathode, and the direction of electron flow.

#### SOLUTION

This reaction involves the reduction of  $\text{Mg}^{2+}$ :

and the oxidation of Fe:

However, the magnesium half-reaction has the more negative electrode potential, and therefore, repels electrons more strongly and undergoes oxidation. The iron half-reaction has the more positive electrode potential, and therefore, attracts electrons more strongly and undergoes reduction. So the reaction as written is *not* spontaneous. (The reaction pairs the reduction of  $\text{Mg}^{2+}$  with the reverse of a half-reaction *above* it in Table 19.1—such pairings are not spontaneous.)

However, the reverse reaction is spontaneous:

The corresponding electrochemical cell is shown in Figure 19.9◀.

This reaction involves the reduction of  $\text{Pb}^{2+}$ :

and the oxidation of iron:

The iron half-reaction has the more negative electrode potential, and therefore, repels electrons and undergoes oxidation. The lead half-reaction has the more positive electrode potential, and therefore, attracts electrons and undergoes reduction. Therefore, the reaction is spontaneous as written. (The reaction pairs the reduction of  $\text{Pb}^{2+}$  with the reverse of a half-reaction *below* it in Table 19.1—such pairings are always spontaneous.) The corresponding electrochemical cell is shown in Figure 19.10◀.

**FOR PRACTICE 19.5** Are the following redox reactions spontaneous under standard conditions?

▲ FIGURE 19.9 Mg/Fe<sup>2+</sup> Electrochemical Cell

▲ FIGURE 19.10 Fe/Pb<sup>2+</sup> Electrochemical Cell

### CONCEPTUAL CONNECTION 19.3

**Selective Oxidation** A solution contains both NaI and NaBr. Which oxidizing agent could you add to the solution to selectively oxidize  $\text{I}^-(aq)$  but not  $\text{Br}^-(aq)$ ?

- (a)  $\text{Cl}_2$       (b)  $\text{H}_2\text{O}_2$       (c)  $\text{CuCl}_2$       (d)  $\text{HNO}_3$

## Predicting Whether a Metal Will Dissolve in Acid

In Chapter 16, we learned that acids dissolve metals. Most acids dissolve metals by the reduction of  $\text{H}^+$  ions to hydrogen gas and the corresponding oxidation of the metal to its ion. For example, if solid Zn is dropped into hydrochloric acid, the following reaction occurs:

We observe the reaction as the dissolving of the zinc and the bubbling of hydrogen gas. The zinc is oxidized and the  $\text{H}^+$  ions are reduced. Notice that this reaction involves the pairing of a reduction half-reaction (the reduction of  $\text{H}^+$ ) with the reverse of a half-reaction that falls below it in Table 19.1. Therefore, this reaction is spontaneous. What happens, however, if we pair the reduction of  $\text{H}^+$  with the oxidation of Cu? The reaction is not spontaneous because it involves pairing the reduction of  $\text{H}^+$  with the reverse of a half-reaction that is listed *above it* in the table. Consequently, copper does not react with  $\text{H}^+$  and does not dissolve in acids such as HCl. In general, *metals whose reduction half-reactions are listed below the reduction of  $\text{H}^+$  to  $\text{H}_2$  in Table 19.1 dissolve in acids, while metals listed above it do not.*

An important exception to this rule is nitric acid ( $\text{HNO}_3$ ), which can oxidize metals through the reduction half-reaction:

Since this half-reaction is above the reduction of  $\text{H}^+$  in Table 19.1,  $\text{HNO}_3$  can oxidize metals (such as copper) that can't be oxidized by HCl.

▲ When zinc is immersed in hydrochloric acid, the zinc is oxidized, forming ions that become solvated in the solution. Hydrogen ions are reduced, forming bubbles of hydrogen gas.

### CONCEPTUAL CONNECTION 19.4

**Metals Dissolving in Acids** Which metal dissolves in  $\text{HNO}_3$  but not in HCl?

- (a) Fe      (b) Au      (c) Ag

## 19.5 Cell Potential, Free Energy, and the Equilibrium Constant

We have seen that a positive standard cell potential ( $E^\circ_{\text{cell}}$ ) corresponds to a spontaneous oxidation–reduction reaction. And we know (from Chapter 18) that the spontaneity of a reaction is determined by the sign of  $\Delta G^\circ$ . Therefore,  $E^\circ_{\text{cell}}$  and  $\Delta G^\circ$  must be related. We also know from Section 18.10 that  $\Delta G^\circ$  for a reaction is related to the equilibrium constant ( $K$ ) for the reaction. Since  $E^\circ_{\text{cell}}$  and  $\Delta G^\circ$  are related, then  $E^\circ_{\text{cell}}$  and  $K$  must also be related.

Cell Potential, Free Energy, and the Equilibrium Constant

Before we look at the nature of each of these relationships in detail, let's consider the following generalizations.

For a spontaneous redox reaction (one that proceeds in the forward direction when all reactants and products are in their standard states):

- $\Delta G^\circ$  is negative ( $<0$ )
- $E^\circ_{\text{cell}}$  is positive ( $>0$ )
- $K > 1$

For a nonspontaneous reaction (one that proceeds in the reverse direction when all reactants and products are in their standard states):

- $\Delta G^\circ$  is positive ( $>0$ )
- $E^\circ_{\text{cell}}$  is negative ( $<0$ )
- $K < 1$

## The Relationship between $\Delta G^\circ$ and $E^\circ_{\text{cell}}$

We can derive a relationship between  $\Delta G^\circ$  and  $E^\circ_{\text{cell}}$  by briefly returning to the definition of potential difference from Section 19.3—a potential difference is a measure of the difference of potential energy per unit charge ( $q$ ):

$$E = \frac{\text{potential energy difference (in J)}}{\text{charge (in C)}}$$

Maximum work ( $w_{\text{max}}$ )   
↓   
Charge ( $q$ )   
↑

Since the potential energy difference represents the maximum amount of work that can be done by the system on the surroundings, we can write:

$$w_{\text{max}} = -qE^\circ_{\text{cell}} \quad [19.1]$$

The negative sign follows the convention used throughout this book that work done by the system on the surroundings is negative.

We can quantify the charge ( $q$ ) that flows in an electrochemical reaction by using **Faraday's constant ( $F$ )**, which represents the charge in coulombs of 1 mol of electrons:

$$F = \frac{96,485 \text{ C}}{\text{mol e}^-}$$

The total charge is  $q = nF$ , where  $n$  is the number of moles of electrons from the balanced chemical equation and  $F$  is Faraday's constant. Substituting  $q = nF$  into Equation 19.1:

$$\begin{aligned} w_{\text{max}} &= -qE^\circ_{\text{cell}} \\ &= -nFE^\circ_{\text{cell}} \end{aligned} \quad [19.2]$$

Finally, recall from Chapter 18 that the standard change in free energy for a chemical reaction ( $\Delta G^\circ$ ) represents the maximum amount of work that can be done by the reaction. Therefore,  $w_{\text{max}} = \Delta G^\circ$ . Making this substitution into Equation 19.2, we arrive at the following important result:

$$\Delta G^\circ = -nFE^\circ_{\text{cell}} \quad [19.3]$$

where  $\Delta G^\circ$  is the standard change in free energy for an electrochemical reaction,  $n$  is the number of moles of electrons transferred in the balanced equation,  $F$  is Faraday's constant, and  $E^\circ_{\text{cell}}$  is the standard cell potential. Example 19.6 shows how to apply this equation to calculate the standard free energy change for an electrochemical cell.

**Example 19.6** Relating  $\Delta G^\circ$  and  $E^\circ_{\text{cell}}$ 

Use the tabulated electrode potentials to calculate  $\Delta G^\circ$  for the reaction:

Is the reaction spontaneous?

**SORT** You are given a redox reaction and asked to find  $\Delta G^\circ$ .

**GIVEN:**  $\text{I}_2(\text{s}) + 2 \text{Br}^-(\text{aq}) \longrightarrow 2 \text{I}^-(\text{aq}) + \text{Br}_2(\text{l})$

**FIND:**  $\Delta G^\circ$

**STRATEGIZE** Refer to the values of electrode potentials in Table 19.1 to calculate  $E^\circ_{\text{cell}}$ . Then use Equation 19.3 to calculate  $\Delta G^\circ$  from  $E^\circ_{\text{cell}}$ .

**CONCEPTUAL PLAN**

**SOLVE** Separate the reaction into oxidation and reduction half-reactions and find the standard electrode potentials for each. Determine  $E^\circ_{\text{cell}}$  by subtracting  $E^\circ_{\text{an}}$  from  $E^\circ_{\text{cat}}$ .

**SOLUTION**

Calculate  $\Delta G^\circ$  from  $E^\circ_{\text{cell}}$ . The value of  $n$  (the number of moles of electrons) corresponds to the number of electrons that are canceled in the half-reactions. Remember that  $1 \text{ V} = 1 \text{ J/C}$ .

$$\begin{aligned} \Delta G^\circ &= -nFE^\circ_{\text{cell}} \\ &= -2 \text{ mol e}^- \left( \frac{96,485 \text{ C}}{\text{mol e}^-} \right) (-0.55 \frac{\text{J}}{\text{C}}) \\ &= +1.1 \times 10^5 \text{ J} \end{aligned}$$

Since  $\Delta G^\circ$  is positive, the reaction is not spontaneous under standard conditions.

**CHECK** The answer is in the correct units (joules) and seems reasonable in magnitude ( $\approx 110 \text{ kJ}$ ). You have seen (in Chapter 18) that values of  $\Delta G^\circ$  typically range from plus or minus tens to hundreds of kilojoules. The sign is positive, as expected for a reaction in which  $E^\circ_{\text{cell}}$  is negative.

**FOR PRACTICE 19.6** Use tabulated electrode potentials to calculate  $\Delta G^\circ$  for the reaction.

Is the reaction spontaneous?

## Periodic Trends and the Direction of Spontaneity for Redox Reactions

Consider the result of Example 19.6. The calculation revealed that the reaction is not spontaneous. Based on conceptual reasoning, which of the following best explains why  $\text{I}_2$  does not oxidize  $\text{Br}^-$ ?

- (a) Br is more electronegative than I; therefore, you do not expect  $\text{Br}^-$  to give up an electron to  $\text{I}_2$ .
- (b) I is more electronegative than Br; therefore, you do not expect  $\text{I}_2$  to give up an electron to  $\text{Br}^-$ .
- (c)  $\text{Br}^-$  is in solution and  $\text{I}_2$  is a solid. Solids do not gain electrons from substances in solution.

## CONCEPTUAL CONNECTION 19.5

## The Relationship between $E_{\text{cell}}^{\circ}$ and $K$

We can derive a relationship between the standard cell potential ( $E_{\text{cell}}^{\circ}$ ) and the equilibrium constant for the redox reaction occurring in the cell ( $K$ ) by returning to the relationship between  $\Delta G^{\circ}$  and  $K$  that we learned in Chapter 18. Recall from Section 18.10 that:

$$\Delta G^{\circ} = -RT \ln K \quad [19.4]$$

By setting Equations 19.3 and 19.4 equal to each other, we get:

$$\begin{aligned} -nFE_{\text{cell}}^{\circ} &= -RT \ln K \\ E_{\text{cell}}^{\circ} &= \frac{RT}{nF} \ln K \end{aligned} \quad [19.5]$$

Equation 19.5 is usually simplified for use at 25 °C by making the following substitutions:

$$R = 8.314 \frac{\text{J}}{\text{mol} \cdot \text{K}}; T = 298.15 \text{ K}; F = \left( \frac{96,485 \text{ C}}{\text{mol e}^{-}} \right); \text{ and } \ln K = 2.303 \log K$$

Substituting into Equation 19.5, we get the following important result:

$$E_{\text{cell}}^{\circ} = \frac{0.0592 \text{ V}}{n} \log K \quad [19.6]$$

where  $E_{\text{cell}}^{\circ}$  is the standard cell potential,  $n$  is the number of moles of electrons transferred in the redox reaction, and  $K$  is the equilibrium constant for the balanced redox reaction at 25 °C. Example 19.7 demonstrates how to use Equation 19.6.

### Example 19.7 Relating $E_{\text{cell}}^{\circ}$ and $K$

Use the tabulated electrode potentials to calculate  $K$  for the oxidation of copper by  $\text{H}^{+}$  (at 25 °C):

**SORT** You are given a redox reaction and asked to find  $K$ .

**GIVEN:**  $\text{Cu(s)} + 2 \text{H}^{+}(\text{aq}) \longrightarrow \text{Cu}^{2+}(\text{aq}) + \text{H}_2(\text{g})$   
**FIND:**  $K$

**STRATEGIZE** Refer to the values of electrode potentials in Table 19.1 to calculate  $E_{\text{cell}}^{\circ}$ . Then use Equation 19.6 to calculate  $K$  from  $E_{\text{cell}}^{\circ}$ .

#### CONCEPTUAL PLAN

**SOLVE** Separate the reaction into oxidation and reduction half-reactions and find the standard electrode potentials for each. Find  $E_{\text{cell}}^{\circ}$  by subtracting  $E_{\text{an}}^{\circ}$  from  $E_{\text{cat}}^{\circ}$ .

#### SOLUTION

##### Oxidation

##### Reduction

Calculate  $K$  from  $E_{\text{cell}}^{\circ}$ . The value of  $n$  (the number of moles of electrons) corresponds to the number of electrons that are canceled in the half-reactions.

$$\begin{aligned} E_{\text{cell}}^{\circ} &= \frac{0.0592 \text{ V}}{n} \log K \\ \log K &= E_{\text{cell}}^{\circ} \frac{n}{0.0592 \text{ V}} \\ \log K &= -0.34 \text{ V} \frac{2}{0.0592 \text{ V}} = -11.486 \\ K &= 10^{-11.486} = 3.3 \times 10^{-12} \end{aligned}$$

**CHECK** The answer has no units, as expected for an equilibrium constant. The magnitude of the answer is small, indicating that the reaction lies far to the left at equilibrium, as expected for a reaction in which  $E_{\text{cell}}^{\circ}$  is negative.

**FOR PRACTICE 19.7** Use the tabulated electrode potentials to calculate  $K$  for the oxidation of iron by  $\text{H}^{+}$  (at 25 °C):  

$$2 \text{Fe}(s) + 6 \text{H}^{+}(aq) \longrightarrow 2 \text{Fe}^{3+}(aq) + 3 \text{H}_2(g)$$

Notice that the fundamental quantity in the given relationships is the standard change in free energy ( $\Delta G^{\circ}$ ). From that quantity, we can calculate both  $E_{\text{cell}}^{\circ}$  and  $K$ . The relationships between these three quantities is summarized with the following diagram:

**Relating  $K$ ,  $\Delta G_{\text{rxn}}^{\circ}$ , and  $E_{\text{cell}}^{\circ}$**  A redox reaction has an equilibrium constant of  $K = 1.2 \times 10^3$ . Which statement is true regarding  $\Delta G_{\text{rxn}}^{\circ}$  and  $E_{\text{cell}}^{\circ}$  for this reaction?

- (a)  $E_{\text{cell}}^{\circ}$  is positive and  $\Delta G_{\text{rxn}}^{\circ}$  is positive.
- (b)  $E_{\text{cell}}^{\circ}$  is negative and  $\Delta G_{\text{rxn}}^{\circ}$  is negative.
- (c)  $E_{\text{cell}}^{\circ}$  is positive and  $\Delta G_{\text{rxn}}^{\circ}$  is negative.
- (d)  $E_{\text{cell}}^{\circ}$  is negative and  $\Delta G_{\text{rxn}}^{\circ}$  is positive.

## CONCEPTUAL CONNECTION 19.6

## 19.6 Cell Potential and Concentration

We have learned how to find  $E_{\text{cell}}^{\circ}$  under standard conditions. For example, we know that when  $[\text{Cu}^{2+}] = 1 \text{ M}$  and  $[\text{Zn}^{2+}] = 1 \text{ M}$ , the following reaction produces a potential of 1.10 V:

However, what if  $[\text{Cu}^{2+}] > 1 \text{ M}$  and  $[\text{Zn}^{2+}] < 1 \text{ M}$ ? For example, how would the cell potential for the following conditions be different from the potential under standard conditions?

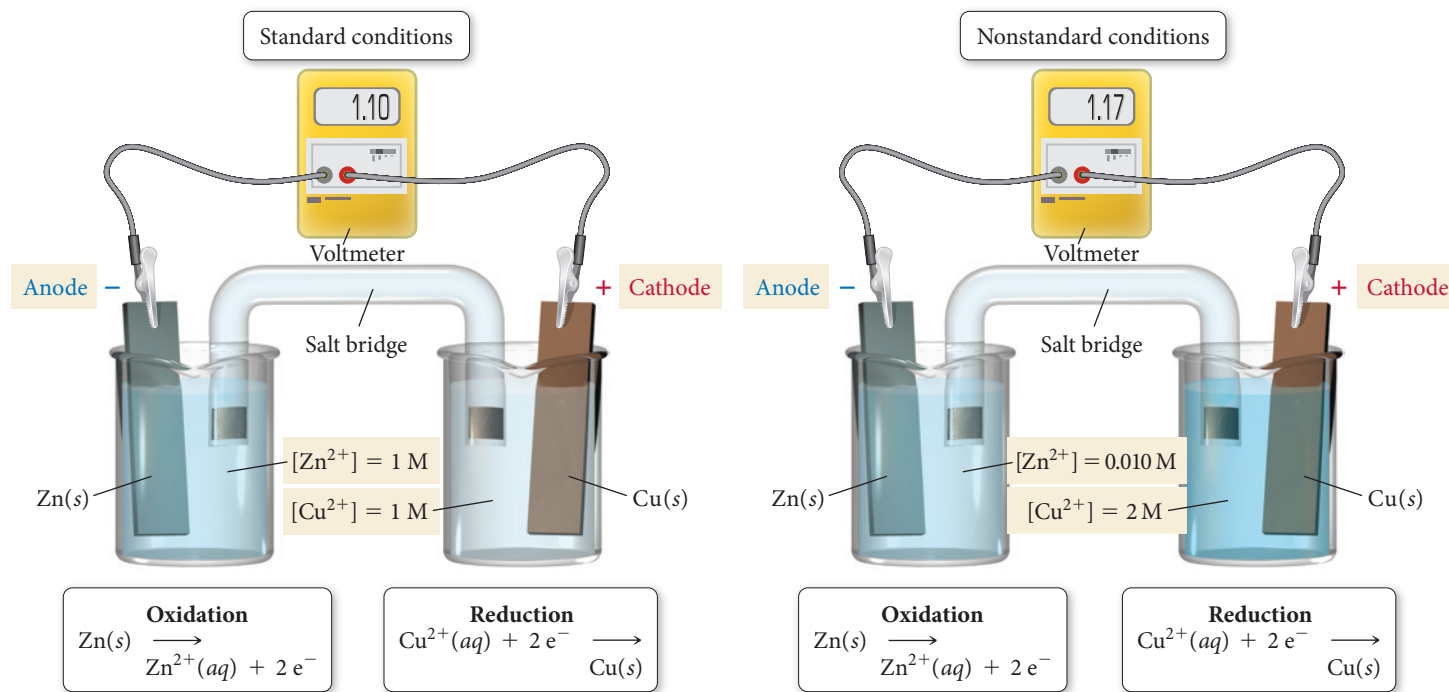

Since the concentration of a reactant is greater than standard conditions, and since the concentration of product is less than standard conditions, we can use Le Châtelier's principle to predict that the reaction has an even stronger tendency to occur in the forward direction and that  $E_{\text{cell}}$  is therefore greater than +1.10 V (Figure 19.11 ►, on the next page).

### Cell Potential under Nonstandard Conditions: The Nernst Equation

We can derive an exact relationship between  $E_{\text{cell}}$  (under nonstandard conditions) and  $E_{\text{cell}}^{\circ}$  by considering the relationship between the change in free energy ( $\Delta G$ ) and the *standard* change in free energy ( $\Delta G^{\circ}$ ) from Section 18.9:

$$\Delta G = \Delta G^{\circ} + RT \ln Q \quad [19.7]$$

**▲ FIGURE 19.11 Cell Potential and Concentration** This figure compares the Zn/Cu<sup>2+</sup> electrochemical cell under standard and nonstandard conditions. In this case, the nonstandard conditions consist of a higher Cu<sup>2+</sup> concentration ([Cu<sup>2+</sup>] > 1 M) at the cathode and a lower Zn<sup>2+</sup> concentration at the anode ([Zn<sup>2+</sup>] < 1 M). According to Le Châtelier's principle, the forward reaction has a greater tendency to occur, resulting in a greater overall cell potential than the cell potential under standard conditions.

where  $R$  is the gas constant (8.314 J/mol · K),  $T$  is the temperature in kelvins, and  $Q$  is the reaction quotient corresponding to the nonstandard conditions. Since we know the relationship between  $\Delta G$  and  $E_{\text{cell}}$  (Equation 19.3), we can substitute into Equation 19.7:

$$\begin{aligned}\Delta G &= \Delta G^{\circ} + RT \ln Q \\ -nFE_{\text{cell}} &= -nFE_{\text{cell}}^{\circ} + RT \ln Q\end{aligned}$$

We then divide each side by  $-nF$  to arrive at:

$$E_{\text{cell}} = E_{\text{cell}}^{\circ} - \frac{RT}{nF} \ln Q \quad [19.8]$$

As we have seen,  $R$  and  $F$  are constants; at  $T = 25^{\circ}\text{C}$ ,  $\frac{RT}{nF} \ln Q = \frac{0.0592 \text{ V}}{n} \log Q$ .

Substituting into Equation 19.8, we arrive at the **Nernst equation**:

$$E_{\text{cell}} = E_{\text{cell}}^{\circ} - \frac{0.0592 \text{ V}}{n} \log Q \quad [19.9]$$

where  $E_{\text{cell}}$  is the cell potential in volts,  $E_{\text{cell}}^{\circ}$  is the *standard* cell potential in volts,  $n$  is the number of moles of electrons transferred in the redox reaction, and  $Q$  is the reaction quotient. Notice that, under standard conditions,  $Q = 1$ , and (since  $\log 1 = 0$ )  $E_{\text{cell}} = E_{\text{cell}}^{\circ}$ , as expected. Example 19.8 shows how to calculate the cell potential under nonstandard conditions.

**Example 19.8** Calculating  $E_{\text{cell}}$  under Nonstandard Conditions

Determine the cell potential for an electrochemical cell based on the following two half-reactions:

**SORT** You are given the half-reactions for a redox reaction and the concentrations of the aqueous reactants and products. You are asked to find the cell potential.

**GIVEN:**  $[\text{MnO}_4^{-}] = 2.0 \text{ M}$ ;  $[\text{H}^{+}] = 1.0 \text{ M}$ ;  $[\text{Cu}^{2+}] = 0.010 \text{ M}$

**FIND:**  $E_{\text{cell}}$

**STRATEGIZE** Use the tabulated values of electrode potentials to calculate  $E_{\text{cell}}^{\circ}$ . Then use Equation 19.9 to calculate  $E_{\text{cell}}$ .

**CONCEPTUAL PLAN**

**SOLVE** Write the oxidation and reduction half-reactions, multiplying by the appropriate coefficients to cancel the electrons. Find the standard electrode potentials for each half-reaction. Find  $E_{\text{cell}}^{\circ}$ .

**SOLUTION**

**Oxidation**

**(Anode):**

**Reduction**

**(Cathode):**

$$E_{\text{cell}}^{\circ} = E_{\text{cat}}^{\circ} - E_{\text{an}}^{\circ} = 1.34 \text{ V}$$

Calculate  $E_{\text{cell}}$  from  $E_{\text{cell}}^{\circ}$ . The value of  $n$  (the number of moles of electrons) corresponds to the number of electrons (six in this case) canceled in the half-reactions. Determine  $Q$  based on the overall balanced equation and the given concentrations of the reactants and products. (Note that pure liquid water, solid  $\text{MnO}_2$ , and solid copper are omitted from the expression for  $Q$ .)

$$\begin{aligned} E_{\text{cell}} &= E_{\text{cell}}^{\circ} - \frac{0.0592 \text{ V}}{n} \log Q \\ &= E_{\text{cell}}^{\circ} - \frac{0.0592 \text{ V}}{n} \log \frac{[\text{Cu}^{2+}]^3}{[\text{MnO}_4^{-}]^2 [\text{H}^{+}]^8} \\ &= 1.34 \text{ V} - \frac{0.0592 \text{ V}}{6} \log \frac{(0.010)^3}{(2.0)^2 (1.0)^8} \\ &= 1.34 \text{ V} - (-0.065 \text{ V}) \\ &= 1.41 \text{ V} \end{aligned}$$

**CHECK** The answer has the correct units (V). The value of  $E_{\text{cell}}$  is larger than  $E_{\text{cell}}^{\circ}$ , as expected based on Le Châtelier's principle because one of the aqueous reactants has a concentration greater than standard conditions and the one aqueous product has a concentration less than standard conditions. Therefore, the reaction has a greater tendency to proceed toward products and a greater cell potential.

**FOR PRACTICE 19.8** Determine the cell potential of an electrochemical cell based on the following two half-reactions:

From Equation 19.9, we can conclude the following:

- When a redox reaction within a voltaic cell occurs under standard conditions,  $Q = 1$ ; therefore,  $E_{\text{cell}} = E_{\text{cell}}^{\circ}$ .

$$\begin{aligned} E_{\text{cell}} &= E_{\text{cell}}^{\circ} - \frac{0.0592 \text{ V}}{n} \log Q \\ &= E_{\text{cell}}^{\circ} - \frac{0.0592 \text{ V}}{n} \log 1 \quad \log 1 = 0 \\ &= E_{\text{cell}}^{\circ} \end{aligned}$$

- When a redox reaction within a voltaic cell occurs under conditions in which  $Q < 1$ , the greater concentration of reactants relative to products drives the reaction to the right, resulting in  $E_{\text{cell}} > E_{\text{cell}}^{\circ}$ .
- When a redox reaction within an electrochemical cell occurs under conditions in which  $Q > 1$ , the greater concentration of products relative to reactants drives the reaction to the left, resulting in  $E_{\text{cell}} < E_{\text{cell}}^{\circ}$ .
- When a redox reaction reaches equilibrium,  $Q = K$ . The redox reaction has no tendency to occur in either direction and  $E_{\text{cell}} = 0$ :

$$\begin{aligned} E_{\text{cell}} &= E_{\text{cell}}^{\circ} - \frac{0.0592 \text{ V}}{n} \log Q \quad E_{\text{cell}}^{\circ} \text{ (see Equation 19.6)} \\ &= E_{\text{cell}}^{\circ} - \frac{0.0592 \text{ V}}{n} \log K \\ &= E_{\text{cell}}^{\circ} - E_{\text{cell}}^{\circ} \\ &= 0 \end{aligned}$$

This last point explains why batteries do not last forever—as the reactants are depleted, the reaction proceeds toward equilibrium and the potential tends toward zero.

## CONCEPTUAL CONNECTION 19.7

**Relating  $Q$ ,  $K$ ,  $E_{\text{cell}}$ , and  $E_{\text{cell}}^{\circ}$**  In an electrochemical cell,  $Q = 0.0010$  and  $K = 0.10$ . What can you conclude about  $E_{\text{cell}}$  and  $E_{\text{cell}}^{\circ}$ ?

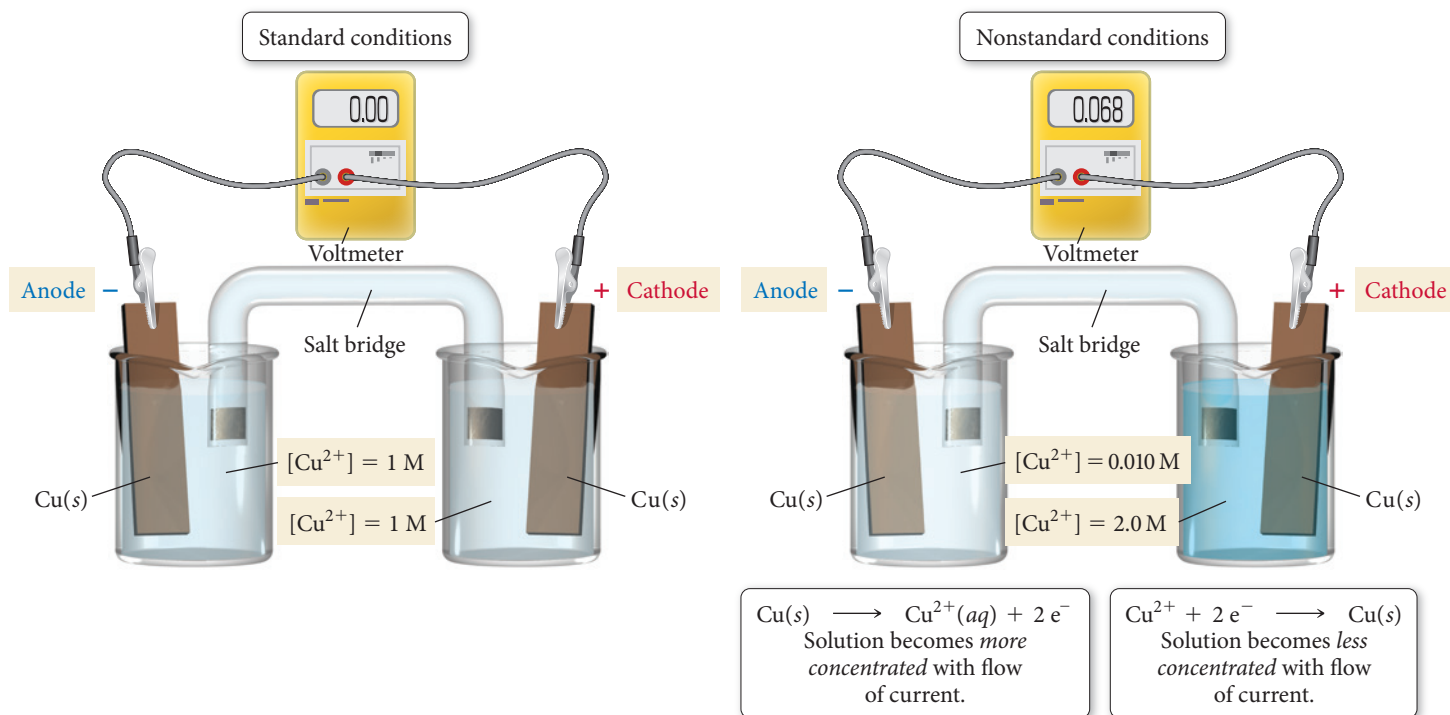

- $E_{\text{cell}}$  is positive and  $E_{\text{cell}}^{\circ}$  is negative.
- $E_{\text{cell}}$  is negative and  $E_{\text{cell}}^{\circ}$  is positive.
- Both  $E_{\text{cell}}$  and  $E_{\text{cell}}^{\circ}$  are positive.
- Both  $E_{\text{cell}}$  and  $E_{\text{cell}}^{\circ}$  are negative.

## Concentration Cells

Since cell potential depends not only on the half-reactions occurring in the cell, but also on the *concentrations* of the reactants and products in those half-reactions, we can construct a voltaic cell in which both half-reactions are the same, but in which *a difference in concentration drives the current flow*. For example, consider the electrochemical cell shown in Figure 19.12, in which copper is oxidized at the anode and copper ions are reduced at the cathode. The second part of Figure 19.12 depicts this cell under nonstandard conditions, with  $[\text{Cu}^{2+}] = 2.0 \text{ M}$  in one half-cell and  $[\text{Cu}^{2+}] = 0.010 \text{ M}$  in the other:

## A Concentration Cell

**▲ FIGURE 19.12  $\text{Cu}/\text{Cu}^{2+}$  Concentration Cell** If two half-cells have the same  $\text{Cu}^{2+}$  concentration, the cell potential is zero. If one half-cell has a greater  $\text{Cu}^{2+}$  concentration than the other, a spontaneous reaction occurs. In the reaction,  $\text{Cu}^{2+}$  ions in the more concentrated cell are reduced (to solid copper), while  $\text{Cu}^{2+}$  ions in the more dilute cell are formed (from solid copper). The concentration of copper ions in the two half-cells tends toward equality.

The half-reactions are identical, and the *standard* cell potential is therefore zero:

Because of the different concentrations in the two half-cells, the cell potential must be calculated using the Nernst equation:

$$\begin{aligned} E_{\text{cell}} &= E_{\text{cell}}^\circ - \frac{0.0592 \text{ V}}{2} \log \frac{0.010}{2.0} \\ &= 0.000 \text{ V} + 0.068 \text{ V} \\ &= 0.068 \text{ V} \end{aligned}$$

The cell produces a potential of 0.068 V. *Electrons spontaneously flow from the half-cell with the lower copper ion concentration to the half-cell with the higher copper ion concentration.* We can imagine a concentration cell in the same way we think about any concentration gradient. If we mix a concentrated solution of  $\text{Cu}^{2+}$  with a dilute solution, the  $\text{Cu}^{2+}$  ions flow from the concentrated solution to the dilute one. Similarly, in a concentration cell, the transfer of electrons *from* the dilute half-cell results in the formation of  $\text{Cu}^{2+}$  ions in the dilute half-cell. The electrons flow to the concentrated cell, where they react with  $\text{Cu}^{2+}$  ions and reduce them to  $\text{Cu(s)}$ . Therefore, *the flow of electrons has the effect of increasing the concentration of  $\text{Cu}^{2+}$  in the dilute cell and decreasing the concentration of  $\text{Cu}^{2+}$  in the concentrated half-cell.*

## Chemistry AND Medicine

## Concentration Cells in Human Nerve Cells

Recall from Section 8.1 that tiny pumps in the membranes of human nerve cells pump ions—especially sodium ( $\text{Na}^+$ ) and potassium ( $\text{K}^+$ )—through those membranes, establishing a concentration gradient for each type of ion. The concentration of sodium ions is higher outside the cell than within, while exactly the opposite is true for potassium ions. These concentration gradients result in an electrical potential across the cell membrane, called the resting potential, of about  $-70$  mV. (The interior of the cell is negative with respect to the exterior.)

When the nerve cell is stimulated, certain channels in the membrane open, allowing  $\text{Na}^+$  ions to rush into the cell and causing the potential to temporarily rise to about  $+30$  mV (Figure 19.13 ▼). Other channels that allow  $\text{K}^+$  ions to rush

▲ FIGURE 19.13 Concentration Changes in Nerve Cells

out of the cell open in turn, bringing the potential back down to near its resting potential. The result is a spike in the electrochemical potential across the membrane, which provides

▲ FIGURE 19.14 Potential Changes across the Nerve Cell Membrane The changes in ion concentrations that take place when a nerve cell is stimulated result in a spike in the electrochemical potential across the membrane.

the stimulus for a similar spike in the neighboring segment of the membrane (Figure 19.14 ▲). In this way, an electrical signal moves down the length of a nerve cell.

When the electrical signal reaches the end of the nerve cell, it triggers the release of a chemical neurotransmitter, which travels to the neighboring nerve cell and stimulates the same kind of electrochemical spike. In this way, neural signals travel throughout the brain and nervous system.

## 19.7 Batteries: Using Chemistry to Generate Electricity

We have seen that we can combine the electron-losing tendency of one substance with the electron-gaining tendency of another to create electrical current in a voltaic cell. Batteries are voltaic cells conveniently packaged to act as portable sources of electricity. The actual oxidation and reduction reactions vary depending on the particular type of battery. In this section, we examine several different types.

### Dry-Cell Batteries

Common batteries, such as the kind in a flashlight, are called **dry-cell batteries** because they do not contain large amounts of liquid water. There are several familiar types of dry-cell batteries. The most inexpensive are composed of a zinc case that acts as the anode (Figure 19.15(a) ►). The zinc is oxidized according to the reaction:

The cathode is a carbon rod immersed in a moist paste of  $\text{MnO}_2$  that also contains  $\text{NH}_4\text{Cl}$ . The  $\text{MnO}_2$  is reduced to  $\text{Mn}_2\text{O}_3$  according to the reaction:

These two half-reactions produce a voltage of about 1.5 V. Two or more of these batteries can be connected in series (cathode-to-anode connection) to produce higher voltages.

The more common **alkaline batteries** (Figure 19.15(b)▶) employ slightly different half-reactions in a basic medium (therefore the name alkaline). In an alkaline battery, the zinc is oxidized in a basic environment:

Alkaline batteries have a longer working life and a longer shelf life than their nonalkaline counterparts.

## Lead–Acid Storage Batteries

The batteries in most automobiles are **lead–acid storage batteries**. These batteries consist of six electrochemical cells wired in series (Figure 19.16▶). Each cell produces 2 V for a total of 12 V. Each cell contains a porous lead anode where oxidation occurs and a lead(IV) oxide cathode where reduction occurs according to the reactions:

Both the anode and the cathode are immersed in sulfuric acid ( $\text{H}_2\text{SO}_4$ ). As electrical current is drawn from the battery, both electrodes become coated with  $\text{PbSO}_4(\text{s})$ . If the battery is run for a long time without recharging, too much  $\text{PbSO}_4(\text{s})$  develops on the surface of the electrodes and the battery goes dead. The lead–acid storage battery can be recharged by an electrical current (which must come from an external source such as an alternator in a car). The current causes the preceding reaction to occur in reverse, converting the  $\text{PbSO}_4(\text{s})$  back to  $\text{Pb}(\text{s})$  and  $\text{PbO}_2(\text{s})$ .

▲ **FIGURE 19.16 Lead–Acid Storage Battery** A lead–acid storage battery consists of six cells wired in series. Each cell contains a porous lead anode and a lead oxide cathode, both immersed in sulfuric acid.

▲ **FIGURE 19.15 Dry-Cell Battery**

(a) In a common dry-cell battery, the zinc case acts as the anode and a graphite rod immersed in a moist, slightly acidic paste of  $\text{MnO}_2$  and  $\text{NH}_4\text{Cl}$  acts as the cathode.

(b) Longer-lived alkaline batteries employ a graphite cathode immersed in a paste of  $\text{MnO}_2$  and a base.

## Other Rechargeable Batteries

The ubiquity of power electronic products such as laptops and smartphones, as well as the growth in popularity of hybrid electric vehicles, drives the need for efficient, long-lasting, rechargeable batteries. The most common types include the **nickel-cadmium (NiCad) battery**, the **nickel-metal hydride (NiMH) battery**, and the **lithium ion battery**.

### The Nickel–Cadmium (NiCad) Battery

Nickel-cadmium batteries consist of a solid cadmium anode and a  $\text{NiO}(\text{OH})(\text{s})$  cathode. The electrolyte is usually  $\text{KOH}(\text{aq})$ . During operation, the cadmium is oxidized and the  $\text{NiO}(\text{OH})$  is reduced according to the equations:

The overall reaction produces about 1.30 V. As current is drawn from the NiCad battery, solid cadmium hydroxide accumulates on the anode and solid nickel(II) hydroxide accumulates on the cathode. But if current is run in the opposite direction, the reactants can be regenerated from the products. A common problem in recharging NiCad and other rechargeable batteries is knowing when to stop. Once all of the products of the reaction are converted back to reactants, the charging process should ideally terminate. If charging does not stop, the electrical current drives other, usually unwanted, reactions such as the electrolysis of water to form hydrogen and oxygen gas. These reactions typically damage the battery and may sometimes even cause an explosion. Consequently, most commercial battery chargers have sensors that measure when the charging is complete. These sensors rely on the small changes in voltage or increases in temperature that occur once the products have all been converted back to reactants.

### The Nickel–Metal Hydride (NiMH) Battery

Although NiCad batteries were the standard rechargeable battery for many years, they are being replaced by other types of rechargeable batteries, in part because of the toxicity of cadmium and the resulting disposal problems. One of these replacements is the nickel-metal hydride or NiMH battery. The NiMH battery employs the same cathode reaction as the NiCad battery, but it employs a different anode reaction. In the anode of a NiMH battery, hydrogen atoms held in a metal alloy are oxidized. If we let M represent the metal alloy, we can write the half-reactions as follows:

In addition to being more environmentally friendly than NiCad batteries, NiMH batteries also have a greater energy density (energy content per unit battery mass), as we can see in Table 19.2. In some cases, a NiMH battery can carry twice the energy of a NiCad battery of the same mass, making NiMH batteries the most common choice for hybrid electric vehicles.

### The Lithium Ion Battery

The newest and most expensive common type of rechargeable battery is the lithium ion battery. Since lithium is the least dense metal ( $0.53 \text{ g/cm}^3$ ), lithium batteries have high-energy densities (see Table 19.2). The lithium battery works differently than the other batteries we have examined so far, and the details of its operation are beyond the scope of

▲ Several types of batteries, including NiCad, NiMH, and lithium ion batteries, are recharged by chargers that use household current.

**TABLE 19.2** Energy Density and Overcharge Tolerance of Several Rechargeable Batteries

Battery Type	Energy Density ( $\text{W} \cdot \text{h/kg}$ )	Overcharge Tolerance
NiCad	45–80	Moderate
NiMH	60–120	Low
Li ion	110–160	Low
Pb storage	30–50	High

our current discussion. Briefly, we can describe operation of the lithium battery as being due primarily to the motion of lithium ions from the anode to the cathode. The anode is composed of graphite into which lithium ions are incorporated between layers of carbon atoms. Upon discharge, the lithium ions spontaneously migrate to the cathode, which consists of a lithium transition metal oxide such as  $\text{LiCoO}_2$  or  $\text{LiMn}_2\text{O}_4$ . The transition metal is reduced during this process. Upon recharging, the transition metal is oxidized, forcing the lithium to migrate back into the graphite (Figure 19.17▶). The flow of lithium ions from the anode to the cathode causes a corresponding flow of electrons in the external circuit. Lithium ion batteries are commonly used in applications where light weight and high-energy density are important. These include smartphones, laptop computers, and digital cameras.

## Fuel Cells

We discussed the potential for *fuel cells* in the opening section of this chapter. Fuel cells may one day replace—or at least work in combination with—centralized power grid electricity. In addition, vehicles powered by fuel cells may one day usurp vehicles powered by internal combustion engines. Fuel cells are like batteries; the key difference is that a battery is self-contained, while in a fuel cell the reactants need to be constantly replenished from an external source. With use, normal batteries lose their ability to generate voltage because the reactants become depleted as electrical current is drawn from the battery. In a **fuel cell**, the reactants—the fuel provided from an external source—constantly flow through the battery, generating electrical current as they undergo a redox reaction.

The most common fuel cell is the hydrogen–oxygen fuel cell (Figure 19.18▼). In this cell, hydrogen gas flows past the anode (a screen coated with platinum catalyst) and undergoes oxidation:

▲ **FIGURE 19.17** Lithium Ion

**Battery** In the lithium ion battery, the spontaneous flow of lithium ions from the graphite anode to the lithium transition metal oxide cathode causes a corresponding flow of electrons in the external circuit.

◀ **FIGURE 19.18** Hydrogen–Oxygen Fuel Cell In this fuel cell, hydrogen and oxygen combine to form water.

## Chemistry IN YOUR DAY The Fuel-Cell Breathalyzer

Police use a device called a breathalyzer to measure the amount of ethyl alcohol ( $\text{CH}_3\text{CH}_2\text{OH}$ ) in the bloodstream of a person suspected of driving under the influence of alcohol (Figure 19.19). Breathalyzers work because the quantity of ethyl alcohol in the breath is proportional to the quantity of ethyl alcohol in the bloodstream. One type of breathalyzer employs a fuel cell to measure the quantity of alcohol in the breath. When a suspect blows into the breathalyzer, ethyl alcohol is oxidized to acetic acid at the anode:

At the cathode, oxygen is reduced:

The overall reaction is the oxidation of ethyl alcohol to acetic acid and water:

The magnitude of electrical current produced depends on the quantity of alcohol in the breath. A higher current results from a higher blood alcohol level. When calibrated correctly, the fuel-cell breathalyzer can precisely measure the blood alcohol level of a suspected drunk driver.

**▲ FIGURE 19.19 Fuel-Cell Breathalyzer** The fuel-cell breathalyzer works by oxidizing ethyl alcohol in the breath to acetic acid. The electrical current that is produced is proportional to the concentration of ethyl alcohol in the breath.

Oxygen gas flows past the cathode (a similar screen) and undergoes reduction:

The half-reactions sum to the following overall reaction:

Notice that the only product is water. In the space shuttle program, hydrogen–oxygen fuel cells consume hydrogen to provide electricity and astronauts drink the water that is produced by the reaction. In order for hydrogen-powered fuel cells to become more widely used, a more readily available source of hydrogen must be developed.

## 19.8 Electrolysis: Driving Nonspontaneous Chemical Reactions with Electricity

In a voltaic cell, a spontaneous redox reaction produces electrical current. In an *electrolytic cell*, electrical current drives an otherwise nonspontaneous redox reaction through a process called **electrolysis**. We have seen that the reaction of hydrogen with

## Electrolysis of Water

◀ **FIGURE 19.20** Electrolysis of Water

Electrical current can decompose water into hydrogen and oxygen gas.

oxygen to form water is spontaneous and can be used to produce an electrical current in a fuel cell. Conversely, by *supplying* electrical current, we can cause the reverse reaction to occur, separating water into hydrogen and oxygen (Figure 19.20▲):

(spontaneous—produces electrical current; occurs in a voltaic cell)

(nonspontaneous—consumes electrical current; occurs in an electrolytic cell)

Recall from Section 19.7 that one of the problems associated with the widespread adoption of hydrogen fuel cells is the scarcity of hydrogen. Where will the hydrogen to power these fuel cells come from? One possible solution is to obtain hydrogen from water through solar-powered electrolysis. A solar-powered electrolytic cell can produce hydrogen from water when the sun is shining. The hydrogen made in this way could be converted back to water to generate electricity and could also be used to power fuel-cell vehicles.

Electrolysis also has numerous other applications. For example, most metals are found in Earth's crust as metal oxides. Converting an oxide to a pure metal requires that the metal be reduced, a nonspontaneous process. Electrolysis can be used to produce these metals. Thus, sodium is produced by the electrolysis of molten sodium chloride (discussed in the following subsection).

Electrolysis is also used to plate metals onto other metals. For example, silver can be plated onto a less expensive metal using the electrolytic cell shown in Figure 19.21▶. In this cell, a silver electrode is placed in a solution containing silver ions. An electrical current causes the oxidation of silver at the anode (replenishing the silver ions in solution) and the reduction of silver ions at the cathode (coating the less expensive metal with solid silver):

▼ **FIGURE 19.21** Silver Plating

Silver can be plated from a solution of silver ions onto metallic objects in an electrolytic cell.

## Electrolytic Cell for Silver Plating

**▲ FIGURE 19.22 Voltaic versus Electrolytic Cells** In a Zn/Cu<sup>2+</sup> voltaic cell, the reaction proceeds in the spontaneous direction. In a Zn<sup>2+</sup>/Cu electrolytic cell, electrical current drives the reaction in the nonspontaneous direction.

Since the standard cell potential of the reaction is zero, the reaction is not spontaneous under standard conditions. An external power source can be used to drive current flow and cause the reaction to occur.

The voltage required to cause electrolysis depends on the specific half-reactions. For example, we have seen that the oxidation of zinc and the reduction of Cu<sup>2+</sup> produce a voltage of 1.10 V under standard conditions:

If a power source producing *more than 1.10 V* is inserted into the Zn/Cu<sup>2+</sup> voltaic cell, electrons can be forced to flow in the opposite direction, causing the reduction of Zn<sup>2+</sup> and the oxidation of Cu, as shown in Figure 19.22▲. Notice that in the electrolytic cell, the anode has become the cathode (oxidation always occurs at the anode) and the cathode has become the anode.

In a *voltaic cell*, the anode is the source of electrons and is therefore labeled with a negative charge. The cathode draws electrons and is therefore labeled with a positive charge. In an *electrolytic cell*, however, the source of the electrons is the external power source. The external power source must *draw electrons away* from the anode; thus, the anode must be connected to the positive terminal of the battery (as shown in Figure 19.22). Similarly, the power source drives electrons toward the cathode (where they are used in reduction), so the cathode must be connected to the *negative* terminal of the battery. The charge labels (+ and -) on an electrolytic cell are opposite of what they are in a voltaic cell.

#### Summarizing Characteristics of Electrochemical Cell Types:

##### In all electrochemical cells:

- ▶ Oxidation occurs at the anode.
- ▶ Reduction occurs at the cathode.

##### In voltaic cells:

- ▶ The anode is the source of electrons and has a negative charge (anode -).
- ▶ The cathode draws electrons and has a positive charge (cathode +).

**In electrolytic cells:**

- ▶ Electrons are drawn away from the anode, which must be connected to the positive terminal of the external power source (anode +).
- ▶ Electrons are forced to the cathode, which must be connected to the negative terminal of the power source (cathode –).

**Predicting the Products of Electrolysis**

Predicting the products of an electrolysis reaction is in some cases relatively straightforward and in other cases more complex. We cover the simpler cases first and follow with the more complex ones.

**Pure Molten Salts**

Consider the electrolysis of a molten salt such as sodium chloride, shown in Figure 19.23.  $\text{Na}^+$  and  $\text{Cl}^-$  are the only species present in the cell. The chloride ion cannot be further reduced ( $-1$  is its lowest oxidation state), so it must be oxidized. The sodium ion cannot be further oxidized ( $+1$  is its highest oxidation state), so it must be reduced. Thus, we can write the half-reactions:

Although the reaction as written is not spontaneous, it can be driven to occur in an electrolytic cell by an external power source.

We can generalize as follows:

- In the electrolysis of a pure molten salt, the anion is oxidized and the cation is reduced.

**Mixtures of Cations or Anions**

What if a molten salt contains more than one anion or cation? For example, suppose our electrolysis cell contains both  $\text{NaCl}$  and  $\text{KCl}$ . Which of the two cations is reduced at the cathode? In order to answer this question, we must determine which of the two cations is more easily reduced.

Although the values of electrode potentials for aqueous solutions given in Table 19.1 do not apply to molten salts, the relative ordering of the electrode potentials does reflect the relative ease with which the metal cations are reduced. We can see from the table that the reduction of  $\text{Na}^+$  is listed *above* the reduction of  $\text{K}^+$ ; that is,  $\text{Na}^+$  has a more positive electrode potential:

Therefore,  $\text{Na}^+$  is easier to reduce than  $\text{K}^+$ . Consequently, in a mixture of  $\text{NaCl}$  and  $\text{KCl}$ ,  $\text{Na}^+$  has a greater tendency to be reduced at the cathode.

Similarly, what if a mixture of molten salts contained more than one anion? For example, in a mixture of  $\text{NaBr}$  and  $\text{NaCl}$ , which of the two anions is oxidized at the cathode? The answer is similar: the anion that is more easily oxidized (the one with the more negative electrode potential):

Since the electrode potential for the bromine half-reaction is more negative, electrons are more easily extracted from it. The bromide ion is therefore oxidized at the anode.

We can generalize as follows:

- The cation that is most easily reduced (the one with the more positive electrode potential) is reduced first.
- The anion that is most easily oxidized (the one with the more negative electrode potential) is oxidized first.

**Electrolysis of a Molten Salt**

**▲ FIGURE 19.23 Electrolysis of Molten NaCl** In the electrolysis of a pure molten salt, the anion (in this case  $\text{Cl}^-$ ) is oxidized and the cation (in this case  $\text{Na}^+$ ) is reduced.

Throughout this discussion, “more positive” means the same thing as “less negative.”

Throughout this discussion, “more negative” means the same thing as “less positive.”

Remember NIO and PIR:

**N.I.O.**—More **N**egative **I**s **O**xidation

**P.I.R.**—More **P**ositive **I**s **R**eduction

### Aqueous Solutions

Electrolysis in an aqueous solution is complicated by the possibility of the electrolysis of water itself. Recall that water can be either oxidized or reduced according to the following half-reactions:

$$E = 0.82 \text{ V} ([\text{H}^+] = 10^{-7} \text{ M})$$

$$E = -0.41 \text{ V} ([\text{OH}^-] = 10^{-7} \text{ M})$$

▲ Pure water is a poor conductor of electrical current, but the addition of an electrolyte allows electrolysis to take place, producing hydrogen and oxygen gas in a stoichiometric ratio.

The electrode potentials under standard conditions are shown to the right of each half-reaction. However, in pure water at room temperature, the concentrations of  $\text{H}^+$  and  $\text{OH}^-$  are not standard. The electrode potentials for  $[\text{H}^+] = 10^{-7} \text{ M}$  and  $[\text{OH}^-] = 10^{-7} \text{ M}$  are shown in blue. Using those electrode potentials, we can calculate  $E_{\text{cell}}$  for the electrolysis of water as follows:

$$E_{\text{cell}} = E_{\text{cat}} - E_{\text{an}} = -0.41 \text{ V} - 0.82 \text{ V} = -1.23 \text{ V}$$

When a battery with a potential of several volts is connected to an electrolysis cell containing pure water, no reaction occurs because the concentration of ions in pure water is too low to conduct any significant electrical current. When an electrolyte such as  $\text{Na}_2\text{SO}_4$  is added to the water, however, electrolysis occurs readily.

In any aqueous solution in which electrolysis is to take place, the electrolysis of water is also possible. For example, consider the electrolysis of a sodium iodide solution, as shown in Figure 19.24 ▼. For the electrolysis of *molten*  $\text{NaI}$ , we can readily predict that  $\text{I}^-$  is oxidized at the anode and that  $\text{Na}^+$  is reduced at the cathode. In an aqueous solution, however, two different oxidation half-reactions are possible at the anode, the oxidation of  $\text{I}^-$  and the oxidation of water:

Similarly, two different reduction half-reactions are possible at the cathode, the reduction of  $\text{Na}^+$  and the reduction of water:

How do we know which reactions actually occur? In both cases, the answer is the same: *the half-reaction that occurs more easily*. For oxidation, the half-reaction with the more negative electrode potential is the easier one from which to extract electrons. In this case, therefore, the iodide ion is oxidized at the anode. For reduction, the half-reaction with the more positive electrode potential is the one that accepts electrons more easily. In this case, therefore, water is reduced at the cathode. Notice that  $\text{Na}^+$  cannot be reduced in an aqueous solution—water is reduced before  $\text{Na}^+$ .

We can make the following generalization:

- The cations of active metals—those that are not easily reduced, such as  $\text{Li}^+$ ,  $\text{K}^+$ ,  $\text{Na}^+$ ,  $\text{Mg}^{2+}$ ,  $\text{Ca}^{2+}$ , and  $\text{Al}^{3+}$ —cannot be reduced from aqueous solutions by electrolysis because water is reduced at a lower voltage.

### Electrolysis of an Aqueous Salt Solution

▲ **FIGURE 19.24** Electrolysis of Aqueous  $\text{NaI}$   
 In this cell,  $\text{I}^-$  is oxidized to  $\text{I}_2$  at the anode and  $\text{H}_2\text{O}$  is reduced to  $\text{H}_2$  at the cathode. Sodium ions are not reduced because their electrode potential is more negative than the electrode potential of water.

### The Electrolysis of Aqueous Sodium Chloride and Overvoltage

An additional complication that we must consider when predicting the products of electrolysis is *overvoltage*—an additional voltage that must be applied in order to make some nonspontaneous reactions occur.

We can demonstrate this concept by considering the electrolysis of a sodium chloride solution, shown in Figure 19.25. In order to predict the product of the electrolysis, we consider the two possible oxidation half-reactions:

and the two possible reduction half-reactions:

Since the oxidation of water has a more negative electrode potential than the oxidation of  $\text{Cl}^-$ , we would initially predict that it would be easier to remove electrons from water, and thus water should be oxidized at the anode. Similarly, since the reduction of water has a more positive electrode potential than the reduction of  $\text{Na}^+$ , we would expect that it would be easier to get water to accept electrons, so water should be reduced at the cathode. In other words, we initially predict that a sodium chloride solution would simply result in the electrolysis of water, producing oxygen gas at the anode and hydrogen gas at the cathode. If we construct such a cell, however, we find that, although hydrogen gas is indeed formed at the cathode (as predicted), oxygen gas is *not* formed at the anode—chlorine gas is formed instead. Why? The answer is that even though the electrode potential for the oxidation of water is 0.82 V, the reaction actually requires a voltage greater than 0.82 V in order to occur. (The reasons for this behavior are related to kinetic factors that are beyond the scope of our current discussion.) This additional voltage, the *overvoltage*, increases the voltage required for the oxidation of water to about 1.4 V. The result is that the chloride ion oxidizes more easily than water and  $\text{Cl}_2(\text{g})$  is observed at the anode.

**▲ FIGURE 19.25 Electrolysis of Aqueous NaCl: The Effect of Overvoltage** Because of overvoltage, the anode reaction of this cell is the oxidation of  $\text{Cl}^-$  to  $\text{Cl}_2$  gas rather than the oxidation of water to  $\text{H}^+$  and  $\text{O}_2$  gas.

### Example 19.9 Predicting the Products of Electrolysis Reactions

Predict the half-reaction occurring at the anode and the half-reaction occurring at the cathode for electrolysis for each reaction.

- (a) a mixture of molten  $\text{AlBr}_3$  and  $\text{MgBr}_2$   
 (b) an aqueous solution of  $\text{LiI}$

#### SOLUTION

- (a) In the electrolysis of a molten salt, the anion is oxidized and the cation is reduced. However, this mixture contains two cations. Start by writing the possible oxidation and reduction half-reactions that might occur. Because  $\text{Br}^-$  is the only anion, write the equation for its oxidation, which occurs at the anode. At the cathode, both the reduction of  $\text{Al}^{3+}$  and the reduction of  $\text{Mg}^{2+}$  are possible. The one that actually occurs is the one that occurs more easily. Since the reduction of  $\text{Al}^{3+}$  has a more positive electrode potential in aqueous solution, this ion is more easily reduced. Therefore, the reduction of  $\text{Al}^{3+}$  occurs at the cathode.

Reduction that actually occurs (more positive potential)

—Continued on the next page

Continued—

- (b) Since LiI is in an aqueous solution, two different oxidation half-reactions are possible at the anode, the oxidation of  $\text{I}^-$  and the oxidation of water. Write half-reactions for each including the electrode potential. Remember to use the electrode potential of water under conditions in which  $[\text{H}^+] = 10^{-7} \text{ M}$ . Since the oxidation of  $\text{I}^-$  has the more negative electrode potential, it is the half-reaction to occur at the anode. Similarly, write half-reactions for the two possible reduction half-reactions that might occur at the cathode, the reduction of  $\text{Li}^+$  and the reduction of water. Since the reduction of water has the more positive electrode potential (even when considering overvoltage, which would raise the necessary voltage by about 0.4–0.6 V), it is the half-reaction to occur at the cathode.

Oxidation that actually occurs  
(more negative potential)

**Oxidation:**

**Oxidation:**

**Reduction:**

Reduction that actually occurs  
(more positive potential)

**FOR PRACTICE 19.9** Predict the half-reactions occurring at the anode and the cathode for the electrolysis of aqueous  $\text{Na}_2\text{SO}_4$ .

## Stoichiometry of Electrolysis

**▲ FIGURE 19.26 Electrolytic Cell for Copper Plating** In this cell, copper ions are plated onto other metals. It takes two moles of electrons to plate one mole of copper atoms.

In an electrolytic cell, electrical current is used to drive a particular chemical reaction. In a sense, the electrons act as a reactant, and therefore, have a stoichiometric relationship with the other reactants and products. Unlike ordinary reactants, for which we usually measure quantity as mass, for electrons we measure quantity as charge.

For example, consider an electrolytic cell used to coat copper onto metals, as shown in Figure 19.26. The half-reaction by which copper is deposited onto the metal is:

For every 2 mol of electrons that flow through the cell, 1 mol of solid copper is plated. We can write the stoichiometric relationship:

We can determine the number of moles of electrons that have flowed in a given electrolysis cell by measuring the total charge that has flowed through the cell, which in turn depends on the *magnitude* of the current and on the *time* that the current runs. Recall from Section 19.3 that the unit of current is the ampere:

$$1 \text{ A} = 1 \frac{\text{C}}{\text{s}}$$

If we multiply the amount of current (in A) flowing through the cell by the time (in s) that the current flowed, we find the total charge that passed through the cell in that time:

$$\text{Current} \left( \frac{\text{C}}{\text{s}} \right) \times \text{time} (\text{s}) = \text{charge} (\text{C})$$

The relationship between charge and the number of moles of electrons is given by Faraday's constant, which, as we saw previously, corresponds to the charge in coulombs of 1 mol of electrons:

$$F = \frac{96,485 \text{ C}}{\text{mol e}^-}$$

These relationships can be used to solve problems involving the stoichiometry of electrolytic cells, as demonstrated in Example 19.10.

**Example 19.10** Stoichiometry of Electrolysis

Gold can be plated out of a solution containing  $\text{Au}^{3+}$  according to the half-reaction:

What mass of gold (in grams) is plated by a 25-minute flow of 5.5 A current?

**SORT** You are given the half-reaction for the plating of gold, which shows the stoichiometric relationship between moles of electrons and moles of gold. You are also given the current and duration. You must find the mass of gold that will be deposited in that time.

**GIVEN:** 3 mol  $\text{e}^{-}$  : 1 mol Au  
5.5 amps  
25 min

**FIND:** g Au

**STRATEGIZE** You need to find the amount of gold, which is related stoichiometrically to the number of electrons that have flowed through the cell. Begin with time in minutes and convert to seconds. Then, because current is a measure of charge per unit time, use the given current and the time to find the number of coulombs. Use Faraday's constant to calculate the number of moles of electrons and the stoichiometry of the reaction to find the number of moles of gold. Finally, use the molar mass of gold to convert to mass of gold.

**CONCEPTUAL PLAN**

**SOLVE** Follow the conceptual plan to solve the problem, canceling units to arrive at the mass of gold.

**SOLUTION**

$$25 \text{ min} \times \frac{60 \text{ s}}{1 \text{ min}} \times \frac{5.5 \text{ C}}{1 \text{ s}} \times \frac{1 \text{ mol e}^{-}}{96,485 \text{ C}} \times \frac{1 \text{ mol Au}}{3 \text{ mol e}^{-}} \times \frac{196.97 \text{ g Au}}{1 \text{ mol Au}} = 5.6 \text{ g Au}$$

**CHECK** The answer has the correct units (g Au). The magnitude of the answer is reasonable if you consider that 10 amps of current for 1 hour is the equivalent of about 1/3 mol of electrons (check for yourself), which would produce 1/9 mol (or about 20 g) of gold.

**FOR PRACTICE 19.10** Silver can be plated out of a solution containing  $\text{Ag}^{+}$  according to the half-reaction:

How much time (in minutes) does it take to plate 12 g of silver using a current of 3.0 A?

**19.9 Corrosion: Undesirable Redox Reactions**

**Corrosion** is the (usually) gradual, nearly always undesired, oxidation of metals that are exposed to oxidizing agents in the environment. From Table 19.1, we can see that the reduction of oxygen in the presence of water has an electrode potential of +0.40 V:

In the presence of acid, the reduction of oxygen has an even more positive electrode potential of +1.23 V:

The reduction of oxygen, therefore, has a strong tendency to occur and can bring about the oxidation of other substances, especially metals. Notice that the half-reactions for the reduction of most metal ions are listed *below* the half-reactions for the reduction of oxygen in Table 19.1. Consequently, the oxidation (or corrosion) of those metals is spontaneous when paired with the reduction of oxygen. Corrosion is the opposite of the process by which metals are extracted from their ores. In extraction, the free metal is reduced out from its ore. In corrosion, the metal is oxidized.

▲ A metal must usually be reduced to extract it from its ore. In corrosion, the metal is oxidized back to its more natural state.

▲ Aluminum is stable because its oxide forms a protective film over the underlying metal, preventing further oxidation.

▼ **FIGURE 19.27 Corrosion of Iron: Rusting** The oxidation of iron occurs at anodic regions on the metal surface. The iron ions migrate to cathodic regions, where they react with oxygen and water to form rust.

## Corrosion of Iron

Given the ease with which metals oxidize in the presence of oxygen, acid, and water, why are metals used so frequently as building materials in the first place? Many metals form oxides that coat the surface of the metal and prevent further corrosion. For example, bare aluminum metal, with an electrode potential of  $-1.66\text{ V}$ , is quickly oxidized in the presence of oxygen. However, the oxide that forms at the surface of aluminum is  $\text{Al}_2\text{O}_3$ . In its crystalline form,  $\text{Al}_2\text{O}_3$  is sapphire, a highly inert and structurally solid substance. The  $\text{Al}_2\text{O}_3$  coating acts to protect the underlying aluminum metal, preventing further corrosion.

The oxides of iron, in contrast, are not structurally stable, and they tend to flake away from the underlying metal, exposing it to further corrosion. A significant part of the iron produced each year is used to replace rusted iron. Rusting is a redox reaction in which iron is oxidized according to the following half-reaction:

This oxidation reaction tends to occur at defects on the surface of the iron—known as *anodic regions* because oxidation is occurring at these locations—as shown in Figure 19.27▼. The electrons produced at the anodic region travel through the metal to areas called *cathodic regions* where they react with oxygen and  $\text{H}^+$  ions dissolved in moisture:

### The Rusting of Iron

(The  $\text{H}^+$  ions come from carbonic acid, which naturally forms in water from carbon dioxide in air.) The overall reaction has a cell potential of  $+1.68\text{ V}$  and is highly spontaneous:

The  $\text{Fe}^{2+}$  ions formed in the anodic regions can migrate through moisture on the surface of the iron to cathodic regions, where they are further oxidized by reaction with more oxygen:

Rust is a hydrated form of iron(III) oxide whose exact composition depends on the conditions under which it forms.

Consider each of the following important aspects of the formation of rust:

- *Moisture must be present for rusting to occur.* The presence of water is necessary because water is a reactant in the last reaction and because charge (either electrons or ions) must be free to flow between the anodic and cathodic regions.
- *Additional electrolytes promote rusting.* The presence of an electrolyte (such as sodium chloride) on the surface of iron promotes rusting because it enhances current flow. This is why cars rust so quickly in cold climates where roads are salted, or in coastal areas where seawater mist is present.
- *The presence of acids promotes rusting.* Because  $\text{H}^+$  ions are involved in the reduction of oxygen, lower pH enhances the cathodic reaction and leads to faster rusting.

## Preventing the Corrosion of Iron

▲ In galvanized nails, a layer of zinc prevents the underlying iron from rusting. The zinc oxidizes in place of the iron, forming a protective layer of zinc oxide.

as a sacrificial electrode does). The oxide of zinc is not crumbly and remains on the nails as a protective coating.

Preventing the rusting of iron is a major industry. The most obvious way to prevent rust is to keep iron dry. Without water, the redox reaction cannot occur. Another way to prevent rust is to coat iron with a substance that is impervious to water. Cars, for example, are painted and sealed to prevent rust. A scratch in the paint can lead to rusting of the underlying iron.

Rust can also be prevented by placing a *sacrificial electrode* in electrical contact with the iron. The sacrificial electrode must be composed of a metal that oxidizes more easily than iron (that is, it must be below iron in Table 19.1). The sacrificial electrode oxidizes in place of the iron (just as the more easily oxidizable species in a mixture is the one to oxidize), protecting the iron from oxidation. A related way to protect iron from rusting is to coat it with a metal that oxidizes more easily than iron. Galvanized nails, for example, are coated with a thin layer of zinc. Since zinc has a more negative electrode potential than iron, it will oxidize in place of the underlying iron (just

▲ A scratch in paint often allows the underlying iron to rust.

▲ If a metal more active than iron, such as magnesium or aluminum, is in electrical contact with iron, the metal rather than the iron will be oxidized. This principle underlies the use of sacrificial electrodes to prevent the corrosion of iron.

**Sacrificial Electrodes** Which of these metals does not act as a sacrificial electrode for iron?

Zn, Mg, Mn, Cu

CONCEPTUAL

## Self-Assessment Quiz

**Q1.** Balance the redox reaction equation (occurring in acidic solution) and choose the correct coefficients for each reactant and product.

- a) 2,1,4  $\longrightarrow$  2,1,2      b) 1,1,2  $\longrightarrow$  1,1,1  
c) 2,1,2  $\longrightarrow$  2,1,1      d) 2,1,2  $\longrightarrow$  2,1,2

**Q2.** Which statement is true for voltaic cells?

- a) Electrons flow from the anode to the cathode.  
b) Electrons flow from the more negatively charged electrode to the more positively charged electrode.  
c) Electrons flow from higher potential energy to lower potential energy.  
d) All of the above are true.

**Q3.** Use Table 19.1 to calculate  $E^\circ_{\text{cell}}$  for the reaction.

- a) 1.77 V      b) 2.03 V  
c) 0.82 V      d) 1.08 V

**Q4.** Use Table 19.1 to determine which statement is true of the voltaic cell pictured here.

- a) Sn is the anode; Ag is the cathode; electrons flow from left to right.  
b) Sn is the cathode; Ag is the anode; electrons flow from left to right.  
c) Sn is the anode; Ag is the cathode; electrons flow from right to left.  
d) Sn is the cathode; Ag is the anode; electrons flow from right to left.

Continued—

- Q5.** Use Table 19.1 to determine which metal *does not* dissolve in hydrochloric acid (HCl).  
a) Zn      b) Cd      c) Cu      d) Fe
- Q6.** The Zn/Zn<sup>2+</sup> electrode has a standard electrode potential of  $E^\circ = -0.76$  V. How does the relative potential energy of an electron at the Zn/Zn<sup>2+</sup> electrode compare to the potential energy of an electron at the standard hydrogen electrode?  
a) An electron at the Zn/Zn<sup>2+</sup> electrode has a higher potential energy than an electron at the standard hydrogen electrode.  
b) An electron at the Zn/Zn<sup>2+</sup> electrode has a lower potential energy than an electron at the standard hydrogen electrode.  
c) An electron at the Zn/Zn<sup>2+</sup> electrode has the same potential energy as an electron at the standard hydrogen electrode.  
d) Nothing can be concluded about the relative potential energy of an electron at the standard electrode potential.
- Q7.** Use Table 19.1 to calculate  $\Delta G^\circ$  for the reaction.  
 $2 \text{MnO}_4^-(aq) + \text{Cd}(s) \longrightarrow 2 \text{MnO}_4^{2-}(aq) + \text{Cd}^{2+}(aq)$   
a) +30.9 kJ    b) -30.9 kJ    c) -185 kJ    d) +185 kJ
- Q8.** A redox reaction has an  $E_{\text{cell}}^\circ = -0.56$  V. What can you conclude about the equilibrium constant ( $K$ ) for the reaction?  
a)  $K < 1$       b)  $K > 1$       c)  $K = 0$   
d) Nothing can be concluded about  $K$  from  $E_{\text{cell}}^\circ$ .
- Q9.** Find  $E_{\text{cell}}$  for an electrochemical cell based on the following reaction with  $[\text{MnO}_4^-] = 2.0$  M,  $[\text{H}^+] = 1.0$  M, and  $[\text{Ag}^+] = 0.010$  M.  $E_{\text{cell}}^\circ$  for the reaction is +0.88 V.  
 $\text{MnO}_4^-(aq) + 4 \text{H}^+(aq) + 3 \text{Ag}(s) \longrightarrow \text{MnO}_2(s) + 2 \text{H}_2\text{O}(l) + 3 \text{Ag}^+(aq)$   
a) 0.83 V    b) 1.00 V    c) 0.76 V    d) 0.93 V
- Q10.** In an electrochemical cell,  $Q = 0.010$  and  $K = 855$ . What can you conclude about  $E_{\text{cell}}$  and  $E_{\text{cell}}^\circ$ ?  
a)  $E_{\text{cell}}$  is positive and  $E_{\text{cell}}^\circ$  is negative.  
b)  $E_{\text{cell}}$  is negative and  $E_{\text{cell}}^\circ$  is positive.  
c)  $E_{\text{cell}}$  and  $E_{\text{cell}}^\circ$  are both negative.  
d)  $E_{\text{cell}}$  and  $E_{\text{cell}}^\circ$  are both positive.
- Q11.** Which reaction occurs at the *anode* of a lead storage battery?  
a)  $\text{Zn}(s) + 2 \text{OH}^-(aq) \longrightarrow \text{Zn}(\text{OH})_2(s) + 2 \text{e}^-$   
b)  $\text{PbO}_2(s) + \text{HSO}_4^-(aq) + 3 \text{H}^+(aq) + 2 \text{e}^- \longrightarrow \text{PbSO}_4(s) + 2 \text{H}_2\text{O}(l)$   
c)  $\text{Pb}(s) + \text{HSO}_4^-(aq) \longrightarrow \text{PbSO}_4(s) + \text{H}^+(aq) + 2 \text{e}^-$   
d)  $\text{O}_2(g) + 2 \text{H}_2\text{O}(l) + 4 \text{e}^- \longrightarrow 4 \text{OH}^-(aq)$
- Q12.** Which reaction could be used to generate electricity in a voltaic electrochemical cell?  
a)  $\text{Pb}^{2+}(aq) + \text{Mg}(s) \longrightarrow \text{Mg}^{2+}(aq) + \text{Pb}(s)$   
b)  $\text{Zn}^{2+}(aq) + \text{Sn}(s) \longrightarrow \text{Sn}^{2+}(aq) + \text{Zn}(s)$   
c)  $\text{NaCl}(aq) + \text{AgNO}_3(aq) \longrightarrow \text{AgCl}(s) + \text{NaNO}_3(aq)$   
d) None of the above
- Q13.** Which reaction occurs at the cathode of an electrolytic cell containing a mixture of molten KCl and ZnCl<sub>2</sub>?  
a)  $\text{K}(s) \longrightarrow \text{K}^+(l) + \text{e}^-$   
b)  $\text{K}^+(l) + \text{e}^- \longrightarrow \text{K}(s)$   
c)  $\text{Zn}^{2+}(l) + 2 \text{e}^- \longrightarrow \text{Zn}(s)$   
d)  $2 \text{Cl}^-(l) \longrightarrow \text{Cl}_2(g) + 2 \text{e}^-$
- Q14.** Copper is plated onto the cathode of an electrolytic cell containing CuCl<sub>2</sub>(aq). How long does it take to plate 111 mg of copper with a current of 3.8 A?  
a)  $1.3 \times 10^3$  s      b) 44 s  
c) 89 s      d) 22 s
- Q15.** Which metal can be used as a sacrificial electrode to prevent the rusting of an iron pipe?  
a) Au      b) Ag      c) Cu      d) Mn

Answers: 1. (a) 2. (d) 3. (d) 4. (a) 5. (c) 6. (a) 7. (c) 8. (a) 9. (b) 10. (d) 11. (c) 12. (a) 13. (c) 14. (c) 15. (d)

## Key Concepts

### Pulling the Plug on the Power Grid (19.1)

- ▶ Oxidation–reduction reactions are reactions in which electrons are transferred from one reactant to another.
- ▶ In the most common form of fuel cell, an electrical current is created as hydrogen is oxidized and oxygen is reduced; water is the only product.

### Balancing Oxidation–Reduction Equations (19.2)

- ▶ Oxidation is the loss of electrons and corresponds to an increase in oxidation state; reduction is the gain of electrons and corresponds to a decrease in oxidation state.
- ▶ We can balance redox reactions using the half-reaction method, in which the oxidation and reduction reactions are balanced separately and then added. This method differs slightly for redox reactions in acidic and in basic solutions.

### Voltaic (or Galvanic) Cells: Generating Electricity from Spontaneous Chemical Reactions (19.3)

- ▶ A voltaic electrochemical cell separates the reactants of a spontaneous redox reaction into two half-cells that are connected by a wire and a means to exchange ions so that electricity is generated.
- ▶ In an electrochemical cell, the electrode where oxidation occurs is the anode and the electrode where reduction occurs is the cathode; electrons flow from the anode to the cathode.
- ▶ The rate of electrons flowing through a wire is measured in amperes (A), and the cell potential is measured in volts (V).
- ▶ A salt bridge allows ions to flow between the half-cell solutions and prevent the buildup of charge.
- ▶ The cell diagram or line notation symbolizes electrochemical cells concisely by separating the components of the reaction using lines or commas.

### Standard Electrode Potentials (19.4)

- ▶ The electrode potentials of half-cells are measured in relation to that of a standard hydrogen electrode, which is assigned an electrode potential of zero under standard conditions (solution concentrations of 1 M, gas pressures of 1 atm, and a temperature of 25 °C).
- ▶ A species with a highly positive  $E^\circ$  has a strong tendency to attract electrons and undergo reduction (and is therefore an excellent oxidizing agent).
- ▶ A species with a highly negative  $E^\circ$  has a strong tendency to repel electrons and undergo oxidation (and is therefore an excellent reducing agent).

### Cell Potential, Free Energy, and the Equilibrium Constant (19.5)

- ▶ In a spontaneous reaction,  $E_{\text{cell}}^\circ$  is positive, the change in free energy ( $\Delta G^\circ$ ) is negative, and the equilibrium constant ( $K$ ) is greater than 1.

- ▶ In a nonspontaneous reaction,  $E_{\text{cell}}^\circ$  is negative,  $\Delta G^\circ$  is positive, and  $K$  is less than 1.
- ▶ Because  $E_{\text{cell}}^\circ$ ,  $\Delta G^\circ$ , and  $K$  all relate to spontaneity, we can derive equations relating all three quantities.

### Cell Potential and Concentration (19.6)

- ▶ The standard cell potential ( $E_{\text{cell}}^\circ$ ) is related to the cell potential ( $E_{\text{cell}}$ ) by the Nernst equation,  $E_{\text{cell}} = E_{\text{cell}}^\circ - (0.0592 \text{ V}/n) \log Q$ .
- ▶ As shown by the Nernst equation,  $E_{\text{cell}}$  is related to the reaction quotient ( $Q$ );  $E_{\text{cell}}$  equals zero when  $Q$  equals  $K$ .
- ▶ In a concentration cell, the reactions at both electrodes are identical and electrons flow because of a difference in concentration. Nerve cells are a biological example of concentration cells.

### Batteries: Using Chemistry to Generate Electricity (19.7)

- ▶ Batteries are packaged voltaic cells.
- ▶ Dry-cell batteries, including alkaline batteries, do not contain large amounts of water.
- ▶ The reactions in rechargeable batteries, such as lead–acid storage, nickel–cadmium, nickel–metal hydride, and lithium ion batteries, can be reversed.
- ▶ Fuel cells are similar to batteries except that fuel-cell reactants must be continually replenished from an external source.

### Electrolysis: Driving Nonspontaneous Chemical Reactions with Electricity (19.8)

- ▶ An electrolytic electrochemical cell differs from a voltaic cell in that (1) an electrical charge is used to drive the reaction, and (2) although the anode is still the site of oxidation and the cathode the site of reduction, they are represented with signs opposite those of a voltaic cell (anode +, cathode –).
- ▶ In electrolysis reactions, the anion is oxidized; if there is more than one anion, the anion with the more negative  $E^\circ$  is oxidized.
- ▶ We can use stoichiometry to calculate the quantity of reactants consumed or products produced in an electrolytic cell.

### Corrosion: Undesirable Redox Reactions (19.9)

- ▶ Corrosion is the undesired oxidation of metal by environmental oxidizing agents.
- ▶ When some metals, such as aluminum, oxidize, they form a stable compound that prevents further oxidation. Iron, in contrast, does not form a structurally stable compound when oxidized, and therefore, rust flakes off and exposes more iron to corrosion.
- ▶ Iron corrosion can be prevented by protecting iron from water, minimizing the presence of electrolytes and acids, or using a sacrificial electrode.

## Key Equations and Relationships

#### Definition of an Ampere (19.3)

$$1 \text{ A} = 1 \text{ C/s}$$

#### Definition of a Volt (19.3)

$$1 \text{ V} = 1 \text{ J/C}$$

#### Standard Hydrogen Electrode (19.4)

#### Equation for Cell Potential (19.4)

$$E_{\text{cell}}^\circ = E_{\text{cathode}}^\circ - E_{\text{anode}}^\circ$$

Relating  $\Delta G^\circ$  and  $E_{\text{cell}}^\circ$  (19.5)

$$\Delta G^\circ = -nFE_{\text{cell}}^\circ \quad F = \frac{96,485 \text{ C}}{\text{mol e}^-}$$

Relating  $E_{\text{cell}}^\circ$  and  $K$  (19.5)

$$E_{\text{cell}}^\circ = \frac{0.0592 \text{ V}}{n} \log K \quad (\text{at } 25^\circ\text{C})$$

The Nernst Equation (19.6)

$$E_{\text{cell}} = E_{\text{cell}}^\circ - \frac{0.0592 \text{ V}}{n} \log Q \quad (\text{at } 25^\circ\text{C})$$

## Key Learning Outcomes

CHAPTER OBJECTIVES	ASSESSMENT
Half-Reaction Method of Balancing Aqueous Redox Equations in Acidic Solution (19.2)	Examples 19.1, 19.2 For Practice 19.1, 19.2 Exercises 37–40
Balancing Redox Reactions Occurring in Basic Solution (19.2)	Example 19.3 For Practice 19.3 Exercises 41, 42
Calculating Standard Potentials for Electrochemical Cells from Standard Electrode Potentials of the Half-Reactions (19.4)	Example 19.4 For Practice 19.4 Exercises 45, 46, 61, 62
	
Predicting Spontaneous Redox Reactions and Sketching Electrochemical Cells (19.4)	Example 19.5 For Practice 19.5 Exercises 43, 44, 47, 48, 51–54
Relating $\Delta G^\circ$ and $E_{\text{cell}}^\circ$ (19.5)	Example 19.6 For Practice 19.6 Exercises 65, 66
Relating $E_{\text{cell}}^\circ$ and $K$ (19.5) 	Example 19.7 For Practice 19.7 Exercises 67–72
Calculating $E_{\text{cell}}$ under Nonstandard Conditions (19.6)	Example 19.8 For Practice 19.8 Exercises 73–78
Predicting the Products of Electrolysis Reactions (19.8)	Example 19.9 For Practice 19.9 Exercises 91–96
Stoichiometry of Electrolysis (19.8)	Example 19.10 For Practice 19.10 Exercises 99–102

## EXERCISES

### Review Questions

- In electrochemistry, spontaneous redox reactions are used for what purpose?
- In electrochemistry, what kind of reaction can be driven by electricity?
- Give the basic definitions of oxidation and reduction and explain the basic procedure for balancing redox reactions.
- Explain the difference between a voltaic (or galvanic) electrochemical cell and an electrolytic cell.
- What reaction (oxidation or reduction) occurs at the anode of a voltaic cell? What is the sign of the anode? Do electrons flow toward or away from the anode?
- What reaction (oxidation or reduction) occurs at the cathode of a voltaic cell? What is the sign of the cathode? Do electrons flow toward or away from the cathode?
- Explain the purpose of a salt bridge in an electrochemical cell.
- What unit is used to measure the magnitude of electrical current? What unit is used to measure the magnitude of a potential difference? Explain how electrical current and potential difference differ.
- What is the definition of the standard cell potential ( $E_{\text{cell}}^\circ$ )? What does a large positive standard cell potential imply about the spontaneity of the redox reaction occurring in the cell? What does a negative standard cell potential imply about the reaction?
- Describe the basic features of a cell diagram (or line notation) for an electrochemical cell.
- Why do some electrochemical cells employ inert electrodes such as platinum?
- Describe the standard hydrogen electrode (SHE) and explain its use in determining standard electrode potentials.

13. How is the cell potential of an electrochemical cell ( $E_{\text{cell}}^{\circ}$ ) related to the potentials of the half-cells?
14. Does a large positive electrode potential indicate a strong oxidizing agent or a strong reducing agent? What about a large negative electrode potential?
15. Is a spontaneous redox reaction obtained by pairing any reduction half-reaction with one listed above it or with one listed below it in Table 19.1?
16. How can Table 19.1 be used to predict whether or not a metal will dissolve in HCl? In  $\text{HNO}_3$ ?
17. Explain why  $E_{\text{cell}}^{\circ}$ ,  $\Delta G_{\text{rxn}}^{\circ}$ , and  $K$  are all interrelated.
18. Does a redox reaction with a small equilibrium constant ( $K < 1$ ) have a positive or a negative  $E_{\text{cell}}^{\circ}$ ? Does it have a positive or a negative  $\Delta G_{\text{rxn}}^{\circ}$ ?
19. How does  $E_{\text{cell}}$  depend on the concentrations of the reactants and products in the redox reaction occurring in the cell? What effect does increasing the concentration of a reactant have on  $E_{\text{cell}}$ ? Increasing the concentration of a product?
20. Use the Nernst equation to show that  $E_{\text{cell}} = E_{\text{cell}}^{\circ}$  under standard conditions.
21. What is a concentration electrochemical cell?
22. What are the anode and cathode reactions in a common dry-cell battery? In an alkaline battery?
23. What are the anode and cathode reactions in a lead–acid storage battery? What happens when the battery is recharged?
24. What are the three common types of portable rechargeable batteries, and how does each one work?
25. What is a fuel cell? What is the most common type of fuel cell, and what reactions occur at its anode and cathode?
26. Explain how a fuel-cell breathalyzer works.
27. List some applications of electrolysis.
28. The anode of an electrolytic cell must be connected to which terminal—positive or negative—of the power source?
29. What species is oxidized, and what species is reduced in the electrolysis of a pure molten salt?
30. If an electrolytic cell contains a mixture of species that can be oxidized, how do you determine which species will actually be oxidized? If it contains a mixture of species that can be reduced, how do you determine which one will actually be reduced?
31. Why does the electrolysis of an aqueous sodium chloride solution produce hydrogen gas at the cathode?
32. What is overvoltage in an electrochemical cell? Why is it important?
33. How is the amount of current flowing through an electrolytic cell related to the amount of product produced in the redox reaction?
34. What is corrosion? Why is corrosion only a problem for some metals (such as iron)?
35. Explain the role of each of the following in promoting corrosion: moisture, electrolytes, and acids.
36. How can the corrosion of iron be prevented?

## Problems by Topic

### Balancing Redox Reactions

37. Balance each redox reaction occurring in acidic aqueous solution.
  - a.  $\text{K(s)} + \text{Cr}^{3+}(\text{aq}) \longrightarrow \text{Cr(s)} + \text{K}^+(\text{aq})$
  - b.  $\text{Al(s)} + \text{Fe}^{2+}(\text{aq}) \longrightarrow \text{Al}^{3+}(\text{aq}) + \text{Fe(s)}$
  - c.  $\text{BrO}_3^-(\text{aq}) + \text{N}_2\text{H}_4(\text{g}) \longrightarrow \text{Br}^-(\text{aq}) + \text{N}_2(\text{g})$
38. Balance each redox reaction occurring in acidic aqueous solution.
  - a.  $\text{Zn(s)} + \text{Sn}^{2+}(\text{aq}) \longrightarrow \text{Zn}^{2+}(\text{aq}) + \text{Sn(s)}$
  - b.  $\text{Mg(s)} + \text{Cr}^{3+}(\text{aq}) \longrightarrow \text{Mg}^{2+}(\text{aq}) + \text{Cr(s)}$
  - c.  $\text{MnO}_4^-(\text{aq}) + \text{Al(s)} \longrightarrow \text{Mn}^{2+}(\text{aq}) + \text{Al}^{3+}(\text{aq})$
39. Balance each redox reaction occurring in acidic aqueous solution.
  - a.  $\text{PbO}_2(\text{s}) + \text{I}^-(\text{aq}) \longrightarrow \text{Pb}^{2+}(\text{aq}) + \text{I}_2(\text{s})$
  - b.  $\text{SO}_3^{2-}(\text{aq}) + \text{MnO}_4^-(\text{aq}) \longrightarrow \text{SO}_4^{2-}(\text{aq}) + \text{Mn}^{2+}(\text{aq})$
  - c.  $\text{S}_2\text{O}_3^{2-}(\text{aq}) + \text{Cl}_2(\text{g}) \longrightarrow \text{SO}_4^{2-}(\text{aq}) + \text{Cl}^-(\text{aq})$
40. Balance each redox reaction occurring in acidic aqueous solution.
  - a.  $\text{I}^-(\text{aq}) + \text{NO}_2^-(\text{aq}) \longrightarrow \text{I}_2(\text{s}) + \text{NO(g)}$
  - b.  $\text{ClO}_4^-(\text{aq}) + \text{Cl}^-(\text{aq}) \longrightarrow \text{ClO}_3^-(\text{aq}) + \text{Cl}_2(\text{g})$
  - c.  $\text{NO}_3^-(\text{aq}) + \text{Sn}^{2+}(\text{aq}) \longrightarrow \text{Sn}^{4+}(\text{aq}) + \text{NO(g)}$
41. Balance each redox reaction occurring in basic aqueous solution.
  - a.  $\text{H}_2\text{O}_2(\text{aq}) + \text{ClO}_2(\text{aq}) \longrightarrow \text{ClO}_2^-(\text{aq}) + \text{O}_2(\text{g})$
  - b.  $\text{Al(s)} + \text{MnO}_4^-(\text{aq}) \longrightarrow \text{MnO}_2(\text{s}) + \text{Al(OH)}_4^-(\text{aq})$
  - c.  $\text{Cl}_2(\text{g}) \longrightarrow \text{Cl}^-(\text{aq}) + \text{ClO}^-(\text{aq})$

42. Balance each redox reaction occurring in basic aqueous solution.

### Voltaic Cells, Standard Cell Potentials, and Direction of Spontaneity

43. Sketch a voltaic cell for each redox reaction. Label the anode and cathode and indicate the half-reaction that occurs at each electrode and the species present in each solution. Also indicate the direction of electron flow.
  - a.  $2 \text{Ag}^+(\text{aq}) + \text{Pb(s)} \longrightarrow 2 \text{Ag(s)} + \text{Pb}^{2+}(\text{aq})$
  - b.  $2 \text{ClO}_2(\text{g}) + 2 \text{I}^-(\text{aq}) \longrightarrow 2 \text{ClO}_2^-(\text{aq}) + \text{I}_2(\text{s})$
  - c.  $\text{O}_2(\text{g}) + 4 \text{H}^+(\text{aq}) + 2 \text{Zn(s)} \longrightarrow 2 \text{H}_2\text{O(l)} + 2 \text{Zn}^{2+}(\text{aq})$
44. Sketch a voltaic cell for each redox reaction. Label the anode and cathode and indicate the half-reaction that occurs at each electrode and the species present in each solution. Also indicate the direction of electron flow.
  - a.  $\text{Ni}^{2+}(\text{aq}) + \text{Mg(s)} \longrightarrow \text{Ni(s)} + \text{Mg}^{2+}(\text{aq})$
  - b.  $2 \text{H}^+(\text{aq}) + \text{Fe(s)} \longrightarrow \text{H}_2(\text{g}) + \text{Fe}^{2+}(\text{aq})$
  - c.  $2 \text{NO}_3^-(\text{aq}) + 8 \text{H}^+(\text{aq}) + 3 \text{Cu(s)} \longrightarrow$   
 $2 \text{NO(g)} + 4 \text{H}_2\text{O(l)} + 3 \text{Cu}^{2+}(\text{aq})$
45. Calculate the standard cell potential for each of the electrochemical cells in Problem 43.
46. Calculate the standard cell potential for each of the electrochemical cells in Problem 44.

47. Consider the voltaic cell:

- Determine the direction of electron flow and label the anode and the cathode.
  - Write a balanced equation for the overall reaction and calculate  $E_{\text{cell}}^{\circ}$ .
  - Label each electrode as negative or positive.
  - Indicate the direction of anion and cation flow in the salt bridge.
48. Consider the voltaic cell:

- Determine the direction of electron flow and label the anode and the cathode.
  - Write a balanced equation for the overall reaction and calculate  $E_{\text{cell}}^{\circ}$ .
  - Label each electrode as negative or positive.
  - Indicate the direction of anion and cation flow in the salt bridge.
49. Use line notation to represent each electrochemical cell in Problem 43.
50. Use line notation to represent each electrochemical cell in Problem 44.
51. Make a sketch of the voltaic cell represented by the line notation. Write the overall balanced equation for the reaction and calculate  $E_{\text{cell}}^{\circ}$ .
- $$\text{Sn(s)} | \text{Sn}^{2+}(\text{aq}) || \text{NO(g)} | \text{NO}_3^{-}(\text{aq}), \text{H}^{+}(\text{aq}) | \text{Pt(s)}$$
52. Make a sketch of the voltaic cell represented by the line notation. Write the overall balanced equation for the reaction and calculate  $E_{\text{cell}}^{\circ}$ .
- $$\text{Mn(s)} | \text{Mn}^{2+}(\text{aq}) || \text{ClO}_2^{-}(\text{aq}) | \text{ClO}_2(\text{g}) | \text{Pt(s)}$$
53. Determine whether or not each redox reaction occurs spontaneously in the forward direction.
- $\text{Ni(s)} + \text{Zn}^{2+}(\text{aq}) \longrightarrow \text{Ni}^{2+}(\text{aq}) + \text{Zn(s)}$
  - $\text{Ni(s)} + \text{Pb}^{2+}(\text{aq}) \longrightarrow \text{Ni}^{2+}(\text{aq}) + \text{Pb(s)}$
  - $\text{Al(s)} + 3 \text{Ag}^{+}(\text{aq}) \longrightarrow \text{Al}^{3+}(\text{aq}) + 3 \text{Ag(s)}$
  - $\text{Pb(s)} + \text{Mn}^{2+}(\text{aq}) \longrightarrow \text{Pb}^{2+}(\text{aq}) + \text{Mn(s)}$

54. Determine whether or not each redox reaction occurs spontaneously in the forward direction.

55. Which metal could you use to reduce  $\text{Mn}^{2+}$  ions but not  $\text{Mg}^{2+}$  ions?
56. Which metal can be oxidized with an  $\text{Sn}^{2+}$  solution but not with an  $\text{Fe}^{2+}$  solution?
57. Determine whether or not each metal dissolves in 1 M HCl. For those metals that do dissolve, write a balanced redox reaction showing what happens when the metal dissolves.
- Al
  - Ag
  - Pb
58. Determine whether or not each metal dissolves in 1 M HCl. For those metals that do dissolve, write a balanced redox reaction showing what happens when the metal dissolves.
- Cu
  - Fe
  - Au
59. Determine whether or not each metal dissolves in 1 M  $\text{HNO}_3$ . For those metals that do dissolve, write a balanced redox reaction showing what happens when the metal dissolves.
- Cu
  - Au
60. Determine whether or not each metal dissolves in 1 M  $\text{HIO}_3$ . For those metals that do dissolve, write a balanced redox equation for the reaction that occurs.
- Au
  - Cr

61. Calculate  $E_{\text{cell}}^{\circ}$  for each balanced redox reaction and determine if the reaction is spontaneous as written.
- $2 \text{Cu(s)} + \text{Mn}^{2+}(\text{aq}) \longrightarrow 2 \text{Cu}^{+}(\text{aq}) + \text{Mn(s)}$
  - $\text{MnO}_2(\text{aq}) + 4 \text{H}^{+}(\text{aq}) + \text{Zn(s)} \longrightarrow \text{Mn}^{2+}(\text{aq}) + 2 \text{H}_2\text{O(l)} + \text{Zn}^{2+}(\text{aq})$
  - $\text{Cl}_2(\text{g}) + 2 \text{F}^{-}(\text{aq}) \longrightarrow \text{F}_2(\text{g}) + 2 \text{Cl}^{-}(\text{aq})$
62. Calculate  $E_{\text{cell}}^{\circ}$  for each balanced redox reaction and determine if the reaction is spontaneous as written.
- $\text{O}_2(\text{g}) + 2 \text{H}_2\text{O(l)} + 4 \text{Ag(s)} \longrightarrow 4 \text{OH}^{-}(\text{aq}) + 4 \text{Ag}^{+}(\text{aq})$
  - $\text{Br}_2(\text{l}) + 2 \text{I}^{-}(\text{aq}) \longrightarrow 2 \text{Br}^{-}(\text{aq}) + \text{I}_2(\text{s})$
  - $\text{PbO}_2(\text{s}) + 4 \text{H}^{+}(\text{aq}) + \text{Sn(s)} \longrightarrow \text{Pb}^{2+}(\text{aq}) + 2 \text{H}_2\text{O(l)} + \text{Sn}^{2+}(\text{aq})$
63. Which metal cation is the best oxidizing agent?
- $\text{Pb}^{2+}$
  - $\text{Cr}^{3+}$
  - $\text{Fe}^{2+}$
  - $\text{Sn}^{2+}$
64. Which metal is the best reducing agent?
- Mn
  - Al
  - Ni
  - Cr

### Cell Potential, Free Energy, and the Equilibrium Constant

65. Use tabulated electrode potentials to calculate  $\Delta G_{\text{rxn}}^{\circ}$  for each reaction at 25 °C.
- $\text{Pb}^{2+}(\text{aq}) + \text{Mg(s)} \longrightarrow \text{Pb(s)} + \text{Mg}^{2+}(\text{aq})$
  - $\text{Br}_2(\text{l}) + 2 \text{Cl}^{-}(\text{aq}) \longrightarrow 2 \text{Br}^{-}(\text{aq}) + \text{Cl}_2(\text{g})$
  - $\text{MnO}_2(\text{s}) + 4 \text{H}^{+}(\text{aq}) + \text{Cu(s)} \longrightarrow \text{Mn}^{2+}(\text{aq}) + 2 \text{H}_2\text{O(l)} + \text{Cu}^{2+}(\text{aq})$
66. Use tabulated electrode potentials to calculate  $\Delta G_{\text{rxn}}^{\circ}$  for each reaction at 25 °C.
- $2 \text{Fe}^{3+}(\text{aq}) + 3 \text{Sn(s)} \longrightarrow 2 \text{Fe(s)} + 3 \text{Sn}^{2+}(\text{aq})$
  - $\text{O}_2(\text{g}) + 2 \text{H}_2\text{O(l)} + 2 \text{Cu(s)} \longrightarrow 4 \text{OH}^{-}(\text{aq}) + 2 \text{Cu}^{2+}(\text{aq})$
  - $\text{Br}_2(\text{l}) + 2 \text{I}^{-}(\text{aq}) \longrightarrow 2 \text{Br}^{-}(\text{aq}) + \text{I}_2(\text{s})$
67. Calculate the equilibrium constant for each of the reactions in Problem 65.

68. Calculate the equilibrium constant for each of the reactions in Problem 66.
69. Calculate the equilibrium constant for the reaction between  $\text{Ni}^{2+}(\text{aq})$  and  $\text{Cd}(\text{s})$  (at 25 °C).
70. Calculate the equilibrium constant for the reaction between  $\text{Fe}^{2+}(\text{aq})$  and  $\text{Zn}(\text{s})$  (at 25 °C).
71. Calculate  $\Delta G_{\text{rxn}}^{\circ}$  and  $E_{\text{cell}}^{\circ}$  for a redox reaction with  $n = 2$  that has an equilibrium constant of  $K = 25$  (at 25 °C).
72. Calculate  $\Delta G_{\text{rxn}}^{\circ}$  and  $E_{\text{cell}}^{\circ}$  for a redox reaction with  $n = 3$  that has an equilibrium constant of  $K = 0.050$  (at 25 °C).

### Nonstandard Conditions and the Nernst Equation

73. A voltaic cell employs the following redox reaction:

Calculate the cell potential at 25 °C under each set of conditions.

- standard conditions
  - $[\text{Sn}^{2+}] = 0.0100 \text{ M}$ ;  $[\text{Mn}^{2+}] = 2.00 \text{ M}$
  - $[\text{Sn}^{2+}] = 2.00 \text{ M}$ ;  $[\text{Mn}^{2+}] = 0.0100 \text{ M}$
74. A voltaic cell employs the redox reaction:

Calculate the cell potential at 25 °C under each set of conditions.

- standard conditions
  - $[\text{Fe}^{3+}] = 1.0 \times 10^{-3} \text{ M}$ ;  $[\text{Mg}^{2+}] = 2.50 \text{ M}$
  - $[\text{Fe}^{3+}] = 2.00 \text{ M}$ ;  $[\text{Mg}^{2+}] = 1.5 \times 10^{-3} \text{ M}$
75. An electrochemical cell is based on these two half-reactions:

Calculate the cell potential at 25 °C.

76. An electrochemical cell is based on these two half-reactions:

Calculate the cell potential at 25 °C.

77. A voltaic cell consists of a  $\text{Zn}/\text{Zn}^{2+}$  half-cell and a  $\text{Ni}/\text{Ni}^{2+}$  half-cell at 25 °C. The initial concentrations of  $\text{Ni}^{2+}$  and  $\text{Zn}^{2+}$  are 1.50 M and 0.100 M, respectively.

- What is the initial cell potential?
- What is the cell potential when the concentration of  $\text{Ni}^{2+}$  has fallen to 0.500 M?
- What are the concentrations of  $\text{Ni}^{2+}$  and  $\text{Zn}^{2+}$  when the cell potential falls to 0.45 V?

78. A voltaic cell consists of a  $\text{Pb}/\text{Pb}^{2+}$  half-cell and a  $\text{Cu}/\text{Cu}^{2+}$  half-cell at 25 °C. The initial concentrations of  $\text{Pb}^{2+}$  and  $\text{Cu}^{2+}$  are 0.0500 M and 1.50 M, respectively.

- What is the initial cell potential?
- What is the cell potential when the concentration of  $\text{Cu}^{2+}$  has fallen to 0.200 M?
- What are the concentrations of  $\text{Pb}^{2+}$  and  $\text{Cu}^{2+}$  when the cell potential falls to 0.35 V?

79. Make a sketch of a concentration cell employing two  $\text{Zn}/\text{Zn}^{2+}$  half-cells. The concentration of  $\text{Zn}^{2+}$  in one of the half-cells is 2.0 M and the concentration in the other half-cell is  $1.0 \times 10^{-3} \text{ M}$ . Label the anode and the cathode and indicate

the half-reaction occurring at each electrode. Also indicate the direction of electron flow.

80. Consider the concentration cell:

- Label the anode and cathode.
  - Indicate the direction of electron flow.
  - Indicate what happens to the concentration of  $\text{Pb}^{2+}$  in each half-cell.
81. A concentration cell consists of two  $\text{Sn}/\text{Sn}^{2+}$  half-cells. The cell has a potential of 0.10 V at 25 °C. What is the ratio of the  $\text{Sn}^{2+}$  concentrations in the two half-cells?
82. A  $\text{Cu}/\text{Cu}^{2+}$  concentration cell has a voltage of 0.22 V at 25 °C. The concentration of  $\text{Cu}^{2+}$  in one of the half-cells is  $1.5 \times 10^{-3} \text{ M}$ . What is the concentration of  $\text{Cu}^{2+}$  in the other half-cell? (Assume the concentration in the unknown cell is the lower of the two concentrations.)

### Batteries, Fuel Cells, and Corrosion

83. Determine the optimum mass ratio of Zn to  $\text{MnO}_2$  in an alkaline battery.
84. What mass of lead sulfate is formed in a lead-acid storage battery when 1.00 g of Pb undergoes oxidation?
85. Refer to the tabulated values of  $\Delta G_f^{\circ}$  in Appendix IIB to calculate  $E_{\text{cell}}^{\circ}$  for a fuel-cell that employs the reaction between methane gas ( $\text{CH}_4$ ) and oxygen to form carbon dioxide and gaseous water.
86. Refer to the tabulated values of  $\Delta G_f^{\circ}$  in Appendix IIB to calculate  $E_{\text{cell}}^{\circ}$  for the fuel-cell breathalyzer, which employs the following reaction. ( $\Delta G_f^{\circ}$  for  $\text{HC}_2\text{H}_3\text{O}_2(\text{g}) = -374.2 \text{ kJ/mol}$ .)

87. Determine whether or not each metal, if coated onto iron, would prevent the corrosion of iron.
- Zn
  - Sn
  - Mn
88. Determine whether or not each metal, if coated onto iron, would prevent the corrosion of iron.
- Mg
  - Cr
  - Cu

## Electrolytic Cells and Electrolysis

89. Consider the electrolytic cell:

- Label the anode and the cathode and indicate the half-reactions occurring at each.
  - Indicate the direction of electron flow.
  - Label the terminals on the battery as positive or negative and calculate the minimum voltage necessary to drive the reaction.
90. Draw an electrolytic cell in which  $\text{Mn}^{2+}$  is reduced to  $\text{Mn}$  and  $\text{Sn}$  is oxidized to  $\text{Sn}^{2+}$ . Label the anode and cathode, indicate the direction of electron flow, and write an equation for the half-reaction occurring at each electrode. What minimum voltage is necessary to drive the reaction?
91. Write equations for the half-reactions that occur in the electrolysis of molten potassium bromide.
92. What products are obtained in the electrolysis of molten  $\text{NaI}$ ?
93. Write equations for the half-reactions that occur in the electrolysis of a mixture of molten potassium bromide and molten lithium bromide.
94. What products are obtained in the electrolysis of a molten mixture of  $\text{KI}$  and  $\text{KBr}$ ?
95. Write equations for the half-reactions that occur at the anode and cathode for the electrolysis of each aqueous solution.
- $\text{NaBr}(aq)$
  - $\text{PbI}_2(aq)$
  - $\text{Na}_2\text{SO}_4(aq)$
96. Write equations for the half-reactions that occur at the anode and cathode for the electrolysis of each aqueous solution.
- $\text{Ni}(\text{NO}_3)_2(aq)$
  - $\text{KCl}(aq)$
  - $\text{CuBr}_2(aq)$

97. Make a sketch of an electrolysis cell that electroplates copper onto other metal surfaces. Label the anode and the cathode and indicate the reactions that occur at each.
98. Make a sketch of an electrolysis cell that electroplates nickel onto other metal surfaces. Label the anode and the cathode and indicate the reactions that occur at each.
99. Copper can be electroplated at the cathode of an electrolysis cell by the half-reaction:

How much time would it take for 325 mg of copper to be plated at a current of 5.6 A?

100. Silver can be electroplated at the cathode of an electrolysis cell by the half-reaction:

What mass of silver would plate onto the cathode if a current of 6.8 A flowed through the cell for 72 min?

101. A major source of sodium metal is the electrolysis of molten sodium chloride. What magnitude of current produces 1.0 kg of sodium metal in 1 hour?
102. What mass of aluminum metal can be produced per hour in the electrolysis of a molten aluminum salt by a current of 25 A?
103. Consider the reaction shown here occurring at 25 °C.

Determine the value of  $E_{\text{cell}}^\circ$  and  $K$  for the reaction and complete the table.

$[\text{B}^{2+}]$	$[\text{A}^{2+}]$	$Q$	$E_{\text{cell}}$	$\Delta G_{\text{rxn}}$
1.00	1.00			
1.00	$1.00 \times 10^{-4}$			
$1.0 \times 10^{-4}$	1.0			
$3.54 \times 10^{-3}$	1.0			

104. Consider the reaction shown here occurring at 25 °C.

Determine  $E_{\text{cell}}^\circ$ ,  $K$ , and  $\Delta G_{\text{rxn}}^\circ$  for the reaction and complete the table.

$[\text{Cd}^{2+}]$	$[\text{Cr}^{2+}]$	$Q$	$E_{\text{cell}}$	$\Delta G_{\text{rxn}}$
1.00	1.00			
1.00	$1.00 \times 10^{-5}$			
$1.00 \times 10^{-5}$	1.00			
$4.18 \times 10^{-4}$	1.00			

## Cumulative Problems

105. Consider the unbalanced redox reaction:

Balance the equation and determine the volume of a 0.500 M  $\text{KMnO}_4$  solution required to completely react with 2.85 g of Zn.

106. Consider the unbalanced redox reaction:

Balance the equation and determine the volume of a 0.850 M  $\text{K}_2\text{Cr}_2\text{O}_7$  solution required to completely react with 5.25 g of Cu.

- 107.** Consider the molecular views of an Al strip and  $\text{Cu}^{2+}$  solution. Draw a similar sketch showing what happens to the atoms and ions after the Al strip is submerged in the solution for a few minutes.

- 108.** Consider the molecular view of an electrochemical cell involving the overall reaction:

Draw a similar sketch of the cell after it has generated a substantial amount of electrical current.

- 109.** Determine whether HI can dissolve each metal sample. If it can, write a balanced chemical reaction showing how the metal dissolves in HI and determine the minimum volume of 3.5 M HI required to completely dissolve the sample.  
a. 2.15 g Al    b. 4.85 g Cu    c. 2.42 g Ag
- 110.** Determine if  $\text{HNO}_3$  can dissolve each metal sample. If it can, write a balanced chemical reaction showing how the metal dissolves in  $\text{HNO}_3$  and determine the minimum volume of 6.0 M  $\text{HNO}_3$  required to completely dissolve the sample.  
a. 5.90 g Au    b. 2.55 g Cu    c. 4.83 g Sn
- 111.** The cell potential of this electrochemical cell depends on the pH of the solution in the anode half-cell.  
 $\text{Pt(s)} | \text{H}_2(\text{g}, 1 \text{ atm}) | \text{H}^+(\text{aq}, ? \text{ M}) || \text{Cu}^{2+}(\text{aq}, 1.0 \text{ M}) | \text{Cu(s)}$   
What is the pH of the solution if  $E_{\text{cell}}$  is 355 mV?
- 112.** The cell potential of this electrochemical cell depends on the gold concentration in the cathode half-cell.  
 $\text{Pt(s)} | \text{H}_2(\text{g}, 1.0 \text{ atm}) | \text{H}^+(\text{aq}, 1.0 \text{ M}) || \text{Au}^{3+}(\text{aq}, ? \text{ M}) | \text{Au(s)}$   
What is the concentration of  $\text{Au}^{3+}$  in the solution if  $E_{\text{cell}}$  is 1.22 V?
- 113.** A friend wants you to invest in a new battery she has designed that produces 24 V in a single voltaic cell. Why should you be wary of investing in such a battery?

- 114.** What voltage can theoretically be achieved in a battery in which lithium metal is oxidized and fluorine gas is reduced? Why might such a battery be difficult to produce?
- 115.** A battery relies on the oxidation of magnesium and the reduction of  $\text{Cu}^{2+}$ . The initial concentrations of  $\text{Mg}^{2+}$  and  $\text{Cu}^{2+}$  are  $1.0 \times 10^{-4} \text{ M}$  and 1.5 M, respectively, in 1.0-liter half-cells.  
a. What is the initial voltage of the battery?  
b. What is the voltage of the battery after delivering 5.0 A for 8.0 h?  
c. How long can the battery deliver 5.0 A before going dead?
- 116.** A rechargeable battery is constructed based on a concentration cell constructed of two  $\text{Ag}/\text{Ag}^+$  half-cells. The volume of each half-cell is 2.0 L, and the concentrations of  $\text{Ag}^+$  in the half-cells are 1.25 M and  $1.0 \times 10^{-3} \text{ M}$ .  
a. How long can this battery deliver 2.5 A of current before it goes dead?  
b. What mass of silver is plated onto the cathode by running at 3.5 A for 5.5 h?  
c. Upon recharging, how long would it take to redissolve  $1.00 \times 10^2 \text{ g}$  of silver at a charging current of 10.0 amps?
- 117.** If a water electrolysis cell operates at a current of 7.8 A, how long will it take to generate 25.0 L of hydrogen gas at a pressure of 25.0 atm and a temperature of 25 °C?
- 118.** When a suspected drunk driver blows 188 mL of his breath through the fuel-cell breathalyzer described in Section 19.7, the breathalyzer produces an average of 324 mA of current for 10 s. Assuming a pressure of 1.0 atm and a temperature of 25 °C, what percent (by volume) of the driver's breath is ethanol?
- 119.** The  $K_{\text{sp}}$  of  $\text{CuI}$  is  $1.1 \times 10^{-12}$ . Find  $E_{\text{cell}}$  for the cell:  
 $\text{Cu(s)} | \text{CuI(s)} | \text{I}^-(\text{aq}, 1.0 \text{ M}) || \text{Cu}^+(\text{aq}, 1.0 \text{ M}) | \text{Cu(s)}$
- 120.** The  $K_{\text{sp}}$  of  $\text{Zn(OH)}_2$  is  $1.8 \times 10^{-14}$ . Find  $E_{\text{cell}}$  for the half-reaction:  
 $\text{Zn(OH)}_2(\text{s}) + 2 \text{e}^- \rightleftharpoons \text{Zn(s)} + 2 \text{OH}^-(\text{aq})$
- 121.** Calculate  $\Delta G_{\text{rxn}}^\circ$  and  $K$  for each reaction.  
a. The disproportionation of  $\text{Mn}^{2+}(\text{aq})$  to  $\text{Mn(s)}$  and  $\text{MnO}_2(\text{s})$  in acid solution at 25 °C.  
b. The disproportionation of  $\text{MnO}_2(\text{s})$  to  $\text{Mn}^{2+}(\text{aq})$  and  $\text{MnO}_4^-(\text{aq})$  in acid solution at 25 °C.
- 122.** Calculate  $\Delta G_{\text{rxn}}^\circ$  and  $K$  for each reaction.  
a. The reaction of  $\text{Cr}^{2+}(\text{aq})$  with  $\text{Cr}_2\text{O}_7^{2-}(\text{aq})$  in acid solution to form  $\text{Cr}^{3+}(\text{aq})$ .  
b. The reaction of  $\text{Cr}^{3+}(\text{aq})$  and  $\text{Cr(s)}$  to form  $\text{Cr}^{2+}(\text{aq})$ . [The electrode potential of  $\text{Cr}^{2+}(\text{aq})$  to  $\text{Cr(s)}$  is  $-0.91 \text{ V}$ .]
- 123.** The molar mass of a metal (M) is 50.9 g/mol; it forms a chloride of unknown composition. Electrolysis of a sample of the molten chloride with a current of 6.42 A for 23.6 minutes produces 1.20 g of M at the cathode. Determine the empirical formula of the chloride.
- 124.** A metal forms the fluoride  $\text{MF}_3$ . Electrolysis of the molten fluoride by a current of 3.86 A for 16.2 minutes deposits 1.25 g of the metal. Calculate the molar mass of the metal.
- 125.** A sample of impure tin of mass 0.535 g is dissolved in strong acid to give a solution of  $\text{Sn}^{2+}$ . The solution is then titrated with a 0.0448 M solution of  $\text{NO}_3^-$ , which is reduced to  $\text{NO(g)}$ . The equivalence point is reached upon the addition of 0.0344 L of the  $\text{NO}_3^-$  solution. Find the percent by mass of tin in the original sample, assuming that it contains no other reducing agents.
- 126.** A 0.0251-L sample of a solution of  $\text{Cu}^+$  requires 0.0322 L of 0.129 M  $\text{KMnO}_4$  solution to reach the equivalence point. The products of the reaction are  $\text{Cu}^{2+}$  and  $\text{Mn}^{2+}$ . What is the concentration of the  $\text{Cu}^{2+}$  solution?

- 127.** A current of 11.3 A is applied to 1.25 L of a solution of 0.552 M HBr converting some of the  $\text{H}^+$  to  $\text{H}_2(\text{g})$ , which bubbles out of solution. What is the pH of the solution after 73 minutes?
- 128.** A 215-mL sample of a 0.500 M NaCl solution with an initial pH of 7.00 is subjected to electrolysis. After 15.0 minutes, a 10.0-mL portion (or aliquot) of the solution was removed from the cell and titrated with 0.100 M HCl solution. The end point in the titration was reached upon addition of 22.8 mL of HCl.

Assuming constant current, what was the current (in A) running through the cell?

- 129.** An  $\text{MnO}_2(\text{s})/\text{Mn}^{2+}(\text{aq})$  electrode in which the pH is 10.24 is prepared. Find the  $[\text{Mn}^{2+}]$  necessary to lower the potential of the half-cell to 0.00 V (at 25 °C).
- 130.** To what pH should you adjust a standard hydrogen electrode to get an electrode potential of  $-0.122$  V? (Assume that the partial pressure of hydrogen gas remains at 1 atm.)

## Challenge Problems

- 131.** Suppose a hydrogen–oxygen fuel-cell generator produces electricity for a house. Use the balanced redox reactions and the standard cell potential to predict the volume of hydrogen gas (at STP) required each month to generate the electricity. Assume the home uses  $1.2 \times 10^3$  kWh of electricity per month.
- 132.** A voltaic cell designed to measure  $[\text{Cu}^{2+}]$  is constructed of a standard hydrogen electrode and a copper metal electrode in the  $\text{Cu}^{2+}$  solution of interest. If you want to construct a calibration curve for how the cell potential varies with the concentration of copper(II), what do you plot in order to obtain a straight line? What is the slope of the line?
- 133.** The surface area of an object to be gold plated is  $49.8 \text{ cm}^2$ , and the density of gold is  $19.3 \text{ g/cm}^3$ . A current of 3.25 A is applied to a solution that contains gold in the +3 oxidation state. Calculate the time required to deposit an even layer of gold  $1.00 \times 10^{-3} \text{ cm}$  thick on the object.
- 134.** To electrodeposit all the Cu and Cd from a solution of  $\text{CuSO}_4$  and  $\text{CdSO}_4$  required 1.20 F of electricity (1 F = 1 mol  $\text{e}^-$ ). The mixture of Cu and Cd that was deposited had a mass of 50.36 g. What mass of  $\text{CuSO}_4$  was present in the original mixture?
- 135.** Sodium oxalate,  $\text{Na}_2\text{C}_2\text{O}_4$ , in solution is oxidized to  $\text{CO}_2(\text{g})$  by  $\text{MnO}_4^-$ , which is reduced to  $\text{Mn}^{2+}$ . A 50.1-mL volume of a solution of  $\text{MnO}_4^-$  is required to titrate a 0.339-g sample of sodium oxalate. This solution of  $\text{MnO}_4^-$  is used to analyze uranium-containing samples. A 4.62-g sample of a uranium-containing material requires 32.5 mL of the solution for titration. The oxidation of the uranium can be represented by the change  $\text{UO}_2^{2+} \longrightarrow \text{UO}_2^{2+}$ . Calculate the percentage of uranium in the sample.
- 136.** Three electrolytic cells are connected in a series. The electrolytes in the cells are aqueous copper(II) sulfate, gold(III) sulfate, and silver nitrate. A current of 2.33 A is applied, and after some time 1.74 g Cu is deposited. How long was the current applied? What mass of gold and silver was deposited?
- 137.** The cell  $\text{Pt(s)}|\text{Cu}^+(1 \text{ M}), \text{Cu}^{2+}(1 \text{ M})||\text{Cu}^+(1 \text{ M})|\text{Cu(s)}$  has  $E^\circ = 0.364 \text{ V}$ . The cell  $\text{Cu(s)}|\text{Cu}^{2+}(1 \text{ M})||\text{Cu}^+(1 \text{ M})|\text{Cu(s)}$  has  $E^\circ = 0.182 \text{ V}$ . Write the cell reaction for each cell and explain the differences in  $E^\circ$ . Calculate  $\Delta G^\circ$  for each cell reaction to help explain these differences.

## Conceptual Problems

- 138.** An electrochemical cell has a positive standard cell potential but a negative cell potential. Which statement is true for the cell?
- $K > 1$ ;  $Q > K$
  - $K < 1$ ;  $Q > K$
  - $K > 1$ ;  $Q < K$
  - $K < 1$ ;  $Q < K$
- 139.** Which oxidizing agent will oxidize  $\text{Br}^-$  but not  $\text{Cl}^-$ ?
- $\text{K}_2\text{Cr}_2\text{O}_7$  (in acid)
  - $\text{KMnO}_4$  (in acid)
  - $\text{HNO}_3$
- 140.** A redox reaction employed in an electrochemical cell has a negative  $\Delta G^\circ_{\text{rxn}}$ . Which statement is true?
- $E^\circ_{\text{cell}}$  is positive;  $K < 1$
  - $E^\circ_{\text{cell}}$  is positive;  $K > 1$
  - $E^\circ_{\text{cell}}$  is negative;  $K > 1$
  - $E^\circ_{\text{cell}}$  is negative;  $K < 1$
- 141.** A redox reaction has an equilibrium constant of  $K = 0.055$ . What is true of  $\Delta G^\circ_{\text{rxn}}$  and  $E^\circ_{\text{cell}}$  for this reaction?

## Active Classroom Learning

## Questions for Group Work

Discuss these questions with the group and record your consensus answer.

- 142.** Balance the redox reactions by following the steps in the text. Rotate through the group, having each group member do the next step in the process and explain that step to the rest of the group.
- $\text{I}_2(\text{s}) + \text{Fe}(\text{s}) \longrightarrow \text{FeI}_2(\text{s})$
  - $\text{Cl}_2(\text{g}) + \text{H}_2\text{O}_2(\text{aq}) \longrightarrow \text{Cl}^-(\text{aq}) + \text{O}_2(\text{g})$  (acidic)
  - $\text{Hg}^{2+}(\text{aq}) + \text{H}_2(\text{g}) \longrightarrow \text{Hg}(\text{l}) + \text{H}_2\text{O}(\text{l})$  (basic)
  - $\text{CH}_3\text{OH}(\text{l}) + \text{O}_2(\text{g}) \longrightarrow \text{CO}_2(\text{g}) + \text{H}_2\text{O}(\text{l})$  (acidic)
- 143.** Have each group member select a half-reaction from Table 19.1. Each member should calculate the standard cell potential of an electrochemical cell formed between each member's half-reaction and the half-reaction of each of the other group members. For each pair of half-reactions, write the overall balanced chemical reaction that will be spontaneous.

- 144.** Calculate  $\Delta G^\circ$  and  $K$  for each reaction the group created in Question 2. For one of the reactions, explain how the sign or magnitude of each quantity ( $E^\circ_{\text{cell}}$ ,  $\Delta G^\circ$ , and  $K$ ) is consistent with the fact that the reaction is spontaneous in the direction written.
- 145.** Design a device that uses an electrochemical cell to determine the amount of  $\text{Cu}^{2+}$  in a sample of water. Describe, in detail, the construction and the theory of operation of your device. If you are able to measure voltage with one-millivolt accuracy, what will the uncertainty in your measured concentration be?
- 146.** Using a library or the Internet, research a fuel cell that uses methanol for fuel. What is the reaction at the anode? What is the reaction at the cathode? What is the overall reaction? What is the standard cell potential? How many kWh can it generate from 1 L (0.792 kg) of methanol?

## Data Interpretation and Analysis

### Concentration and emf in Voltaic Cells

**147.** A series of experiments is conducted using a voltaic cell consisting of a Zn/Zn<sup>2+</sup> half-cell and a Cu/Cu<sup>2+</sup> half-cell at 25 °C similar to the cell in Figure 19.11. The cell potential is measured using different concentrations of the Zn<sup>2+</sup> ions and Cu<sup>2+</sup> ions, and the data are recorded in Table a.

[Zn <sup>2+</sup> ] (M)	[Cu <sup>2+</sup> ] (M)	$E_{\text{cell}}$ (volts)	$\log\{[\text{Zn}^{2+}]/[\text{Cu}^{2+}]\}$
2.00	0.00100	1.000	
1.00	0.00100	1.012	
0.100	0.00100	1.042	
0.0100	0.00100	1.075	
0.00100	0.00100	1.10	
0.00100	2.00	1.20	
0.0100	2.00	1.17	
0.100	2.00	1.14	
1.00	2.00	1.11	
2.00	2.00	1.10	

**TABLE a** Concentrations of Zn<sup>2+</sup> and Cu<sup>2+</sup> and Measured Cell Potential

Use the information provided in the questions and table to answer the following questions:

- a. Complete Table a (either by hand or with a spreadsheet program) and graph the cell potential versus  $\log\{[\text{Zn}^{2+}]/[\text{Cu}^{2+}]\}$  in Figure a►.

**▲ FIGURE a** Cell Potential as a Function of  $\log\{[\text{Zn}^{2+}]/[\text{Cu}^{2+}]\}$ .

- b. To obtain a cell potential of 1.15 volts using a Zn-Cu cell, should the concentration of Zn<sup>2+</sup> be greater than, less than, or equal to the concentration of Cu<sup>2+</sup>? Explain your answer.
- c. Show that there are at least three different combinations of concentrations of Zn<sup>2+</sup> and Cu<sup>2+</sup> ions capable of generating a cell potential of +1.15 V.
- d. Use your graph from part a to determine the cell potential when [Zn<sup>2+</sup>] = 0.050 M and [Cu<sup>2+</sup>] = 1.75 M.
- e. Consider a Zn-Cu cell with the following initial concentrations: [Cu<sup>2+</sup>] = 2.00 M and [Zn<sup>2+</sup>] = 0.010 M. As this cell operates over a period of time, sketch a graph (qualitative) of [Cu<sup>2+</sup>] and [Zn<sup>2+</sup>] as a function of time.

## Answers to Conceptual Connections

### Voltaic Cells

**19.1 (a)** Electrons are negatively charged, and therefore, flow away from the more negatively charged electrode and toward the more positively charged electrode.

### Standard Electrode Potentials

**19.2 (b)** A negative electrode potential indicates that an electron at that electrode has greater potential energy than it has at a standard hydrogen electrode.

### Selective Oxidation

**19.3 (d)** The reduction of HNO<sub>3</sub> is below the reduction of Br<sub>2</sub> and above the reduction of I<sub>2</sub> in Table 19.1. Since any reduction half-reaction is spontaneous when paired with the reverse of a half-reaction below it in the table, the reduction of HNO<sub>3</sub> is spontaneous when paired with the oxidation of I<sup>-</sup> but is not spontaneous when paired with the oxidation of Br<sup>-</sup>.

### Metals Dissolving in Acids

**19.4 (c)** Ag falls above the half-reaction for the reduction of H<sup>+</sup> but below the half-reaction for the reduction of NO<sub>3</sub><sup>-</sup> in Table 19.1.

### Periodic Trends and the Direction of Spontaneity for Redox Reactions

**19.5 (a)** Br is more electronegative than I. If the two atoms were in competition for the electron, the electron would go to the more electronegative atom (Br). Therefore, I<sub>2</sub> does not spontaneously gain electrons from Br<sup>-</sup>.

### Relating $K$ , $\Delta G_{\text{rxn}}^\circ$ , and $E_{\text{cell}}^\circ$

**19.6 (c)** Since  $K > 1$ , the reaction is spontaneous under standard conditions (when  $Q = 1$ , the reaction proceeds toward the products). Therefore,  $E_{\text{cell}}^\circ$  is positive and  $\Delta G_{\text{rxn}}^\circ$  is negative.

### Relating $Q$ , $K$ , $E_{\text{cell}}$ , and $E_{\text{cell}}^\circ$

**19.7 (a)** Since  $K < 1$ ,  $E_{\text{cell}}^\circ$  is negative (under standard conditions, the reaction is not spontaneous). Since  $Q < K$ ,  $E_{\text{cell}}$  is positive (the reaction is spontaneous under the nonstandard conditions of the cell).

### Sacrificial Electrodes

**19.8** Cu. The electrode potential for Fe is more negative than that of Cu. Therefore, Fe oxidizes more easily than Cu.

# Radioactivity and Nuclear Chemistry

I am among those who think that science has great beauty. A scientist in his laboratory is not only a technician; he is also a child placed before natural phenomena which impress him like a fairy tale.

**KEY LEARNING OUTCOMES 972**

In this chapter, we examine radioactivity and nuclear chemistry, both of which involve changes within the *nuclei* of atoms. Unlike ordinary chemical processes, in which elements retain their identity, nuclear processes often result in one element changing into another, frequently emitting tremendous amounts of energy. Radioactivity has numerous applications, including the diagnosis and treatment of medical conditions such as cancer, thyroid disease, abnormal kidney and bladder function, and heart disease. Naturally occurring radioactivity allows us to estimate the age of fossils, rocks, and ancient artifacts. And radioactivity, perhaps most famously, led to the discovery of nuclear fission, used for electricity generation and nuclear weapons.

▲ Antibodies labeled with radioactive atoms can be used to diagnose an infected appendix.

## 20.1 Diagnosing Appendicitis

One morning a few years ago I awoke with a dull pain on the lower right side of my abdomen that was worse by early afternoon. Since pain in this area can indicate appendicitis (inflammation of the appendix), and since I know that appendicitis can be dangerous if left untreated, I went to the hospital emergency room. The doctor who examined me recommended a simple blood test to determine my white blood cell count. Patients with appendicitis usually have a high white blood cell count because the body is trying to fight the infection. In my case, the test was negative—I had a normal white blood cell count.

Although my symptoms were consistent with appendicitis, the negative blood test clouded the diagnosis. The doctor said that I could elect to have my appendix removed anyway (even though it might be healthy) or I could submit to another test that might confirm the appendicitis. I chose the additional test, which involved *nuclear medicine*, an area of medical practice that employs *radioactivity* to diagnose and treat disease. **Radioactivity** is the emission of subatomic particles or high-energy electromagnetic radiation by the nuclei of certain atoms. Such atoms are said to be **radioactive**. Most radioactive emissions can pass through many types of matter (such as skin and muscle, in this case).

During the test, antibodies—naturally occurring molecules that fight infection—were labeled with radioactive atoms and then injected into my bloodstream. Because antibodies attack infection, they migrate to areas of the body where infection is present. If my appendix was indeed infected, the antibodies would accumulate there. I waited about an hour, and then a technician took me to a room and laid me on a table. She inserted a photographic film in a panel above me and removed the covering that prevents exposure of the film. Radioactivity is invisible to the eye, but it exposes photographic film. If my appendix had been infected, it would have (by then) contained a high concentration of the radioactively labeled antibodies. The antibodies would emit radiation and expose the film. The test, however, was negative. No radioactivity was emanating from my appendix. After several hours, the pain in my abdomen subsided and I went home. I never did find out what caused the pain.

▲ The greenish light emitted from glow-in-the-dark toys is phosphorescence.

## 20.2 The Discovery of Radioactivity

Radioactivity was first observed in 1896 by a French scientist named Antoine-Henri Becquerel (1852–1908). Becquerel was interested in the newly discovered X-rays (see Chapter 7), which were a hot topic of physics research in his time. He hypothesized that X-rays were emitted in conjunction with **phosphorescence**, the long-lived *emission* of light that sometimes follows the absorption of light by certain atoms and molecules. Phosphorescence is probably most familiar to you as the *glow* in glow-in-the-dark products (such as toys or stickers). After such a product is exposed to light, it reemits some of that light, usually at slightly longer wavelengths. If you turn off the room lights or put the glow-in-the-dark product in the dark, you see the greenish glow of the emitted light.

Becquerel hypothesized that this visible greenish glow was associated with the emission of X-rays (which are invisible).

To test his hypothesis, Becquerel placed crystals—composed of potassium uranyl sulfate, a compound known to phosphoresce—on top of a photographic plate wrapped in black cloth. He then exposed the crystals to sunlight. He knew the crystals had phosphoresced because he could see the emitted light when he brought them back into the dark. If the crystals had also emitted X-rays, the X-rays would have passed through the black cloth and exposed the underlying photographic plate. Becquerel performed the experiment several times and always got the same result—the photographic plate showed a dark exposure spot where the crystals had been (Figure 20.1). Becquerel believed his hypothesis was correct and presented the results—that phosphorescence and X-rays were linked—to the French Academy of Sciences.

Becquerel later retracted his results, however, when he discovered that a photographic plate with the same crystals showed a dark exposure spot even when the plate and the crystals were stored in a drawer and not exposed to sunlight. Becquerel realized that the crystals themselves were constantly emitting something that exposed the photographic plate, regardless of whether or not they phosphoresced. Becquerel concluded that it was the uranium within the crystals that was the source of the emissions, and he named the emissions *uranic rays*.

▲ **FIGURE 20.1 The Discovery of Radioactivity** This photographic plate (with Becquerel's original comments at top) played a key role in the discovery of radioactivity. Becquerel placed a uranium-containing compound on the plate (which was wrapped in black cloth to shield it from visible light). The plate was darkened by some unknown form of penetrating radiation that was produced continuously, independently of phosphorescence.

Soon after Becquerel's discovery, a young graduate student named Marie Sklodowska Curie (1867–1934) (one of the first women in France to pursue doctoral work) decided to study uranic rays for her doctoral thesis. Her first task was to determine whether any other substances besides uranium (the heaviest known element at the time) emitted these rays. In her search, Curie discovered two new elements, both of which also emitted uranic rays. Curie named one of her newly discovered elements polonium, after her home country of Poland. The other element she named radium, because of its high level of radioactivity. Radium is so radioactive that it gently glows in the dark and emits significant amounts of heat. Since it was clear that these rays were not unique to uranium, Curie changed the name of uranic rays to radioactivity. In 1903, Curie and her husband, Pierre Curie, as well as Becquerel were all awarded the Nobel Prize in physics for the discovery of radioactivity. In 1911, Curie received a second Nobel Prize, this time in chemistry, for her discovery of the two new elements.

## 20.3 Types of Radioactivity

While Curie focused her work on discovering the different kinds of radioactive elements, Ernest Rutherford and others focused on characterizing the radioactivity itself. These scientists found that the emissions are produced by the nuclei of radioactive atoms. Such nuclei are unstable and spontaneously decompose, emitting small pieces of themselves to gain stability. These fragments are the radioactivity that Becquerel and Curie detected. Natural radioactivity can be categorized into several different types, including *alpha* ( $\alpha$ ) *decay*, *beta* ( $\beta$ ) *decay*, *gamma* ( $\gamma$ ) *ray emission*, and *positron emission*. In addition, some unstable atomic nuclei can attain greater stability by absorbing electrons from one of the atoms' own orbitals, a process called *electron capture*.

In order to understand these different types of radioactivity, we must briefly review the notation for symbolizing isotopes from Section 2.6. Recall that we can represent any isotope with the following notation:

Mass number ( $A$ ) = the sum of the number of protons and number of neutrons in the nucleus

Atomic number ( $Z$ ) = the number of protons in the nucleus

Since  $A$  represents the sum of the number of protons and neutrons, and since  $Z$  represents the number of protons, the number of neutrons in the nucleus ( $N$ ) is  $A - Z$ .

$$\begin{array}{c} N = A - Z \\ \uparrow \\ \text{Number of neutrons} \end{array}$$

For example, the symbol  $^{21}_{10}\text{Ne}$  represents the neon isotope containing 10 protons and 11 neutrons. The symbol  $^{20}_{10}\text{Ne}$  represents the neon isotope containing 10 protons and 10 neutrons. Remember that most elements have several different isotopes. When we are discussing nuclear properties, we often refer to a particular isotope (or species) of an element as a **nuclide**.

We represent the main subatomic particles—protons, neutrons, and electrons—with similar notation.

Proton symbol  $^1_1\text{p}$  Neutron symbol  $^1_0\text{n}$  Electron symbol  $^0_{-1}\text{e}$

The 1 in the lower left of the proton symbol represents 1 proton, and the 0 in the lower left corner of the neutron symbol represents 0 protons. The  $-1$  in the lower left corner of the electron symbol is a bit different from the other atomic numbers, but it will make sense to you when we see it in the context of nuclear decay a bit later in this section.

▲ Marie Curie, one of the first women in France to pursue a doctoral degree, was twice awarded the Nobel Prize, in 1903 and 1911. She is seen here with her daughters, in about 1905. Irène (left) became a distinguished nuclear physicist in her own right, winning a Nobel Prize in 1935. Eve (right) wrote a highly acclaimed biography of her mother.

Element 96 is named curium in honor of Marie Curie and her contributions to our understanding of radioactivity.

▲ Radium, discovered by Marie Curie, is so radioactive that it glows visibly and emits heat.

Types of Radioactivity

## Alpha Decay

**▲ FIGURE 20.2 Alpha Decay** In alpha decay, a nucleus emits a particle composed of two protons and two neutrons (a helium-4 nucleus).

Alpha ( $\alpha$ ) Decay

**Alpha ( $\alpha$ ) decay** occurs when an unstable nucleus emits a particle composed of two protons and two neutrons (Figure 20.2 ◀). Since two protons and two neutrons combined are identical to a helium-4 nucleus, the symbol for alpha radiation is the symbol for helium-4:

When an element emits an alpha particle, the number of protons in its nucleus changes, transforming the element into a different element. We symbolize this phenomenon with a **nuclear equation**, an equation that represents nuclear processes such as radioactivity. For example, the nuclear equation for the alpha decay of uranium-238 is:

The original atom is the *parent nuclide*, and the product of the decay is the *daughter nuclide*. In this case, uranium-238 (the parent nuclide) becomes thorium-234 (the daughter nuclide). Unlike a chemical reaction, in which elements retain their identities, in a nuclear reaction elements often change their identities. Like a chemical equation, however, a nuclear equation must be balanced. *The sum of the atomic numbers on both sides of a nuclear equation must be equal, and the sum of the mass numbers on both sides must also be equal:*

Reactants	Products
Sum of mass numbers = 238	Sum of mass numbers = 234 + 4 = 238
Sum of atomic numbers = 92	Sum of atomic numbers = 90 + 2 = 92

We can deduce the identity and symbol of the daughter nuclide in any alpha decay from the mass and atomic number of the parent nuclide. During alpha decay, the mass number decreases by 4 and the atomic number decreases by 2, as shown in Example 20.1.

### Example 20.1 Writing Nuclear Equations for Alpha Decay

Write the nuclear equation for the alpha decay of Ra-224.

#### SOLUTION

Begin with the symbol for Ra-224 on the left side of the equation and the symbol for an alpha particle on the right side.

Equalize the sum of the mass numbers and the sum of the atomic numbers on both sides of the equation by writing the appropriate mass number and atomic number for the unknown daughter nuclide.

Refer to the periodic table to determine the identity of the unknown daughter nuclide from its atomic number and write its symbol. Since the atomic number is 86, the daughter nuclide is radon (Rn).

**FOR PRACTICE 20.1** Write the nuclear equation for the alpha decay of Po-216.

Alpha radiation is the 18-wheeler truck of radioactivity. The alpha particle is by far the most massive of all particles commonly emitted by radioactive nuclei. Consequently, alpha radiation has the most potential to interact with and damage other molecules, including biological ones. Highly energetic radiation interacts with other molecules and atoms by ionizing them. When radiation ionizes molecules within the

As we discuss in Section 20.4, nuclei are unstable when they are too large or when they contain an unbalanced ratio of neutrons to protons.

In nuclear chemistry, we are primarily interested in changes within the nucleus; therefore, the 2+ charge that we would normally write for a helium nucleus is omitted for an alpha particle.

cells of living organisms, the cells can usually repair the damage. However, in some cases the cells can die or begin to reproduce abnormally. The ability of radiation to ionize other molecules and atoms is called its **ionizing power**. Of all types of radioactivity, alpha radiation has the highest ionizing power.

However, alpha particles, because of their large size, have the lowest **penetrating power**—the ability to penetrate matter. (Imagine a semi trying to get through a traffic jam.) In order for radiation to damage important molecules within living cells, it must penetrate into the cell. Alpha radiation does not easily penetrate into cells because it can be stopped by a sheet of paper, by clothing, or even by air. Consequently, a low-level alpha emitter that remains outside the body is relatively safe. However, consuming large amounts of an alpha emitter can be dangerous because the alpha particles then have direct access to the molecules that compose organs and tissues.

## Beta ( $\beta$ ) Decay

**Beta ( $\beta$ ) decay** occurs when an unstable nucleus emits an electron (Figure 20.3▶). How does a nucleus, which contains only protons and neutrons, emit an electron? In some unstable nuclei, a neutron changes into a proton and emits an electron:

The symbol for a beta ( $\beta$ ) particle in a nuclear equation is:

We represent beta decay with this nuclear equation:

The  $-1$  reflects the charge of the electron, which is equivalent to an atomic number of  $-1$  in a nuclear equation. When an atom emits a beta particle, its atomic number increases by 1 because it then has an additional proton. For example, the nuclear equation for the beta decay of radium-228 is:

Notice that the nuclear equation is balanced—the sum of the mass numbers on both sides is equal, and the sum of the atomic numbers on both sides is equal.

Beta radiation is the four-door sedan of radioactivity. Beta particles are much less massive than alpha particles and consequently have a lower ionizing power. However, because of their smaller size, beta particles have a higher penetrating power and only something as substantive as a sheet of metal or a thick piece of wood stops them. Consequently, a beta emitter outside of the body poses a higher risk than an alpha emitter. If ingested, however, the beta emitter does less damage than an alpha emitter.

## Gamma ( $\gamma$ ) Ray Emission

**Gamma ( $\gamma$ ) ray emission** is significantly different from alpha or beta radiation. Gamma radiation is a form of *electromagnetic* radiation (see Section 7.2). Gamma rays are high-energy (short-wavelength) photons. The symbol for a gamma ray is:

A gamma ray has no charge and no mass. When a gamma-ray photon is emitted from a radioactive atom, it does not change the mass number or the atomic number of the element. Gamma rays are usually emitted from nuclei in excited states or in conjunction with other types of radiation. For example, the alpha emission of U-238 (discussed previously) is also accompanied by the emission of a gamma ray:

The emission of gamma rays in conjunction with other types of radiation is so common that it is often left out of nuclear equations. Nuclear chemists simply understand that the gamma rays are emitted along with the other types of decay. However, in some instances, there can be a delay between the initial decay and the subsequent emission of gamma ray. The initial decay leaves the daughter nucleus in *metastable* state (an unstable state that can exist for a prolonged period of time). The daughter then emits a

### Beta Decay

▲ **FIGURE 20.3 Beta Decay**

In beta decay, a neutron emits an electron and becomes a proton.

This kind of beta radiation is also called beta minus ( $\beta^-$ ) radiation due to its negative charge.

See Section 7.2 for a review of electromagnetic radiation.

gamma particle at a later time. For example, technetium-99 has a gamma-emitting metastable state:

The m next to the mass number stands for metastable.

Gamma rays are the motorbikes of radioactivity. They have the lowest ionizing power, but the highest penetrating power. (Imagine a motorbike zipping through a traffic jam.) Shielding gamma rays requires several inches of lead or thick slabs of concrete.

### Positron Emission

**▲ FIGURE 20.4 Positron Emission** In positron emission, a proton emits a positron and becomes a neutron.

Positron emission can be thought of as a type of beta emission and is sometimes referred to as beta plus emission ( $\beta^+$ ).

## Positron Emission

**Positron emission** occurs when an unstable nucleus emits a positron (Figure 20.4 ◀). A **positron** is the *antiparticle* of the electron; it has the same mass as an electron, but the opposite charge. If a positron collides with an electron, the two particles annihilate each other, releasing energy in the form of gamma rays. In positron emission, a proton is converted into a neutron and emits a positron:

The symbol for a positron in a nuclear equation is:

We represent positron emission with this nuclear equation:

When an atom emits a positron, its atomic number *decreases* by 1 because it has one less proton after emission. Consider the nuclear equation for the positron emission of phosphorus-30 as an example:

We can determine the identity and symbol of the daughter nuclide in any positron emission in a manner similar to that used for alpha and beta decay, as shown in Example 20.2. Positrons are similar to beta particles in their ionizing and penetrating power.

## Electron Capture

Unlike the forms of radioactive decay that we have discussed so far, electron capture involves a particle being *absorbed by* rather than *emitted from* an unstable nucleus. **Electron capture** occurs when a nucleus assimilates an electron from an inner orbital of its electron cloud. Like positron emission, the net effect of electron capture is the conversion of a proton into a neutron:

We represent electron capture with this nuclear equation:

When an atom undergoes electron capture, its atomic number decreases by 1 because it has one less proton. For example, when Ru-92 undergoes electron capture, its atomic number changes from 44 to 43:

Table 20.1 summarizes the different kinds of radiation.

### Example 20.2 Writing Nuclear Equations for Beta Decay, Positron Emission, and Electron Capture

Write the nuclear equation for each type of decay.

(a) beta decay in Bk-249

(b) positron emission in O-15

(c) electron capture in I-111

<b>SOLUTION</b>	
<b>(a)</b> In beta decay, the atomic number <i>increases</i> by 1 and the mass number remains unchanged. The daughter nuclide is element number 98, californium.	${}^{249}_{97}\text{Bk} \longrightarrow {}^{249}_{98}\text{?} + {}^0_{-1}\text{e}$ ${}^{249}_{97}\text{Bk} \longrightarrow {}^{249}_{98}\text{Cf} + {}^0_{-1}\text{e}$
<b>(b)</b> In positron emission, the atomic number <i>decreases</i> by 1 and the mass number remains unchanged. The daughter nuclide is element number 7, nitrogen.	${}^{15}_8\text{O} \longrightarrow {}^{15}_7\text{?} + {}^0_{+1}\text{e}$ ${}^{15}_8\text{O} \longrightarrow {}^{15}_7\text{N} + {}^0_{+1}\text{e}$
<b>(c)</b> In electron capture, the atomic number also <i>decreases</i> by 1 and the mass number remains unchanged. The daughter nuclide is element number 52, tellurium.	${}^{111}_{53}\text{I} + {}^0_{-1}\text{e} \longrightarrow {}^{111}_{52}\text{?}$ ${}^{111}_{53}\text{I} + {}^0_{-1}\text{e} \longrightarrow {}^{111}_{52}\text{Te}$
<b>FOR PRACTICE 20.2</b>	
<b>(a)</b> Write three nuclear equations to represent the nuclear decay sequence that begins with the alpha decay of U-235 followed by a beta decay of the daughter nuclide and then another alpha decay.	
<b>(b)</b> Write the nuclear equation for the positron emission of Na-22.	
<b>(c)</b> Write the nuclear equation for electron capture in Kr-76.	
<b>FOR MORE PRACTICE 20.2</b> Potassium-40 can decay to produce Ar-40. What is the method of decay? Write the nuclear equation for this decay.	

TABLE 20.1 Modes of Radioactive Decay

Decay Mode	Process	Change in: A Z N/Z*	Example
$\alpha$	 Parent nuclide → Daughter nuclide + $\alpha$ particle	-4 -2 Increase	${}^{238}_{92}\text{U} \longrightarrow {}^{234}_{90}\text{Th} + {}^4_2\text{He}$
$\beta$	 Parent nuclide → Daughter nuclide + $\beta$ particle Neutron becomes a proton	0 +1 Decrease	${}^{228}_{88}\text{Ra} \longrightarrow {}^{228}_{89}\text{Ac} + {}^0_{-1}\text{e}$
$\gamma$	 Excited nuclide → Stable nuclide + Photon	0 0 None	${}^{99m}_{43}\text{Tc} \longrightarrow {}^{99}_{43}\text{Tc} + {}^0_0\gamma$
Positron emission	 Parent nuclide → Daughter nuclide + Positron Proton becomes a neutron	0 -1 Increase	${}^{30}_{15}\text{P} \longrightarrow {}^{30}_{14}\text{Si} + {}^0_{+1}\text{e}$
Electron capture	 Parent nuclide + ${}^0_{-1}\text{e} \longrightarrow$ Daughter nuclide Proton becomes a neutron	0 -1 Increase	${}^{92}_{44}\text{Ru} + {}^0_{-1}\text{e} \longrightarrow {}^{92}_{43}\text{Tc}$

\* Neutron-to-proton ratio

## CONCEPTUAL CONNECTION 20.1

**Alpha and Beta Decay** Consider the graphical representation of a series of decays shown here.

The arrow labeled  $x$  and the arrow labeled  $y$  each correspond to what kind of decay?

- (a)  $x$  corresponds to alpha decay and  $y$  corresponds to positron emission.
- (b)  $x$  corresponds to positron emission and  $y$  corresponds to alpha decay.
- (c)  $x$  corresponds to alpha decay and  $y$  corresponds to beta decay.
- (d)  $x$  corresponds to beta decay and  $y$  corresponds to alpha decay.

## 20.4 The Valley of Stability: Predicting the Type of Radioactivity

▼ **FIGURE 20.5 Stable and Unstable Nuclei** A plot of  $N$  (the number of neutrons) versus  $Z$  (the number of protons) for all known nuclei. The green dots represent stable nuclei and the yellow dots represent unstable nuclei. A nucleus with an  $N/Z$  ratio that is too high tends to undergo beta decay. A nucleus with an  $N/Z$  ratio that is too low tends to undergo positron emission or electron capture.

So far, we have described various different types of radioactivity. But we have not discussed what causes a particular nuclide to be radioactive in the first place. And why do some nuclides decay via alpha decay, while others decay via beta decay or positron emission? The answers to these questions are not simple, but we can get a basic idea of the factors that influence the stability of the nucleus and the nature of its decay.

A nucleus is a collection of protons (positively charged) and neutrons (uncharged). We know that positively charged particles such as protons repel one another. So what binds the nucleus together? A fundamental force of physics known as the **strong force** binds the nucleus together. All **nucleons**—protons and neutrons—are attracted to one another by the strong force. However, the strong force acts only at very short distances. We can think of the stability of a nucleus as a balance between the *repulsive* coulombic force among protons and the *attractive* strong force among all nucleons. The neutrons in a nucleus, therefore, play an important role in stabilizing the nucleus because they attract other nucleons (through the strong force) but lack the repulsive force associated with positive charge.

It might seem that adding more neutrons would *always* lead to greater stability, so that the more neutrons the better. This is not the case, however, because protons and neutrons occupy energy levels in a nucleus that are similar to those occupied by electrons in an atom. As you add more neutrons, the neutrons must occupy increasingly higher energy levels within the nucleus. At some point, the energy payback from the strong force is not enough to compensate for the high energy state that the neutrons must occupy.

An important number in determining nuclear stability is the *ratio* of neutrons to protons ( $N/Z$ ). Figure 20.5 is a plot of the number of neutrons versus the number of protons for all known nuclei. The yellow dots represent unstable nuclei and the green dots represent stable ones. The region of the graph with the green dots (stable nuclei) is known as the *valley* (or *island*) of *stability*. Notice that for the lighter elements, the  $N/Z$  ratio of stable nuclei is about 1 (equal numbers of neutrons and protons). For example, the most abundant isotope of carbon ( $Z = 6$ ) is carbon-12, which contains six protons and six neutrons. However, beyond about  $Z = 20$ , the  $N/Z$  ratio of stable nuclei begins to get larger. For example, at  $Z = 44$  stable nuclei have  $N/Z$  ratios of about 1.275 and at  $Z = 80$ , the  $N/Z$  ratio reaches about 1.5. Above  $Z = 83$ , stable nuclei do not exist—bismuth ( $Z = 83$ ) is the heaviest element with stable (nonradioactive) isotopes.

The type of radioactivity emitted by a nuclide depends in part on the  $N/Z$  ratio.

**$N/Z$  too high:** Nuclides that lie above the valley of stability have too many neutrons and tend to convert neutrons to protons via beta decay. The process of undergoing beta decay moves the nuclide down in the plot in Figure 20.5 and closer to (or into) the valley of stability.

**$N/Z$  too low:** Nuclides that lie below the valley of stability have too many protons and tend to convert protons to neutrons via positron emission or electron capture. This moves the nuclide up in the plot in Figure 20.5 and closer to (or into) the valley of stability.

One way to decide whether a particular nuclide has an  $N/Z$  that is too high, too low, or about right is to consult Figure 20.5. Those nuclides that lie within the valley of stability are stable. Alternatively, we can also compare the mass number of the nuclide to the atomic mass listed in the periodic table for the corresponding element. The atomic mass is an average of the masses of the stable nuclides for an element and thus represents an  $N/Z$  that is about right. For example, suppose we want to evaluate  $N/Z$  for Ru-112. Ruthenium has an atomic mass of 101.07, so we know that the nuclide with a mass number of 112 contains too many neutrons and therefore has an  $N/Z$  that is too high. The following example demonstrates how to apply these considerations in predicting the mode of decay for a nucleus.

### Example 20.3 Predicting the Type of Radioactive Decay

Predict whether each nuclide is more likely to decay via beta decay or positron emission.

- (a) Mg-28      (b) Mg-22      (c) Mo-102

#### SOLUTION

- (a) Magnesium-28 has 16 neutrons and 12 protons, so  $N/Z = 1.33$ . However, for  $Z = 12$ , you can see from Figure 20.5 that stable nuclei should have an  $N/Z$  of about 1. Alternatively, you can see from the periodic table that the atomic mass of magnesium is 24.31. Therefore, a nuclide with a mass number of 28 is too heavy to be stable because the  $N/Z$  ratio is too high and Mg-28 undergoes *beta decay*, resulting in the conversion of a neutron to a proton.
- (b) Magnesium-22 has 10 neutrons and 12 protons, so  $N/Z = 0.83$  (too low). Alternatively, you can see from the periodic table that the atomic mass of magnesium is 24.31. A nuclide with a mass number of 22 is too light; the  $N/Z$  ratio is too low. Therefore, Mg-22 undergoes *positron emission*, resulting in the conversion of a proton to a neutron. (Electron capture would accomplish the same thing as positron emission, but in Mg-22, positron emission is the only decay mode observed.)
- (c) Molybdenum-102 has 60 neutrons and 42 protons, so  $N/Z = 1.43$ . However, for  $Z = 42$ , you can see from Figure 20.5 that stable nuclei should have  $N/Z$  ratios of about 1.3. Alternatively, you can see from the periodic table that the atomic mass of molybdenum is 95.94. A nuclide with a mass number of 102 is too heavy to be stable; the  $N/Z$  ratio is too high. Therefore, Mo-102 undergoes *beta decay*, resulting in the conversion of a neutron to a proton.

**FOR PRACTICE 20.3** Predict whether each nuclide is more likely to decay via beta decay or positron emission.

- (a) Pb-192      (b) Pb-212      (c) Xe-114

### Magic Numbers

In addition to the  $N/Z$  ratio, the *actual number* of protons and neutrons also affects the stability of the nucleus. Table 20.2 shows the number of nuclei with different possible combinations of even or odd nucleons. Notice that a large number of stable nuclides have both an even number of protons and an even number of neutrons. Only five stable nuclides have an odd and odd combination.

**TABLE 20.2** Number of Stable Nuclides with Even and Odd Numbers of Nucleons

Z	N	Number of Nuclides
Even	Even	157
Even	Odd	53
Odd	Even	50
Odd	Odd	5

## A Decay Series

**▲ FIGURE 20.6** The Uranium-238 Radioactive Decay Series

Uranium-238 decays via a series of steps ending in Pb-206, a stable element. Each diagonal line to the left represents an alpha decay, and each diagonal line to the right represents a beta decay.

**▲ FIGURE 20.7** Thermoluminescent Dosimeter

A thermoluminescent dosimeter contains crystals that when heated emit light in proportion to radiation exposure.

The reason for this is that nucleons occupy energy levels within the nucleus much as electrons occupy energy levels within an atom. Just as atoms with certain numbers of electrons are uniquely stable (in particular, the number of electrons associated with the noble gases: 2, 10, 18, 36, 54, etc.), so atoms with certain numbers of nucleons ( $N$  or  $Z = 2, 8, 20, 28, 50, 82$ , and  $N = 126$ ) are uniquely stable. These numbers are referred to as **magic numbers**. Nuclei containing a magic number of protons or neutrons are particularly stable. Since the magic numbers are even, this accounts in part for the abundance of stable nuclides with even numbers of nucleons. Moreover, nucleons also have a tendency to pair (much as electrons pair). This tendency and the resulting stability of paired nucleons also contribute to the abundance of stable nuclides with even numbers of nucleons.

## Radioactive Decay Series

Atoms with  $Z > 83$  are radioactive and decay in one or more steps involving primarily alpha and beta decay (with some gamma decay to carry away excess energy). For example, uranium (atomic number 92) is the heaviest naturally occurring element. Its most common isotope is U-238, an alpha emitter that decays to Th-234:

The daughter nuclide, Th-234, is itself radioactive—it is a beta emitter that decays to Pa-234:

Protactinium-234 is also radioactive, decaying to U-234 via beta emission. Radioactive decay continues until a stable nuclide, Pb-206, is reached. Figure 20.6 illustrates the entire uranium-238 decay series.

## 20.5 Detecting Radioactivity

The particles emitted by radioactive nuclei are very energetic and therefore can be readily detected. In a radiation detector, the particles are detected through their interactions with atoms or molecules. The most common radiation detectors are **thermoluminescent dosimeters** (Figure 20.7), which are issued to people working with or near radioactive substances. These dosimeters contain crystals of salts such as calcium fluoride that are excited by the ionizing radiation. The excited electrons are trapped by impurities that are intentionally introduced into the crystals. When the crystals are heated, the electrons relax to their ground state, emitting light. The amount of light emitted is proportional to the radiation exposure. These dosimeters are collected and processed regularly as a way to monitor a person's exposure. We discuss the effects and measurement of exposure in more detail in Section 20.11.

Radioactivity can be instantly detected with devices such as a **Geiger-Müller counter** (Figure 20.8). In this instrument (commonly referred to as a Geiger counter), particles emitted by radioactive nuclei pass through an argon-filled chamber. The energetic particles create a trail of ionized argon atoms. High voltage applied between a wire within the chamber and the chamber itself causes these newly formed ions to produce an electrical signal that can be displayed on a meter or turned into an audible click. Each click corresponds to a radioactive particle passing through the argon gas chamber. This clicking is the stereotypical sound most people associate with a radiation detector.

A second type of device commonly used to detect radiation instantly is a **scintillation counter**. In a scintillation counter, radioactive emissions pass through a material (such as NaI or CsI) that emits ultraviolet or visible light in response to excitation by high-energy photons. The photons excite the atoms to a higher-energy state. The atoms release this energy as light, which is detected and turned into an electrical signal that is read on a meter.

**▲ FIGURE 20.8 Geiger-Müller Counter** When ionizing radiation passes through the argon-filled chamber, it ionizes the argon atoms, giving rise to a brief, tiny pulse of electrical current that is transduced onto a meter or into an audible click.

## 20.6 The Kinetics of Radioactive Decay and Radiometric Dating

Radioactivity is a natural component of our environment. The ground beneath you most likely contains radioactive atoms that emit radiation. The food you eat contains a residual quantity of radioactive atoms that are absorbed into your body fluids and incorporated into tissues. Small amounts of radiation from space make it through our atmosphere to constantly bombard Earth. Humans and other living organisms have evolved in this environment and have adapted to survive in it.

One reason for the radioactivity in our environment is the instability of all atomic nuclei beyond atomic number 83 (bismuth). Every element with more than 83 protons in its nucleus is unstable and therefore radioactive. In addition, some isotopes of elements with fewer than 83 protons are also unstable and radioactive. Radioactive nuclides *persist* in our environment because new radioactive nuclides are constantly being formed and because many of the existing ones decay away only very slowly.

All radioactive nuclei decay via first-order kinetics, so the rate of decay in a particular sample is directly proportional to the number of nuclei present as indicated in the equation:

$$\text{Rate} = kN$$

where  $N$  is the number of radioactive nuclei and  $k$  is the rate constant. Different radioactive nuclides decay into their daughter nuclides with different rate constants. Some nuclides decay quickly (large rate constant), while others decay slowly (small rate constant).

The time it takes for one-half of the parent nuclides in a radioactive sample to decay to the daughter nuclides is the *half-life* and is identical to the concept of half-life for chemical reactions that we discussed in Chapter 14. Thus, the relationship between the half-life of a nuclide and its rate constant is given by the same expression (Equation 14.19) that we derived for a first-order reaction in Section 14.4:

$$t_{1/2} = \frac{0.693}{k} \quad [20.1]$$

Nuclides that decay quickly have short half-lives and large rate constants—they are considered very active (many decay events per unit time). Nuclides that decay slowly have long half-lives and are less active (fewer decay events per unit time). For example, thorium-232 is an alpha emitter with a half-life of  $1.4 \times 10^{10}$  years, or 14 billion years. A sample of Th-232 containing 1 million atoms decays to  $\frac{1}{2}$  million atoms in 14 billion

You may find it useful to review the discussion of first-order kinetics in Section 14.3.

years and then to  $\frac{1}{4}$  million in another 14 billion years and so on. Notice that a radioactive sample does *not* decay to *zero* atoms in two half-lives—we can’t add two half-lives together to get a “whole” life. The amount that remains after one half-life is always one-half of what was present at the start. The amount that remains after two half-lives is one-quarter of what was present at the start, and so on.

TABLE 20.3 Selected Nuclides and Their Half-Lives

Nuclide	Half-Life	Type of Decay
$^{232}_{90}\text{Th}$	$1.4 \times 10^{10}$ yr	Alpha
$^{238}_{92}\text{U}$	$4.5 \times 10^9$ yr	Alpha
$^{14}_6\text{C}$	5715 yr	Beta
$^{220}_{86}\text{Rn}$	55.6 s	Alpha
$^{219}_{90}\text{Th}$	$1.05 \times 10^{-6}$ s	Alpha

Some nuclides have very short half-lives. For example, radon-220 has a half-life of approximately 1 minute (Figure 20.9▼). A 1-million-atom sample of radon-220 decays to  $\frac{1}{4}$  million radon-220 atoms in just two minutes and to approximately 1000 atoms in 10 minutes. Table 20.3 lists several nuclides and their half-lives.

► FIGURE 20.9 The Decay of Radon-220 Radon-220 decays with a half-life of approximately 1 minute.

CONCEPTUAL CONNECTION 20.2

**Half-Life** Consider this graph representing the decay of a radioactive nuclide.

- What is the half-life of the nuclide?
- (a) 625 years                      (b) 1250 years  
(c) 2500 years                    (d) 3125 years

## The Integrated Rate Law

Recall from Chapter 14 that for first-order chemical reactions, the concentration of a reactant as a function of time is given by the integrated rate law:

$$\ln \frac{[A]_t}{[A]_0} = -kt \quad [20.2]$$

Because nuclear decay follows first-order kinetics, we can substitute the number of nuclei for concentration to arrive at the equation:

$$\ln \frac{N_t}{N_0} = -kt \quad [20.3]$$

where  $N_t$  is the number of radioactive nuclei at time  $t$  and  $N_0$  is the initial number of radioactive nuclei. Example 20.4 demonstrates the use of this equation.

### Example 20.4 Radioactive Decay Kinetics

Plutonium-236 is an alpha emitter with a half-life of 2.86 years. If a sample initially contains 1.35 mg of Pu-236, what mass of Pu-236 is present after 5.00 years?

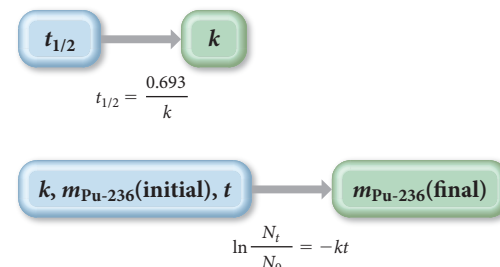

**SORT** You are given the initial mass of Pu-236 in a sample and asked to find the mass after 5.00 years.

**GIVEN:**  $m_{\text{Pu-236}}(\text{initial}) = 1.35 \text{ mg}$ ;  
 $t = 5.00 \text{ yr}$ ;  $t_{1/2} = 2.86 \text{ yr}$

**FIND:**  $m_{\text{Pu-236}}(\text{final})$

**STRATEGIZE** Use the integrated rate law (Equation 20.3) to solve this problem. You must determine the value of the rate constant ( $k$ ) from the half-life expression (Equation 20.1).

**CONCEPTUAL PLAN**

Use the value of the rate constant, the initial mass of Pu-236, and the time along with integrated rate law to find the final mass of Pu-236. Since the mass of the Pu-236 ( $m_{\text{Pu-236}}$ ) is directly proportional to the number of atoms ( $N$ ), and since the integrated rate law contains the ratio ( $N_t/N_0$ ), you can substitute the initial and final masses for the initial and final number of atoms.

**SOLVE** Follow your plan. Begin by determining the rate constant from the half-life.

**SOLUTION**

$$\begin{aligned} t_{1/2} &= \frac{0.693}{k} \\ k &= \frac{0.693}{t_{1/2}} = \frac{0.693}{2.86 \text{ yr}} \\ &= 0.2423/\text{yr} \end{aligned}$$

Solve the integrated rate law for  $N_t$  and substitute the values of the rate constant, the initial mass of Pu-236, and the time into the solved equation. Calculate the final mass of Pu-236.

$$\begin{aligned} \ln \frac{N_t}{N_0} &= -kt \\ \frac{N_t}{N_0} &= e^{-kt} \\ N_t &= N_0 e^{-kt} \\ N_t &= 1.35 \text{ mg} [e^{-(0.2423/\text{yr})(5.00 \text{ yr})}] \\ N_t &= 0.402 \text{ mg} \end{aligned}$$

**CHECK** The units of the answer (mg) are correct. The magnitude of the answer (0.402 mg) is about one-third of the original mass (1.35 mg), which seems reasonable given that the amount of time is between one and two half-lives. (One half-life would result in one-half of the original mass, and two half-lives would result in one-fourth of the original mass.)

**FOR PRACTICE 20.4** How long will it take for the 1.35 mg sample of Pu-236 in Example 20.4 to decay to 0.100 mg?

Since radioactivity is a first-order process, the rate of decay is linearly proportional to the number of nuclei in the sample. Therefore, the initial rate of decay ( $\text{rate}_0$ ) and the rate of decay at time  $t$  ( $\text{rate}_t$ ) can also be used in the integrated rate law:

$$\text{Rate}_t = kN_t \quad \text{Rate}_0 = kN_0$$

$$\frac{N_t}{N_0} = \frac{\text{rate}_t/k}{\text{rate}_0/k} = \frac{\text{rate}_t}{\text{rate}_0}$$

Substituting into Equation 20.3, we get the following result:

$$\ln \frac{\text{rate}_t}{\text{rate}_0} = -kt \quad [20.4]$$

We can use Equation 20.4 to predict how the rate of decay of a radioactive sample will change with time or how much time has passed based on how the rate has changed (see examples later in this section).

The radioactive isotopes in our environment and their predictable decay with time can therefore be used to estimate the age of rocks or artifacts containing those isotopes. The technique is known as **radiometric dating**, and we examine two different types individually.

## CONCEPTUAL CONNECTION 20.3

**Half-Life and the Amount of Radioactive Sample** A sample initially contains 1.6 moles of a radioactive isotope. How much of the sample remains after four half-lives?

- (a) 0.0 mol      (b) 0.10 mol      (c) 0.20 mol      (d) 0.40 mol

▲ The Dead Sea Scrolls are 2000-year-old biblical manuscripts. Their age was determined by radiocarbon dating.

Libby received the Nobel Prize in 1960 for the development of radiocarbon dating.

A steady state is a set of conditions that results in constant concentrations of the relevant species.

## Radiocarbon Dating: Using Radioactivity to Measure the Age of Fossils and Artifacts

Archaeologists, geologists, anthropologists, and other scientists use **radiocarbon dating**, a technique devised in 1949 by Willard Libby (1908–1980) at the University of Chicago, to estimate the ages of fossils and artifacts. For example, in 1947, young shepherds searching for a stray goat near the Dead Sea (east of Jerusalem) entered a cave and discovered ancient scrolls that had been stuffed into jars. These scrolls—now named the Dead Sea Scrolls—are 2000-year-old texts of the Hebrew Bible, predating other previously discovered manuscripts by almost a thousand years.

The Dead Sea Scrolls, like other ancient artifacts, contain a radioactive signature that reveals their age. This signature results from the presence of carbon-14 (which is radioactive) in the environment. Carbon-14 is constantly formed in the upper atmosphere by the neutron bombardment of nitrogen:

After it forms, carbon-14 decays back to nitrogen by beta emission with a half-life of 5715 years:

The continuous formation of carbon-14 in the atmosphere and its continuous decay to nitrogen-14 produce a nearly constant steady-state amount of atmospheric carbon-14. The atmospheric carbon-14 is oxidized to carbon dioxide and incorporated into plants by photosynthesis. The C-14 then makes its way up the food chain and ultimately into all living organisms. As a result, the tissues in all living plants, animals, and humans contain the same ratio of carbon-14 to carbon-12 ( ${}^{14}\text{C} : {}^{12}\text{C}$ ) as that found in the atmosphere. When a living organism dies, however, it stops incorporating new carbon-14 into its tissues. The  ${}^{14}\text{C} : {}^{12}\text{C}$  ratio then begins to decrease with a half-life of 5715 years.

Because many artifacts, including the Dead Sea Scrolls, are made from materials that were once living—such as papyrus, wood, or other plant and animal derivatives—the  ${}^{14}\text{C} : {}^{12}\text{C}$  ratio in these artifacts indicates their age. For example, suppose an ancient artifact

has a  $^{14}\text{C} : ^{12}\text{C}$  ratio that is 25% of that found in living organisms. How old is the artifact? Because it contains one-quarter as much carbon-14 as a living organism, it is two half-lives or 11,460 years old. The maximum age that can be estimated from carbon-14 dating is about 50,000 years—beyond that, the amount of carbon-14 is too low to measure accurately.

We can check the accuracy of carbon-14 dating against objects whose ages are known from historical sources. These kinds of comparisons reveal that ages obtained from C-14 dating deviate from the actual ages by up to about 5%. For a 6000-year-old object, that is an error of about 300 years. The reason for the deviations is the variance of atmospheric C-14 levels over time.

In order to make C-14 dating more accurate, scientists have studied the carbon-14 content of western bristlecone pine trees, which can live up to 5000 years. The tree trunks of the pines contain growth rings corresponding to each year of the tree's life, and the wood laid down in each ring incorporates carbon derived from the carbon dioxide in the atmosphere at that time. The rings thus provide a historical record of the atmospheric carbon-14 content. In addition, the rings of living trees can be correlated with the rings of dead trees (if the lifetimes of the trees overlap), allowing the record to be extended back about 11,000 years. Using the data from the bristlecone pine, we can correct the 5% deviations from historical dates. In this way, the known ages of bristlecone pine trees are used to calibrate C-14 dating, resulting in more accurate results.

▲ Western bristlecone pine trees can live up to 5000 years; scientists can precisely determine the age of a tree by counting the annual rings in its trunk. In this way, the trees can calibrate the time scale for radiocarbon dating.

### Example 20.5 Radiocarbon Dating

A skull believed to belong to an ancient human being has a carbon-14 decay rate of 4.50 disintegrations per minute per gram of carbon (4.50 dis/min  $\cdot$  g C). If living organisms have a decay rate of 15.3 dis/min  $\cdot$  g C, how old is the skull? (The decay rate is directly proportional to the amount of carbon-14 present.)

**SORT** You are given the current rate of decay for the skull and the assumed initial rate. You are asked to find the age of the skull, which is the time that passed in order for the rate to have reached its current value.

**STRATEGIZE** Use the expression for half-life (Equation 20.1) to find the rate constant ( $k$ ) from the half-life for C-14, which is 5715 years (Table 20.3).

Use the value of the rate constant and the initial and current rates to find  $t$  from the integrated rate law (Equation 20.4).

**SOLVE** Begin by finding the rate constant from the half-life.

Substitute the rate constant and the initial and current rates into the integrated rate law and solve for  $t$ .

**GIVEN:**  $\text{rate}_t = 4.50 \text{ dis/min} \cdot \text{g C}$ ;  
 $\text{rate}_0 = 15.3 \text{ dis/min} \cdot \text{g C}$ ;

**FIND:**  $t$

**CONCEPTUAL PLAN**

**SOLUTION**

$$\begin{aligned}
 t_{1/2} &= \frac{0.693}{k} \\
 k &= \frac{0.693}{t_{1/2}} = \frac{0.693}{5715 \text{ yr}} \\
 &= 1.213 \times 10^{-4} / \text{yr} \\
 \ln \frac{\text{rate}_t}{\text{rate}_0} &= -kt \\
 t &= -\frac{\ln \frac{\text{rate}_t}{\text{rate}_0}}{k} = -\frac{\ln \frac{4.50 \text{ dis/min} \cdot \text{g C}}{15.3 \text{ dis/min} \cdot \text{g C}}}{1.213 \times 10^{-4} / \text{yr}} \\
 &= 1.0 \times 10^4 \text{ yr}
 \end{aligned}$$

—Continued on the next page

Continued—

**CHECK** The units of the answer (yr) are correct. The magnitude of the answer is about 10,000 years, which is a little less than two half-lives. This value is reasonable given that two half-lives would result in a decay rate of about  $3.8 \text{ dis/min} \cdot \text{g C}$ .

**FOR PRACTICE 20.5** A researcher claims that an ancient scroll originated from Greek scholars in about 500 B.C. Its carbon-14 decay rate is 89% of that found in living organisms. How old is the scroll, and could it be authentic?

## Chemistry IN YOUR DAY Radiocarbon Dating and the Shroud of Turin

The Shroud of Turin—kept in the cathedral of Turin in Italy—is a linen cloth bearing a mysterious image. Many people have interpreted the image as that of a man who appears to have been crucified. The image becomes clearer if the shroud is photographed and viewed as a negative. Some claim that the shroud is the original burial cloth of Jesus, miraculously imprinted with his image. In 1988, the Roman Catholic Church chose three independent laboratories to perform radiocarbon dating on the shroud. The laboratories took samples of the cloth and measured the carbon-14 content. The three independent laboratories all arrived at similar results—the shroud was made from linen originating in about A.D. 1325. Although some have disputed the results (and continue to do so), and although no scientific test is 100% reliable, newspapers around the world announced that the Shroud did not date back to biblical times.

► The linen cloth known as the Shroud of Turin bears the image of a man believed by some to be Jesus.

### Uranium/Lead Dating

Radiocarbon dating can only measure the ages of objects that were once living and that are relatively young ( $<50,000$  years). Other radiometric dating techniques can measure the ages of prehistoric objects that were never alive. The most dependable technique relies on the ratio of uranium-238 to lead-206 within igneous rocks (rocks of volcanic origin). This technique measures the time that has passed since the rock solidified (at which point the “radiometric clock” is reset).

Because U-238 decays into Pb-206 with a half-life of  $4.5 \times 10^9$  years, the relative amounts of U-238 and Pb-206 in a uranium-containing rock reveal its age. For example, if a rock originally contained U-238 and currently contains equal amounts of U-238 and Pb-206, it is 4.5 billion years old, assuming that the rock did not contain any Pb-206 when it was formed. The latter assumption can be tested because the lead that results from the decay of uranium has a different isotopic composition than the lead that was deposited in rocks at the time of their formation. Example 20.6 shows how we can use the relative amounts of Pb-206 and U-238 to estimate a rock’s age.

### Example 20.6 Using Uranium/Lead Dating to Estimate the Age of a Rock

A meteor contains 0.556 g of Pb-206 to every 1.00 g of U-238. Assuming that the meteor did not contain any Pb-206 at the time of its formation, determine the age of the meteor. Uranium-238 decays to lead-206 with a half-life of 4.5 billion years.

**SORT** You are given the current masses of Pb-206 and U-238 in a rock and asked to find its age. You are also given the half-life of U-238.

**GIVEN:**  $m_{\text{U-238}} = 1.00 \text{ g}$ ;  $m_{\text{Pb-206}} = 0.556 \text{ g}$ ;  
 $t_{1/2} = 4.5 \times 10^9 \text{ yr}$

**FIND:**  $t$

**STRATEGIZE** Use the integrated rate law (Equation 20.3) to solve this problem. To do so, first determine the value of the rate constant ( $k$ ) from the half-life expression (Equation 20.1).

Before substituting into the integrated rate law, you need the ratio of the current amount of U-238 to the original amount ( $N_t/N_0$ ). The current mass of uranium is simply 1.00 g. The initial mass includes the current mass (1.00 g) plus the mass that has decayed into lead-206, which you can determine from the current mass of Pb-206.

Use the value of the rate constant and the initial and current amounts of U-238 and the integrated rate law to find  $t$ .

### CONCEPTUAL PLAN

**SOLVE** Follow your plan. Begin by finding the rate constant from the half-life.

### SOLUTION

$$t_{1/2} = \frac{0.693}{k}$$

$$k = \frac{0.693}{t_{1/2}} = \frac{0.693}{4.5 \times 10^9 \text{ yr}}$$

$$= 1.54 \times 10^{-10} / \text{yr}$$

Determine the mass in grams of U-238 required to form the given mass of Pb-206.

Substitute the rate constant and the initial and current masses of U-238 into the integrated rate law and solve for  $t$ . (The initial mass of U-238 is the sum of the current mass and the mass required to form the given mass of Pb-206.)

$$0.556 \text{ g Pb-206} \times \frac{1 \text{ mol Pb-206}}{206 \text{ g Pb-206}} \times \frac{1 \text{ mol U-238}}{1 \text{ mol Pb-206}} \times \frac{238 \text{ g U-238}}{1 \text{ mol U-238}}$$

$$= 0.6424 \text{ g U-238}$$

$$\ln \frac{N_t}{N_0} = -kt$$

$$t = -\frac{\ln \frac{N_t}{N_0}}{k} = -\frac{\ln \frac{1.00 \text{ g}}{1.00 \text{ g} + 0.6424 \text{ g}}}{1.54 \times 10^{-10} / \text{yr}}$$

$$= 3.2 \times 10^9 \text{ yr}$$

**CHECK** The units of the answer (yr) are correct. The magnitude of the answer is about 3.2 billion years, which is less than one half-life. This value is reasonable given that less than half of the uranium in the meteor has decayed into lead.

**FOR PRACTICE 20.6** A rock contains a Pb-206 to U-238 mass ratio of 0.145 : 1.00. Assuming that the rock did not contain any Pb-206 at the time of its formation, determine its age.

## The Age of Earth

The uranium/lead radiometric dating technique as well as other radiometric dating techniques (such as the decay of potassium-40 to argon-40) have been widely used to measure the ages of rocks on Earth and have produced highly consistent results. Rocks with ages greater than 3.5 billion years have been found on every continent. The oldest rocks have an age of approximately 4.0 billion years, establishing a lower limit for Earth's age (Earth is at least as old as its oldest rocks). The ages of about 70 meteorites that have struck Earth have also been extensively studied and have been found to be about 4.5 billion years old. Since the meteorites were formed at the same time as our solar system (which includes Earth), the best estimate for Earth's age is therefore about 4.5 billion years. That age is consistent with the estimated age of our universe—about 13.7 billion years.

The age of the universe is estimated from its expansion rate, which can be measured by examining changes in the wavelength of light from distant galaxies.

## 20.7 The Discovery of Fission: The Atomic Bomb and Nuclear Power

The element with atomic number 100 is named fermium in honor of Enrico Fermi.

In the mid-1930s Enrico Fermi (1901–1954), an Italian physicist, attempted to synthesize a new element by bombarding uranium—the heaviest known element at that time—with neutrons. Fermi speculated that if a neutron could be incorporated into the nucleus of a uranium atom, the nucleus might undergo beta decay, converting a neutron into a proton. If that happened, a new element, with atomic number 93, would be synthesized for the first time. The nuclear equation for the process is shown here:

Fermi performed the experiment and detected the emission of beta particles. However, his results were inconclusive. Had he synthesized a new element? Fermi never chemically examined the products to determine their composition and therefore could not say with certainty that he had.

Three researchers in Germany—Lise Meitner (1878–1968), Fritz Strassmann (1902–1980), and Otto Hahn (1879–1968)—repeated Fermi’s experiments and then performed careful chemical analysis of the products. What they found in the products—several elements *lighter* than uranium—would change the world forever. On January 6, 1939, Meitner, Strassmann, and Hahn reported that the neutron bombardment of uranium resulted in **nuclear fission**—the splitting of the uranium atom. The nucleus of the neutron-bombarded uranium atom was split into barium, krypton, and other smaller products. They also determined that the process emits enormous amounts of energy. A nuclear equation for a fission reaction, showing how uranium breaks apart into the daughter nuclides, is shown here:

Notice that the initial uranium atom is the U-235 isotope, which constitutes less than 1% of all naturally occurring uranium. U-238, the most abundant uranium isotope, does not undergo fission. Notice also that the process produces three neutrons, which have the potential to initiate fission in three other U-235 atoms.

Scientists quickly realized that a sample rich in U-235 could undergo a **chain reaction** in which neutrons produced by the fission of one uranium nucleus would induce fission in other uranium nuclei (Figure 20.10▶). This self-amplifying reaction is capable of producing an enormous amount of energy. This is the energy that is harnessed in an atomic bomb. However, to make a bomb, a **critical mass** of U-235—enough U-235 to produce a self-sustaining reaction—is necessary.

▲ Lise Meitner in Otto Hahn’s Berlin laboratory. Together with Hahn and Fritz Strassmann, Meitner determined that U-235 could undergo nuclear fission.

### The Manhattan Project

Fearing that Nazi Germany would develop a bomb based on nuclear fission, several U.S. scientists persuaded Albert Einstein, the most famous scientist of the time, to write a letter to President Franklin Roosevelt warning of this possibility. Einstein wrote, “. . . and it is conceivable—though much less certain—that extremely powerful bombs of a new type may thus be constructed. A single bomb of this type, carried by boat and exploded in a port, might very well destroy the whole port together with some of the surrounding territory.”

## Fission Chain Reaction

◀ **FIGURE 20.10** A Self-

**Amplifying Chain Reaction** The fission of one U-235 nucleus emits neutrons that can then initiate fission in other U-235 nuclei, resulting in a chain reaction that releases enormous amounts of energy.

Albert Einstein  
Old Grove Rd.  
Massau Point  
Peconic, Long Island

August 2nd, 1939

F.D. Roosevelt,  
President of the United States,  
White House  
Washington, D.C.

Sir:

Some recent work by E. Fermi and L. Szilard, which has been communicated to me in manuscript, leads me to expect that the element uranium may be turned into a new and important source of energy in the immediate future. Certain aspects of the situation which has arisen seem to call for watchfulness and, if necessary, quick action on the part of the Administration. I believe therefore that it is my duty to bring to your attention the following facts and recommendations:

In the course of the last four months it has been made probable - through the work of Joliot in France as well as Fermi and Szilard in America - that it may become possible to set up a nuclear chain reaction in a large mass of uranium, by which vast amounts of power and large quantities of new radium-like elements would be generated. Now it appears almost certain that this could be achieved in the immediate future.

This new phenomenon would also lead to the construction of bombs, and it is conceivable - though much less certain - that extremely powerful bombs of a new type may thus be constructed. A single bomb of this type, carried by boat and exploded in a port, might very well destroy the whole port together with some of the surrounding territory. However, such bombs might very well prove to be too heavy for transportation by air.

◀ Einstein's letter (part of which is shown here) encouraged Franklin Roosevelt to fund research for a fission bomb.

Einstein's letter helped persuade Roosevelt, and in 1941 he assembled the resources to begin the costliest scientific project ever attempted. The top-secret endeavor was called the *Manhattan Project* and its primary goal was to build an atomic bomb before the Germans did. Physicist J. R. Oppenheimer (1904–1967) led the project at a high-security research facility in Los Alamos, New Mexico. Four years later, on July 16, 1945, the United States detonated the world's first nuclear weapon at a test site in New Mexico. The first atomic bomb exploded with a force equivalent to 18,000 tons of dynamite. Ironically, the Germans—who had *not* made a successful nuclear bomb—had already been defeated by this time. Instead, the United States used the atomic bomb on Japan. One bomb was dropped on Hiroshima and a second bomb was dropped on Nagasaki. Together, the bombs killed approximately 200,000 people and led to Japan's surrender.

▲ On July 16, 1945, in the New Mexico desert, the world's first atomic bomb was detonated. It had the power of 18,000 tons of dynamite.

## Nuclear Power: Using Fission to Generate Electricity

Nuclear reactions, such as fission, generate enormous amounts of energy. In a nuclear bomb, the energy is released all at once. The energy can also be released more slowly and used for peaceful purposes such as electricity generation. In the United States, nuclear fission generates about 20% of electricity. In some other countries, nuclear fission generates as much as 70% of electricity. To get an idea of the amount of energy released during fission, imagine a hypothetical nuclear-powered car. Suppose the fuel for such a car was a uranium cylinder about the size of a pencil. How often would you have to refuel the car? The energy content of the uranium cylinder is equivalent to about 1000 twenty-gallon tanks of gasoline. If you refuel your gasoline-powered car once a week, your nuclear-powered car could go 1000 weeks—almost 20 years—before refueling.

Similarly, a nuclear-powered electricity generation plant can produce a lot of electricity from a small amount of fuel. Such plants exploit the heat created by fission, using it to boil water and make steam, which then turns the turbine on a generator to produce electricity (Figure 20.11 ▼). The fission reaction occurs in the nuclear core of

### Nuclear Reactor

▲ **FIGURE 20.11 A Nuclear Reactor** The fission of U-235 in the core of a nuclear power plant generates heat that creates steam and turns a turbine on an electrical generator. Control rods are raised or lowered to control the fission reaction. (Note that the water carrying heat away from the reactor core is contained within its own pipes and does not come into direct contact with the steam that drives the turbines.)

the power plant. The core consists of uranium fuel rods—enriched to about 3.5% U-235—interspersed between retractable neutron-absorbing control rods. When the control rods are retracted from the fuel rod assembly, the chain reaction can occur. When the control rods are fully inserted into the fuel assembly, however, they absorb the neutrons that would otherwise induce fission, shutting down the chain reaction. By retracting or inserting the control rods, the operator increases or decreases the rate of fission. In this way, the fission reaction is controlled to produce the right amount of heat needed for electricity generation. In case of a power failure, the control rods automatically drop into the fuel rod assembly, shutting down the fission reaction.

A typical nuclear power plant generates enough electricity for a city of about one million people and uses about 50 kg of fuel per day. In contrast, a coal-burning power plant uses about 2,000,000 kg of fuel to generate the same amount of electricity. Furthermore, a nuclear power plant generates no air pollution and no greenhouse gases. A coal-burning power plant emits pollutants such as carbon monoxide, nitrogen oxides, and sulfur oxides. Coal-burning power plants also emit carbon dioxide, a greenhouse gas.

## Problems with Nuclear Power

Nuclear power generation, however, is not without problems. Foremost among them is the danger of nuclear accidents. In spite of safety precautions, the fission reaction occurring in a nuclear power plant can overheat. The most famous examples of this occurred in Chernobyl, in the former Soviet Union, on April 26, 1986, and at the Fukushima Daiichi Nuclear Power Plant in Japan in March of 2011.

In the Chernobyl incident, operators of the plant were performing an experiment designed to reduce maintenance costs. In order to perform the experiment, they had to disable many of the safety features of the reactor core. The experiment failed with disastrous results. The nuclear core, composed partly of graphite, overheated and began to burn. The accident caused 31 immediate deaths and produced a fire that scattered radioactive debris into the atmosphere, making much of the surrounding land (within about a 32-kilometer radius) uninhabitable. As bad as the accident was, however, it was not a nuclear detonation. A nuclear power plant *cannot* become a nuclear bomb. The uranium fuel used in electricity generation is not sufficiently enriched in U-235 to produce a nuclear detonation. U.S. nuclear power plants have additional safety features designed to prevent similar accidents. For example, U.S. nuclear power plants have large containment structures to contain radioactive debris in the event of an accident.

In the 2011 Japanese accident, a 9.0 magnitude earthquake triggered a tsunami that flooded the coastal plant and caused the cooling system pumps to fail. Three of the nuclear cores within the plant dramatically overheated and experienced a partial meltdown (in which the fuel becomes so hot that it melts). The accident was intensified by the loss of water in the fuel storage ponds (pools of water normally used to keep spent fuel cool), which caused the fuel stored in the ponds to also overheat. The release of radiation into the environment, however, while significant, was much lower in Japan than at Chernobyl. In fact, no radioactivity-related deaths were reported at the Fukushima plant or the surrounding area. The cleanup of the site, however, will continue for many years.

A second problem associated with nuclear power is waste disposal. Although the amount of nuclear fuel used in electricity generation is small compared to other fuels, some of the products of the reaction are radioactive and have long half-lives. What do we do with this waste? Currently, in the United States, nuclear waste is stored on site at the nuclear power plants. A single permanent disposal site was being developed in Yucca Mountain, Nevada, to store U.S. waste. However, in 2010, the Obama administration halted the development of this project and formed the Blue Ribbon Commission on America's Nuclear Future to explore alternatives. The committee has made several important recommendations. These include the development of both a temporary above-ground storage facility and a permanent underground facility. However, the committee has not made any decisions regarding Yucca Mountain as a potential site for the storage facility.

▲ In 1986, the reactor core at Chernobyl (in what is now Ukraine) overheated, exploded, and destroyed part of the containment structure. The release of radioactive nuclides into the environment forced the government to relocate over 335,000 people.

Reactor cores in the United States are not made of graphite and cannot burn in the way that the Chernobyl core did.

## 20.8 Converting Mass to Energy: Mass Defect and Nuclear Binding Energy

Nuclear fission produces large amounts of energy. But where does the energy come from? We can answer this question by carefully examining the masses of the reactants and products in the fission equation from Section 20.7:

Mass Reactants		Mass Products	
${}^{235}_{92}\text{U}$	235.04392 amu	${}^{140}_{56}\text{Ba}$	139.910581 amu
${}^1_0\text{n}$	1.00866 amu	${}^{93}_{36}\text{Kr}$	92.931130 amu
		$3{}^1_0\text{n}$	3(1.00866) amu
<b>Total</b>	<b>236.05258 amu</b>		<b>235.86769 amu</b>

Notice that the products of the nuclear reaction have *less mass* than the reactants. The missing mass is converted to energy. In Chapter 1, we learned that matter is conserved in chemical reactions. In nuclear reactions matter can be converted to energy. The relationship between the amount of matter that is lost and the amount of energy formed is given by Einstein's famous equation relating the two quantities:

$$E = mc^2$$

where  $E$  is the energy produced,  $m$  is the mass lost, and  $c$  is the speed of light.

For example, in the fission reaction just shown, we calculate the quantity of energy produced as follows:

$$\begin{aligned}\text{Mass lost } (m) &= 236.05258 \text{ amu} - 235.86769 \text{ amu} \\ &= 0.18489 \text{ amu} \times \frac{1.66054 \times 10^{-27} \text{ kg}}{1 \text{ amu}} \\ &= 3.0702 \times 10^{-28} \text{ kg}\end{aligned}$$

$$\begin{aligned}\text{Energy produced } (E) &= mc^2 \\ &= 3.0702 \times 10^{-28} \text{ kg} (2.9979 \times 10^8 \text{ m/s})^2 \\ &= 2.7593 \times 10^{-11} \text{ J}\end{aligned}$$

The result ( $2.7593 \times 10^{-11} \text{ J}$ ) is the energy produced when one nucleus of U-235 undergoes fission. This may not seem like much energy, but it is only the energy produced by the fission of a *single* nucleus. We can also calculate the energy produced *per mole* of U-235 to compare it to a chemical reaction:

$$2.7593 \times 10^{-11} \frac{\text{J}}{\text{U-235 atom}} \times \frac{6.0221 \times 10^{23} \text{ U-235 atoms}}{1 \text{ mol U-235}} = 1.6617 \times 10^{13} \text{ J/mol U-235}$$

The energy produced by the fission of 1 mol of U-235 is about 17 billion kJ. In contrast, a highly exothermic chemical reaction produces 1000 kJ per mole of reactant. Fission produces over a million times more energy per mole than chemical processes.

### Mass Defect and Nuclear Binding Energy

We can examine the formation of a stable nucleus from its component particles as a nuclear reaction in which mass is converted to energy. For example, consider the formation of helium-4 from its components:

Mass Reactants		Mass Products	
$2{}^1_1\text{H}$	2(1.00783) amu	${}^4_2\text{He}$	4.00260 amu
$2{}^1_0\text{n}$	2(1.00866) amu		
<b>Total</b>	<b>4.03298 amu</b>		<b>4.00260 amu</b>

In a chemical reaction, there are also mass changes associated with the emission or absorption of energy. Because the energy involved in chemical reactions is so much smaller than that of nuclear reactions, however, these mass changes are completely negligible.

The electrons are contained on the left side in the two  ${}^1_1\text{H}$ , and on the right side in  ${}^4_2\text{He}$ . If you write the equation using only two protons on the left ( $2{}^1_1\text{p}$ ), you must also add two electrons to the left.

A helium-4 atom has less mass than the sum of the masses of its separate components. This difference in mass, known as the **mass defect**, exists in all stable nuclei. The energy corresponding to the mass defect—obtained by substituting the mass defect into the equation  $E = mc^2$ —is the **nuclear binding energy**, the amount of energy required to break apart the nucleus into its component nucleons.

Although chemists often report energies in joules, nuclear physicists often use the electron volt (eV) or megaelectron volt (MeV):  $1 \text{ MeV} = 1.602 \times 10^{-13} \text{ J}$ . Unlike energy in joules, which is typically reported per mole, energy in electron volts is reported per nucleus. A particularly useful conversion for calculating and reporting nuclear binding energies is the relationship between amu (mass units) and MeV (energy units):

$$1 \text{ amu} = 931.5 \text{ MeV}$$

A mass defect of 1 amu, when substituted into the equation  $E = mc^2$ , gives an energy of 931.5 MeV. Using this conversion factor, we can readily calculate the binding energy of the helium nucleus:

$$\begin{aligned} \text{Mass defect} &= 4.03298 \text{ amu} - 4.00260 \text{ amu} \\ &= 0.03038 \text{ amu} \end{aligned}$$

$$\begin{aligned} \text{Nuclear binding energy} &= 0.03038 \text{ amu} \times \frac{931.5 \text{ MeV}}{1 \text{ amu}} \\ &= 28.30 \text{ MeV} \end{aligned}$$

The binding energy of the helium nucleus is 28.30 MeV. In order to compare the binding energy of one nucleus to that of another, we calculate the *binding energy per nucleon*, which is the nuclear binding energy of a nuclide divided by the number of nucleons in the nuclide. For helium-4, we calculate the binding energy per nucleon as follows:

$$\begin{aligned} \text{Binding energy per nucleon} &= \frac{28.30 \text{ MeV}}{4 \text{ nucleons}} \\ &= 7.075 \text{ MeV per nucleon} \end{aligned}$$

We can calculate the binding energy per nucleon for other nuclides in the same way. For example, the nuclear binding energy of carbon-12 is 7.680 MeV per nucleon. Since the binding energy per nucleon of carbon-12 is greater than that of helium-4, we conclude the carbon-12 nuclide is more *stable* (it has lower potential energy).

An electron volt is defined as the kinetic energy of an electron that has been accelerated through a potential difference of 1 V.

### Example 20.7 Mass Defect and Nuclear Binding Energy

Calculate the mass defect and nuclear binding energy per nucleon (in MeV) for C-16, a radioactive isotope of carbon with a mass of 16.014701 amu.

#### SOLUTION

Calculate the mass defect as the difference between the mass of one C-16 atom and the sum of the masses of six hydrogen atoms and 10 neutrons.

$$\begin{aligned} \text{Mass defect} &= 6(\text{mass } {}^1_1\text{H}) + 10(\text{mass } {}^1_0\text{n}) - \text{mass } {}^{16}_6\text{C} \\ &= 6(1.00783 \text{ amu}) + 10(1.00866 \text{ amu}) - 16.014701 \text{ amu} \\ &= 0.118879 \text{ amu} \end{aligned}$$

Calculate the nuclear binding energy by converting the mass defect (in amu) into MeV. (Use  $1 \text{ amu} = 931.5 \text{ MeV}$ .)

$$0.118879 \text{ amu} \times \frac{931.5 \text{ MeV}}{1 \text{ amu}} = 110.74 \text{ MeV}$$

Determine the nuclear binding energy per nucleon by dividing by the number of nucleons in the nucleus.

$$\begin{aligned} \text{Nuclear binding energy per nucleon} &= \frac{110.74 \text{ MeV}}{16 \text{ nucleons}} \\ &= 6.921 \text{ MeV/nucleon} \end{aligned}$$

**FOR PRACTICE 20.7** Calculate the mass defect and nuclear binding energy per nucleon (in MeV) for U-238, which has a mass of 238.050784 amu.

## ► FIGURE 20.12 Nuclear

**Binding Energy per Nucleon** The nuclear binding energy per nucleon (a measure of the stability of a nucleus) reaches a maximum at Fe-56. Energy can be obtained either by breaking a heavy nucleus up into lighter ones (fission) or by combining lighter nuclei into heavier ones (fusion).

### The Nuclear Binding Energy Curve

Figure 20.12▲ shows the binding energy per nucleon plotted as a function of mass number ( $A$ ). The binding energy per nucleon is relatively low for small mass numbers and increases until about  $A = 60$ , where it reaches a maximum. Nuclides with mass numbers of about 60, therefore, are among the most stable. Beyond  $A = 60$ , the binding energy per nucleon decreases again. Figure 20.12 illustrates why nuclear fission is a highly exothermic process. When a heavy nucleus, such as U-235, breaks up into smaller nuclei, such as Ba-140 and Kr-93, the binding energy per nucleon increases. This is analogous to a chemical reaction in which weak bonds break and strong bonds form. In both cases, the process is exothermic. Figure 20.12 also reveals that the *combining* of two lighter nuclei (below  $A = 60$ ) to form a heavier nucleus is exothermic as well. This process is called *nuclear fusion*, which we discuss in the next section of this chapter.

## 20.9 Nuclear Fusion: The Power of the Sun

### Deuterium-Tritium Fusion Reaction

### ▲ FIGURE 20.13 A Nuclear Fusion Reaction

In this reaction, two heavy isotopes of hydrogen, deuterium (hydrogen-2) and tritium (hydrogen-3), fuse to form helium-4 and a neutron.

Nuclear fission is the *splitting* of a heavy nucleus to form two or more lighter ones. **Nuclear fusion**, by contrast, is the *combination* of two light nuclei to form a heavier one. Both fusion and fission emit large amounts of energy because, as we have just seen, they both form daughter nuclides with greater binding energies per nucleon than the parent nuclides. Nuclear fusion is the energy source of stars, including our sun. In stars, hydrogen atoms fuse together to form helium atoms, emitting energy in the process.

Nuclear fusion is also the basis of hydrogen bombs. A modern hydrogen bomb has up to 1000 times the explosive force of the first atomic bombs. These bombs employ the fusion reaction shown here:

In this reaction, deuterium (the isotope of hydrogen with one neutron) and tritium (the isotope of hydrogen with two neutrons) combine to form helium-4 and a neutron (Figure 20.13◀). Because fusion reactions require two positively charged nuclei (which repel each other) to fuse together, extremely high temperatures are required. In a hydrogen bomb, a small fission bomb is detonated first, creating temperatures and pressures high enough for fusion to proceed.

Nuclear fusion has been intensely investigated as a way to produce electricity. Because of the higher energy density—fusion provides about ten times more energy per gram of fuel than does fission—and because the products of the reaction are

less problematic than those of fission, fusion holds promise as a future energy source. However, despite concerted efforts, the generation of electricity by fusion remains elusive. One of the main problems is the high temperature required for fusion to occur—no material can withstand those temperatures. Using powerful magnetic fields or laser beams, scientists have succeeded in compressing and heating nuclei to the point where fusion has been initiated and even sustained for brief periods of time (Figure 20.14▶). To date, however, the amount of energy generated by fusion reactions has been less than the amount required to get it to occur. After years of spending billions of dollars on fusion research, the U.S. Congress has reduced funding for these projects. Whether fusion will ever be a viable energy source remains uncertain.

## 20.10 Nuclear Transmutation and Transuranium Elements

One of the goals of the early chemists of the Middle Ages, who were known as *alchemists*, was the transformation of ordinary metals into gold. Many alchemists hoped to turn low-cost metals, such as lead or tin, into precious metals, and in this way become wealthy. These alchemists were never successful because their attempts were merely chemical—they mixed different metals together or tried to get them to react with other substances in order to turn them into gold. In a chemical reaction, an element retains its identity, so a less valuable metal—such as lead—always remains lead, even when it forms a compound with another element.

*Nuclear* reactions, in contrast to chemical reactions, result in the transformation of one element into another, a process known as **transmutation**. We have already seen how this occurs in radioactive decay, in fission, and in fusion. In addition, other nuclear reactions that transmute elements are possible. For example, in 1919 Ernest Rutherford bombarded nitrogen-17 with alpha particles to form oxygen:

Irène Joliot-Curie (daughter of Marie Curie) and her husband Frédéric bombarded aluminum-27 with alpha particles to form phosphorus:

In the 1930s, scientists began building devices that accelerate particles to high velocities, opening the door to even more possibilities. These devices are generally of two types, the **linear accelerator** and the **cyclotron**.

In a single-stage linear accelerator, a charged particle such as a proton is accelerated in an evacuated tube. The accelerating force is provided by a potential difference (or voltage) between the ends of the tube. In multistage linear accelerators, such as the Stanford Linear Accelerator (SLAC) at Stanford University, a series of tubes of increasing length are connected to a source of alternating voltage, as shown in Figure 20.15▼. The voltage alternates in such a way that, as a positively charged particle leaves a particular tube,

### Tokamak Fusion Reactor

▲ **FIGURE 20.14 Tokamak Fusion Reactor** A tokamak uses powerful magnetic fields to confine nuclear fuel at the enormous temperatures needed for fusion. The high temperatures produce a *plasma*, a state of matter in which some fraction of the atoms are ionized.

▲ The Joliot-Curies won the 1935 Nobel Prize in chemistry for their work on nuclear transmutation.

▼ **FIGURE 20.15 The Linear Accelerator** In a multistage linear accelerator, the charge on successive tubes is rapidly alternated in such a way that as a positively charged particle leaves a particular tube, that tube becomes positively charged, repelling the particle toward the next tube. At the same time, the tube that the particle is now approaching becomes negatively charged, pulling the particle toward it. This process repeats through a number of tubes until the particle has been accelerated to a high velocity.

▲ The Stanford Linear Accelerator (top) is located at Stanford University in California. The Fermi National Accelerator Laboratory complex in Batavia, Illinois (bottom), includes two cyclotrons in a figure-8 configuration.

▲ **FIGURE 20.16 The Cyclotron** In a cyclotron, two semicircular D-shaped structures are subjected to an alternating voltage. A charged particle, starting from a point between the two, is accelerated back and forth between them, while additional magnets cause the particle to move in a spiral path.

that tube becomes positively charged, repelling the particle to the next tube. At the same time, the tube that the particle is now approaching becomes negatively charged, pulling the particle toward it. This continues throughout the linear accelerator, allowing the particle to be accelerated to velocities up to 90% of the speed of light. When particles of this speed collide with a target, they produce a shower of subatomic particles that can be studied. For example, researchers using the Stanford Linear Accelerator were awarded the 1990 Nobel Prize in physics for discovering evidence that protons and neutrons were composed of still smaller subatomic particles called *quarks*.

In a cyclotron, a similarly alternating voltage is used to accelerate a charged particle, only this time the alternating voltage is applied between the two semicircular halves of the cyclotron (Figure 20.16▲). A charged particle originally in the middle of the two semicircles is accelerated back and forth between them. Additional magnets cause the particle to move in a spiral path. As the charged particle spirals out from the center, it gains speed and eventually exits the cyclotron aimed at the target.

With linear accelerators or cyclotrons, all sorts of nuclear transmutations can be achieved. In this way, scientists have made nuclides that don't normally exist in nature. For example, uranium-238 can be made to collide with carbon-12 to form an element with atomic number 98:

This element was named californium (Cf) because it was first produced (by a slightly different nuclear reaction) at the University of California at Berkeley. Many other nuclides with atomic numbers larger than that of uranium have been synthesized since the 1940s. These synthetic elements—called transuranium elements—have been added to the periodic table.

Most synthetic elements are unstable and have very short half-lives. Some exist for only fractions of a second after they are made.

## CONCEPTUAL CONNECTION 20.4

**Nuclear Transformations** Californium-252 is bombarded with a boron-10 nucleus to produce another nuclide and six neutrons. Which nuclide forms?

## 20.11 The Effects of Radiation on Life

As we discussed in Section 20.2, the energy associated with radioactivity can ionize molecules. When radiation ionizes important molecules in living cells, problems can develop. The ingestion of radioactive materials—especially alpha and beta emitters—is

particularly dangerous because the radioactivity once inside the body can do additional damage. The effects of radiation can be divided into three different types, which we discuss in this section: acute radiation damage, increased cancer risk, and genetic effects.

## Acute Radiation Damage

Acute radiation damage results from exposure to large amounts of radiation in a short period of time. The main sources of this kind of exposure are nuclear bombs and exposed nuclear reactor cores. These high levels of radiation kill large numbers of cells. Rapidly dividing cells, such as those in the immune system and the intestinal lining, are most susceptible to radiation. Consequently, people exposed to high levels of radiation have weakened immune systems and a lowered ability to absorb nutrients from food. In milder cases, recovery is possible with time. In more extreme cases, death results, often from infection.

## Increased Cancer Risk

Lower doses of radiation over extended periods of time can increase cancer risk. Radiation increases cancer risk because it can damage DNA, the molecules in cells that carry instructions for cell growth and replication. When the DNA within a cell is damaged, the cell normally dies. Occasionally, however, changes in DNA cause cells to grow abnormally and to become cancerous. These cancerous cells grow into tumors that can spread and, in some cases, cause death. Cancer risk increases with increasing radiation exposure. However, cancer is so prevalent and has so many convoluted causes that determining an exact threshold for increased cancer risk from radiation exposure is difficult.

We explain DNA in more detail in Chapter 22.

## Genetic Defects

Another possible result of radiation exposure is genetic defects in future generations. If radiation damages the DNA of reproductive cells—such as eggs or sperm—then the offspring that develop from those cells may have genetic abnormalities. Genetic defects of this type have been observed in laboratory animals exposed to high levels of radiation. However, such genetic defects—with a clear causal connection to radiation exposure—have yet to be verified in humans, even in studies of Hiroshima survivors.

## Measuring Radiation Exposure and Dose

We can measure radiation exposure in a number of different ways. One method is to measure **exposure**, the number of decay events to which a person is exposed. The unit used for this type of exposure measurement is the *curie* (Ci), defined as  $3.7 \times 10^{10}$  decay events per second. A person exposed to a curie of radiation from an alpha emitter is bombarded by  $3.7 \times 10^{10}$  alpha particles per second. However, recall that different kinds of radiation produce different effects. For example, we know that alpha radiation has a much greater ionizing power than beta radiation. Consequently, a certain number of alpha decays occurring within a person's body (due to the ingestion of an alpha emitter) do more damage than the same number of beta decays. If the alpha emitter and beta emitter are external to the body, however, the radiation from the alpha emitter is largely stopped by clothing or the skin (due to the low penetrating power of alpha radiation), whereas the radiation from the beta emitter penetrates the skin and causes more damage. Consequently, the curie is not an effective measure of how much biological tissue damage the radiation actually does.

A better way to assess radiation exposure is to measure radiation **dose**, the amount of energy actually absorbed by body tissue. The units used for this type of exposure measurement are the *gray* (Gy), which corresponds to 1 J of energy absorbed per kilogram of body tissue, and the *rad* (for radiation absorbed dose), which corresponds to 0.01 Gy:

$$1 \text{ gray (Gy)} = 1 \text{ J/kg body tissue}$$

$$1 \text{ rad} = 0.01 \text{ J/kg body tissue}$$

Although these units measure the actual energy absorbed by bodily tissues, they still do not account for the amount of damage to biological molecules caused by that energy absorption, which differs from one type of radiation to another and from one type of biological tissue to another. For example, when a gamma ray passes through

biological tissue, the energy absorbed is spread out over the long distance that the radiation travels through the body, resulting in a low ionization density within the tissue. When an alpha particle passes through biological tissue, in contrast, the energy is absorbed over a much shorter distance, resulting in a much higher ionization density. The higher ionization density results in greater damage, even though the amount of energy absorbed by the tissue might be the same.

Consequently, a correction factor, called the **biological effectiveness factor**, or **RBE** (for *Relative Biological Effectiveness*), is usually multiplied by the dose in rads to obtain the dose in a unit called the **rem** for *roentgen equivalent man*:

Dose in rads × biological effectiveness factor = dose in rem

The biological effectiveness factor for alpha radiation, for example, is much higher than that for gamma radiation.

On average, each adult is exposed to approximately 310 mrem of radiation per year from natural sources shown in Table 20.4. The majority of this exposure comes from radon, one of the products in the uranium decay series. As we can see from Table 20.4, however, some medical procedures also involve exposure levels similar to those received from natural sources. The increased use of computed tomography (CT) scans over the last decade—which have associated exposures of 200–1600 mrem—has raised some concerns about the overuse of that technology in medicine.

It takes much more than the average natural radiation dose or the dose from a medical diagnostic procedure to produce significant health effects in humans. The first measurable effect, a decreased white blood cell count, occurs at instantaneous exposures of approximately 20 rem (Table 20.5). Exposures of 100 rem produce a definite increase in cancer risk, and exposures of over 500 rem often result in death.

A *roentgen* is defined as the amount of radiation that produces  $2.58 \times 10^{-1}$  C of charge per kg of air.

The SI unit that corresponds to the rem is the sievert (Sv). However, the rem is still commonly used in the United States. The conversion factor is 1 rem = 0.01 Sv.

TABLE 20.4 Radiation Dose by Source for Persons Living in the United States

Source	Dose
<b>Natural Radiation</b>	
A 5-hour jet airplane ride	2.5 mrem/trip (0.5 mrem/hr at 39,000 feet) (whole body dose)
Cosmic radiation from outer space	27 mrem/yr (whole body dose)
Terrestrial radiation	28 mrem/yr (whole body dose)
Natural radionuclides in the body	35 mrem/yr (whole body dose)
Radon gas	200 mrem/yr (lung dose)
<b>Diagnostic Medical Procedures</b>	
Chest X-ray	8 mrem (whole body dose)
Dental X-rays (panoramic)	30 mrem (skin dose)
Dental X-rays (two bitewings)	80 mrem (skin dose)
Mammogram	138 mrem per image
Barium enema (X-ray portion only)	406 mrem (bone marrow dose)
Upper gastrointestinal tract test	244 mrem (X-ray portion only) (bone marrow dose)
Thallium heart scan	500 mrem (whole body dose)
Computed tomography (CT) head	200 mrem (whole body dose)
Computed tomography (CT) abdomen and pelvis	1000 mrem (whole body dose)
<b>Consumer Products</b>	
Building materials	3.5 mrem/yr (whole body dose)
Luminous watches (H-3 and Pm-147)	0.04–0.1 mrem/yr (whole body dose)
Tobacco products (to smokers of 30 cigarettes per day)	16,000 mrem/yr (bronchial epithelial dose)

Source: Department of Health and Human Services, National Institutes of Health.

TABLE 20.5 Effects of Instantaneous Radiation Exposure

Approximate Dose (rem)	Probable Outcome
20–100	Decreased white blood cell count; possible increase in cancer risk
100–400	Radiation sickness including vomiting and diarrhea; skin lesions; increase in cancer risk
500	Death (often within 2 months)
1000	Death (often within 2 weeks)
2000	Death (within hours)

**Radiation Dose** Suppose a person ingests equal amounts of two nuclides, both of which are beta emitters (of roughly equal energy). Nuclide A has a half-life of 8.5 hours and Nuclide B has a half-life of 15.0 hours. Both nuclides are eliminated from the body within 24 hours of ingestion. Which of the two nuclides produces the greater radiation dose?

## 20.12 Radioactivity in Medicine and Other Applications

Radioactivity is often perceived as dangerous; however, it is also immensely useful to physicians in the diagnosis and treatment of disease and has numerous other valuable applications. The use of radioactivity in medicine can be broadly divided into *diagnostic techniques* (which diagnose disease) and *therapeutic techniques* (which treat disease).

### Diagnosis in Medicine

The use of radioactivity in diagnosis usually involves a **radiotracer**, a radioactive nuclide attached to a compound or introduced into a mixture in order to track the movement of the compound or mixture within the body. Tracers are useful in the diagnosis of disease because of two main factors: (1) the sensitivity with which radioactivity can be detected, and (2) the identical chemical behavior of a radioactive nucleus and its nonradioactive counterpart. For example, the thyroid gland naturally concentrates iodine. When a patient is given small amounts of iodine-131 (a radioactive isotope of iodine), the radioactive iodine accumulates in the thyroid, just as nonradioactive iodine does. However, the radioactive iodine emits radiation, which can be detected with great sensitivity and used to measure the rate of iodine uptake by the thyroid, and thus to image the gland.

Because different radiotracers are taken up preferentially by different organs or tissues, various radiotracers are used to monitor metabolic activity and image a variety of organs and structures, including the kidneys, heart, brain, gallbladder, bones, and arteries, as shown in Table 20.6. Radiotracers can also be employed to locate infections or cancers within the body. To locate an infection, antibodies are labeled (or tagged) with a radioactive nuclide, such as technetium-99m (where “m” means metastable), and administered to the patient. The tagged antibodies aggregate at the infected site, as described in Section 20.1. Cancerous tumors can be detected because they naturally concentrate phosphorus. When a patient is given phosphorus-32 (a radioactive isotope of phosphorus) or a phosphate compound incorporating another radioactive isotope such as Tc-99m, the tumors concentrate the radioactive substance and become sources of radioactivity that can be detected (Figure 20.17▲).

▲ **FIGURE 20.17 A Bone Scan** These images, front and rear views of the human body, were created by the gamma ray emissions of Tc-99m. Such scans are used to locate cancer that has metastasized (spread) to the bones from a primary tumor elsewhere.

TABLE 20.6 Common Radiotracers			
Nuclide	Type of Emission	Half-Life	Body Part Studied
Technetium-99m	Gamma (primarily)	6.01 hours	Various organs, bones
Iodine-131	Beta	8.0 days	Thyroid
Iron-59	Beta	44.5 days	Blood, spleen
Thallium-201	Electron capture	3.05 days	Heart
Fluorine-18	Positron emission	1.83 hours	PET studies of heart, brain
Phosphorus-32	Beta	14.3 days	Tumors in various organs

**▲ FIGURE 20.18 A PET Scan** The colored areas indicate regions of high metabolic activity in the brain of a schizophrenic patient experiencing hallucinations.

A specialized imaging technique known as **positron emission tomography (PET)** employs positron-emitting nuclides, such as fluorine-18, synthesized in cyclotrons. The fluorine-18 is attached to a metabolically active substance such as glucose and administered to the patient. As the glucose travels through the bloodstream and to the heart and brain, it carries the radioactive fluorine, which decays with a half-life of just under two hours. When a fluorine-18 nuclide decays, it emits a positron that immediately combines with any nearby electrons. Since a positron and an electron are antiparticles, they annihilate one other, producing two gamma rays that travel in exactly opposing directions. The gamma rays can be detected by an array of detectors that can locate the point of origin of the rays with great accuracy. The result is a set of highly detailed images that show both the rate of glucose metabolism and structural features of the imaged organ (Figure 20.18 ◀).

### Radiotherapy in Medicine

Because radiation kills cells and is particularly effective at killing rapidly dividing cells, it is often used as a therapy for cancer (cancer cells reproduce much faster than normal cells). Medical technicians focus high-energy photons on internal tumors to kill them. The photon beam is usually moved in a circular path around the tumor (Figure 20.19 ▼), maximizing the exposure of the tumor while minimizing the exposure of the surrounding healthy tissue. Nonetheless, cancer patients receiving such treatment usually develop the symptoms of radiation sickness, which include vomiting, skin burns, and hair loss.

**► FIGURE 20.19 Radiotherapy for Cancer** This treatment involves exposing a malignant tumor to gamma rays generated by nuclides such as cobalt-60. The beam is moved in a circular pattern around the tumor to maximize exposure of the tumor to radiation while minimizing the exposure of healthy tissues.

You may wonder why radiation—which is known to cause cancer—is also used to treat cancer. The answer lies in risk analysis. A cancer patient is normally exposed to radiation doses of about 100 rem. Such a dose increases cancer risk by about 1%. However, if the patient has a 100% chance of dying from the cancer that he already has, such a risk becomes acceptable, especially since there is a significant chance of curing the cancer.

## Other Applications

Radioactivity is often used to kill microorganisms. For example, physicians use radiation to sterilize medical devices that are to be surgically implanted. The radiation kills bacteria that might otherwise lead to infection. Similarly, radiation is used to kill bacteria and parasites in foods. Like the pasteurization of milk, the irradiation of foods makes them safer to consume and gives them a longer shelf life (Figure 20.20▶). The irradiation of raw meat and poultry kills *E. coli* and *Salmonella*, bacteria that can lead to serious illness and even death when consumed. The irradiation of food does not, however, make the food itself radioactive, nor does it decrease the nutritional value of the food. In the United States, the irradiation of many different types of foods—including beef, poultry, potatoes, flour, and fruit—has been approved by the U.S. Food and Drug Administration (FDA) and the U.S. Department of Agriculture (USDA).

Radioactivity is also used to control harmful insect populations. For example, fruit flies can be raised in large numbers in captivity and sterilized with radiation. When these fruit flies are released, they mate with wild fruit flies but do not produce offspring. The efforts of the wild fruit flies, which might otherwise lead to reproduction, are wasted, and the next generation of flies is smaller than it would otherwise have been. Similar strategies have been employed to control the populations of disease-carrying mosquitoes.

**▲ FIGURE 20.20 Irradiation of Food** Irradiation kills microbes that cause food to decay, allowing for longer and safer storage. The food is not made radioactive, and its properties are unchanged in the process. These strawberries were picked at the same time, but those on the bottom were irradiated before storage.

## Self-Assessment Quiz

- Q1.** Which daughter nuclide forms when polonium-214 undergoes alpha decay?
- ${}_{86}^{218}\text{Rn}$
  - ${}_{85}^{214}\text{At}$
  - ${}_{83}^{214}\text{Bi}$
  - ${}_{82}^{210}\text{Pb}$
- Q2.** Which nuclear equation accurately represents the beta decay of Xe-133?
- ${}_{54}^{133}\text{Xe} \longrightarrow {}_{55}^{133}\text{Cs} + {}_{-1}^0\text{e}$
  - ${}_{54}^{133}\text{Xe} \longrightarrow {}_{53}^{133}\text{I} + {}_{+1}^0\text{e}$
  - ${}_{54}^{133}\text{Xe} + {}_{-1}^0\text{e} \longrightarrow {}_{53}^{133}\text{I}$
  - ${}_{54}^{133}\text{Xe} \longrightarrow {}_{52}^{129}\text{Cs} + {}_{2}^4\text{He}$
- Q3.** Which nuclide is most likely to undergo beta decay?
- Si-22
  - Rb-91
  - Ar-35
  - Co-52
- Q4.** Which form of radioactive decay would you be most likely to detect if it were happening in the room next to the one you are currently in?
- alpha
  - beta
  - gamma
  - positron emission

- Q5.** The chart shows the mass of a decaying nuclide versus time. What is the half-life of the decay?

- 15 min
  - 25 min
  - 35 min
  - 70 min
- Q6.** Iron-59 is a beta emitter with a half-life of 44.5 days. If a sample initially contains 132 mg of iron-59, how much iron-59 is left in the sample after 265 days?
- 0.00 mg
  - 2.13 mg
  - 33.2 mg
  - 66.0 mg

Continued—

**Q7.** An artifact has a carbon-14 decay rate of 8.55 disintegrations per minute per gram of carbon (8.55 dis/min · g C). Living organisms have carbon-14 decay rate of 15.3 dis/min · g C. How old is the artifact? (The half-life of carbon-14 is 5715 yr.)

- a)  $4.81 \times 10^3$  yr                      b)  $2.10 \times 10^3$  yr  
c)  $3.20 \times 10^3$  yr                      d)  $1.21 \times 10^{-4}$  yr

**Q8.** An igneous rock contains a Pb-206/U-238 mass ratio of 0.372. How old is the rock? (U-238 decays into Pb-206 with a half-life of  $4.5 \times 10^9$  yr.)

- a)  $4.50 \times 10^9$  yr                      b)  $6.42 \times 10^9$  yr  
c)  $2.05 \times 10^9$  yr                      d)  $2.32 \times 10^9$  yr

**Q9.** Calculate the nuclear binding energy per nucleon for cobalt-59, the only stable isotope of cobalt. The mass of

cobalt-59 is 58.933198 amu. (The mass of  $^1_1\text{H}$  is 1.00783 amu, and the mass of a neutron is 1.00866 amu.)

- a) 517.3 MeV  
b) 8.768 MeV  
c) 19.16 MeV  
d)  $1.011 \times 10^{-5}$  MeV

**Q10.** Which problem is not associated with nuclear power generation?

- a) danger of overheated nuclear core  
b) waste disposal  
c) global warming  
d) none of the above (All of the above are problems associated with nuclear power generation.)

Answers: 1. d) 2. a) 3. b) 4. c) 5. c) 6. b) 7. a) 8. d) 9. b) 10. c)

### Key Concepts

#### Diagnosing Appendicitis (20.1)

- ▶ Radioactivity is the emission of subatomic particles or energetic electromagnetic radiation by the nuclei of certain atoms.
- ▶ Because some radioactive emissions can pass through matter, radioactivity is useful in medicine and many other areas of study.

#### The Discovery of Radioactivity (20.2)

- ▶ Radioactivity was discovered by Antoine-Henri Becquerel when he found that uranium causes a photographic exposure in the absence of light.

- ▶ Marie Skłodowska Curie later determined that this phenomenon was not unique to uranium, and she began calling the rays that produced the exposure radioactivity. Curie also discovered two new elements, polonium and radium.

#### Types of Radioactivity (20.3)

- ▶ The major types of natural radioactivity are alpha ( $\alpha$ ) decay, beta ( $\beta$ ) decay, gamma ( $\gamma$ ) ray emission, and positron emission.
- ▶ Alpha radiation is helium nuclei. Beta particles are electrons. Gamma rays are electromagnetic radiation of very high energy. Positrons are the antiparticles of electrons.

- ▶ A nucleus may absorb one of its orbital electrons in a process called electron capture.
- ▶ We can represent each radioactive process with a nuclear equation that illustrates how the parent nuclide changes into the daughter nuclide. In a nuclear equation, although the specific types of atoms may not balance, the atomic numbers and mass numbers must.
- ▶ Each type of radioactivity has a different ionizing and penetrating power. These values are inversely related; a particle with a higher ionizing power has a lower penetrating power. Alpha particles are the most massive and they have the highest ionizing power, followed by beta particles and positrons, which are equivalent in their ionizing power. Gamma rays have the lowest ionizing power.

### The Valley of Stability: Predicting the Type of Radioactivity (20.4)

- ▶ The stability of a nucleus, and therefore the probability that it will undergo radioactive decay, depends largely on two factors. The first is the ratio of neutrons to protons ( $N/Z$ ) because neutrons provide a strong force that overcomes the electromagnetic repulsions between the positive protons. This ratio is one for smaller elements but becomes greater than one for larger elements. The second factor related to nuclei stability is a concept known as magic numbers; certain numbers of nucleons are more stable than others.

### Detecting Radioactivity (20.5)

- ▶ Radiation detectors determine the quantity of radioactivity in an area or sample.
- ▶ Thermoluminescent dosimeters employ salt crystals for detection of radiation; such detectors do not provide an instantaneous response.
- ▶ Two detectors that instantly register the amount of radiation are the Geiger-Müller counter, which uses the ionization of argon by radiation to produce an electrical signal, and the scintillation counter, which uses the emission of light induced by radiation.

### The Kinetics of Radioactive Decay and Radiometric Dating (20.6)

- ▶ All radioactive elements decay according to first-order kinetics (Chapter 14); the half-life equation and the integrated rate law for radioactive decay are derived from the first-order rate laws.
- ▶ The kinetics of radioactive decay is used to date objects and artifacts. The age of materials that were once part of living organisms is measured by carbon-14 dating. The age of ancient rocks and Earth itself is determined by uranium/lead dating.

### The Discovery of Fission: The Atomic Bomb and Nuclear Power (20.7)

- ▶ Fission is the splitting of an atom, such as uranium-235, into two atoms of lesser atomic weight.
- ▶ Because the fission of one uranium-235 atom releases enormous amounts of energy and produces neutrons that can split other

uranium-235 atoms, the energy from these collective reactions can be harnessed in an atomic bomb or nuclear reactor.

- ▶ Nuclear power produces no air pollution and requires little mass to release lots of energy; however, there is always a danger of accidents, and it is difficult to dispose of nuclear waste.

### Converting Mass to Energy: Mass Defect and Nuclear Binding Energy (20.8)

- ▶ In a nuclear fission reaction, mass is converted into energy.
- ▶ The difference in mass between a nuclide and the individual protons and neutrons that compose it is the mass defect, and the corresponding energy, calculated from Einstein's equation  $E = mc^2$ , is the nuclear binding energy.
- ▶ The stability of a nucleus is determined by the binding energy per nucleon, which increases up to mass number 60 and then decreases.

### Nuclear Fusion: The Power of the Sun (20.9)

- ▶ Stars produce their energy by the process that is the opposite of fission: nuclear fusion, the combination of two light nuclei to form a heavier one.
- ▶ Modern nuclear weapons employ fusion. Although fusion has been examined as a possible method to produce electricity, experiments with hydrogen fusion have thus far been more costly than productive.

### Nuclear Transmutation and Transuranium Elements (20.10)

- ▶ Nuclear transmutation, the changing of one element to another element, was used to create the transuranium elements, elements with atomic numbers greater than that of uranium.
- ▶ Two devices are most commonly used to accelerate particles to the high speeds necessary for transmutation reactions: the linear accelerator and the cyclotron. Both use alternating voltage to propel particles by electromagnetic forces.

### The Effects of Radiation on Life (20.11)

- ▶ The effects of radiation can be grouped into three categories. Acute radiation damage is caused by a large exposure to radiation for a short period of time. Lower radiation exposures may result in increased cancer risk because of damage to DNA. Genetic defects are caused by damage to the DNA of reproductive cells.
- ▶ The most effective unit of measurement for the amount of radiation absorbed is the rem, which takes into account the different penetrating and ionizing powers of the various types of radiation.

### Radioactivity in Medicine (20.12)

- ▶ Radioactivity is central to the diagnosis of medical problems by means of radiotracers and positron emission tomography (PET). Both of these techniques can provide data about the appearance and metabolic activity of an organ, or help locate a tumor.
- ▶ Radiation is also used to treat cancer because it kills cells. Radiation can kill bacteria in foods and control harmful insect populations.

## Key Equations and Relationships

The First-Order Rate Law (20.6)

$$\text{Rate} = kN$$

The Half-Life Equation (20.6)

$$t_{1/2} = \frac{0.693}{k} \quad k = \text{rate constant}$$

The Integrated Rate Law (20.6)

$$\ln \frac{N_t}{N_0} = -kt \quad N_t = \text{number of radioactive nuclei at time } t$$

$$N_0 = \text{initial number of radioactive nuclei}$$

Einstein's Energy-Mass Equation (20.6)

$$E = mc^2$$

Key Learning Outcomes

CHAPTER OBJECTIVES	ASSESSMENT
Writing Nuclear Equations for Alpha Decay (20.3) 	Example 20.1   For Practice 20.1   Exercises 31–36
Writing Nuclear Equations for Beta Decay, Positron Emission, and Electron Capture (20.3)	Example 20.2   For Practice 20.2   For More Practice 20.2 Exercises 31–36
Predicting the Type of Radioactive Decay (20.4)	Example 20.3   For Practice 20.3   Exercises 41, 42
Using Radioactive Decay Kinetics (20.6)	Example 20.4   For Practice 20.4   Exercises 45–52
Using Radiocarbon Dating (20.6) 	Example 20.5   For Practice 20.5   Exercises 53, 54
Using Uranium/Lead Dating to Estimate the Age of a Rock (20.6)	Example 20.6   For Practice 20.6   Exercises 55, 56
Determining the Mass Defect and Nuclear Binding Energy (20.8)	Example 20.7   For Practice 20.7   Exercises 65–72

EXERCISES

Review Questions

- What is radioactivity? Who discovered it? How was it discovered?
- Explain Marie Curie’s role in the discovery of radioactivity.
- Define  $A$ ,  $Z$ , and  $X$  in the following notation used to specify a nuclide:  ${}^A_ZX$ .
- Use the notation from Question 3 to write symbols for a proton, a neutron, and an electron.
- What is an alpha particle? What happens to the mass number and atomic number of a nuclide that emits an alpha particle?
- What is a beta particle? What happens to the mass number and atomic number of a nuclide that emits a beta particle?
- What is a gamma ray? What happens to the mass number and atomic number of a nuclide that emits a gamma ray?
- What is a positron? What happens to the mass number and atomic number of a nuclide that emits a positron?
- Describe the process of electron capture. What happens to the mass number and atomic number of a nuclide that undergoes electron capture?
- Rank alpha particles, beta particles, positrons, and gamma rays in terms of: (a) increasing ionizing power; (b) increasing penetrating power.
- Explain why the ratio of neutrons to protons ( $N/Z$ ) is important in determining nuclear stability. How can you use the  $N/Z$  ratio of a nuclide to predict the kind of radioactive decay that it might undergo?
- What are magic numbers? How are they important in determining the stability of a nuclide?
- Describe the basic way that each device detects radioactivity: (a) thermoluminescent dosimeter; (b) Geiger-Müller counter; and (c) scintillation counter.
- Explain the concept of half-life with respect to radioactive nuclides. What rate law is characteristic of radioactivity?
- Explain the main concepts behind the technique of radiocarbon dating. How can radiocarbon dating be corrected for changes in atmospheric concentrations of C-14? What range of ages can be reliably determined by C-14 dating?
- How is the uranium to lead ratio in a rock used to estimate its age? How does this dating technique provide an estimate for Earth’s age? How old is Earth according to this dating method?
- Describe fission. Include the concepts of chain reaction and critical mass in your description. How and by whom was fission discovered? Explain how fission can be used to generate electricity.
- What was the Manhattan Project? Briefly describe its development and culmination.
- Describe the advantages and disadvantages of using fission to generate electricity.
- The products of a nuclear reaction usually have a different mass than the reactants. Why?
- Explain the concepts of mass defect and nuclear binding energy. At what mass number does the nuclear binding energy per nucleon peak? What is the significance of this?
- What is fusion? Why can fusion and fission both produce energy? Explain.
- What are some of the problems associated with using fusion to generate electricity?

24. Explain transmutation and provide one or two examples.
25. How does a linear accelerator work? For what purpose is it used?
26. Explain the basic principles of cyclotron function.
27. How does radiation affect living organisms?
28. Explain why different kinds of radiation affect biological tissues differently, even though the amount of radiation exposure may be the same.

## Problems by Topic

### Radioactive Decay and Nuclide Stability

31. Write a nuclear equation for the indicated decay of each nuclide.
  - a. U-234 (alpha)
  - b. Th-230 (alpha)
  - c. Pb-214 (beta)
  - d. N-13 (positron emission)
  - e. Cr-51 (electron capture)
32. Write a nuclear equation for the indicated decay of each nuclide.
  - a. Po-210 (alpha)
  - b. Ac-227 (beta)
  - c. Tl-207 (beta)
  - d. O-15 (positron emission)
  - e. Pd-103 (electron capture)
33. Write a partial decay series for Th-232 undergoing the sequential decays:  $\alpha$ ,  $\beta$ ,  $\beta$ ,  $\alpha$ .
34. Write a partial decay series for Rn-220 undergoing the sequential decays:  $\alpha$ ,  $\alpha$ ,  $\beta$ ,  $\beta$ .
35. Fill in the missing particles in each nuclear equation.
  - a.  $\text{_____} \rightarrow {}^{217}_{85}\text{At} + {}^4_2\text{He}$
  - b.  ${}^{241}_{94}\text{Pu} \rightarrow {}^{241}_{95}\text{Am} + \text{_____}$
  - c.  ${}^{19}_{11}\text{Ne} \rightarrow {}^{19}_{10}\text{Ne} + \text{_____}$
  - d.  ${}^{75}_{34}\text{Se} + \text{_____} \rightarrow {}^{75}_{33}\text{As}$
36. Fill in the missing particles in each nuclear equation.
  - a.  ${}^{241}_{95}\text{Am} \rightarrow {}^{237}_{93}\text{Np} + \text{_____}$
  - b.  $\text{_____} \rightarrow {}^{233}_{92}\text{U} + {}^0_{-1}\text{e}$
  - c.  ${}^{237}_{93}\text{Np} \rightarrow \text{_____} + {}^4_2\text{He}$
  - d.  ${}^{75}_{35}\text{Br} \rightarrow \text{_____} + {}^0_{+1}\text{e}$
37. Determine whether or not each nuclide is likely to be stable. State your reasons.
  - a. Mg-26
  - b. Ne-25
  - c. Co-51
  - d. Te-124
38. Determine whether or not each nuclide is likely to be stable. State your reasons.
  - a. Ti-48
  - b. Cr-63
  - c. Sn-102
  - d. Y-88
39. The first six elements of the first transition series have the following number of stable isotopes:

Element	Number of Stable Isotopes
Sc	1
Ti	5
V	1
Cr	3
Mn	1
Fe	4

Explain why Sc, V, and Mn each have only one stable isotope while the other elements have several.

29. Explain the significance of the biological effectiveness factor in measuring radiation exposure. What types of radiation would you expect to have the highest biological effectiveness factor?
30. Describe some of the medical uses, both in diagnosis and in treatment of disease, of radioactivity.
40. Neon and magnesium each have three stable isotopes while sodium and aluminum each have only one. Explain why this might be so.
41. Predict a likely mode of decay for each unstable nuclide.
  - a. Mo-109
  - b. Ru-90
  - c. P-27
  - d. Sn-100
42. Predict a likely mode of decay for each unstable nuclide.
  - a. Sb-132
  - b. Te-139
  - c. Fr-202
  - d. Ba-123
43. Which nuclide in each pair would you expect to have the longer half-life?
  - a. Cs-113 or Cs-125
  - b. Fe-62 or Fe-70
44. Which nuclide in each pair would you expect to have the longer half-life?
  - a. Cs-149 or Cs-139
  - b. Fe-45 or Fe-52

### The Kinetics of Radioactive Decay and Radiometric Dating

45. One of the nuclides in spent nuclear fuel is U-235, an alpha emitter with a half-life of 703 million years. How long will it take for the amount of U-235 to reach 10.0% of its initial amount?
46. A patient is given 0.050  $\mu\text{g}$  of technetium-99m, a radioactive isotope with a half-life of about 6.0 hours. How long does it take for the radioactive isotope to decay to  $1.0 \times 10^{-3} \mu\text{g}$ ? (Assume no excretion of the nuclide from the body.)
47. A radioactive sample contains 1.55 g of an isotope with a half-life of 3.8 days. What mass of the isotope remains after 5.5 days?
48. At 8:00 A.M., a patient receives a 1.5- $\mu\text{g}$  dose of I-131 to treat thyroid cancer. If the nuclide has a half-life of eight days, what mass of the nuclide remains in the patient at 5:00 P.M. the next day? (Assume no excretion of the nuclide from the body.)
49. A sample of F-18 has an initial decay rate of  $1.5 \times 10^5/\text{s}$ . How long will it take for the decay rate to fall to  $2.5 \times 10^3/\text{s}$ ? (F-18 has a half-life of 1.83 hours.)
50. A sample of Tl-201 has an initial decay rate of  $5.88 \times 10^4/\text{s}$ . How long will it take for the decay rate to fall to 287/s? (Tl-201 has a half-life of 3.042 days.)
51. A wooden boat discovered just south of the Great Pyramid in Egypt has a carbon-14/carbon-12 ratio that is 72.5% of that found in living organisms. How old is the boat?
52. A layer of peat beneath the glacial sediments of the last ice age has a carbon-14/carbon-12 ratio that is 22.8% of that found in living organisms. How long ago was this ice age?
53. An ancient skull has a carbon-14 decay rate of 0.85 disintegration per minute per gram of carbon (0.85 dis/min  $\cdot$  g C). How old is the skull? (Assume that living organisms have a carbon-14 decay rate of 15.3 dis/min  $\cdot$  g C and that carbon-14 has a half-life of 5715 yr.)

54. A mammoth skeleton has a carbon-14 decay rate of 0.48 disintegration per minute per gram of carbon (0.48 dis/min · g C). When did the mammoth live? (Assume that living organisms have a carbon-14 decay rate of 15.3 dis/min · g C and that carbon-14 has a half-life of 5715 yr.)
55. A rock from Australia contains 0.438 g of Pb-206 to every 1.00 g of U-238. Assuming that the rock did not contain any Pb-206 at the time of its formation, how old is the rock?
56. A meteor has a Pb-206:U-238 mass ratio of 0.855:1.00. What is the age of the meteor? (Assume that the meteor did not contain any Pb-206 at the time of its formation.)

### Fission, Fusion, and Transmutation

57. Write the nuclear reaction for the neutron-induced fission of U-235 to form Xe-144 and Sr-90. How many neutrons are produced in the reaction?
58. Write the nuclear reaction for the neutron-induced fission of U-235 to produce Te-137 and Zr-97. How many neutrons are produced in the reaction?
59. Write the nuclear equation for the fusion of two H-2 atoms to form He-3 and one neutron.
60. Write the nuclear equation for the fusion of H-3 with H-1 to form He-4.
61. A breeder nuclear reactor is a reactor in which nonfissionable (nonfissile) U-238 is converted into fissionable (fissile) Pu-239. The process involves bombardment of U-238 by neutrons to form U-239, which then undergoes two sequential beta decays. Write nuclear equations for this process.
62. Write the series of nuclear equations to represent the bombardment of Al-27 with a neutron to form a product that subsequently undergoes a beta decay.
63. Rutherfordium-257 was synthesized by bombarding Cf-249 with C-12. Write the nuclear equation for this reaction.
64. Element 107, now named bohrium, was synthesized by German researchers by colliding bismuth-209 with chromium-54 to form a bohrium isotope and one neutron. Write the nuclear equation to represent this reaction.

### Energetics of Nuclear Reactions, Mass Defect, and Nuclear Binding Energy

65. If 1.0 g of matter is converted to energy, how much energy is formed?
66. A typical home uses approximately  $1.0 \times 10^3$  kWh of energy per month. If the energy came from a nuclear reaction, what mass would have to be converted to energy per year to meet the energy needs of the home?

67. Calculate the mass defect and nuclear binding energy per nucleon of each nuclide.
- O-16 (atomic mass = 15.994915 amu)
  - Ni-58 (atomic mass = 57.935346 amu)
  - Xe-129 (atomic mass = 128.904780 amu)
68. Calculate the mass defect and nuclear binding energy per nucleon of each nuclide.
- Li-7 (atomic mass = 7.016003 amu)
  - Ti-48 (atomic mass = 47.947947 amu)
  - Ag-107 (atomic mass = 106.905092 amu)
69. Calculate the quantity of energy produced per gram of U-235 (atomic mass = 235.043922 amu) for the neutron-induced fission of U-235 to form Xe-144 (atomic mass = 143.9385 amu) and Sr-90 (atomic mass = 89.907738 amu) (discussed in Problem 57).
70. Calculate the quantity of energy produced per mole of U-235 (atomic mass = 235.043922 amu) for the neutron-induced fission of U-235 to produce Te-137 (atomic mass = 136.9253 amu) and Zr-97 (atomic mass = 96.910950 amu) (discussed in Problem 58).
71. Calculate the quantity of energy produced per gram of reactant for the fusion of two H-2 (atomic mass = 2.014102 amu) atoms to form He-3 (atomic mass = 3.016029 amu) and one neutron (discussed in Problem 59).
72. Calculate the quantity of energy produced per gram of reactant for the fusion of H-3 (atomic mass = 3.016049 amu) with H-1 (atomic mass = 1.007825 amu) to form He-4 (atomic mass = 4.002603 amu) (discussed in Problem 60).

### Effects and Applications of Radioactivity

73. A 75-kg human has a dose of 32.8 rad of radiation. How much energy is absorbed by the person's body? Compare this energy to the amount of energy absorbed by the person's body if he or she jumped from a chair to the floor (assume that the chair is 0.50 m from the ground and that all of the energy from the fall is absorbed by the person).
74. If a 55-gram laboratory mouse has a dose of 20.5 rad of radiation, how much energy is absorbed by the mouse's body?
75. PET studies require fluorine-18, which is produced in a cyclotron and decays with a half-life of 1.83 hours. Assuming that the F-18 can be transported at 60.0 miles/hour, how close must the hospital be to the cyclotron if 65% of the F-18 produced makes it to the hospital?
76. Suppose a patient is given 1.55  $\mu$ g of I-131, a beta emitter with a half-life of 8.0 days. Assuming that none of the I-131 is eliminated from the person's body in the first 4.0 hours of treatment, what is the exposure (in Ci) during those first four hours?

## Cumulative Problems

77. Complete each nuclear equation and calculate the energy change (in J/mol of reactant) associated with each (Be-9 = 9.012182 amu, Bi-209 = 208.980384 amu, He-4 = 4.002603 amu, Li-6 = 6.015122 amu, Ni-64 = 63.927969 amu, Rg-272 = 272.1535 amu, Ta-179 = 178.94593 amu, and W-179 = 178.94707 amu).
- $\text{_____} + {}^9_4\text{Be} \longrightarrow {}^6_3\text{Li} + {}^4_2\text{He}$
  - ${}^{209}_{83}\text{Bi} + {}^{64}_{28}\text{Ni} \longrightarrow {}^{272}_{111}\text{Rg} + \text{_____}$
  - ${}^{179}_{74}\text{W} + \text{_____} \longrightarrow {}^{179}_{73}\text{Ta}$

78. Complete each nuclear equation and calculate the energy change (in J/mol of reactant) associated with each (Al-27 = 26.981538 amu, Am-241 = 241.056822 amu, He-4 = 4.002603 amu, Np-237 = 237.048166 amu, P-30 = 29.981801 amu, S-32 = 31.972071 amu, and Si-29 = 28.976495 amu).
- ${}^{27}_{13}\text{Al} + {}^4_2\text{He} \longrightarrow {}^{30}_{15}\text{P} + \text{_____}$
  - ${}^{32}_{16}\text{S} + \text{_____} \longrightarrow {}^{29}_{14}\text{Si} + {}^4_2\text{He}$
  - ${}^{241}_{95}\text{Am} \longrightarrow {}^{237}_{93}\text{Np} + \text{_____}$

79. Write the nuclear equation for the most likely mode of decay for each unstable nuclide.
- Ru-114
  - Ra-216
  - Zn-58
  - Ne-31
80. Write the nuclear equation for the most likely mode of decay for each unstable nuclide.
- Kr-74
  - Th-221
  - Ar-44
  - Nb-85
81. Bismuth-210 is a beta emitter with a half-life of 5.0 days. If a sample contains 1.2 g of Bi-210 (atomic mass = 209.984105 amu), how many beta emissions occur in 13.5 days? If a person's body intercepts 5.5% of those emissions, to what amount of radiation (in Ci) is the person exposed?
82. Polonium-218 is an alpha emitter with a half-life of 3.0 minutes. If a sample contains 55 mg of Po-218 (atomic mass = 218.008965 amu), how many alpha emissions occur in 25.0 minutes? If the polonium is ingested by a person, to what amount of radiation (in Ci) is the person exposed?
83. Radium-226 (atomic mass = 226.025402 amu) decays to radon-224 (a radioactive gas) with a half-life of  $1.6 \times 10^3$  years. What volume of radon gas (at 25.0 °C and 1.0 atm) does 25.0 g of radium produce in 5.0 days? (Report your answer to two significant digits.)
84. In one of the neutron-induced fission reactions of U-235 (atomic mass = 235.043922 amu), the products are Ba-140 and Kr-93 (a radioactive gas). What volume of Kr-93 (at 25.0 °C and 1.0 atm) is produced when 1.00 g of U-235 undergoes this fission reaction?
85. When a positron and an electron annihilate one another, the resulting mass is completely converted to energy. Calculate the energy associated with this process in kJ/mol.
86. A typical nuclear reactor produces about 1.0 MW of power per day. What is the minimum rate of mass loss required to produce this much energy?
87. Find the binding energy in an atom of  $^3\text{He}$ , which has a mass of 3.016030 amu.
88. The overall hydrogen burning reaction in stars can be represented as the conversion of four protons to one  $\alpha$  particle. Use the data for the mass of H-1 and He-4 to calculate the energy released by this process.
89. The nuclide  $^{247}\text{Es}$  can be made by bombardment of  $^{238}\text{U}$  in a reaction that emits five neutrons. Identify the bombarding particle.
90. The nuclide  $^6\text{Li}$  reacts with  $^2\text{H}$  to form two identical particles. Identify the particles.
91. The half-life of  $^{238}\text{U}$  is  $4.5 \times 10^9$  yr. A sample of rock of mass 1.6 g produces 29 dis/s. Assuming all the radioactivity is due to  $^{238}\text{U}$ , find the percent by mass of  $^{238}\text{U}$  in the rock.
92. The half-life of  $^{232}\text{Th}$  is  $1.4 \times 10^{10}$  yr. Find the number of disintegrations per hour emitted by 1.0 mol of  $^{232}\text{Th}$ .
93. A 1.50-L gas sample at 745 mm Hg and 25.0 °C contains 3.55% radon-220 by volume. Radon-220 is an alpha emitter with a half-life of 55.6 s. How many alpha particles are emitted by the gas sample in 5.00 minutes?
94. A 228-mL sample of an aqueous solution contains 2.35%  $\text{MgCl}_2$  by mass. Exactly one-half of the magnesium ions are Mg-28, a beta emitter with a half-life of 21 hours. What is the decay rate of Mg-28 in the solution after 4.00 days? (Assume a density of 1.02 g/mL for the solution.)
95. When a positron and an electron collide and annihilate each other, two photons of equal energy are produced. Find the wavelength of these photons.
96. The half-life of  $^{235}\text{U}$ , an alpha emitter, is  $7.1 \times 10^8$  yr. Calculate the number of alpha particles emitted by 1.0 mg of this nuclide in 1.0 minute.
97. Given that the energy released in the fusion of two deuterons to a  $^3\text{He}$  and a neutron is 3.3 MeV, and in the fusion to tritium and a proton it is 4.0 MeV, calculate the energy change for the process  $^3\text{He} + ^1_0\text{n} \longrightarrow ^3_1\text{H} + ^1_1\text{p}$ . Suggest an explanation for why this process occurs at much lower temperatures than either of the first two.
98. The nuclide  $^{18}\text{F}$  decays by both electron capture and  $\beta^+$  decay. Find the difference in the energy released by these two processes. The atomic masses are  $^{18}\text{F} = 18.000950$  and  $^{18}\text{O} = 17.9991598$ .

## Challenge Problems

99. The space shuttle carries about 72,500 kg of solid aluminum fuel, which is oxidized with ammonium perchlorate according to the reaction shown here:

The space shuttle also carries about 608,000 kg of oxygen (which reacts with hydrogen to form gaseous water).

- Assuming that aluminum and oxygen are the limiting reactants, determine the total energy produced by these fuels. ( $\Delta H_f^\circ$  for solid ammonium perchlorate is  $-295$  kJ/mol.)
- Suppose that a future space shuttle is powered by matter-antimatter annihilation. The matter could be normal hydrogen (containing a proton and an electron) and the antimatter could be antihydrogen (containing an antiproton and a positron). What mass of antimatter is required to produce the energy equivalent of the aluminum and oxygen fuel currently carried on the space shuttle?

100. Suppose that an 85.0-gram laboratory animal ingests 10.0 mg of a substance that contained 2.55% by mass Pu-239, an alpha emitter with a half-life of 24,110 years.

- What is the animal's initial radiation exposure in curies?
- If all of the energy from the emitted alpha particles is absorbed by the animal's tissues, and if the energy of each emission is  $7.77 \times 10^{-12}$  J, what is the dose in rads to the animal in the first 4.0 hours following the ingestion of the radioactive material? Assuming a biological effectiveness factor of 20, what is the 4.0-hour dose in rems?

101. In addition to the natural radioactive decay series that begins with U-238 and ends with Pb-206, there are natural radioactive decay series that begin with U-235 and Th-232. Both of these series end with nuclides of Pb. Predict the likely end product of each series and the number of  $\alpha$  decay steps that occur.

- 102.** The hydride of an unstable nuclide of a Group IIA metal,  $\text{MH}_2(\text{s})$ , decays by  $\alpha$ -emission. A 0.025-mol sample of the hydride is placed in an evacuated 2.0 L container at 298 K. After 82 minutes, the pressure in the container is 0.55 atm. Find the half-life of the nuclide.
- 103.** The nuclide  $^{38}\text{Cl}$  decays by beta emission with a half-life of 37.2 min. A sample of 0.40 mol of  $\text{H}^{38}\text{Cl}$  is placed in a 6.24-L container. After 74.4 min the pressure is 1650 mmHg. What is the temperature of the container?

## Conceptual Problems

- 105.** Closely examine the diagram representing the beta decay of fluorine-21 and draw in the missing nucleus.

- 106.** Approximately how many half-lives must pass for the amount of radioactivity in a substance to decrease to below 1% of its initial level?
- 107.** A person is exposed for three days to identical amounts of two different nuclides that emit positrons of roughly equal energy. The half-life of nuclide A is 18.5 days and the half-life of nuclide B is 255 days. Which of the two nuclides poses the greater health risk?
- 108.** Identical amounts of two different nuclides, an alpha emitter and a gamma emitter, with roughly equal half-lives are spilled in a building adjacent to your bedroom. Which of the two

nuclides is likely to pose the greater health threat to you while you sleep in your bed? If you accidentally wander into the building and ingest equal amounts of the two nuclides, which of the two is likely to pose the greater health threat?

- 109.** Drugstores in many areas now carry tablets, under such trade names as Iosat and NoRad, designed to be taken in the event of an accident at a nuclear power plant or a terrorist attack that releases radioactive material. These tablets contain potassium iodide (KI). Can you explain the nature of the protection that they provide? (*Hint:* see the label in the photo.)

## Active Classroom Learning

### Questions for Group Work

Discuss these questions with the group and record your consensus answer.

- 110.** Complete the table of particles involved in radioactive decay.

Particle Name	Symbol	Mass Number	Atomic Number or Charge
alpha particle	$^4_2\text{He}$		
	$^0_{-1}\text{e}$		-1
gamma ray	$^0_0\gamma$		
positron		0	
	$^1_0\text{n}$	1	
proton	$^1_1\text{p}$		

- 111.** Have each group member study a different mode of radioactive decay (alpha, beta, gamma, positron emission, or electron capture) and present it to the group. Each presentation should include a description of the process, a description of

how the atomic and mass numbers change, and at least one specific example. Presentations should also address the questions: What do all nuclear reactions have in common and how do they differ from each other?

- 112.** Two students are discussing whether or not the total mass changes during a nuclear reaction. The first student insists that mass is conserved. The second student says that mass is converted into energy. Explain the context in which each student is correct and how that fact is applied to solve problems.
- 113.** Write all the balanced nuclear equation for each step of the nuclear decay sequence that starts with U-238 and ends with U-234. Refer to Figure 20.6 for the decay processes involved.
- 114.** Radon-220 undergoes alpha decay with a half-life of 55.6 s. Assume there are 16,000 atoms present initially and make a table showing how many atoms will be present at 0 s, 55.6 s, 111.2 s, 166.8 s, 222.4 s, and 278.0 s (all multiples of the half-life). Now calculate how many atoms will be present at 50 s, 100 s, and 200 s (not multiples of the half-life). Make a graph with number of atoms present on the y-axis and total time on the x-axis.

## Data Interpretation and Analysis

### The Use of Technetium-99m for Medical Diagnosis

**115.** Radioisotopes are useful for medical diagnosis because once ingested the isotopes accumulate in various organs such as the liver, lungs, lymph nodes, and bones. The energy emitted from the decay of the isotopes provides a way to image an organ or bone.

The radioactive isotope Technetium-99m ("m" means metastable) is prepared by bombarding Molybdenum-99 with deuterons:

Once formed,  ${}^{99\text{m}}_{43}\text{Tc}$  decays to  ${}^{99}_{43}\text{Tc}$  by a release of gamma rays:

A patient is given a dose of 0.060 mg of  ${}^{99\text{m}}_{43}\text{Tc}$  and data in Table a are obtained:

Time (h)	Mass of ${}^{99\text{m}}_{43}\text{Tc}$ (mg)	Emission (photons/s)
0.00	0.0600	6000
2.00	0.0476	4762
4.00	0.0378	3781
6.00		3003
8.00	0.0239	
10.00		1893
12.00		
14.00	0.0120	

**TABLE a** Technetium-m Emission

Use the information provided in the question and the table to answer the following questions:

- Given that all radioactive decay follows first-order kinetics, determine the half-life of  ${}^{99\text{m}}_{43}\text{Tc}$ .
- Determine the decay constant,  $k$ , for  ${}^{99\text{m}}_{43}\text{Tc}$ .
- Complete the information in the table.
- How many atoms of  ${}^{99\text{m}}_{43}\text{Tc}$  are present at  $t = 0.0$  h?
- How many atoms of  ${}^{99\text{m}}_{43}\text{Tc}$  are present at  $t = 12.06$  h?

## Answers to Conceptual Connections

### Alpha and Beta Decay

**20.1 (c)** The arrow labeled  $x$  represents a decrease of two neutrons and two protons, indicative of alpha decay. The arrow labeled  $y$  represents a decrease of one neutron and an increase of one proton, indicative of beta decay.

### Half-Life

**20.2 (b)** The half-life is the time it takes for the number of nuclei to decay to one-half of their original number.

### Half-Life and the Amount of Radioactive Sample

**20.3 (b)** 0.10 mol. The sample loses one-half of the number of moles per half-life; so over the course of four half-lives, the amount falls to 0.10 mol.

### Nuclear Transformations

**20.4** Lawrencium-256

### Radiation Exposure

**20.5** Nuclide A. Because nuclide A has a shorter half-life, more of the nuclides will decay, and therefore produce radiation, before they exit the body.

# Organic Chemistry

Organic chemistry just now is enough to drive one mad. It gives one the impression of a primeval, tropical forest full of the most remarkable things. . . .

**KEY LEARNING OUTCOMES 1016**

Organic chemistry is the study of carbon-containing compounds. Carbon is unique in the sheer number of compounds that it forms. Millions of organic compounds are known, and researchers discover new ones every day. Carbon is also unique in the *diversity* of compounds that it forms. In most cases, a fixed number of carbon atoms can combine with a fixed number of atoms of another element to form many different compounds. For example, 10 carbon atoms and 22 hydrogen atoms form 75 distinctly different compounds. With carbon as the backbone, nature is able to take the same combination of atoms and bond them together in slightly different ways to produce a huge variety of substances. It is not surprising that life is based on the chemistry of carbon because life needs diversity to exist, and organic chemistry is nothing if not diverse. In this chapter, we peer into Friedrich Wöhler's "primeval tropical forest" (see chapter-opening quotation) and discover the most remarkable things.

▲ About half of all men's colognes contain at least some patchouli alcohol ( $C_{15}H_{26}O$ ), an organic compound (pictured here) derived from the patchouli plant. Patchouli alcohol has a pungent, musty, earthy fragrance.

## 21.1 Fragrances and Odors

Have you ever ridden an elevator with someone wearing too much perfume? Or found yourself too close to a skunk? Or caught a whiff of rotting fish? What causes these fragrances and odors? When we inhale certain molecules called odorants, they bind with olfactory receptors in our noses. This interaction sends a nerve signal to the brain that we experience as a smell. Some smells, such as that of perfume, are pleasant (when not overdone). Other smells, such as that of the skunk or rotting fish, are unpleasant. Our sense of smell helps us identify food, people, and other organisms, and it alerts us to dangers such as polluted air or spoiled food. Smell (olfaction) is one way we probe the environment around us.

$\text{CH}_3\text{CH}=\text{CHCH}_2\text{SH}$   
2-Butene-1-thiol

$\begin{array}{c} \text{CH}_3 \\ | \\ \text{CH}_3\text{CHCH}_2\text{CH}_2\text{SH} \end{array}$   
3-Methyl-1-butanethiol

▲ The smell of skunk is due primarily to the molecules shown here.

Odorants, if they are to reach our noses, must be volatile. However, many volatile substances have no scent at all. Nitrogen, oxygen, water, and carbon dioxide molecules, for example, are constantly passing through our noses, yet they produce no smell because they do not bind to olfactory receptors. Most common smells are caused by **organic molecules**, molecules containing carbon combined with several other elements, such as hydrogen, nitrogen, oxygen, and sulfur. Organic molecules are responsible for the smells of roses, vanilla, cinnamon, almond, jasmine, body odor, and rotting fish. When you wander into a rose garden, you experience the sweet smell caused in part by geraniol, an organic compound emitted by roses. Men's colognes often contain patchouli alcohol, an earthy-smelling organic compound extracted from the patchouli plant. If you have been in the vicinity of skunk spray (or have been unfortunate enough to be sprayed yourself), you are familiar with the unpleasant smell of 2-butene-1-thiol and 3-methyl-1-butanethiol, two particularly odorous compounds present in the secretion that skunks use to defend themselves.

The study of compounds containing carbon combined with one or more of the elements mentioned previously (hydrogen, nitrogen, oxygen, and sulfur), including their properties and their reactions, is **organic chemistry**. Besides composing much of what we smell, organic compounds are prevalent in foods, drugs, petroleum products, and pesticides. Organic chemistry is also the basis for living organisms. Life has evolved based on carbon-containing compounds, making organic chemistry of utmost importance to any person interested in understanding living organisms.

## 21.2 Carbon: Why It Is Unique

Why did life evolve based on the chemistry of carbon? Why is life not based on some other element? The answer may not be simple, but we do know that life—in order to exist—must entail complexity, and carbon chemistry is clearly complex. The number of compounds containing carbon is greater than the number of compounds containing all of the other elements combined. The reasons for carbon's unique and versatile behavior include its ability to form four covalent bonds, its ability to form double and triple bonds, and its tendency to *catenate* (that is, to form chains).

### Carbon's Tendency to Form Four Covalent Bonds

Carbon—with its four valence electrons—forms four covalent bonds. Consider the Lewis structure and space-filling models of two simple carbon compounds, methane and ethane:

The geometry about a carbon atom forming four single bonds is tetrahedral, as shown in the figure for methane. Carbon's ability to form four bonds, and to form those bonds with a number of different elements, results in the potential to form many different compounds. As you learn to draw structures for organic compounds, always remember to draw carbon with four bonds.

### Carbon's Ability to Form Double and Triple Bonds

Carbon atoms also form double bonds (trigonal planar geometry) and triple bonds (linear geometry), adding even more diversity to the number of compounds that carbon forms. Consider the Lewis structure and space-filling models of the carbon compounds ethene and ethyne:

## Chemistry IN YOUR DAY

### Vitalism and the Perceived Differences between Organic and Inorganic Compounds

**B**y the end of the eighteenth century, chemists had learned that compounds could be broadly categorized as either organic or inorganic. Organic compounds come from living things, whereas inorganic compounds come from the nonliving things on Earth. Sugar—obtained from sugarcane or the sugar beet—is a common example of an organic compound. Salt—mined from the ground or extracted from ocean water—is a common example of an inorganic compound.

Organic and inorganic compounds are different, not only in their origin, but also in their properties. Organic compounds are easily decomposed. Sugar, for example, readily decomposes into carbon and water when heated. (Think of the last time you burned something sugary in a pan or in the oven.) Inorganic compounds are more difficult to decompose. Salt decomposes only when heated to very high temperatures.

Even more curious to these early chemists was their inability to synthesize a single organic compound in the laboratory. Although they were able to synthesize many inorganic compounds, despite concerted efforts, they were not able to synthesize any organic compounds.

The origin and properties of organic compounds led early chemists to postulate that organic compounds were unique to living organisms. They hypothesized that living organisms contained a *vital force*—a mystical or supernatural power—that allowed them to produce organic compounds. They thought that producing an organic compound outside of a living organism was impossible because the vital force was not present. This belief—which became known as *vitalism*—explained why no chemist had succeeded in synthesizing an organic compound in the laboratory.

An experiment performed in 1828 by German chemist Friedrich Wöhler (1800–1882) marked the beginning of the

end of vitalism. Wöhler heated ammonium cyanate (an inorganic compound) and formed urea (an organic compound):

Urea was a known organic compound that had previously been isolated only from urine. Although it was not realized at the time, Wöhler's simple experiment was a key step in opening all of life to scientific investigation. He showed that the compounds composing living organisms—like all compounds—follow scientific laws and can be studied and understood.

Today, known organic compounds number in the millions, and modern organic chemistry is a vast field that produces substances as diverse as drugs, petroleum products, and plastics.

Friedrich Wöhler

► The synthesis of urea in 1828 by German chemist Friedrich Wöhler marked the beginning of the end for vitalism.

In contrast, silicon (the element in the periodic table with properties closest to that of carbon) does not readily form double or triple bonds because the greater size of silicon atoms results in a Si—Si bond that is too long for much overlap between nonhybridized *p* orbitals.

### Carbon's Tendency to Catenate

Carbon, more than any other element, can bond to itself to form chain, branched, and ring structures as we can see in propane, isobutane, and cyclohexane:

Propane

Isobutane

Cyclohexane

Although other elements can form chains, none surpasses carbon at this ability. Silicon, for example, can form chains with itself. However, silicon's affinity for oxygen (the Si—O bond is stronger than the Si—Si bond) coupled with the prevalence of oxygen in

our atmosphere means that silicon–silicon chains are readily oxidized to form silicates (the silicon–oxygen compounds that compose a significant proportion of minerals). By contrast, the C—C bond (347 kJ/mol) and the C—O bond (359 kJ/mol) are nearly the same strength, allowing carbon chains to exist relatively peacefully in an oxygen-rich environment. Silicon’s affinity for oxygen robs it of the rich diversity that catenation provides to carbon.

## 21.3 Hydrocarbons: Compounds Containing Only Carbon and Hydrogen

Hydrocarbons—compounds that contain only carbon and hydrogen—are the simplest organic compounds. However, because of the uniqueness of carbon, many different kinds of hydrocarbons exist. We use hydrocarbons as fuels. Candle wax, oil, gasoline, liquid petroleum (LP) gas, and natural gas are all composed of hydrocarbons. Hydrocarbons are also the starting materials in the synthesis of many different consumer products, including fabrics, soaps, dyes, cosmetics, drugs, plastic, and rubber.

As shown in Figure 21.1 ▼, we classify hydrocarbons into four different types: **alkanes**, **alkenes**, **alkynes**, and **aromatic hydrocarbons**. We differentiate alkanes, alkenes, and alkynes—also called **aliphatic hydrocarbons**—based on the kinds of bonds between carbon atoms. (We discuss aromatic hydrocarbons in detail in Section 21.7.) As Table 21.1 illustrates, alkanes have only single bonds between carbon atoms, alkenes have a double bond, and alkynes have a triple bond.

► **FIGURE 21.1** Four Types of Hydrocarbons

**TABLE 21.1** Alkanes, Alkenes, Alkynes

Type of Hydrocarbon	Type of Bonds	Generic Formula*	Example
Alkanes	All single	$C_nH_{2n+2}$	$\begin{array}{c} \text{H} & \text{H} \\   &   \\ \text{H}-\text{C}- & \text{C}-\text{H} \\   &   \\ \text{H} & \text{H} \end{array}$ Ethane
Alkenes	One (or more) double	$C_nH_{2n}$	$\begin{array}{c} \text{H} & & \text{H} \\ & \diagdown & / \\ & \text{C}=\text{C} \\ & / & \diagdown \\ \text{H} & & \text{H} \end{array}$ Ethene
Alkynes	One (or more) triple	$C_nH_{2n-2}$	$\text{H}-\text{C}\equiv\text{C}-\text{H}$ Ethyne

\*  $n$  is the number of carbon atoms. These formulas apply only to noncyclic structures containing no more than one multiple bond.

## Drawing Hydrocarbon Structures

Throughout this book, we have relied primarily on molecular formulas as the simplest way to represent compounds. In organic chemistry molecular formulas are insufficient because, as we have already discussed, the same atoms can bond together in different ways to form different compounds. For example, consider an alkane with four carbon atoms and 10 hydrogen atoms. Two different structures, named butane and isobutane, are possible:

Butane and isobutane are **structural isomers**, molecules with the same molecular formula but different structures. Because of their different structures, they have different properties—indeed, they are different compounds. Isomerism is ubiquitous in organic chemistry. Butane has two structural isomers. Pentane ( $\text{C}_5\text{H}_{12}$ ) has three, hexane ( $\text{C}_6\text{H}_{14}$ ) has five, and decane ( $\text{C}_{10}\text{H}_{22}$ ) has 75!

We represent the structure of a particular hydrocarbon with a **structural formula**, a formula that shows not only the numbers of each kind of atoms, but also how the atoms are bonded. Organic chemists use several different kinds of structural formulas. For example, we can represent butane and isobutane in each of the following ways:

The structural formula shows all of the carbon and hydrogen atoms in the molecule and how they are bonded. The *condensed structural formula* groups the hydrogen atoms with the carbon atom to which they are bonded. Condensed structural formulas may show some of the bonds (as the previous examples do) or none at all. We can also write the condensed structural formula for butane as  $\text{CH}_3\text{CH}_2\text{CH}_2\text{CH}_3$ . The *carbon skeleton formula* (also called a line formula) shows the carbon-carbon bonds only as lines. Each end or bend of a line represents a carbon atom bonded to as many hydrogen atoms as necessary to form a total of four bonds. Carbon skeleton formulas allow us to draw complex structures quickly.

Note that structural formulas are generally not three-dimensional representations of molecules—as space-filling or ball-and-stick models are—but rather two-dimensional representations that show how atoms are bonded together. As such, the most important feature of a structural formula is the *connectivity* of the atoms, not the exact way the formula is drawn. For example, consider the two condensed structural formulas for butane and the corresponding space-filling models below them as shown on the right.

A carbon skeleton formula is called a *line formula* because it uses lines to represent a molecule.

Since rotation about single bonds is relatively unhindered at room temperature, the two structural formulas are identical, even though they are drawn differently.

We represent double and triple bonds in structural formulas with double or triple lines. For example, we draw the structural formulas for  $C_3H_6$  (propene) and  $C_3H_4$  (propyne) as follows:

The kind of structural formula we use depends on how much information we want to portray. Example 21.1 illustrates how to write structural formulas for a compound.

### Example 21.1 Writing Structural Formulas for Hydrocarbons

Write the structural formulas and carbon skeleton formulas for the five isomers of  $C_6H_{14}$  (hexane).

#### SOLUTION

To begin, draw the carbon backbone of the straight-chain isomer.

Next, determine the carbon backbone structure of the other isomers by arranging the carbon atoms in four other unique ways.

Fill in all the hydrogen atoms so that each carbon forms four bonds.

Write the carbon skeleton formulas by using lines to represent each carbon-carbon bond. Remember that each end and each bend represents a carbon atom.	
<b>FOR PRACTICE 21.1</b> Write the structural formulas and carbon skeleton formulas for the three isomers of $C_5H_{12}$ (pentane).	

**Organic Structures** Which structure is an *isomer* of the molecule shown here (and not just the same structure)?

### CONCEPTUAL CONNECTION 21.1

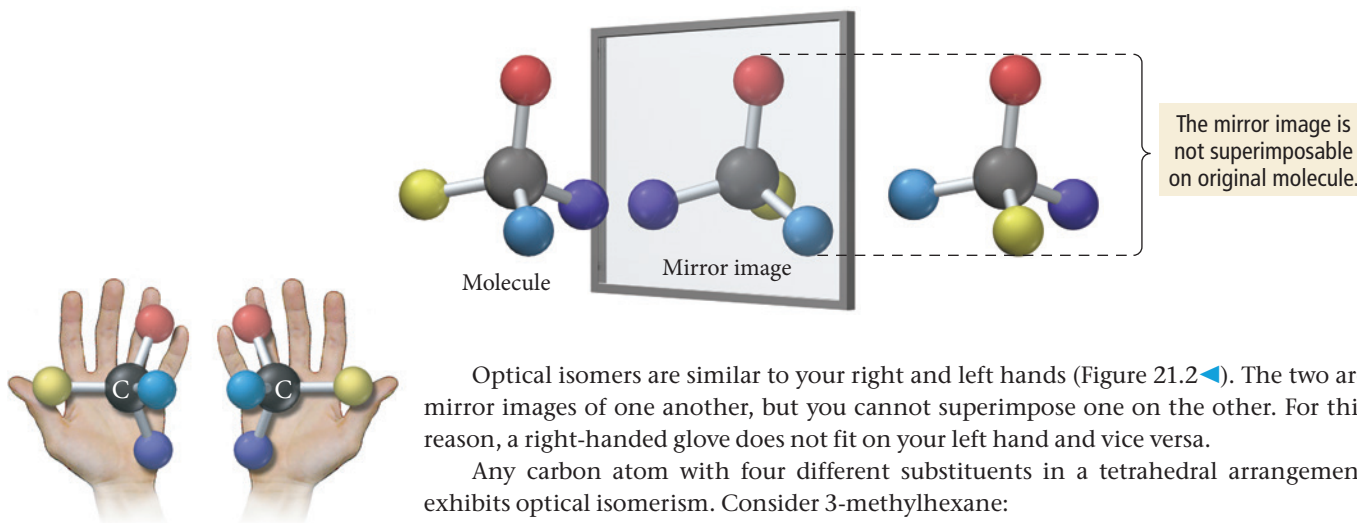

## Stereoisomerism and Optical Isomerism

**Stereoisomers** are molecules in which the atoms have the same connectivity but a different spatial arrangement. We categorize stereoisomers into two types: geometric (or cis-trans) isomers and optical isomers. We discuss geometric isomers in Section 21.5.

**Optical isomers** are two molecules that are nonsuperimposable mirror images of one another. Consider the molecule shown here with its mirror image:

The molecule cannot be superimposed onto its mirror image. If we swing the mirror image around to try to superimpose the two, we find that there is no way to get all four substituent atoms to align together. (A substituent is an atom or group of atoms that is substituted for a hydrogen atom in an organic compound.)

▲ **FIGURE 21.2** Mirror Images

The left and right hands are nonsuperimposable mirror images, just as are optical isomers.

Optical isomers of 3-methylhexane

The molecules shown here are nonsuperimposable mirror images and are optical isomers of one other.

Optical isomers are also called **enantiomers**. Any molecule, such as 3-methylhexane, that exhibits optical isomerism is said to be **chiral**, from the Greek word *cheir*, which means “hand.” Optical isomerism is important, not only to organic chemistry, but also to biology and biochemistry. Most biological molecules are chiral and usually only one or the other enantiomer is active in biological systems. For example, glucose, the primary fuel of cells, is chiral. Only one of the enantiomers of glucose has that familiar sweet taste, and only that enantiomer can fuel cellular functioning; the other enantiomer is not even metabolized by the body.

Some of the physical and chemical properties of enantiomers are indistinguishable from one another. For example, both of the optical isomers of 3-methylhexane have identical freezing points, melting points, and densities. However, the properties of enantiomers differ from one another in two important ways: (1) in the direction in which they rotate polarized light and (2) in their chemical behavior in a chiral environment.

### Rotation of Polarized Light

*Plane-polarized light* is light that is made up of electric field waves that oscillate in only one plane as shown in Figure 21.3. When a beam of plane-polarized light is directed through a sample containing only one of two optical isomers, the plane of polarization of the light is rotated as shown in Figure 21.4. One of the two optical isomers rotates the polarization of the light clockwise and is the **dextrorotatory** isomer (or the *d* isomer). The other isomer rotates the polarization of the light counterclockwise and is the **levorotatory** isomer (or the *l* isomer). An equimolar mixture of both optical isomers does not rotate the polarization of light at all and is called a **racemic mixture**.

*Dextrorotatory* means turning clockwise or to the right. *Levorotatory* means turning counterclockwise or to the left.

**FIGURE 21.3 Plane-Polarized Light** The electric field of plane-polarized light oscillates in one plane.

**FIGURE 21.4 Rotation of Plane-Polarized Light** Plane-polarized light rotates as it passes through a sample containing only one of two optical isomers.

### Chemical Behavior in a Chiral Environment

Optical isomers also exhibit different chemical behavior when they are in a chiral environment (a chiral environment is one that is not superimposable on its mirror image). Enzymes are large biological molecules that catalyze reactions in living organisms and provide chiral environments. Consider the following simplified picture of two enantiomers in a chiral environment:

One of the enantiomers fits the template, but the other does not, no matter how it is rotated. In this way, an enzyme is able to catalyze the reaction of one enantiomer because that particular enantiomer fits the “template.” As we have already seen, most biological molecules are chiral, and usually only one or the other enantiomer is active in biological systems.

### Optical Isomers Which molecule exhibits optical isomerism?

CONCEPTUAL  
CONNECTION 21.2

## 21.4 Alkanes: Saturated Hydrocarbons

Alkanes (hydrocarbons containing only single bonds) are often referred to as **saturated hydrocarbons** because they are saturated (loaded to capacity) with hydrogen. The simplest hydrocarbons are methane ( $\text{CH}_4$ ), the main component of natural gas; ethane ( $\text{C}_2\text{H}_6$ ), a minority component in natural gas; and propane ( $\text{C}_3\text{H}_8$ ), the main component of LP gas:

Methane

Ethane

Propane

Alkanes containing four or more carbon atoms may be straight or branched (as we have already seen). The straight-chain isomers are often called normal alkanes, or *n*-alkanes. As the number of carbon atoms increases in the *n*-alkanes, so does their boiling point (as shown in Table 21.2). The increase is due to the increasing dispersion force with increasing molar mass (see Section 11.3). Methane, ethane, propane, and *n*-butane are all gases at room temperature, but the next *n*-alkane in the series, pentane, is a liquid at room temperature. Pentane is a component of gasoline. Table 21.3 summarizes the *n*-alkanes through decane, which contains 10 carbon atoms. Like pentane, hexane through decane are all components of gasoline. Table 21.4 summarizes the uses of hydrocarbons.

**TABLE 21.2** *n*-Alkane Boiling Points

<i>n</i> -Alkane	Boiling Point (°C)
Methane	-161.5
Ethane	-88.6
Propane	-42.1
<i>n</i> -Butane	-0.5
<i>n</i> -Pentane	36.0
<i>n</i> -Hexane	68.7
<i>n</i> -Heptane	98.5
<i>n</i> -Octane	125.6

**TABLE 21.3** *n*-Alkanes

<i>n</i>	Name	Molecular Formula $\text{C}_n\text{H}_{2n+2}$	Structural Formula	Condensed Structural Formula
1	Methane	$\text{CH}_4$	$\begin{array}{c} \text{H} \\   \\ \text{H}-\text{C}-\text{H} \\   \\ \text{H} \end{array}$	$\text{CH}_4$

TABLE 21.4 Uses of Hydrocarbons

Number of Carbon Atoms	State	Major Uses
1–4	Gas	Heating fuel, cooking fuel
5–7	Low-boiling liquids	Solvents, gasoline
6–18	Liquids	Gasoline
12–24	Liquids	Jet fuel, portable-stove fuel
18–50	High-boiling liquids	Diesel fuel, lubricants, heating oil
50+	Solids	Petroleum jelly, paraffin wax

## Naming Alkanes

Many organic compounds have common names that we can learn only through familiarity. Because of the sheer number of organic compounds, however, we need a systematic method of nomenclature. In this book, we adopt the nomenclature system recommended by the IUPAC (International Union of Pure and Applied Chemistry), which is used throughout the world. In this system, the longest continuous chain of carbon atoms—called the base chain—determines the base name of the compound. The root of the base name depends on the number of carbon atoms in the base chain, as shown in Table 21.5. Base names for alkanes always have the ending *-ane*. Groups of carbon atoms branching off the base chain are alkyl groups and are named as substituents. Remember that a *substituent* is an atom or group of atoms that has been substituted for a hydrogen atom in an organic compound. Common alkyl groups are shown in Table 21.6.

**TABLE 21.5** Prefixes for Base Names of Alkane Chains

Number of Carbon Atoms	Prefix
1	meth-
2	eth-
3	prop-
4	but-
5	pent-
6	hex-
7	hept-
8	oct-
9	non-
10	dec-

**TABLE 21.6** Common Alkyl Groups

Condensed Structural Formula	Name	Condensed Structural Formula	Name
$\text{—CH}_3$	Methyl	$\begin{array}{c} \text{—CHCH}_3 \\   \\ \text{CH}_3 \end{array}$	Isopropyl
$\text{—CH}_2\text{CH}_3$	Ethyl	$\begin{array}{c} \text{—CH}_2\text{CHCH}_3 \\   \\ \text{CH}_3 \end{array}$	Isobutyl
$\text{—CH}_2\text{CH}_2\text{CH}_3$	Propyl	$\begin{array}{c} \text{—CHCH}_2\text{CH}_3 \\   \\ \text{CH}_3 \end{array}$	sec-Butyl
$\text{—CH}_2\text{CH}_2\text{CH}_2\text{CH}_3$	Butyl	$\begin{array}{c} \text{CH}_3 \\   \\ \text{—CCH}_3 \\   \\ \text{CH}_3 \end{array}$	tert-Butyl

The procedure in Examples 21.2 and 21.3 will allow you to systematically name many alkanes. The procedure is in the left column and two examples of applying the procedure are in the center and right columns.

## Procedure for...

### Naming Alkanes

- Count the number of carbon atoms in the longest continuous carbon chain to determine the base name of the compound. Locate the prefix corresponding to this number of atoms in Table 21.5 and add the ending *-ane* to form the base name.

#### Example 21.2

##### Naming Alkanes

Name this alkane:

##### SOLUTION

This compound has five carbon atoms in its longest continuous chain.

The correct prefix from Table 21.5 is *pent-*. The base name is pentane.

#### Example 21.3

##### Naming Alkanes

Name this alkane:

##### SOLUTION

This compound has eight carbon atoms in its longest continuous chain.

The correct prefix from Table 21.5 is *oct-*. The base name is octane.

<p>2. Consider every branch from the base chain to be a substituent. Name each substituent according to Table 21.6.</p>	<p>This compound has one substituent named <i>ethyl</i>.</p> $\text{CH}_3-\text{CH}_2-\text{CH}-\text{CH}_2-\text{CH}_3$ 	<p>This compound has one substituent named <i>ethyl</i> and two named <i>methyl</i>.</p> $\text{CH}_3-\text{CH}-\text{CH}_2-\text{CH}-\text{CH}_2-\text{CH}_2-\text{CH}-\text{CH}_3$ 
<p>3. Beginning with the end closest to the branching, number the base chain and assign a number to each substituent. (If two substituents occur at equal distances from each end, go to the next substituent to determine from which end to start numbering.)</p>	<p>Number the base chain as follows:</p> $\overset{1}{\text{CH}_3}-\overset{2}{\text{CH}_2}-\overset{3}{\text{CH}}-\overset{4}{\text{CH}_2}-\overset{5}{\text{CH}_3}$ $\quad \quad \quad \text{CH}_2$ $\quad \quad \quad \text{CH}_3$ <p>Assign the number 3 to the ethyl substituent.</p>	<p>Number the base chain as follows:</p> $\overset{1}{\text{CH}_3}-\overset{2}{\text{CH}}-\overset{3}{\text{CH}_2}-\overset{4}{\text{CH}}-\overset{5}{\text{CH}_2}-\overset{6}{\text{CH}_2}-\overset{7}{\text{CH}}-\overset{8}{\text{CH}_3}$ $\quad \quad \quad \text{CH}_3 \quad \quad \quad \text{CH}_2 \quad \quad \quad \text{CH}_3$ $\quad \quad \quad \text{CH}_3 \quad \quad \quad \text{CH}_3$ <p>Assign the number 4 to the ethyl substituent and the numbers 2 and 7 to the two methyl substituents.</p>
<p>4. Write the name of the compound in the following format: (substituent number)-(substituent name)-(base name). If there are two or more substituents, give each one a number and list them alphabetically with hyphens between words and numbers.</p>	<p>The name of the compound is:</p> <p style="text-align: center;">3-ethylpentane</p>	<p>The basic form of the name of the compound is:</p> <p style="text-align: center;">4-ethyl-2,7-methyloctane</p> <p>List ethyl before methyl because substituents are listed in alphabetical order.</p>
<p>5. If a compound has two or more identical substituents, indicate the number of identical substituents with the prefix <i>di-</i> (2), <i>tri-</i> (3), or <i>tetra-</i> (4) before the substituent's name. Separate the numbers indicating the positions of the substituents relative to each other with a comma. Do not take the prefixes into account when alphabetizing.</p>	<p>Does not apply to this compound.</p>	<p>This compound has two methyl substituents; therefore, the name of the compound is:</p> <p style="text-align: center;">4-ethyl-2,7-dimethyloctane</p>
	<p><b>FOR PRACTICE 21.2</b></p> <p>Name this alkane:</p> $\text{CH}_3-\text{CH}_2-\text{CH}-\text{CH}_2-\text{CH}_2-\text{CH}_3$ $\quad \quad \quad \text{CH}_3$	<p><b>FOR PRACTICE 21.3</b></p> <p>Name this alkane:</p> $\text{CH}_3-\text{CH}_2-\text{CH}-\text{CH}_2-\text{CH}-\text{CH}_2-\text{CH}_3$ $\quad \quad \quad \text{CH}_3 \quad \quad \quad \text{CH}_3$

**Example 21.4** Naming Alkanes

Name this alkane:  $\text{CH}_3-\underset{\text{CH}_3}{\text{CH}}-\text{CH}_2-\underset{\text{CH}_3}{\text{CH}}-\text{CH}_3$

**SOLUTION**

1. The longest continuous carbon chain has five atoms. Therefore, the base name is pentane.

2. This compound has two substituents, both of which are named methyl.

3. Since both substituents are equidistant from the ends, it does not matter from which end you start numbering.

4, 5. Use the general form for the name:

(substituent number)-(substituent name)(base name)

Because this compound contains two identical substituents, step 5 from the naming procedure applies and you use the prefix *di*-. Indicate the position of each substituent with a number separated by a comma.

2,4-dimethylpentane

**FOR PRACTICE 21.4** Name this alkane:  $\text{CH}_3-\underset{\text{CH}_3}{\text{CH}}-\text{CH}_2-\underset{\text{CH}_3}{\text{CH}}-\underset{\text{CH}_3}{\text{CH}}-\text{CH}_3$

**21.5 Alkenes and Alkynes**

Alkenes are hydrocarbons containing at least one double bond between carbon atoms. Alkynes contain at least one triple bond. Because of the double or triple bond, alkenes and alkynes have fewer hydrogen atoms than the corresponding alkanes and are therefore called **unsaturated hydrocarbons** because they are not loaded to capacity with hydrogen. Recall that noncyclic alkenes have the formula  $\text{C}_n\text{H}_{2n}$  and noncyclic alkynes have the formula  $\text{C}_n\text{H}_{2n-2}$ . The simplest alkene is ethene ( $\text{C}_2\text{H}_4$ ), also called ethylene:

The general formulas shown here for alkenes and alkynes assume only one multiple bond.

Ethene or ethylene

$\text{C}_2\text{H}_4$

Formula

Structural formula

Space-filling model

The geometry about each carbon atom in ethene is trigonal planar (see Example 10.8 for the valence bond model of ethene), making ethene a flat, rigid molecule. Ethene is a ripening agent in fruit such as bananas. When a banana within a cluster of bananas begins to ripen, it emits ethene. The ethene then causes other bananas in the cluster to ripen. Banana farmers usually pick bananas green for ease of shipping. When the bananas arrive at their destination, the fruit is often “gassed” with ethene to initiate ripening. Table 21.7 lists the names and structures of several other alkenes. Most of them do not have familiar uses except their presence as minority components in fuels.

TABLE 21.7 Alkenes

$n$	Name	Molecular Formula $C_nH_{2n}$	Structural Formula	Condensed Structural Formula
2	Ethene	$C_2H_4$	$\begin{array}{c} H & & H \\ & \backslash & / \\ & C = C \\ & / & \backslash \\ H & & H \end{array}$	$CH_2=CH_2$
3	Propene	$C_3H_6$	$\begin{array}{c} H & & H & H \\ & \backslash & / &   \\ & C = C & - C - H \\ & / & &   \\ H & & & H \end{array}$	$CH_2=CHCH_3$
4	1-Butene*	$C_4H_8$	$\begin{array}{c} H & & H & H & H \\ & \backslash & / &   &   \\ & C = C & - C - C - H \\ & / & &   &   \\ H & & & H & H \end{array}$	$CH_2=CHCH_2CH_3$
5	1-Pentene*	$C_5H_{10}$	$\begin{array}{c} H & & H & H & H & H \\ & \backslash & / &   &   &   \\ & C = C & - C - C - C - H \\ & / & &   &   &   \\ H & & & H & H & H \end{array}$	$CH_2=CHCH_2CH_2CH_3$
6	1-Hexene*	$C_6H_{12}$	$\begin{array}{c} H & & H & H & H & H & H \\ & \backslash & / &   &   &   &   \\ & C = C & - C - C - C - C - H \\ & / & &   &   &   &   \\ H & & & H & H & H & H \end{array}$	$CH_2=CHCH_2CH_2CH_2CH_3$

\* These alkenes have one or more isomers depending on the position of the double bond. The isomers shown here have the double bond in the 1 position, meaning the first carbon-carbon bond of the chain.

The simplest alkyne is ethyne,  $C_2H_2$ , also known as acetylene:

Ethyne or  
acetylene

Formula

Structural formula

Space-filling model

The geometry about each carbon atom in ethyne is linear, making ethyne a linear molecule. Ethyne (or acetylene) is commonly used as fuel for welding torches. Table 21.8 shows the names and structures of several other alkynes. Like alkenes, the alkynes do not have familiar uses other than their presence as minority components of gasoline.

## Naming Alkenes and Alkynes

We name alkenes and alkynes in the same way we name alkanes with the following exceptions:

- The base chain is the longest continuous carbon chain *that contains the double or triple bond*.
- The base name has the ending *-ene* for alkenes and *-yne* for alkynes.
- We number the base chain to give the double or triple bond the lowest possible number.
- We insert a number indicating the position of the double or triple bond (lowest possible number) just before the base name.

▲ Welding torches burn ethyne in pure oxygen to produce the very hot flame needed for melting metals.

For example, the alkene and alkyne shown here are 2-methyl-2-pentene and 1-butyne:

**TABLE 21.8** Alkynes

<i>n</i>	Name	Molecular Formula $\text{C}_n\text{H}_{2n-2}$	Structural Formula	Condensed Structural Formula
2	Ethyne	$\text{C}_2\text{H}_2$	$\text{H}-\text{C}\equiv\text{C}-\text{H}$	$\text{CH}\equiv\text{CH}$
3	Propyne	$\text{C}_3\text{H}_4$	$\begin{array}{c} \text{H} \\   \\ \text{H}-\text{C}\equiv\text{C}-\text{C}-\text{H} \\   \\ \text{H} \end{array}$	$\text{CH}\equiv\text{CCH}_3$
4	1-Butyne*	$\text{C}_4\text{H}_6$	$\begin{array}{c} \text{H} \quad \text{H} \\   \quad   \\ \text{H}-\text{C}\equiv\text{C}-\text{C}-\text{C}-\text{H} \\   \quad   \\ \text{H} \quad \text{H} \end{array}$	$\text{CH}\equiv\text{CCH}_2\text{CH}_3$
5	1-Pentyne*	$\text{C}_5\text{H}_8$	$\begin{array}{c} \text{H} \quad \text{H} \quad \text{H} \\   \quad   \quad   \\ \text{H}-\text{C}\equiv\text{C}-\text{C}-\text{C}-\text{C}-\text{H} \\   \quad   \quad   \\ \text{H} \quad \text{H} \quad \text{H} \end{array}$	$\text{CH}\equiv\text{CCH}_2\text{CH}_2\text{CH}_3$
6	1-Hexyne*	$\text{C}_6\text{H}_{10}$	$\begin{array}{c} \text{H} \quad \text{H} \quad \text{H} \quad \text{H} \\   \quad   \quad   \quad   \\ \text{H}-\text{C}\equiv\text{C}-\text{C}-\text{C}-\text{C}-\text{C}-\text{H} \\   \quad   \quad   \quad   \\ \text{H} \quad \text{H} \quad \text{H} \quad \text{H} \end{array}$	$\text{CH}\equiv\text{CCH}_2\text{CH}_2\text{CH}_2\text{CH}_3$

\* These alkynes have one or more isomers depending on the position of the triple bond. The isomers shown here have the triple bond in the 1 position, meaning the first carbon-carbon bond of the chain.

### Example 21.5 Naming Alkenes and Alkynes

Name each compound.

#### SOLUTION

- (a) 1. The longest continuous carbon chain containing the double bond has six carbon atoms. The base name is therefore *hexene*.

<p>2. The two substituents are both methyl.</p>	
<p>3. One of the exceptions listed previously states that, in naming alkenes, you should number the chain so that the <i>double bond</i> has the lowest number. In this case, the double bond is equidistant from the ends. Assign the double bond the number 3. The two methyl groups are then at positions 3 and 4.</p>	
<p>4, 5. Use the general form for the name: (substituent number)-(substituent name)(base name) Because this compound contains two identical substituents, step 5 of the naming procedure applies. Use the prefix <i>di-</i>. In addition, indicate the position of each substituent with a number separated by a comma. Because this compound is an alkene, specify the position of the double bond, isolated by hyphens, just before the base name.</p>	<p>3,4-dimethyl-3-hexene</p>
<p><b>(b)</b> 1. The longest continuous carbon chain containing the triple bond is five carbon atoms long; therefore, the base name is <i>pentyne</i>.</p>	
<p>2. There are two substituents; one is a methyl group and the other an isopropyl group.</p>	
<p>3. Number the base chain, giving the triple bond the lowest number (1). Assign the isopropyl and methyl groups the numbers 3 and 4, respectively.</p>	
<p>4. Use the general form for the name: (substituent number)-(substituent name)(base name) Since there are two substituents, list both of them in alphabetical order. Because this compound is an alkyne, specify the position of the triple bond with a number isolated by hyphens just before the base name.</p>	<p>3-isopropyl-4-methyl-1-pentyne</p>

## Geometric (Cis-Trans) Isomerism in Alkenes

A major difference between a single bond and a double bond is the degree to which rotation occurs about the bond. As discussed in Section 10.7, rotation about a double bond is highly restricted due to the overlap between unhybridized  $p$  orbitals on the adjacent carbon atoms.

Consider the difference between 1,2-dichloroethane and 1,2-dichloroethene:

The hybridization of the carbon atoms in 1,2-dichloroethane is  $sp^3$ , resulting in relatively free rotation about the sigma single bond. Consequently, the two structures are identical at room temperature because they quickly interconvert:

In contrast, rotation about the double bond (sigma + pi) in 1,2-dichloroethene is restricted, so at room temperature, 1,2-dichloroethene exists in two isomeric forms:

These two forms of 1,2-dichloroethene are different compounds with different properties as shown in Table 21.9. This kind of isomerism is a type of stereoisomerism (see Section 21.3) called **geometric** (or **cis-trans**) **isomerism**. We distinguish between the two isomers with the designations *cis* (meaning “same side”) and *trans* (meaning “opposite sides”). Cis-trans isomerism is common in alkenes. As another example, consider *cis*- and *trans*-2-butene. Like the two isomers of 1,2-dichloroethene, these two isomers have different physical properties. For example, *cis*-2-butene boils at 3.7 °C, and *trans*-2-butene boils at 0.9 °C:

TABLE 21.9 Physical Properties of *cis*- and *trans*-1,2-Dichloroethene

Name	Structure	Space-filling Model	Density (g/mL)	Melting Point (°C)	Boiling Point (°C)
<i>cis</i> -1,2-Dichloroethene			1.284	−80.5	60.1
<i>trans</i> -1,2-Dichloroethene			1.257	−49.4	47.5

## 21.6 Hydrocarbon Reactions

One of the most common hydrocarbon reactions is combustion, the burning of hydrocarbons in the presence of oxygen. Hydrocarbon combustion reactions are highly exothermic and are commonly used to warm homes and buildings, to generate electricity, and to power the engines of cars, ships, and airplanes. It is not an exaggeration to say that hydrocarbon combustion makes our current way of life possible. Approximately 90% of energy produced in the United States is generated by hydrocarbon combustion.

Alkanes, alkenes, and alkynes all undergo combustion. In a combustion reaction, the hydrocarbon reacts with oxygen to form carbon dioxide and water:

### Reactions of Alkanes

In addition to combustion reactions, alkanes also undergo *substitution* reactions, in which one or more hydrogen atoms on an alkane are replaced by one or more other atoms. The most common substitution reaction is halogen substitution (also referred to as halogenation). For example, methane can react with chlorine gas in the presence of heat or light to form chloromethane:

Ethane reacts with chlorine gas to form chloroethane:

Multiple halogenation reactions can occur because halogens can replace more than one of the hydrogen atoms on an alkane. For example, chloromethane can react with chlorine, and the product of that reaction can react again (and so on):

The general form for halogen substitution reactions is:

Notice that the halogenation of hydrocarbons requires initiation with heat or light, which causes the chlorine–chlorine bond to break:

The resulting chlorine atoms are *free radicals* (see Section 9.9), as the dot that represents each chlorine atom's unpaired electron indicates. Chlorine radicals are highly reactive and attack the C—H bond in hydrocarbons. The subsequent reaction proceeds by this mechanism:

Notice that a chlorine free radical is produced as a product of the last step. This free radical can go on to react again, unless it encounters another chlorine free radical, in which case it reacts with it to re-form  $\text{Cl}_2$ .

## Reactions of Alkenes and Alkynes

Alkenes and alkynes undergo addition reactions in which molecules add across (on either side of) the multiple bond. For example, ethene reacts with chlorine gas to form dichloroethane:

The addition of chlorine converts the carbon–carbon double bond into a single bond because each carbon atom bonds to a chlorine atom.

Alkenes and alkynes can also add hydrogen in hydrogenation reactions. For example, in the presence of an appropriate catalyst, propene reacts with hydrogen gas to form propane:

Hydrogenation reactions convert unsaturated hydrocarbons into saturated hydrocarbons. For example, hydrogenation reactions convert unsaturated vegetable oils into saturated fats. Most vegetable oils are unsaturated because their carbon chains contain double bonds. The double bonds put bends into the carbon chains that result in less efficient packing of molecules; thus vegetable oils are liquids at room temperature, while saturated fats are solids at room temperature. When food manufacturers add hydrogen to the double bonds of vegetable oil, the unsaturated fat is converted into a saturated fat, turning the liquid oil into a solid at room temperature. The words “partially hydrogenated vegetable oil” on a label indicate a food product that contains saturated fats made via hydrogenation reactions.

Alkenes can also add unsymmetrical reagents across the double bond. For example, ethene reacts with hydrogen chloride to form chloroethane:

We often indicate the presence of a catalyst by adding a label over the reaction arrow.

▲ Partially hydrogenated vegetable oil is a saturated fat that is made by hydrogenating unsaturated fats.

If the alkene itself is also unsymmetrical, then the addition of an unsymmetrical reagent leads to the potential for two different products. For example, when HCl reacts with propene, two products are possible:

When this reaction is carried out in the lab, however, only the 2-chloropropane forms. We can predict the product of the addition of an unsymmetrical reagent to an unsymmetrical alkene with Markovnikov's rule, which states the following:

**When a polar reagent is added to an unsymmetrical alkene, the positive end (the least electronegative part) of the reagent adds to the carbon atom that has the most hydrogen atoms.**

In most reactions of this type, the positive end of the reagent is hydrogen; therefore, the hydrogen atom bonds to the carbon atom that already contains the most hydrogen atoms.

### Example 21.6 Alkene Addition Reactions

Determine the products of each reaction.

#### SOLUTION

- (a) The reaction of 1-butene with bromine is an example of a symmetric addition. The bromine adds across the double bond, and each carbon forms a single bond to a bromine atom.

- (b) The reaction of 1-butene with hydrogen bromide is an example of an unsymmetrical addition. Apply Markovnikov's rule to determine which carbon the hydrogen bonds with and which carbon the bromine atom bonds with. Markovnikov's rule predicts that the hydrogen bonds to the end carbon in this case.

**FOR PRACTICE 21.6** Determine the products of each reaction.

## 21.7 Aromatic Hydrocarbons

As you might imagine, determining the structure of organic compounds has not always been easy. During the mid-1800s chemists were working to determine the structure of a particularly stable organic compound named benzene ( $C_6H_6$ ). In 1865, Friedrich August Kekulé (1829–1896) had a dream in which he envisioned chains of carbon atoms as snakes. The snakes danced before him, and one of them twisted around and bit its tail. Based on that vision, Kekulé proposed the following structure for benzene:

This structure has alternating single and double bonds. When we examine the carbon–carbon bond lengths in benzene, however, we find that all the bonds are the same length, which indicates that the following resonance structures are a more accurate representation of benzene:

The true structure of benzene is a hybrid of the two resonance structures. We often represent benzene with the following carbon skeletal formula (or line formula):

The ring represents the delocalized  $\pi$  electrons that occupy the molecular orbital shown superimposed on the ball-and-stick model. When drawing benzene rings, either by themselves or as parts of other compounds, organic chemists use either this diagram or just one of the resonance structures with alternating double bonds. Both representations indicate the same thing—a benzene ring.

The benzene ring structure occurs in many organic compounds. An atom or group of atoms can be substituted for one or more of the six hydrogen atoms on the ring to form compounds referred to as substituted benzenes, such as chlorobenzene and phenol:

Because many compounds containing benzene rings have pleasant aromas, benzene rings are also called *aromatic rings*, and compounds containing them are called *aromatic compounds*. Aromatic compounds are responsible for the pleasant smells of cinnamon, vanilla, and jasmine.

### Naming Aromatic Hydrocarbons

Monosubstituted benzenes—benzenes in which only one of the hydrogen atoms has been substituted—are often named as derivatives of benzene:

Recall from Section 9.8 that the actual structure of a molecule represented by resonance structures is intermediate between the two resonance structures and is called a *resonance hybrid*.

These names take the general form:

(name of substituent)benzene

However, many monosubstituted benzenes have names that can only be learned through familiarity. Some common ones are shown here:

Toluene

Aniline

Phenol

Styrene

Some substituted benzenes, especially those with large substituents, are named by treating the benzene ring as the substituent. In these cases, the benzene substituent is referred to as a **phenyl group**:

**Disubstituted benzenes**—benzenes in which two hydrogen atoms have been substituted—are numbered, and the substituents are listed alphabetically. We determine the order of numbering on the ring by the alphabetical order of the substituents:

When the two substituents are identical, we use the prefix *di*-:

Also in common use, in place of numbering, are the prefixes *ortho* (1,2 disubstituted), *meta* (1,3 disubstituted), and *para* (1,4 disubstituted):

Compounds containing fused aromatic rings are called polycyclic aromatic hydrocarbons. Some common examples (shown in Figure 21.5, on the next page) include naphthalene, the substance that composes mothballs, and pyrene, a carcinogen found in cigarette smoke.

► **FIGURE 21.5 Polycyclic Aromatic Compounds** The structures of some common polycyclic aromatic compounds contain fused rings.

## Reactions of Aromatic Compounds

We might expect benzene to react similarly to the alkenes, readily undergoing addition reactions across its double bonds. However, because of electron delocalization around the ring and the resulting greater stability, benzene does not typically undergo addition reactions. Instead, benzene undergoes substitution reactions in which the hydrogen atoms are replaced by other atoms or groups of atoms as shown in the following examples:

The substances shown over the arrows are catalysts needed to increase the rate of the reaction.

## 21.8 Functional Groups

Most other families of organic compounds are hydrocarbons with a *functional group*—a characteristic atom or group of atoms—inserted into the hydrocarbon. A group of organic compounds that all have the same functional group is a *family*. For example, the members of the family of alcohols each have an —OH functional group and the general formula R—OH, where R represents a hydrocarbon group. (That is, we refer to the hydrocarbon group as an “R group.”) Some specific examples include methanol and isopropyl alcohol (also known as rubbing alcohol):

The presence of a functional group in a hydrocarbon alters the properties of the compound significantly. For example, methane is a nonpolar gas. By contrast, methanol—methane with an —OH group substituted for one of the hydrogen atoms—is a polar, hydrogen-bonded liquid at room temperature. Although each member of a family is unique and different, their common functional group causes some similarities in both their physical and chemical properties. Table 21.10 lists some common functional groups, their general formulas, and an example of each.

**TABLE 21.10** Some Common Functional Groups

Family	General Formula*	Condensed General Formula	Example	Name
Alcohols	R—OH	ROH	CH <sub>3</sub> CH <sub>2</sub> OH	Ethanol (ethyl alcohol)
Ethers	R—O—R	ROR	CH <sub>3</sub> OCH <sub>3</sub>	Dimethyl ether
Aldehydes	$\begin{array}{c} \text{O} \\    \\ \text{R}-\text{C}-\text{H} \end{array}$	RCHO	$\begin{array}{c} \text{O} \\    \\ \text{CH}_3-\text{C}-\text{H} \end{array}$	Ethanal (acetaldehyde)
Ketones	$\begin{array}{c} \text{O} \\    \\ \text{R}-\text{C}-\text{R} \end{array}$	RCOR	$\begin{array}{c} \text{O} \\    \\ \text{CH}_3-\text{C}-\text{CH}_3 \end{array}$	Propanone (acetone)
Carboxylic acids	$\begin{array}{c} \text{O} \\    \\ \text{R}-\text{C}-\text{OH} \end{array}$	RCOOH	$\begin{array}{c} \text{O} \\    \\ \text{CH}_3-\text{C}-\text{OH} \end{array}$	Ethanoic acid (acetic acid)
Esters	$\begin{array}{c} \text{O} \\    \\ \text{R}-\text{C}-\text{OR} \end{array}$	RCOOR	$\begin{array}{c} \text{O} \\    \\ \text{CH}_3-\text{C}-\text{OCH}_3 \end{array}$	Methyl acetate
Amines	$\begin{array}{c} \text{R} \\   \\ \text{R}-\text{N}-\text{R} \end{array}$	R <sub>3</sub> N	$\begin{array}{c} \text{H} \\   \\ \text{CH}_3\text{CH}_2-\text{N}-\text{H} \end{array}$	Ethylamine

\*In ethers, ketones, esters, and amines, the R groups may be the same or different.

## 21.9 Alcohols

As we discussed in Section 21.8, **alcohols** are organic compounds containing the —OH functional group, or **hydroxyl group**, and they have the general formula R—OH. In addition to methanol and isopropyl alcohol, ethanol and 1-butanol (shown here) are also common alcohols:

### Naming Alcohols

The names of alcohols are like the names of alkanes with the following differences:

- The base chain is the longest continuous carbon chain that contains the —OH functional group.
- The base name has the ending *-ol*.
- We number the base chain to assign the —OH group the lowest possible number.
- We insert a number indicating the position of the —OH group just before the base name. For example:

### About Alcohols

The familiar alcohol in alcoholic beverages, ethanol, is most commonly formed by the yeast fermentation of sugars, such as glucose, from fruits and grains:

Alcoholic beverages contain ethanol, water, and a few other components that impart flavor and color. Beer usually contains 3–6% ethanol. Wine contains about 12–14% ethanol, and spirits—beverages like whiskey, rum, or tequila—range from 40% to 80% ethanol, depending on their *proof*. The proof of an alcoholic beverage is twice the percentage of its ethanol content, so an 80-proof whiskey contains 40% ethanol. Ethanol is used as a gasoline additive because it increases the octane rating of gasoline and fosters its complete combustion, reducing the levels of certain pollutants such as carbon monoxide and the precursors of ozone.

Isopropyl alcohol (or 2-propanol) is available at any drugstore under the name of rubbing alcohol. It is commonly used as a disinfectant for wounds and to sterilize medical instruments. Isopropyl alcohol should never be consumed internally, as it is highly toxic. Four ounces of isopropyl alcohol can cause death. A third common alcohol is methanol, also called wood alcohol. Methanol is commonly used as a laboratory solvent and as a fuel additive. Like isopropyl alcohol, methanol is toxic and should never be consumed.

### Alcohol Reactions

Alcohols undergo a number of reactions including substitution, elimination (or dehydration), and oxidation. Alcohols also react with active metals to form strong bases.

## Substitution

Alcohols react with acids such as HBr to form halogenated hydrocarbons:

In these reactions, the halogen replaces the hydroxyl group on the alcohol. For example, ethanol reacts with hydrobromic acid to form bromoethane and water:

## Elimination (or Dehydration)

In the presence of concentrated acids such as  $\text{H}_2\text{SO}_4$ , alcohols react and eliminate water, forming an alkene. For example, ethanol eliminates water to form ethene according to the reaction:

## Oxidation

In organic chemistry, we think of oxidation and reduction in terms of the changes to the carbon atoms in the molecule. Thus, oxidation is the gaining of oxygen or the losing of hydrogen by a carbon atom. Reduction is the loss of oxygen or the gaining of hydrogen by a carbon atom. We can draw a series showing relative states of oxidation:

In this view, an alcohol is a partially oxidized hydrocarbon; it can be further oxidized to form an aldehyde or carboxylic acid, or it can be reduced to form a hydrocarbon (but this is rare). For example, ethanol can be oxidized to acetic acid according to the reaction:

## Reaction with Active Metals

Alcohols react with active metals, such as sodium, much as water does. For example, methanol reacts with sodium to form *sodium methoxide* and hydrogen gas:

The reaction of *water* with sodium produces *sodium hydroxide* and hydrogen gas:

In both cases, a strong base forms ( $\text{OH}^-$  for water and  $\text{CH}_3\text{O}^-$  for methanol).

**Example 21.7** Alcohol Reactions

Determine the type of reaction (substitution, dehydration, oxidation, or reaction with an active metal) that occurs in each case, and write formulas for the products.

**SOLUTION**

(a) An alcohol reacting with an acid is an example of a *substitution reaction*. The product of the substitution reaction is a halogenated hydrocarbon and water.

(b) An alcohol in solution with sodium dichromate and acid undergoes an *oxidation reaction*. The product of the oxidation reaction is a carboxylic acid functional group. (We discuss carboxylic acid functional groups in detail in Section 21.11.)

**FOR PRACTICE 21.7** Determine the type of reaction (substitution, dehydration, oxidation, or reaction with an active metal) that occurs in each case, and write formulas for the products.

**21.10 Aldehydes and Ketones**

**Aldehydes** and **ketones** have the following general formulas:

The functional group for both aldehydes and ketones is the **carbonyl group**:

Ketones have an R group attached to both sides of the carbonyl, while aldehydes have one R group and a hydrogen atom. (An exception is formaldehyde, which is an aldehyde with two H atoms bonded to the carbonyl group.)

The condensed structural formula for aldehydes is RCHO and that for ketones is RCOR.

Other common aldehydes and ketones are shown in Figure 21.6 ▼.

▲ **FIGURE 21.6** Common Aldehydes and Ketones

## Naming Aldehydes and Ketones

Many aldehydes and ketones have common names that we can learn only by becoming familiar with them, but we can systematically name simple aldehydes according to the number of carbon atoms in the longest continuous carbon chain that contains the carbonyl group. We form the base name from the name of the corresponding alkane by dropping the *-e* and adding the ending *-al*:

We name simple ketones according to the longest continuous carbon chain containing the carbonyl group, forming the base name from the name of the corresponding alkane by dropping the letter *-e* and adding the ending *-one*. For ketones, we number the chain to give the carbonyl group the lowest possible number:

## About Aldehydes and Ketones

The most familiar aldehyde is probably formaldehyde, shown earlier in this section. Formaldehyde is a gas with a pungent odor. It is often mixed with water to make formalin, a preservative and disinfectant. Formaldehyde is also found in wood smoke, which is one reason that smoking is an effective method of food preservation—the formaldehyde kills bacteria. Aromatic aldehydes, those that also contain an aromatic ring, have pleasant aromas. For example, vanillin causes the smell of vanilla, cinnamaldehyde is the sweet-smelling component of cinnamon, and benzaldehyde accounts for the smell of almonds (Figure 21.7 ▼):

▲ **FIGURE 21.7** The Nutty Aroma of Almonds Benzaldehyde is partly responsible for the smell of almonds.

▲ **FIGURE 21.8 The Fragrance of Raspberries** Ionone is partly responsible for the smell of raspberries.

The most familiar ketone is acetone, the main component of nail polish remover. Other ketones have more pleasant aromas. For example, carvone is largely responsible for the smell of spearmint, 2-heptanone (among other compounds) for the smell of cloves, and ionone for the smell of raspberries (Figure 21.8▲):

## Aldehyde and Ketone Reactions

Aldehydes and ketones can be formed by the *oxidation* of alcohols. For example, ethanol can be oxidized to ethanal, and 2-propanol can be oxidized to 2-propanone (or acetone):

In the reverse reaction, an aldehyde or ketone is reduced to an alcohol. For example, 2-butanone can be reduced to 2-butanol in the presence of a reducing agent:

The carbonyl group in aldehydes and ketones is unsaturated, much like the double bond in an alkene. Because of this feature, the most common reactions of aldehydes and ketones are **addition reactions**. However, in contrast to the carbon-carbon double bond in alkenes, which is nonpolar, the double bond in the carbonyl group is highly polar (Figure 21.9▶). Consequently, additions across the double bond result in the more electronegative part of the reagent bonding to the carbon atom and the less electronegative part (often hydrogen) bonding to the oxygen atom. For example, HCN adds across the carbonyl double bond in formaldehyde:

**▲ FIGURE 21.9 Charge Density Plots of the Carbonyl Group** The carbonyl group is highly polar, as shown in these plots of electrostatic potential.

## 21.11 Carboxylic Acids and Esters

**Carboxylic acids** and **esters** have the general formulas:

The condensed structural formula for carboxylic acids is  $\text{RCOOH}$ ; for esters it is  $\text{RCOOR}$ .

Figure 21.10► shows the structures of some common carboxylic acids and esters.

### Naming Carboxylic Acids and Esters

We systematically name carboxylic acids according to the number of carbon atoms in the longest chain containing the  $-\text{COOH}$  functional group. We form the base name by dropping the  $-e$  from the name of the corresponding alkane and adding the ending  $-oic\ acid$ :

We name esters as if they were derived from a carboxylic acid by replacing the H on the OH with an alkyl group. The R group from the parent acid forms the base name of the compound. We change the  $-ic$  on the name of the corresponding carboxylic acid to  $-ate$ , and drop  $acid$ , naming the R group that replaced the H on the carboxylic acid as an alkyl group with the ending  $-yl$ , as shown in the following examples:

### About Carboxylic Acids and Esters

Like all acids, carboxylic acids taste sour. The most familiar carboxylic acid is ethanoic acid, better known by its common name, acetic acid. Acetic acid is the active ingredient in vinegar. It can form by the oxidation of ethanol, which is why wines left open to air become sour. Some yeasts and bacteria also form acetic acid when they metabolize sugars in bread dough. These are added to bread dough to make sourdough bread. Other common carboxylic acids include methanoic acid (formic acid), present in bee

**▲ FIGURE 21.10 Common Carboxylic Acids and Esters**

Citric acid

▲ **FIGURE 21.11 The Tart Taste of Limes** Citric acid is partly responsible for the sour taste of limes.

stings and ant bites; lactic acid, which collects in muscles after intense exercise causing soreness; and citric acid, found in limes, lemons, and oranges (Figure 21.11 ▲):

Esters are best known for their sweet smells. Methyl butanoate is largely responsible for the smell and taste of apples, and ethyl butanoate is partly responsible for the smell and taste of pineapples (see Figure 21.12 ▼):

▲ **FIGURE 21.12 The Aroma of Pineapple** Ethyl butanoate is partly responsible for the aroma of pineapples.

## Carboxylic Acid and Ester Reactions

Carboxylic acids act as weak acids in solution:

Like all acids, carboxylic acids react with strong bases via neutralization reactions. For example, propanoic acid reacts with sodium hydroxide to form sodium propanoate and water:

A carboxylic acid reacts with an alcohol to form an ester via a **condensation reaction**, a reaction in which two (or more) organic compounds join, often with the loss of water (or some other small molecule):

An important example of this reaction is the formation of acetylsalicylic acid (aspirin) from ethanoic acid (acetic acid) and salicylic acid (originally obtained from the bark of the willow tree):

If we subject a carboxylic acid to high temperatures, it undergoes a condensation reaction with itself to form an acid anhydride (anhydride means “without water”):

We can add water to an acid anhydride to reverse the reaction just shown and regenerate the carboxylic acid molecules.

**Oxidation** Arrange the compounds from least oxidized to most oxidized.

- (a)  $\text{CH}_3\text{—C}(=\text{O})\text{—CH}_3$                       (b)  $\text{CH}_3\text{—C}(=\text{O})\text{—O—CH}_3$
- (c)  $\text{CH}_3\text{—CH}_2\text{—CH}_3$                       (d)  $\text{CH}_3\text{—CH}(\text{OH})\text{—CH}_3$

### CONCEPTUAL CONNECTION 21.3

## 21.12 Ethers

**Ethers** are organic compounds with the general formula ROR. The two R groups may be identical or they may be different. Some common ethers are shown in Figure 21.13 ▼.

### Naming Ethers

Common names for ethers have the format:

(R group 1) (R group 2) ether

▲ FIGURE 21.13 Ethers

If the two R groups differ, we use each of their names in alphabetical order. If the two R groups are the same, we use the prefix *di*-. Some examples include:

## About Ethers

The most common ether is diethyl ether. Diethyl ether is a useful laboratory solvent because it can dissolve many organic compounds and it has a low boiling point (34.6 °C). The low boiling point allows for easy removal of the solvent. Diethyl ether was used as a general anesthetic for many years. When inhaled, diethyl ether depresses the central nervous system, causing unconsciousness and insensitivity to pain. Its use as an anesthetic, however, has decreased in recent years because other compounds have the same anesthetic effect with fewer side effects (such as nausea).

### 21.13 Amines

The simplest nitrogen-containing compound is ammonia (NH<sub>3</sub>). **Amines** are organic compounds containing nitrogen that are derived from ammonia with one or more of the hydrogen atoms replaced by alkyl groups. Like ammonia, amines are weak bases. We systematically name amines according to the hydrocarbon groups attached to the nitrogen and assign the ending *-amine*:

Amines are most commonly known for their awful odors. When a living organism dies, the bacteria that feast on its proteins emit amines. For example, trimethylamine causes the smell of rotten fish, and cadaverine causes the smell of decaying animal flesh:

## Amine Reactions

Just as carboxylic acids act as weak acids, so amines act as weak bases:

Like all bases, amines react with strong acids to form salts called ammonium salts. For example, methylamine reacts with hydrochloric acid to form methylammonium chloride:

An important amine reaction that we will see again in Chapter 22 is the condensation reaction between a carboxylic acid and an amine to form an amide:

This reaction is responsible for the formation of proteins from amino acids (see Section 22.4).

## Self-Assessment Quiz

**Q1.** Which property of carbon is related to its ability to form a large number of compounds?

- a) its tendency to form four covalent bonds
- b) its ability to form double and triple bonds
- c) its tendency to catenate
- d) all of the above

**Q2.** What is the correct formula for the alkane (noncyclical) containing eight carbon atoms?

- a)  $C_8H_{16}$
- b)  $C_8H_{18}$
- c)  $C_8H_{14}$
- d)  $C_8H_8$

**Q3.** Which structure is not an isomer of  $CH_3CH_2CH_2CH_2CH_3$ ?

- d) None of the above (all are isomers).

**Q4.** Which structure can exhibit optical isomerism?

**Q5.** Name the compound:

- a) 4-ethyl-5-methylhexane
- b) 3-ethyl-2-methylhexane
- c) 3-ethyl-2-methylnonane
- d) 4-methyl-5-ethylhexane

**Q6.** Name the compound:

- a) 4-methyl-2-pentyne
- b) 2-methyl-3-pentyne
- c) 2-methyl-3-hexyne
- d) 4-methyl-2-hexyne

**Q7.** Determine the product of the reaction:

**Q8.** Determine the product of the reaction:

Continued—

Q9. Which compound is an ester?

Q10. Which compound is most likely to have a foul odor?

Answers: 1. (d) 2. (b) 3. (a) 4. (c) 5. (b) 6. (a) 7. (d) 8. (d) 9. (d) 10. (b)

### Key Concepts

#### Fragrances and Odors (21.1)

- Organic chemistry is the study of organic compounds, which contain carbon (and other elements including hydrogen, oxygen, and nitrogen).

#### Carbon (21.2)

- Carbon forms more compounds than all the other elements combined.

- Carbon's four valence electrons (in conjunction with its size) allow carbon to form four bonds (in the form of single, double, or triple bonds).
- Carbon also has the capacity to catenate, to form long chains, because of the strength of the carbon-carbon bond.

#### Hydrocarbons (21.3)

- Organic compounds containing only carbon and hydrogen are hydrocarbons, the key components of our world's fuels.

- ▶ We categorize hydrocarbons into four different types: alkanes, alkenes, alkynes, and aromatic hydrocarbons.
- ▶ Stereoisomers are molecules that feature the same atoms bonded in the same order but arranged differently in space. Optical isomerism, a type of stereoisomerism, occurs when two molecules are nonsuperimposable mirror images of one another.

### Alkanes (21.4)

- ▶ Alkanes are saturated hydrocarbons—they contain only single bonds and are therefore represented by the generic formula  $C_nH_{2n+2}$ . Alkane names always end in *-ane*.

### Alkenes and Alkynes (21.5)

- ▶ Alkenes and alkynes are unsaturated hydrocarbons—they contain double bonds (alkenes) or triple bonds (alkynes) and are represented by the generic formulas  $C_nH_{2n}$  and  $C_nH_{2n-2}$ , respectively.
- ▶ Alkene names end in *-ene* and alkynes end in *-yne*.
- ▶ Because rotation about a double bond is severely restricted, geometric (or *cis-trans*) isomerism occurs in alkenes.

### Hydrocarbon Reactions (21.6)

- ▶ The most common hydrocarbon reaction is probably combustion, in which hydrocarbons react with oxygen to form carbon dioxide and water; this reaction is exothermic and is used to provide most of our society's energy.
- ▶ Alkanes can also undergo substitution reactions, where heat or light causes another atom, commonly a halogen such as bromine, to be substituted for a hydrogen atom.
- ▶ Unsaturated hydrocarbons undergo addition reactions. If the addition reaction is between two unsymmetrical molecules, Markovnikov's rule predicts that the positive end of the polar reagent adds to the carbon with the most hydrogen atoms.

### Aromatic Hydrocarbons (21.7)

- ▶ Aromatic hydrocarbons contain six-membered benzene rings represented with alternating single and double bonds that become equivalent through resonance. These compounds are called aromatic because they often produce pleasant fragrances.
- ▶ Because of the stability of the aromatic ring, benzene is more stable than a straight-chain alkene, and it undergoes substitution rather than addition reactions.

### Functional Groups (21.8)

- ▶ Characteristic groups of atoms, such as hydroxyl ( $-OH$ ), are functional groups. Molecules that contain the same functional group have similar chemical and physical properties and are referred to as families.

### Alcohols (21.9)

- ▶ The family of alcohols contains the  $-OH$  group and is named with the suffix *-ol*.

- ▶ Alcohols are commonly used in gasoline, in alcoholic beverages, and in sterilization procedures.
- ▶ Alcohols undergo substitution reactions, in which a substituent such as a halogen replaces the hydroxyl group.
- ▶ Alcohols undergo elimination reactions, in which water is eliminated across a bond to form an alkene, and oxidation or reduction reactions.
- ▶ Alcohols also react with active metals to form alkoxide ions and hydrogen gas.

### Aldehydes and Ketones (21.10)

- ▶ Aldehydes and ketones both contain a carbonyl group (a carbon atom double-bonded to oxygen).
- ▶ In aldehydes, the carbonyl group is at the end of a carbon chain, while in ketones it is between two other carbon atoms.
- ▶ Aldehydes are named with the suffix *-al* and ketones with the suffix *-one*.
- ▶ A carbonyl can be formed by the oxidation of an alcohol or reverted to an alcohol by reduction.
- ▶ Like alkenes, carbonyls undergo addition reactions; however, because the carbon-oxygen bond is highly polar, the electronegative component of the reagent always adds to the carbon atom, and the less electronegative part adds to the oxygen.

### Carboxylic Acids and Esters (21.11)

- ▶ Carboxylic acids contain a carbonyl group and a hydroxide on the same carbon and are named with the suffix *-oic acid*.
- ▶ Esters contain a carbonyl group bonded to an oxygen atom that is in turn bonded to an R group; they are named with the suffix *-oate*.
- ▶ Carboxylic acids taste sour, such as acetic acid in vinegar, while esters smell sweet.
- ▶ Carboxylic acids react as weak acids but can also form esters through condensation reactions with alcohols.

### Ethers (21.12)

- ▶ The family of ethers contains an oxygen atom between two R groups.
- ▶ Ethers are named with the ending *-yl ether*.

### Amines (21.13)

- ▶ Amines are organic compounds that contain nitrogen and are named with the suffix *-amine*.
- ▶ They are known for their terrible odors; the smell of decaying animal flesh is produced by cadaverine.
- ▶ Amines act as weak bases and produce a salt when mixed with a strong acid.
- ▶ The combination of an amine with a carboxylic acid leads to a condensation reaction; in our bodies, this reaction produces proteins from amino acids.

Writing Structural Formulas for Hydrocarbons (21.3)	Example 21.1 For Practice 21.1 Exercises 35, 36
Naming Alkanes (21.4)	Examples 21.2, 21.3, 21.4 For Practice 21.2, 21.3, 21.4 Exercises 41, 42
Naming Alkenes and Alkynes (21.5)	Example 21.5 For Practice 21.5 Exercises 51–54
Writing Reactions: Addition Reactions (21.6)	Example 21.6 For Practice 21.6 Exercises 57–60

## EXERCISES

### Review Questions

- What kinds of molecules often trigger our sense of smell?
- What is organic chemistry?
- What is unique about carbon and carbon-based compounds? Why did life evolve around carbon?
- Why does carbon form such a large diversity of compounds?
- Why does silicon exhibit less diversity of compounds than carbon does?
- Describe the geometry and hybridization about a carbon atom that forms
  - four single bonds.
  - two single bonds and one double bond.
  - one single bond and one triple bond.
- What are hydrocarbons? What are their main uses?
- What are the main classifications of hydrocarbons? What are their generic molecular formulas?
- Explain the differences between a structural formula, a condensed structural formula, a carbon skeleton formula, a ball-and-stick model, and a space-filling model.
- What are structural isomers? How do the properties of structural isomers differ from one another?
- What are optical isomers? How do the properties of optical isomers differ from one another?
- Define each term related to optical isomerism: enantiomers, chiral, dextrorotatory, levorotatory, racemic mixture.
- What is the difference between saturated and unsaturated hydrocarbons?
- What are the key differences in the way that alkanes, alkenes, and alkynes are named?
- Explain geometric isomerism in alkenes. How do the properties of geometric isomers differ from one another?
- Describe and provide an example of a hydrocarbon combustion reaction.
- What kinds of reactions are common to alkanes? List an example of each.
- Describe each kind of reaction.
  - substitution reaction
  - addition reaction
  - elimination reaction
- What kinds of reactions are common to alkenes? Give an example of each.
- Explain Markovnikov's rule and give an example of a reaction to which it applies.
- What is the structure of benzene? What are the different ways in which this structure is represented?
- What kinds of reactions are common to aromatic compounds? Provide an example of each.
- What is a functional group? List some examples.
- What is the generic structure of alcohols? Write the structures of two specific alcohols.
- Explain oxidation and reduction with respect to organic compounds.
- What kinds of reactions are common to alcohols? Provide an example of each.
- What are the generic structures for aldehydes and ketones? Write a structure for a specific aldehyde and ketone.
- What kinds of reactions are common to aldehydes and ketones? List an example of each.
- What are the generic structures for carboxylic acids and esters? Write a structure for a specific carboxylic acid and ester.
- What kinds of reactions are common to carboxylic acids and esters? Provide an example of each.
- What is the generic structure of ethers? Write the structures of two specific ethers.
- What is the generic structure of amines? Write the structures of two specific amines.

### Problems by Topic

#### Hydrocarbons

- Based on the molecular formula, determine whether each compound is an alkane, alkene, or alkyne. (Assume that the hydrocarbons are noncyclical and there is no more than one multiple bond.)
  - $\text{C}_5\text{H}_{12}$
  - $\text{C}_3\text{H}_6$
  - $\text{C}_7\text{H}_{12}$
  - $\text{C}_{11}\text{H}_{22}$
- Based on the molecular formula, determine whether each compound is an alkane, alkene, or alkyne. (Assume that the hydrocarbons are noncyclical and there is no more than one multiple bond.)
  - $\text{C}_8\text{H}_{16}$
  - $\text{C}_4\text{H}_6$
  - $\text{C}_7\text{H}_{16}$
  - $\text{C}_2\text{H}_2$

35. Write structural formulas for each of the nine structural isomers of heptane.
36. Write structural formulas for any 6 of the 18 structural isomers of octane.
37. Determine whether each compound exhibits optical isomerism.
- $\text{CCl}_4$
  - $\text{CH}_3-\text{CH}_2-\underset{\text{CH}_3}{\text{CH}}-\text{CH}_2-\text{CH}_2-\text{CH}_2-\text{CH}_3$

38. Determine whether each compound exhibits optical isomerism.
- $\text{CH}_3\text{CH}_2\text{CHClCH}_3$
  - $\text{CH}_3\text{CCl}_2\text{CH}_3$

39. Determine whether the molecules in each pair are the same or enantiomers.

40. Determine whether the molecules in each pair are the same or enantiomers.

## Alkanes

41. Name each alkane.

42. Name each alkane.

43. Draw a structure for each alkane.

- 3-ethylhexane
- 3-ethyl-3-methylpentane
- 2,3-dimethylbutane
- 4,7-diethyl-2,2-dimethylnonane

44. Draw a structure for each alkane.

- 2,2-dimethylpentane
- 3-isopropylheptane
- 4-ethyl-2,2-dimethylhexane
- 4,4-diethyloctane

45. Complete and balance each hydrocarbon combustion reaction.

- $\text{CH}_3\text{CH}_2\text{CH}_3 + \text{O}_2 \longrightarrow$
- $\text{CH}_3\text{CH}_2\text{CH}=\text{CH}_2 + \text{O}_2 \longrightarrow$
- $\text{CH}\equiv\text{CH} + \text{O}_2 \longrightarrow$

46. Complete and balance each hydrocarbon combustion reaction.

- $\text{CH}_3\text{CH}_2\text{CH}_2\text{CH}_3 + \text{O}_2 \longrightarrow$
- $\text{CH}_2=\text{CHCH}_3 + \text{O}_2 \longrightarrow$
- $\text{CH}\equiv\text{CCH}_2\text{CH}_3 + \text{O}_2 \longrightarrow$

47. List all the possible products for each alkane substitution reaction. (Assume monosubstitution.)

- $\text{CH}_3\text{CH}_3 + \text{Br}_2 \longrightarrow$
- $\text{CH}_3\text{CH}_2\text{CH}_3 + \text{Cl}_2 \longrightarrow$
- $\text{CH}_2\text{Cl}_2 + \text{Br}_2 \longrightarrow$
- $\text{CH}_3-\underset{\text{CH}_3}{\text{CH}}-\text{CH}_3 + \text{Cl}_2 \longrightarrow$

48. List all the possible products for each alkane substitution reaction. (Assume monosubstitution.)

- $\text{CH}_4 + \text{Cl}_2 \longrightarrow$
- $\text{CH}_3\text{CH}_2\text{Br} + \text{Br}_2 \longrightarrow$
- $\text{CH}_3\text{CH}_2\text{CH}_2\text{CH}_3 + \text{Cl}_2 \longrightarrow$
- $\text{CH}_3\text{CHBr}_2 + \text{Br}_2 \longrightarrow$

### Alkenes and Alkynes

49. Write structural formulas for each of the possible isomers of *n*-hexene that are formed by moving the position of the double bond.

50. Write structural formulas for each of the possible isomers of *n*-pentyne that are formed by moving the position of the triple bond.

51. Name each alkene.

- $\text{CH}_2=\text{CH}-\text{CH}_2-\text{CH}_3$

52. Name each alkene.

- $\text{CH}_3-\text{CH}_2-\text{CH}=\text{CH}-\text{CH}_2-\text{CH}_3$

53. Name each alkyne.

- $\text{CH}_3-\text{C}\equiv\text{C}-\text{CH}_3$

54. Name each alkyne.

- $\text{CH}\equiv\text{C}-\underset{\text{CH}_3}{\text{CH}}-\text{CH}_3$

55. Draw the correct structure for each compound.

- 4-octyne
- 3-nonene
- 3,3-dimethyl-1-pentyne
- 5-ethyl-3,6-dimethyl-2-heptene

56. Draw the correct structure for each compound.

- 2-hexene
- 1-heptyne
- 4,4-dimethyl-2-hexene
- 3-ethyl-4-methyl-2-pentene

57. List the products of each alkene addition reaction.

58. What are the products of each alkene addition reaction?

59. Complete each hydrogenation reaction.

60. Complete each hydrogenation reaction.

## Aromatic Hydrocarbons

61. Name each monosubstituted benzene.

62. Name each monosubstituted benzene.

63. Name each compound in which the benzene ring is best treated as a substituent.

64. Name each compound in which the benzene ring is best treated as a substituent.

65. Name each disubstituted benzene.

66. Name each disubstituted benzene.

67. Draw the structure for each compound.

- isopropylbenzene
- meta*-dibromobenzene
- 1-chloro-4-methylbenzene

68. Draw the structure for each compound.

- ethylbenzene
- 1-iodo-2-methylbenzene
- para*-diethylbenzene

69. What are the products of each aromatic substitution reaction?

70. What are the products of each aromatic substitution reaction?

## Alcohols

71. Name each alcohol.

72. Draw the structure for each alcohol.

- 2-butanol
- 2-methyl-1-propanol
- 3-ethyl-1-hexanol
- 2-methyl-3-pentanol

73. List the products of each alcohol reaction.

74. List the products of each alcohol reaction.

## Aldehydes and Ketones

75. Name each aldehyde or ketone.

76. Draw the structure of each aldehyde or ketone.

- hexanal
- 2-pentanone
- 2-methylbutanal
- 4-heptanone

77. Determine the product of the addition reaction.

78. Determine the product of the addition reaction.

## Carboxylic Acids and Esters

79. Name each carboxylic acid or ester.

80. Draw the structure of each carboxylic acid or ester.

- pentanoic acid
- methyl hexanoate
- 3-ethylheptanoic acid
- butyl ethanoate

81. Determine the products of each carboxylic acid reaction.

82. Determine the products of each carboxylic acid reaction.

## Ethers

83. Name each ether.

- $\text{CH}_3-\text{CH}_2-\text{CH}_2-\text{O}-\text{CH}_2-\text{CH}_3$
- $\text{CH}_3-\text{CH}_2-\text{CH}_2-\text{CH}_2-\text{CH}_2-\text{O}-\text{CH}_2-\text{CH}_3$
- $\text{CH}_3-\text{CH}_2-\text{CH}_2-\text{O}-\text{CH}_2-\text{CH}_2-\text{CH}_3$
- $\text{CH}_3-\text{CH}_2-\text{O}-\text{CH}_2-\text{CH}_2-\text{CH}_2-\text{CH}_3$

84. Draw the structure for each ether.

- ethyl propyl ether
- dibutyl ether
- methyl hexyl ether
- dipentyl ether

## Amines

85. Name each amine.

86. Draw the structure for each amine.

- isopropylamine
- triethylamine
- butylethylamine

87. Classify each amine reaction as acid-base or condensation and list its products.

- $\text{CH}_3\text{NHCH}_3 + \text{HCl} \longrightarrow$
- $\text{CH}_3\text{CH}_2\text{NH}_2 + \text{CH}_3\text{CH}_2\text{COOH} \longrightarrow$
- $\text{CH}_3\text{NH}_2 + \text{H}_2\text{SO}_4 \longrightarrow$

88. List the products of each amine reaction.

- $\text{N}(\text{CH}_2\text{CH}_3)_3 + \text{HNO}_3 \longrightarrow$

## Cumulative Problems

89. Identify each organic compound as an alkane, alkene, alkyne, aromatic hydrocarbon, alcohol, ether, aldehyde, ketone, carboxylic acid, ester, or amine, and provide a name for the compound.

90. Identify each organic compound as an alkane, alkene, alkyne, aromatic hydrocarbon, alcohol, ether, aldehyde, ketone, carboxylic acid, ester, or amine, and provide a name for the compound.

91. Name each compound.

92. Name each compound.

93. Determine whether the two structures are isomers or the same molecule drawn in two different ways.

94. Determine whether the two structures are isomers or the same molecule drawn two different ways.

95. What minimum amount of hydrogen gas, in grams, is required to completely hydrogenate 15.5 kg of 2-butene?

96. How many kilograms of  $\text{CO}_2$  does the complete combustion of 3.8 kg of *n*-octane produce?

97. Classify each organic reaction as combustion, alkane substitution, alkene addition or hydrogenation, aromatic substitution, or alcohol substitution, elimination, or oxidation.

98. Determine the products of each reaction.

99. Draw the structure that corresponds to each name and indicate which structures can exist as stereoisomers.

a. 3-methyl-1-pentene

b. 3,5-dimethyl-2-hexene

c. 3-propyl-2-hexene

- 100.** Identify the two compounds that display stereoisomerism and draw their structures.
- 3-methyl-3-pentanol
  - 2-methyl-2-pentanol
  - 3-methyl-2-pentanol
  - 2-methyl-3-pentanol
  - 2,4-dimethyl-3-pentanol
- 101.** There are 11 structures (ignoring stereoisomerism) with the formula  $C_4H_8O$  that have no carbon branches. Draw the structures and identify the functional groups in each.

## Challenge Problems

- 105.** Determine the one or two steps it takes to get from the starting material to the product using the reactions found in this chapter.

- 106.** Given the following synthesis of ethyl 3-chloro-3-methylbutanoate, fill in the missing intermediates or reactants.

- 107.** For the chlorination of propane, the two isomers shown here are possible.

- 102.** There are eight structures with the formula  $C_3H_7NO$  in which the O is part of a carbonyl group. Draw the structures and identify the functional groups in each.
- 103.** Explain why carboxylic acids are much stronger acids than alcohols.
- 104.** The hydrogen at C-1 of 1-butyne is much more acidic than the one at C-1 in 1-butene. Explain.

Propane has six hydrogen atoms on terminal carbon atoms—called primary ( $1^\circ$ ) hydrogen atoms—and two hydrogen atoms on the interior carbon atom—called secondary ( $2^\circ$ ) hydrogen atoms.

- If the two different types of hydrogen atoms were equally reactive, what ratio of 1-chloropropane to 2-chloropropane would we expect as monochlorination products?
  - The result of a reaction yields 55% 2-chloropropane and 45% 1-chloropropane. What can we conclude about the relative reactivity of the two different kinds of hydrogen atoms? Determine a ratio of the reactivity of one type of hydrogen atom to the other.
- 108.** There are two isomers of  $C_4H_{10}$ . Suppose that each isomer is treated with  $\text{Cl}_2$  and the products that have the composition  $C_4H_8\text{Cl}_2$  are isolated. Find the number of different products that form from each of the original  $C_4H_{10}$  compounds. Do not consider optical isomerism.
- 109.** Identify the compounds formed in the previous problem that are chiral.
- 110.** Nitromethane has the formula  $\text{CH}_3\text{NO}_2$ , with the N bonded to the C and without O—O bonds. Draw its two most important contributing structures.
- What is the hybridization of the C, and how many hybrid orbitals are in the molecule?
  - What is the shortest bond?
  - Between which two atoms is the strongest bond found?
  - Predict whether the HCH bond angles are greater or less than  $109.5^\circ$  and justify your prediction.
- 111.** Free radical fluorination of methane is uncontrollably violent, and free radical iodination of methane is a very poor reaction. Explain these observations in light of bond energies.
- 112.** There are two compounds with the formula  $C_3H_6$ , one of which does not have a multiple bond. Draw its structure and explain why it is much less stable than the isomer with the double bond.
- 113.** Consider molecules that have two carbons and two chlorines. Draw the structures of three of these with no dipole moment and two with a dipole moment.

## Conceptual Problems

114. Pick the more oxidized structure in each pair.

115. Draw the structure and name a compound with the formula  $\text{C}_8\text{H}_{18}$  that forms only one product with the formula  $\text{C}_8\text{H}_{17}\text{Br}$  when it is treated with  $\text{Br}_2$ .

116. Determine whether each structure is chiral.

### Active Classroom Learning

## Questions for Group Work

Discuss these questions with the group and record your consensus answer.

117. Have each group member select a different functional group. Individually, draw and name a compound containing your functional group. Pass your drawing to the group member on your right and your compound name to the group member on your left. Name the compound for the drawing you received and draw the compound whose name you received.

118. Using complete sentences, compare and contrast each of the following. Mention at least two similarities and two differences for each.

- salt and sugar
- methane and 3-methylheptane
- aldehydes and ketones

119. The octane rating for gasoline is a measurement of how readily a fuel combusts compared to 2,2,4-trimethylpentane, an isomer of octane.

- Draw 2,2,4-trimethylpentane and verify that it is an isomer of octane.
- Draw four other isomers of octane.
- Select one of the isomers and draw it so that it looks different on the page, but is still the exact same compound.
- Name the isomer you drew in part c.
- Define “isomer” using a complete sentence.

120. Working individually, have each group member select from the chapter a reaction characteristic of a particular organic functional group. Individually, write out your reaction with one of the following left as a blank: one reactant, one product, or reaction conditions. Pass your reaction to the group member on your right. Have group members fill in the blank of the reaction they receive.

## Data Interpretation and Analysis

### Preparation of Fruit-Scented Esters

121. Ester compounds often have a sweet, pleasant odor. Many characteristic fruit scents are largely due to the natural presence of one or more ester compounds. As such, artificial scents for foods are often composed of complex mixtures of various esters. The exact identities and ratios of ingredients that compose particular scents are closely guarded secrets in the food and fragrance industry.

Suppose that you are a chemist working for a company that is creating a new line of air fresheners. The company is considering three scents: apple, pear, and pineapple. The project manager has asked you to prepare the ester compounds that are largely responsible for these scents. The carbon skeleton formulas for these ester compounds are shown in Figure a.

▲ **FIGURE a** Structures of Ester Compounds Responsible for Various Fruit Scents

To prepare these esters, you have been given the alcohols listed in Table a and an adequate supply of all other necessary reagents, solvents, equipment, and the like.

Reagent	Molar mass (g/mol)	Density (g/mL)	Cost, per 1.00 L
methanol	32.04	0.79	\$46.20
ethanol	46.07	0.79	\$112.00
1-propanol	60.10	0.80	\$72.70
1-butanol	74.12	0.81	\$72.60

**TABLE a** Molar Mass, Density, and Cost of Alcohol Compounds for Ester Compound Preparation

Use the information provided in the figure and the table to answer the following questions:

- Provide a name for each ester that you will prepare.
- Draw the structure of each alcohol listed in Table a.
- Determine the procedure you will use to prepare each ester, using the reactions found in this chapter. (Hint: Recall that esters are derived from a carboxylic acid and an alcohol.)
- Calculate the cost to prepare 100.0 g of each ester. Which one will be the most expensive to prepare? Which ester will be the least expensive? (Consider only the cost of the alcohols in Table a and disregard the costs of other reagents. Assume 100% yield for all reactions.)
- The scent of an apple is due to many different ester compounds including butyl acetate, pentyl acetate, ethyl pentanoate, pentylpentanoate, and pentylhexanoate. Draw structures for each of these ester compounds.

## Answers to Conceptual Connections

### Organic Structures

- 21.1 (d)** The others are simply the same structure drawn in slightly different ways.

### Optical Isomers

- 21.2 (b)** This structure is the only one that contains a carbon atom (the one on the left) with four different substituent groups attached (a Br atom, a Cl atom, an H atom, and a CH<sub>3</sub> group).

### Oxidation

- 21.3 (c, d, a, b)** Oxidation includes the gain of oxygen or the loss of hydrogen.

# Biochemistry

**KEY LEARNING OUTCOMES 1055**

In Chapter 21, we examined organic chemistry and discussed the different types of organic compounds and their structures and chemistry. In this chapter, we turn to biochemical compounds, those organic compounds important in living organisms. Biochemistry—the area of study at the interface between chemistry and biology that strives to understand living organisms at the molecular level—exploded in the second half of the twentieth century. That explosion began with the discovery of the structure of DNA in 1953 by James D. Watson and Francis H. C. Crick and continues to this day, most recently marked by the 2003 completion of the Human Genome Project, which succeeded in mapping the 3 billion base pairs within the DNA of humans. The benefits of biochemistry to humankind are numerous, ranging from a better understanding of illnesses and better drugs to cure them to a better understanding of ourselves and our origins.

▲ This image timeline marks the important events in the treatment of diabetes.

## 22.1 Diabetes and the Synthesis of Human Insulin

Diabetes afflicts over 16 million people in the United States alone. Today, it is a chronic but generally manageable ailment; at the beginning of the twentieth century, however, diabetes was often fatal. The most dangerous form, type 1 diabetes, develops when the pancreas does not make enough *insulin*, a protein that promotes the absorption of glucose from the blood into cells, where glucose is used for energy. Consequently, people with diabetes have high blood-sugar levels that can lead to a number of complications, including heart disease, blindness, and kidney failure. Before 1922, the only option

diabetics had was to control their blood-sugar levels through diet, but this was often not enough to overcome the disease.

Important advances throughout the twentieth century dramatically changed the prognosis for diabetics. The initial breakthrough came in 1922, when researchers first injected insulin from animal sources into a diabetic. The insulin worked, resulting in a nearly complete recovery for the patient. Within a year, insulin harvested from the pancreases of slaughtered pigs became widely available, and, for many patients, diabetes became a long-term manageable disease. However, insulin taken from pigs and cattle is not identical to human insulin, and some patients do not tolerate the animal insulin as well as others.

In 1955, Frederick Sanger (1918–2013) discovered the detailed chemical structure of human insulin. As we will see later in this chapter, proteins are biological molecules composed of repeating units called amino acids (of which there are 20 different types in humans). Sanger was able to determine the specific sequence of amino acids in human insulin, work for which he received the 1958 Nobel Prize in Chemistry. Knowing the amino acid sequence allowed researchers to synthesize human insulin in the laboratory by 1963. Unfortunately, they could not make sufficient amounts to meet the needs of diabetics.

The growing field of biotechnology, however, allowed a fledgling company called Genentech to synthesize human insulin on a large scale by the early 1980s. Researchers at Genentech were able to insert the human *gene* for insulin—the blueprint that determines how insulin is synthesized in humans—into the DNA of bacterial cells. When the bacteria reproduced in culture, they made copies of the inserted human insulin gene and passed it on to their offspring. Furthermore, as the growing bacterial culture synthesized the bacterial proteins that it needed to grow and survive, it also synthesized human insulin. In other words, researchers at Genentech were able to get bacteria to produce human insulin for them! The ability to synthesize human insulin in this way revolutionized the treatment of diabetes, resulting in better health and extended lives for hundreds of millions of people who suffer from this disease.

The study of the chemistry occurring in living organisms is **biochemistry**, the topic of this chapter. Many biologically important molecules are very large and complex—they are *macromolecules*. However, understanding their structures is not as difficult as you might imagine because most of them consist of much smaller, simpler components linked together into long chains (*polymers*). In this chapter, we divide our study of biochemistry along the lines of the major chemical components of cells: lipids, carbohydrates, proteins, and nucleic acids.

## 22.2 Lipids

**Lipids** are the chemical components of the cell that are insoluble in water but soluble in nonpolar solvents. Fatty acids, fats, oils, phospholipids, glycolipids, and steroids are all lipids. Their insolubility in water makes it possible for lipids to compose the structural components of cell membranes, which separate the aqueous interior of the cell from its aqueous environment in the body. Lipids also play a role in long-term energy storage and insulation.

### Fatty Acids

One type of lipid is the **fatty acid**, a carboxylic acid (see Section 21.11) with a long hydrocarbon tail. The general structure for a fatty acid contains the carboxylic acid group:

Fatty acid general structure

The R on the left side of the structure represents a hydrocarbon chain containing 3 to 19 carbon atoms. Fatty acids differ only in their R group.

Myristic acid, found in butterfat and in coconut oil, has the R group  $\text{CH}_3(\text{CH}_2)_{12}$ . Myristic acid is a *saturated* fatty acid: its carbon chain has no double bonds:

Other fatty acids—called *monounsaturated* or *polyunsaturated* fatty acids—have one or more double bonds in their carbon chains. For example, oleic acid—found in olive oil, peanut oil, and human fat—is a monounsaturated fatty acid:

The long hydrocarbon tails of fatty acids make them insoluble in water. Table 22.1 lists several fatty acids, some common sources for each, and their melting points. Notice that the melting points of the fatty acids *increase* as their carbon chain lengths increase. The longer the chains, the greater the dispersion forces between adjacent molecules in the solid state, and the higher the melting point. Notice also that the melting points *decrease* with the presence of double bonds. For example, stearic acid and oleic acid have the same number of carbon atoms, but stearic acid melts at 70 °C and oleic acid melts at 4 °C. The double bond puts a “kink” in the carbon chain that makes it more difficult for neighboring molecules to interact over the entire length of the chain (Figure 22.1 ►, on the next page), thus lowering the melting point.

Dispersion forces are discussed in Section 11.3.

**TABLE 22.1 Fatty Acids**

Saturated Fatty Acids					
Name	Number of Carbons		mp (°C)	Structure	Sources
Butyric acid	4		−7.9	CH <sub>3</sub> CH <sub>2</sub> CH <sub>2</sub> COOH	Milk fat
Caproic acid	10		31	CH <sub>3</sub> (CH <sub>2</sub> ) <sub>8</sub> COOH	Milk fat, whale oil
Myristic acid	14		59	CH <sub>3</sub> (CH <sub>2</sub> ) <sub>12</sub> COOH	Butterfat, coconut oil
Palmitic acid	16		64	CH <sub>3</sub> (CH <sub>2</sub> ) <sub>14</sub> COOH	Beef fat, butterfat
Stearic acid	18		70	CH <sub>3</sub> (CH <sub>2</sub> ) <sub>16</sub> COOH	Beef fat, butterfat
Unsaturated Fatty Acids					
Name	Number of Carbons	Number of Double Bonds	mp (°C)	Structure	Sources
Oleic acid	18	1	4	CH <sub>3</sub> (CH <sub>2</sub> ) <sub>7</sub> CH=CH(CH <sub>2</sub> ) <sub>7</sub> COOH	Olive oil, peanut oil
Linoleic acid	18	2	−5	CH <sub>3</sub> (CH <sub>2</sub> ) <sub>4</sub> (CH=CHCH <sub>2</sub> ) <sub>2</sub> (CH <sub>2</sub> ) <sub>6</sub> COOH	Linseed oil, corn oil
Linolenic acid	18	3	−11	CH <sub>3</sub> CH <sub>2</sub> (CH=CHCH <sub>2</sub> ) <sub>3</sub> (CH <sub>2</sub> ) <sub>6</sub> COOH	Linseed oil, corn oil

## The Effect of Unsaturation

▲ **FIGURE 22.1 The Effect of Unsaturation** A double bond results in a bend in the carbon chain of a fatty acid or fat. The bend makes it more difficult for neighboring molecules to interact over the entire length of the carbon chain, thus lowering the melting point.

## Fats and Oils

Fats and oils are **triglycerides**, triesters composed of glycerol with three fatty acids attached. Triglycerides form when a glycerol molecule reacts with three fatty acids:

We discussed the general structure of esters in Section 20.11.

The bonds that join the glycerol to the fatty acids are called **ester linkages**. For example, tristearin—the main component of beef fat—forms from the reaction of glycerol and three stearic acid molecules (Figure 22.2▼). If the fatty acids in a triglyceride are saturated,

▲ **FIGURE 22.2 The Formation of Tristearin** The reaction between glycerol and stearic acid forms tristearin.

### Tristearin: A Saturated Fat

Tristearin, mp 72 °C

▲ Tristearin is a triglyceride found in lard; it is a saturated fat.

the triglyceride is a **saturated fat** and tends to be solid at room temperature. Triglycerides from warm-blooded animals (for example, lard from pigs) are generally saturated.

If the fatty acids in a triglyceride are unsaturated, the triglyceride is an **unsaturated fat**, or an oil, and tends to be liquid at room temperature. Triglycerides from plants (olive oil, corn oil, canola oil, etc.) or from cold-blooded animals (fish oil) are generally unsaturated.

### Triolein: A Monounsaturated Fat

Triolein, mp -4 °C

Triolein is a triglyceride found in olive oil; it is a monounsaturated fat.

Most of the fats and oils in our diet are triglycerides. During digestion, triglycerides are broken down into fatty acids, glycerol, monoglycerides, and diglycerides. These products pass through the intestinal wall and reassemble into triglycerides before they are absorbed into the blood. This process is slower than the digestion of other food types, and for this reason eating fats and oils gives a lasting feeling of fullness.

The effect of fats and oils on health has been widely debated. Some diets call for a drastic reduction of our daily intake of fats and oils, whereas others actually call for an *increase* in fats and oils. The U.S. Food and Drug Administration (FDA) recommends moderate consumption of fats and oils, less than 30% of total caloric intake.

## Other Lipids

Additional lipids found in cells include phospholipids, glycolipids, and steroids.

**Phospholipids** have the same basic structure as triglycerides, except that one of the fatty acid groups is replaced with a phosphate group. Unlike a fatty acid, which is nonpolar, the phosphate group is polar. A phospholipid molecule therefore has a polar region and a nonpolar region. Consider the structure of phosphatidylcholine, a phospholipid found in the cell membranes of higher animals (Figure 22.3▶ on the next page). The polar part of the molecule is *hydrophilic* (has a strong affinity for water), while the nonpolar part is *hydrophobic* (is repelled by water).

**Glycolipids** have similar structures and properties. The nonpolar section of a glycolipid is composed of a fatty acid chain and a hydrocarbon chain. The polar section is a

► **FIGURE 22.3****Phosphatidylcholine**

Phosphatidylcholine is a phospholipid. The structure is similar to a triglyceride except that one of the fatty acid groups is replaced with a phosphate group.

▲ **FIGURE 22.4 Schematic for Phospholipid or Glycolipid**

We represent a phospholipid or a glycolipid as a circle (the polar part of the molecule) with two long tails (the nonpolar part of the molecule).

▲ **FIGURE 22.5 Lipid Bilayer**

Lipid bilayers are composed of phospholipids or glycolipids arranged in a structure that encapsulates cells and many cellular structures.

sugar molecule such as glucose. We often portray phospholipids or glycolipids schematically as a circle with two long tails (Figure 22.4 ◀). The circle represents the polar, hydrophilic part of the molecule, and the tails represent the nonpolar, hydrophobic parts. Phospholipids and glycolipids are key components of cell membranes; the polar parts interact with the aqueous environments inside and outside the cell, and the nonpolar parts interact with each other, forming a double-layered structure called a **lipid bilayer** (Figure 22.5 ◀). Lipid bilayers encapsulate cells and many cellular structures.

**Steroids** are lipids with a four-ring structure:

Cholesterol, testosterone, and  $\beta$ -estradiol are common steroids:

Hormones are chemical messengers that are released by cells in one part of the body and cause an effect in cells in another part of the body.

Although cholesterol has a bad reputation, it serves many important functions in the body. Like phospholipids and glycolipids, cholesterol is part of cell membranes. Cholesterol also serves as a starting material (or precursor) for the body's synthesis of other steroids such as testosterone, a principal male hormone, and  $\beta$ -estradiol, a principal female hormone.

## 22.3 Carbohydrates

Carbohydrates are responsible for short-term storage of energy in living organisms, and they make up the main structural components of plants. Carbohydrates—as their name, which means carbon and water, implies—often have the general formula  $(\text{CH}_2\text{O})_n$ . Structurally, we identify **carbohydrates** as polyhydroxy aldehydes or ketones. For example, glucose, with the formula  $\text{C}_6\text{H}_{12}\text{O}_6$ , has the following structure:

Glucose is a six-carbon aldehyde (that is, it contains the  $-\text{CHO}$  group) with  $-\text{OH}$  groups on five of the six carbon atoms. The many  $-\text{OH}$  groups make glucose soluble in water (and therefore in blood), which is crucial to glucose's role as the primary fuel of cells. Glucose is easily transported in the bloodstream and is soluble within the aqueous interior of a cell. We broadly classify carbohydrates as simple carbohydrates (or simple sugars) and complex carbohydrates.

The name should not be taken literally—the hydrogen and oxygen in carbohydrates do not bond together in the same way that they bond in water.

Recall from Section 21.10 that aldehydes have the general structure  $\text{RCHO}$  and ketones have the general structure  $\text{RCOR}$ .

### Simple Carbohydrates: Monosaccharides and Disaccharides

**Monosaccharides**—meaning “one sugar”—are the simplest carbohydrates. Monosaccharides contain between three and eight carbon atoms and have only one aldehyde or ketone functional group. The general names for monosaccharides begin with a prefix that indicates the number of carbon atoms, followed by the suffix *-ose*. The most common carbohydrates in living organisms are pentoses and hexoses.

Glucose, the structure of which we saw previously, is an example of a **hexose**, a six-carbon sugar. Glucose is also an example of an **aldose**, a sugar with an aldehyde group. Often, we combine these two ways of designating sugars; glucose is an *aldohexose* (*aldo-* indicates that it is an aldehyde; *-hex-* indicates that it has six carbon atoms; and *-ose* indicates that it is a carbohydrate).

Another common carbohydrate is fructose, a polyhydroxy *ketone* with the following structure:

3-carbon sugar: triose  
4-carbon sugar: tetrose  
5-carbon sugar: pentose  
6-carbon sugar: hexose  
7-carbon sugar: heptose  
8-carbon sugar: octose

Glucose and fructose are structural isomers—they both have the same formula ( $\text{C}_6\text{H}_{12}\text{O}_6$ ), but they have different structures. Fructose is a **ketose**, a sugar that is a

ketone. Since fructose has six carbon atoms, it is a *keto*hexose. Fructose, often called fruit sugar, is in many fruits and vegetables and is a major component of honey.

### Example 22.1 Carbohydrates and Optical Isomerism

Closely examine the structure of glucose shown here. Does glucose exhibit optical isomerism (discussed in Section 21.3)? If so, which carbon atoms are chiral?

#### SOLUTION

Any carbon atom with four different substituents attached to it is chiral. Glucose has four chiral carbon atoms (labeled 2, 3, 4, and 5) and therefore exhibits optical isomerism.

Variations in the positions of the —OH and —H groups on these carbon atoms result in a number of different possible isomers for glucose. For example, switching the relative positions of the —OH and —H group on the carbon atom closest to the carbonyl group results in mannose, an optical isomer of glucose.

**FOR PRACTICE 22.1** Examine the structure of fructose (p. 1043). Does fructose exhibit optical isomerism? How many of the carbon atoms in fructose are chiral?

**▲ FIGURE 22.6 Intramolecular Reaction of Glucose to Form a Ring** The alcohol group on C5 in glucose reacts with the carbonyl group (C1) to form a closed ring.

Most five- and six-carbon monosaccharides undergo intramolecular reactions that convert their straight carbon chain into a ring. For example, in glucose, the alcohol group on C5 reacts with the carbonyl group (C1), as shown in Figure 22.6 to form the ring structure shown here:

In a glucose solution, the vast majority of the molecules are in ring form. However, the molecules in ring form exist in equilibrium with a small fraction in the open-chain form. Other common monosaccharides, in their ring form, include fructose (discussed previously in its straight-chain form) and galactose shown at the right.

Galactose, also known as brain sugar, is a hexose usually found combined with other monosaccharides in disaccharides such as lactose (see next paragraph). Galactose also occurs within the brain and nervous system of most animals. Galactose and glucose differ only in the stereochemistry at C4. Notice that in galactose the —OH group is roughly perpendicular to the plane of the ring while in glucose it is roughly in the same plane as the ring.

Two monosaccharides can link together via a **glycosidic linkage** to form a **disaccharide**, a carbohydrate that can be decomposed into two simpler sugars. For example, glucose and fructose join to form sucrose, commonly known as table sugar (Figure 22.7▶). When we eat disaccharides, the link between individual monosaccharides is broken during digestion by **hydrolysis**, the splitting of a chemical bond with water that results in the addition of H and OH to the products. The resultant monosaccharides readily pass through the intestinal wall and enter the bloodstream to become fuel for cells.

## Complex Carbohydrates

Monosaccharides can also link to form a type of natural polymer (or biopolymer) called a **polysaccharide**, a long, chain-like molecule composed of many bonded monosaccharide units. Polysaccharides are known as **complex carbohydrates** because of their long chains of sugars. The most common polysaccharides are *cellulose*, *starch*, and *glycogen*, all three of which are composed of repeating glucose units. The main difference among them lies in the way the units are bonded to each other. In cellulose, the oxygen atoms are roughly parallel with the planes of the rings. This is referred to as a  $\beta$ -glycosidic linkage. In starch and glycogen, the oxygen atoms joining neighboring glucose units point down relative to the planes of the rings. This is an  $\alpha$ -glycosidic linkage:

**▲ FIGURE 22.7 Formation of a Glycosidic Linkage** Glucose and fructose can join, eliminating water and forming a glycosidic linkage that results in the disaccharide sucrose, commonly known as table sugar.

◀ The primary difference between starch and cellulose is in the way the units are bonded together.

Cellulose

The main structural component of plants, **cellulose**, is the most abundant organic substance on Earth and consists of glucose units bonded together by  $\beta$ -glycosidic linkages. This structure allows neighboring cellulose molecules to form multiple hydrogen bonds with one another, resulting in the rigid and structurally stable properties we associate with wood and fiber. Humans lack the enzyme required to digest cellulose. When we eat cellulose (usually called fiber when it is present in foods), it passes right through our intestines, providing bulk to stools and preventing constipation. In contrast, some bacteria have the enzyme required to metabolize cellulose into its component glucose units. These bacteria are common in the guts of termites and ruminants such as cows, allowing them to extract caloric content from cellulose.

Starch

The main energy storage medium for plants is **starch**, the soft, pliable substance abundant in potatoes and grains. Starch is composed of two slightly different polysaccharides, *amylose* and *amylopectin*. Both are made up of glucose units bonded together by  $\alpha$ -glycosidic linkages, but amylopectin contains branches in the chains. When animals digest starch, the link between individual glucose units is broken by hydrolysis, allowing glucose molecules to pass through the intestinal wall and into the bloodstream.

Glycogen

The structure of **glycogen** is similar to that of amylopectin, but the chain is even more highly branched. Animals use glycogen to store glucose in the muscles. Glycogen’s highly branched structure leaves many end groups that can be quickly hydrolyzed to meet energy needs. When muscles become depleted of glycogen, muscle movement and exercise become much more difficult. Marathon runners often “hit the wall” at about mile 20 because they have depleted most of the glycogen from their muscles.

22.4 Proteins and Amino Acids

Proteins are the workhorse molecules in living organisms; they are involved in virtually every facet of cell structure and function. For example, most of the chemical reactions that occur in living organisms are enabled by **enzymes**, proteins that act as catalysts in biochemical reactions. Without enzymes, life would be impossible. Proteins are also the structural elements of muscle, skin, and cartilage. They transport oxygen in the blood, act as antibodies to fight disease, and function as hormones to regulate metabolic processes. Proteins reign supreme as the working molecules of life. Table 22.2 summarizes the functions of some of the important classes of proteins and lists examples of each.

TABLE 22.2 Protein Functions

Class of Protein	Primary Function	Example
Structural proteins	Compose structures within living organisms	Collagen (skin, tendon, cartilage), keratin (hair, fingernails)
Enzymes	Catalyze and control biochemical reactions	DNA polymerase (involved in replication of DNA)
Hormones	Regulate metabolic processes	Insulin (regulates glucose metabolism)
Transport proteins	Transport substances from one place to another	Hemoglobin (transports oxygen)
Storage proteins	Provide source of essential nutrients	Casein (protein in mammalian milk)
Contractile and motile proteins	Mediate motion and muscle contraction	Actin and myosin (provide muscle contraction)
Protective proteins	Protect and defend cells	Antibodies (neutralize infectious agents)

## Amino Acids: The Building Blocks of Proteins

Proteins are polymers of amino acids. Each **amino acid** molecule consists of a carbon atom—called the  $\alpha$ -carbon—bonded to four different groups: an amine group, an R group (also called a side chain), a carboxylic acid group, and a hydrogen atom:

In a protein, the presence of an R group does not necessarily indicate a pure alkyl group. See Table 22.3 for possible R groups.

Amino acids differ from each other in their R groups. For example, the R group in alanine is a methyl group ( $\text{CH}_3$ ):

Other amino acids are glycine ( $\text{R} = \text{H}$ ), phenylalanine ( $\text{R} = \text{CH}_2\text{C}_6\text{H}_5$ ), serine ( $\text{R} = \text{CH}_2\text{OH}$ ), aspartic acid ( $\text{R} = \text{CH}_2\text{COOH}$ ), and lysine ( $\text{R} = \text{CH}_2\text{CH}_2\text{CH}_2\text{CH}_2\text{NH}_2$ ):

The R groups, or side chains, differ chemically. For example, phenylalanine has a large nonpolar R group, whereas serine has a polar one. Aspartic acid has an acidic R group, whereas lysine, since it contains nitrogen, has a basic one. When amino acids are strung together to make a protein, the chemical properties of the R groups determine the structure and properties of the protein. Table 22.3 shows the most common amino acids in proteins and their three-letter abbreviations. The diversity of amino acids creates the possibility for an even larger diversity of proteins.

TABLE 22.3 Common Amino Acids

Glycine (Gly)

Alanine (Ala)

Valine (Val)

Leucine (Leu)

Isoleucine (Ile)

Proline (Pro)

Methionine (Met)

Cysteine (Cys)

Serine (Ser)

Threonine (Thr)

Aspartic acid (Asp)

Glutamic acid (Glu)

Asparagine (Asn)

Glutamine (Gln)

Lysine (Lys)

Arginine (Arg)

Histidine (His)

Phenylalanine (Phe)

Tyrosine (Tyr)

Tryptophan (Trp)

Because all amino acids (except glycine) contain four different groups attached to a tetrahedral carbon (the  $\alpha$ -carbon), all amino acids (except glycine) are chiral about that carbon. The amino acids that compose naturally occurring proteins are the *Lenantiomers*, and they are called L-amino acids. Why life on Earth is based on this enantiomer over the other is an interesting question that remains to be answered. (It seems just as likely that life could have used the D-enantiomer.)

Although we usually write the structures of amino acids as neutral, their actual structure is ionic and depends on pH. In general, amino acids undergo an intramolecular acid–base reaction and form a *dipolar ion*, or *zwitterion*:

At room temperature this equilibrium lies far to the right. Since one side of the dipolar ion is positively charged and the other negatively charged, amino acids are highly polar and soluble in water. They also have fairly high melting points (usually  $>200^\circ\text{C}$ ). In addition, the intramolecular acid–base reaction makes amino acids less acidic and less basic than most carboxylic acids and amines, respectively.

## Peptide Bonding between Amino Acids

Amino acids link together through the reaction of the amine end of one amino acid with the carboxylic end of another:

The resulting bond is a **peptide bond**, and the resulting molecule—two amino acids linked together—is a **dipeptide**. When two or more amino acids link in this way, the molecule they form has two distinct ends: an amino terminal (or N-terminal end) and a carboxyl terminal (or C-terminal end). A *tripeptide* is three amino acids joined by peptide bonds; a *tetrapeptide* is four; and so on. Short chains of amino acids are called *oligopeptides* generally, and longer chains (more than 20) are called **polypeptides**. Functional proteins usually contain one or more polypeptide chains, with each chain consisting of hundreds or even thousands of amino acids joined by peptide bonds.

The formation of a peptide bond is an example of a condensation reaction (see Section 21.11).

### Example 22.2 Peptide Bonds

Show the reaction by which valine, cysteine, and phenylalanine (in that order) link via peptide bonds. Designate valine as N-terminal and label the N-terminal and C-terminal ends in the resulting tripeptide.

—Continued on the next page

Continued—

**SOLUTION**

Peptide bonds form when the carboxylic end of one amino acid reacts with the amine end of another amino acid.

**FOR PRACTICE 22.2** Show the reaction by which alanine, threonine, and serine (in that order) link via peptide bonds. Designate alanine as the N-terminal and label the N-terminal and C-terminal ends in the resulting tripeptide.

## CONCEPTUAL CONNECTION 22.1

**Peptides** How many different tripeptides can form from the three amino acids listed here? (The amino acids are indicated using the three-letter amino acid abbreviations from Table 22.3.)

Ser, Ala, Gly

## 22.5 Protein Structure

A protein's structure is critical to its function. For example, recall from Section 22.1 that insulin is a protein that promotes the absorption of glucose out of the blood and into muscle cells where the glucose is needed for energy. Insulin recognizes muscle cells because muscle cell surfaces contain *insulin receptors*, molecules that fit a specific portion of the insulin protein. If insulin were a different shape, it would not latch onto insulin receptors on muscle cells and could not do its job. Thus, the shape or *conformation* of a protein is crucial to its function.

We can broadly classify proteins into two main structural categories: fibrous proteins and globular proteins (Figure 22.8►). **Fibrous proteins** tend to have relatively

## Fibrous and Globular Proteins

◀ **FIGURE 22.8 Fibrous and Globular Proteins** Proteins are broadly divided into fibrous proteins (which have relatively simple linear structures) and globular proteins (which have more complex three-dimensional structures).

simple linear structures and be insoluble in aqueous solutions. They serve primarily structural functions within living organisms. Collagen and keratin, for example, are both fibrous proteins (see Table 22.2). **Globular proteins** tend to have more complex structures but are often roughly spherical in overall shape. Globular proteins are generally structured so that polar side chains on amino acids are oriented toward the exterior of the protein, while nonpolar side chains are oriented toward the interior of the protein. Consequently, globular proteins tend to be soluble in water, but they maintain a nonpolar environment within the protein that excludes water. Hemoglobin and insulin are both globular proteins.

Protein structure is analyzed at four levels: primary structure, secondary structure, tertiary structure, and quaternary structure (Figure 22.9▼). We examine each of these categories separately.

▼ **FIGURE 22.9 Levels of Protein Structure** Protein structure is analyzed at four levels: primary, secondary, tertiary, and quaternary.

## Levels of Protein Structure

▲ The genetic disease known as sickle-cell anemia results in red blood cells with a sickle shape. These cells impede circulation of blood, causing damage to major organs.

► **FIGURE 22.10 Primary Structure of Egg-White Lysozyme** Primary structure refers to the sequence of amino acids in a protein.

## Primary Structure

The **primary structure** of a protein is the sequence of amino acids in its chain(s). Primary structure, which determines the other three kinds of structure, is maintained by the covalent peptide bonds between individual amino acids. The primary structure of egg-white lysozyme—a protein that helps fight infection—is shown in Figure 22.10 ▼. The figure illustrates the amino acid sequence, the N-terminal and C-terminal ends, and the presence of *disulfide linkages*, covalent cross-links between cysteine amino acids in the polymer. We discuss disulfide linkages in more detail later in the section on tertiary structure. Researchers determined the first amino acid sequences for proteins in the 1950s. Today, the amino acid sequences for thousands of proteins are known.

Changes in the amino acid sequence of a protein, even minor ones, can destroy the function of a protein. Hemoglobin, as we saw in Chapter 15, is a protein that transports oxygen in the blood. It is composed of four polypeptide chains made up of a total of 574 amino acid units. If valine is replaced by glutamic acid in just one position on two of these chains, the disease known as sickle-cell anemia results. The red blood cells of people with sickle-cell anemia take on a sickle shape that impedes circulation, causing damage to major organs. In the past, sickle-cell anemia was fatal, often resulting in death before age 30—all due to a change in a few atoms of two amino acids out of 574. Modern therapies have extended the life span of people with sickle-cell anemia so that they now live into their 40s and 50s.

▼ **FIGURE 22.11 The  $\alpha$ -Helix Structure** The  $\alpha$ -helix is an example of secondary protein structure.

$\alpha$ -Helix protein structure

## Secondary Structure

The **secondary structure** of a protein refers to certain regular periodic or repeating patterns in the arrangement of protein chains. Secondary structure is maintained by interactions between amino acids that are fairly close together in the linear sequence of the protein chain or that are adjacent to each other on neighboring chains or chains that fold back on themselves. The most common of these patterns is the  **$\alpha$ -helix**, shown in Figure 22.11 ◀. In the  $\alpha$ -helix structure, the amino acid chain wraps into a tight coil from which side chains extend. The structure is maintained by hydrogen-bonding interactions between NH and CO groups along the peptide backbone of the protein. Some proteins—such as keratin, which composes human hair—have the  $\alpha$ -helix pattern throughout their entire chain. Other proteins have very little or no  $\alpha$ -helix pattern in their chain.

◀ **FIGURE 22.12 The β-Pleated Sheet Structure** The β-pleated sheet is a secondary protein structure.

A second common pattern in the secondary structure of proteins is the **β-pleated sheet** (Figure 22.12▲). In this structure, the chain is extended (as opposed to coiled) and forms a zigzag pattern. The peptide backbones of neighboring chains interact with one another through hydrogen bonding to form zigzag-shaped sheets. Some proteins—such as silk—have the β-pleated sheet structure throughout their entire chains. Since the protein chains in the β-pleated sheet are fully extended, silk is inelastic. Many proteins have some sections that are β-pleated sheet, other sections that are α-helical, and still other sections that have less regular patterns referred to as **random coils**.

## Tertiary Structure

The **tertiary structure** of a protein consists of the large-scale bends and folds resulting from interactions between the R groups of amino acids that are separated by large distances in the linear sequence of the protein chain. These interactions, shown in Figure 22.13▼, include hydrogen bonding, disulfide linkages (covalent bonds between cysteine amino acids), hydrophobic interactions (attractions between large, nonpolar side chains), and salt bridges (acid-base interactions between acidic and basic side chains). Fibrous proteins generally lack tertiary structure; they simply extend in a long continuous chain with some secondary structure. Globular proteins, by contrast, fold in on themselves, forming complex globular shapes rich in tertiary structure.

### Interactions That Maintain Tertiary Structure

◀ **FIGURE 22.13 Interactions within Proteins** The tertiary structure of a protein is maintained by interactions between the R groups of amino acids that are separated by large distances in the linear sequence of the protein chain.

## Quaternary Structure

Some proteins—called *monomeric* proteins—are composed of only one polypeptide chain. However, *multimeric* proteins are composed of several polypeptide chains, called subunits. We just saw, for example, that hemoglobin is composed of four such subunits. The way that subunits fit together in a multimeric protein is referred to as the **quaternary structure** of the protein. Quaternary structure is maintained by the same types of interactions that maintain tertiary structure, but the interactions are between amino acids on different subunits.

### Summarizing Protein Structure:

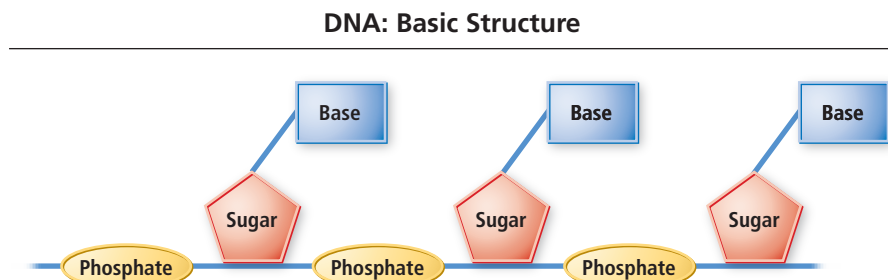

- ▶ Primary structure is the amino acid sequence. It is maintained by the peptide bonds that hold amino acids together.
- ▶ Secondary structure refers to the repeating patterns in the arrangement of protein chains. These are maintained by interactions between the peptide backbones of amino acids that are close together in the chain sequence or adjacent to each other on neighboring chains. Secondary structure is characteristic of fibrous proteins, but globular proteins also frequently feature regions of  $\alpha$ -helix,  $\beta$ -pleated sheet, and random coil secondary structure.
- ▶ Tertiary structure refers to the large-scale twists and folds of globular proteins. These are maintained by interactions between the R groups of amino acids that are separated by long distances in the chain sequence.
- ▶ Quaternary structure refers to the arrangement of subunits in proteins that have more than one polypeptide chain. Quaternary structure is maintained by interactions between amino acids on different subunits.

## 22.6 Nucleic Acids: Blueprints for Proteins

We have seen that the amino acid sequence in a protein determines that protein's structure and function. If the amino acid sequence is incorrect, the protein is unlikely to function properly. How do cells in living organisms synthesize the many thousands of different required proteins, each with the correct amino acid sequence? The answer lies in **nucleic acids**, molecules that serve as blueprints for protein synthesis. Nucleic acids employ a chemical code to specify the correct amino acid sequences for proteins. Nucleic acids are broadly divided into two types: deoxyribonucleic acid, or DNA, which exists primarily in the nucleus of the cell; and ribonucleic acid, or RNA, which exists throughout the cell.

### The Basic Structure of Nucleic Acids

Like proteins, nucleic acids are polymers. The individual units composing nucleic acids are **nucleotides**. Each nucleotide has three parts: a sugar, a base, and a phosphate group that serves as a link between sugars (Figure 22.14 ▼).

▲ **FIGURE 22.14 DNA Structure** DNA is composed of repeating units called nucleotides. Each nucleotide contains a sugar, a base, and a phosphate group.

## Sugars

In DNA, the sugar is deoxyribose, whereas in RNA the sugar is ribose:

The base attaches to the sugar at C1, and the phosphate attaches to the sugar at C3 and C5. When a base is attached to the sugar, the numbers of the carbon atoms in the sugar ring are primed to distinguish them from the carbon atoms on the bases (which are not primed). For example, C5 becomes C5' and C3 becomes C3'.

## Bases

Every nucleotide in DNA has the same sugar, but each nucleotide has just one of four different bases. In DNA, the four bases are adenine (A), cytosine (C), guanine (G), and thymine (T). Each of these bases bonds to the sugar via the nitrogen atom circled in the illustrations shown here:

### Purine Bases

### Pyrimidine Bases

Adenine and guanine are called *purine* bases because they resemble the bicyclic compound purine. Cytosine and thymine are called *pyrimidine* bases because they resemble the monocyclic compound pyrimidine:

In RNA, the base uracil (U), also a pyrimidine base, replaces thymine. Uracil and thymine differ only in a methyl ( $-\text{CH}_3$ ) group:

## Base Pairing in DNA

▲ **FIGURE 22.15 Base Pairing in DNA** The bases in nucleic acids are complementary. Each pyrimidine base pairs with only one purine base (G with C, A with T) via specific hydrogen bonds that occur between the two bases.

The bases in nucleic acids are **complementary**—that is, each one precisely pairs with another base. Each pyrimidine base pairs with only one purine base via specific hydrogen bonds that occur between the two bases. More specifically, guanine pairs only with cytosine through three hydrogen bonds, and adenine pairs only with thymine through two hydrogen bonds as shown in Figure 22.15▲. In other words, guanine is complementary to cytosine and adenine is complementary to thymine. This base pairing is central to DNA replication, as we discuss in Section 22.7.

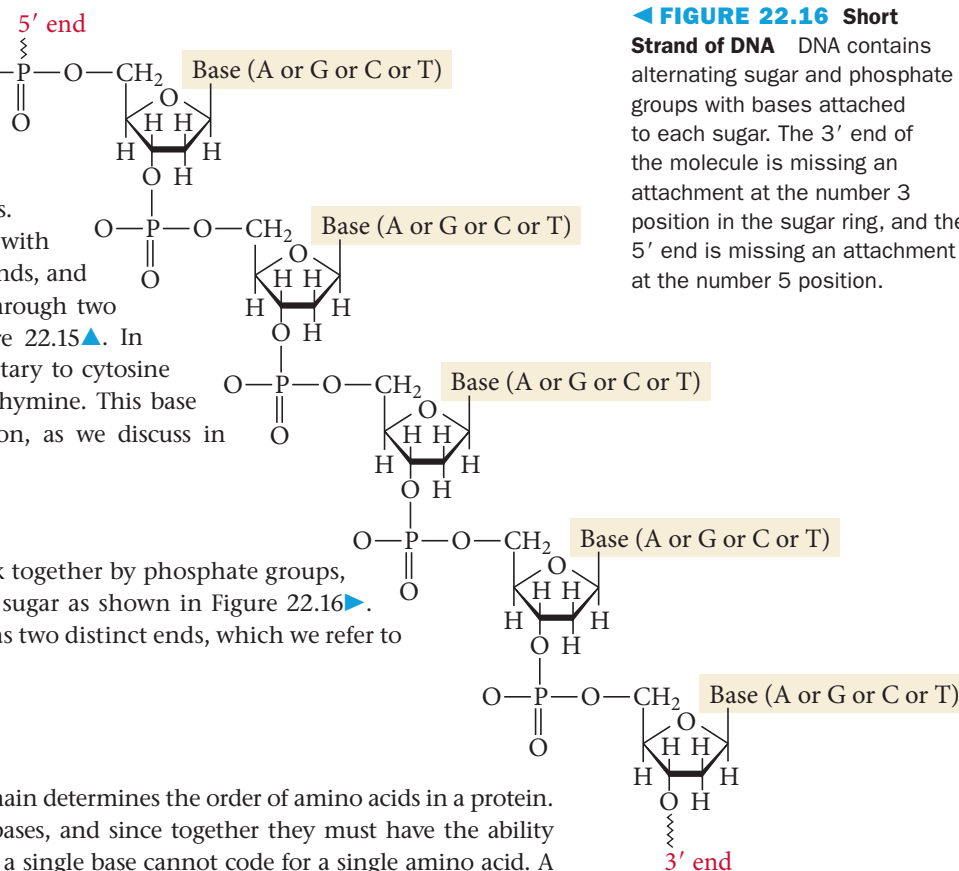

## Phosphate Links

The sugar units in nucleic acids link together by phosphate groups, which bind to C5' and C3' of the sugar as shown in Figure 22.16▶. Note that a nucleic acid molecule has two distinct ends, which we refer to as the 5' end and the 3' end.

## The Genetic Code

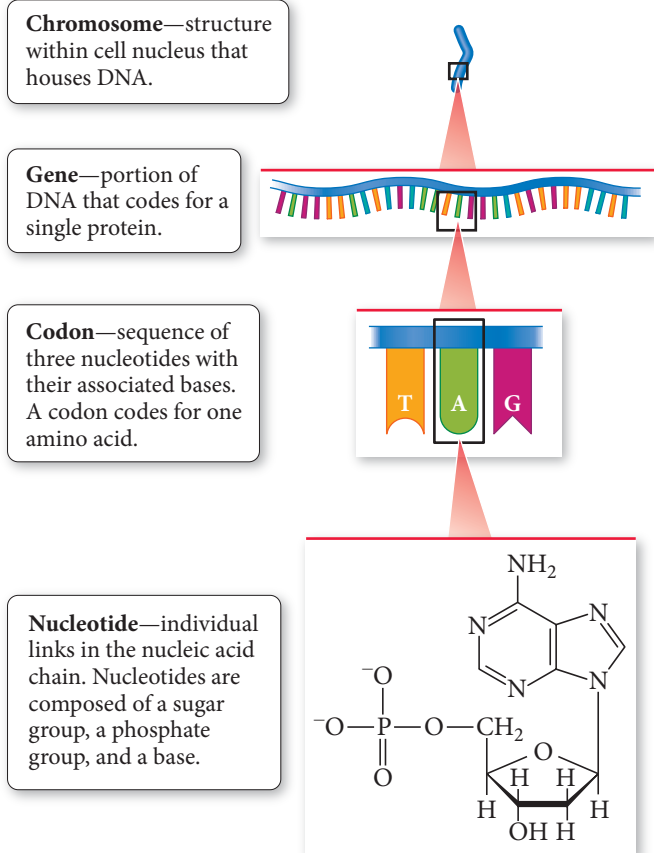

The order of bases in a nucleic acid chain determines the order of amino acids in a protein. However, since there are only four bases, and since together they must have the ability to code for 20 different amino acids, a single base cannot code for a single amino acid. A

▶ **FIGURE 22.16 Short Strand of DNA** DNA contains alternating sugar and phosphate groups with bases attached to each sugar. The 3' end of the molecule is missing an attachment at the number 3 position in the sugar ring, and the 5' end is missing an attachment at the number 5 position.

## Genetic Structure

▲ **FIGURE 22.17 Genetic Structure** The hierarchical structure of genetic information is chromosome, gene, codon, and nucleotide.

sequence of three nucleotides—called a **codon**—codes for each amino acid (Figure 22.17 ▲). The genetic code—the code that identifies the amino acid specified by a particular codon—was worked out in 1961. It is nearly universal—the same codons specify the same amino acids in nearly all organisms. For example, in DNA the sequence AGT codes for the amino acid serine, and the sequence ACC codes for the amino acid threonine. It does not matter if the DNA is in a rat, a bacterium, or a human—the code is the same.

A **gene** is a sequence of codons within a DNA molecule that codes for a single protein. Since proteins vary in size from a few dozen to thousands of amino acids, genes vary in length from dozens to thousands of codons. For example, egg-white lysozyme (see Figure 22.10) is composed of 129 amino acids. So the lysozyme gene contains 129 codons—one for each amino acid in the lysozyme protein. Each codon is like a three-letter word that specifies one amino acid. String the correct number of codons together in the correct sequence, and you have a gene, the instructions for the amino acid sequence in a protein. Genes are contained in structures called **chromosomes** (Figure 22.18 ►). A human cell generally contains 46 chromosomes in its nucleus.

▲ **FIGURE 22.18 Chromosomes** Genes are contained in structures called chromosomes. Most human cells contain 46 chromosomes.

In addition to having a codon for each amino acid, genes also contain additional coding that signals, for example, where the gene begins and where it ends.

**The Genetic Code** Assuming you have four different bases, how many amino acids can you code for with two-base sequences? Three-base sequences?

CONCEPTUAL  
**CONNECTION 22.2**

## 22.7 DNA Replication, the Double Helix, and Protein Synthesis

Most of the cells in our bodies contain all of the genes required to make all of the proteins that we need—the DNA within any one cell is *complete*. However, any particular cell does not express all those genes; it does not synthesize all those proteins. Cells synthesize only the proteins that are important to their function. For example, a pancreatic cell expresses the insulin gene within its nucleus to synthesize insulin. Pancreatic cells do not express the gene for keratin (the protein in hair), even though the keratin gene is also contained in their nuclei. The cells in our scalp, in contrast, which also have both insulin and keratin genes in their nuclei, synthesize keratin but not insulin.

▲ **FIGURE 22.19 Watson and Crick** James Watson and Francis Crick discovered the structure of DNA, including the double helix and the pairing of complementary bases.

### DNA Replication and the Double Helix

The human body contains on the order of  $10^{13}$  cells, most of which have complete copies of the DNA that originally was present in a single cell (the fertilized egg). When a cell divides, it makes complete copies of its DNA for each daughter cell. The ability of DNA to copy itself is related to its structure, discovered in 1953 by James D. Watson and Francis H. C. Crick. Watson and Crick, aided by evidence from X-ray diffraction photos (see Section 12.2), determined that DNA exists as two complementary strands wound around each other in a double helix (Figure 22.19◀). The strands are antiparallel, so one runs  $3' \rightarrow 5'$  while the other runs  $5' \rightarrow 3'$ . The bases on each DNA strand are directed toward the interior of the helix, where they hydrogen-bond to their complementary bases on the other strand. For example, if a section of DNA contains the bases:

the complementary strand has the sequence:

As we saw earlier, A pairs only with T, and C pairs only with G. The two complementary strands are tightly wrapped into a helical coil, the famous DNA double helix structure (Figure 22.20▼).

► **FIGURE 22.20 DNA Double Helix** Two complementary strands of DNA wrap around one another to form a double helix.

◀ **FIGURE 22.21 DNA Replication**

When a cell is about to divide, its DNA unwinds. With the help of the enzyme DNA polymerase, a complement to each daughter strand is formed, resulting in two complete copies of the original DNA.

When a cell is about to divide, the DNA unwinds and the hydrogen bonds joining the complementary bases break (Figure 22.21▲), forming two daughter strands. With the help of the enzyme DNA polymerase, a complement to each daughter strand—with the correct complementary bases in the correct sequence—forms. The hydrogen bonds between the old strands and the newly complementary strands then re-form, resulting in two complete copies of the original DNA, one for each daughter cell.

## Protein Synthesis

Living organisms must continually synthesize thousands of proteins to survive, each when it is needed and in the quantities required. When a cell needs to make a particular protein, the gene—the section of the DNA that codes for that particular protein—unravels. Complementary copies of that gene are then synthesized (or transcribed) as single strands of *messenger RNA* (or mRNA). The mRNA moves out of the cell's nucleus to structures in the cytoplasm called *ribosomes*.

At the ribosome, protein synthesis occurs. The ribosome (which has a large subunit and a small subunit) moves along the mRNA chain that codes for the protein, “reading” the sequence of codons. At each codon, the specified amino acid is brought into place and a peptide bond forms with the previous amino acid (Figure 22.22▼). As the ribosome moves along the mRNA, the protein forms. All of this is orchestrated by enzymes that catalyze the necessary reactions.

▲ **FIGURE 22.22 Protein Synthesis** A ribosome moves along a strand of mRNA, joining amino acids to form a protein.

## Chemistry AND Medicine | The Human Genome Project

In 1990, the U.S. Department of Energy (DOE) and the National Institutes of Health (NIH) embarked on a 15-year project to map the human genome, all of the genetic material of a human being. Over 2500 researchers from 18 countries contributed to this research, which has been referred to as the Mount Everest of biology. An initial draft of the map was completed in 2001 and the final draft was completed in 2003. Here, we highlight some of what has been learned through this massive undertaking.

- The human genome contains 3165 million nucleotide base pairs.
- The average gene contains about 3000 base pairs. The largest gene is for the protein dystrophin (dystrophin deficiency is the root cause of muscular dystrophy); it contains 2.4 million base pairs.
- The human genome contains about 30,000 genes. The function of over half of these is still unknown. Before the Human Genome Project, researchers had estimated that humans had about 100,000 genes. The number of genes in humans is not much larger than the number found in many simpler organisms. For example, the number of genes in a roundworm is nearly 20,000. Whatever makes humans unique, it is not the number of genes in our genome.
- Less than 2% of human DNA actually consists of genes. These genes are aggregated in seemingly random areas within the genome, with vast expanses of noncoding DNA between the coding regions. This stands in contrast to other organisms, which tend to have more uniform distribution of genes throughout their genome.
- The order of DNA base pairs is 99.9% identical in all humans.
- About 1.4 million single base-pair differences (called SNPs for single-nucleotide polymorphisms) have been identified in the human genome. Understanding SNPs can help in identifying individuals who are susceptible to certain diseases. Knowledge of SNPs may also allow physicians to tailor drugs to match individuals.

Knowledge of the human genome is expected to lead to the development of new therapies in several ways. First, knowledge of genes can lead to smart drug design. Instead of developing drugs by trial and error (the current procedure for many drugs), knowledge of a specific gene will allow scientists to design drugs to carry out a specific function related to that gene or its protein product. Second, human genes themselves can provide the blueprint for the production of certain types of drugs, either in the laboratory or by other organisms. For example, in Section 22.1 we discussed how insulin is made by inserting the insulin gene into bacteria, which then synthesize the needed drug. Intriguingly, it may even be possible to replace abnormal or missing genes in the cells of diseased patients. Such gene therapies are still in the early stages of development, but they may eventually give us a powerful new tool for combating inherited diseases.

Although the completion of the Human Genome Project may seem like the end, it is really just the beginning. Thousands of studies in the coming years will rely on the data obtained through this endeavor.

### Summarizing DNA Coding:

- ▶ DNA contains the code for the sequence of amino acids in proteins.
- ▶ A codon—three nucleotides with their bases—codes for one amino acid.
- ▶ A gene—a sequence of codons—codes for one protein.
- ▶ Genes are contained in structures called chromosomes that occur within cells. Humans have 46 chromosomes in the nuclei of their cells.
- ▶ When a human cell divides, each daughter cell receives a complete copy of the DNA—all 46 chromosomes.
- ▶ When a cell synthesizes a protein, the base sequence of the gene that codes for that protein is transferred to mRNA. The mRNA then moves to a ribosome, where the amino acids are linked in the correct sequence to synthesize the protein. The general sequence of information flow is:

DNA → RNA → PROTEIN

## Self-Assessment Quiz

**Q1.** Which compound is a lipid?

**Q2.** Which compound is a carbohydrate?

**Q3.** Which compound is an amino acid?

**Q4.** The sequence of amino acids in a protein chain is an example of which kind of protein structure?

- a) primary                      b) secondary  
c) tertiary                      d) quaternary

**Q5.** A section of DNA contains the bases ATTCGGAA. What is the correct sequence of bases in the complementary strand?

- a) CGGATTCC                      b) ATTCGGAA  
c) AAGGCTTA                      d) TAAGCCTT

**Q6.** A codon is a sequence within DNA that codes for what?

- a) an amino acid                      b) a protein  
c) a carbohydrate                      d) a fat

**Q7.** Which of the functions listed is *not* attributed to proteins?

- a) catalyze biochemical reactions  
b) transport substances from one place to another  
c) mediate muscle contraction  
d) none of the above (all of these functions are attributed to proteins)

**Q8.** Which is a primary function of nucleic acids?

- a) energy storage  
b) coding the amino acid sequence for proteins  
c) oxygen transport  
d) regulation of metabolic processes

Continued—

**Q9.** Peptide bonds occur in which type of biochemical compounds?

- a) lipids                      b) carbohydrates  
c) proteins                  d) nucleic acids

**Q10.** How many nucleotides are required to code for all of the amino acids in a protein that contains 186 amino acids?

- a) 186              b) 372              c) 558              d) 1

Answers: 1. (b) 2. (a) 3. (c) 4. (a) 5. (d) 6. (a) 7. (d) 8. (d) 9. (c) 10. (c)

## Chapter 22 IN REVIEW

### Key Terms

#### Section 22.1

biochemistry (1030)

#### Section 22.2

lipid (1030)  
fatty acid (1030)  
triglyceride (1032)  
ester linkage (1032)  
saturated fat (1033)  
unsaturated fat (1033)  
phospholipid (1033)  
glycolipid (1033)  
lipid bilayer (1034)  
steroid (1034)

#### Section 22.3

carbohydrate (1035)  
monosaccharide (1035)

hexose (1035)  
aldose (1035)  
ketose (1035)  
glycosidic linkage (1037)  
disaccharide (1037)  
hydrolysis (1037)  
polysaccharide (1037)  
complex carbohydrate (1037)  
cellulose (1038)  
starch (1038)  
glycogen (1038)

#### Section 22.4

enzyme (1038)  
amino acid (1039)  
peptide bond (1041)  
dipeptide (1041)  
polypeptide (1041)

#### Section 22.5

fibrous protein (1042)  
globular protein (1043)  
primary structure (1044)  
secondary structure (1044)  
 $\alpha$ -helix (1044)  
 $\beta$ -pleated sheet (1045)  
random coil (1045)  
tertiary structure (1045)  
quaternary structure (1046)

#### Section 22.6

nucleic acid (1046)  
nucleotide (1046)  
complementary (1048)  
codon (1049)  
gene (1049)  
chromosome (1049)

### Key Concepts

#### Diabetes and the Synthesis of Human Insulin (22.1)

- ▶ Diabetes is a chronic illness that occurs when the pancreas cannot make enough insulin, a protein that promotes the absorption of glucose into cells.
- ▶ The chemical structure of insulin was discovered in 1955 by Frederick Sanger, who made it possible for insulin to be synthesized in the laboratory.
- ▶ Eventually, scientists inserted the human gene that codes for the production of insulin into bacteria, which were then able to produce enough insulin to supply diabetics.

#### Lipids (22.2)

- ▶ Lipids are biological chemicals that are nonpolar and, therefore, insoluble in water. In our bodies, lipids compose cell membranes, store energy, and provide insulation.
- ▶ A type of lipid called a fatty acid is a carboxylic acid with a long hydrocarbon chain. Fatty acids can be saturated, meaning they contain the maximum number of hydrogen atoms, or unsaturated, meaning they contain one or more carbon-carbon double bonds. Saturated fatty acids experience greater intermolecular forces,

making them solid at room temperature, while unsaturated fatty acids are liquids.

- ▶ Fats and oils are triglycerides, triesters composed of glycerol bonded by ester linkages to three fatty acids. Like fatty acids, triglycerides can be saturated (fats) or unsaturated (oils).
- ▶ Other lipids include phospholipids, made up of a glycerol bonded to two nonpolar fatty acids and a polar phosphate group, used in animal cell membranes; glycolipids, similar to phospholipids but with a sugar molecule as their polar head; and steroids, four-ringed lipids that include cholesterol and sex hormones.

#### Carbohydrates (22.3)

- ▶ Carbohydrates are polyhydroxy aldehydes or ketones and generally have the formula  $(\text{CH}_2\text{O})_n$ . They are important to short-term energy storage and plant structure composition.
- ▶ Monosaccharides, the simplest carbohydrates, contain three to eight carbons with one aldehyde or ketone functional group. Glucose, an example of a hexose, can exist both in a linear form and a ring form.

- ▶ Two monosaccharides combine to form a disaccharide. For example, glucose and fructose combine to form sucrose. The glycosidic linkages that connect the two monosaccharides are broken during digestion by hydrolysis.
- ▶ Polysaccharides are polymers of monosaccharides known as complex carbohydrates. They include cellulose, also called fiber, the main structural component of plants; starch, an energy storage compound found in potatoes and grains; and glycogen, used by animals to store glucose in the muscles.

### Proteins and Amino Acids (22.4)

- ▶ Proteins are polymers of amino acids and serve a variety of biological functions including structure composition, metabolic regulation, and muscle contraction. Enzymes are particularly important proteins that catalyze biochemical reactions in cells.
- ▶ An amino acid contains a carbon atom bonded to an amine group, a carboxylic acid group, a hydrogen atom, and an R group. There are 20 amino acids in humans, and they differ only in their R group.
- ▶ Amino acids form peptide bonds between the amine end of one amino acid with the carboxylic end of another, creating dipeptides, tripeptides, and so on, or polypeptides, large examples of which are called proteins.

### Protein Structure (22.5)

- ▶ Protein structure and shape are critical to protein function.
- ▶ Proteins can be broadly divided into two structural categories. Fibrous proteins are generally linear, insoluble structures that serve structural functions. Globular proteins fold into roughly spherical conformations with nonpolar side chains oriented to the interior and polar side chains oriented to the exterior; this structure makes globular proteins soluble in water.
- ▶ Protein structure can be analyzed at four levels. The primary structure is the sequence of the amino acid chain. The secondary structure refers to certain regular repeating patterns in the arrangement of protein chains, such as  $\alpha$ -helix and  $\beta$ -pleated sheet patterns. The tertiary structure refers to large-scale bends and folds due to interactions between the R groups of amino acids such as hydrogen bonding, disulfide linkages, hydrophobic interactions, and salt bridges.

Quaternary structure shows the way that monomeric subunits fit together in multimeric proteins that have more than one polypeptide chain.

### Nucleic Acids (22.6)

- ▶ Nucleic acids, such as DNA and RNA, are the chemical blueprints used to synthesize proteins. Nucleic acids are polymers of nucleotides, which are each composed of a sugar, a base, and a phosphate group.
- ▶ The bases of DNA are adenine (A), cytosine (C), guanine (G), and thymine (T), which are subject to complementary pairing: each pyrimidine base combines with only one purine base.
- ▶ Phosphate links bind the C5' carbon of one sugar with the C3' carbon of another sugar to make the polymeric chain.
- ▶ The order of the bases in a nucleic acid chain specifies the order of amino acids in a protein.
- ▶ Each amino acid is coded by a codon, a sequence of three bases. A gene is a sequence of codons that codes for a specific protein. Genes, in turn, are contained in structures called chromosomes.

### DNA Replication, the Double Helix, and Protein Synthesis (22.7)

- ▶ Though the DNA code is complete in any cell in the body, every cell does not express every gene. Cells only express the genes relevant to their function.
- ▶ DNA is composed of two complementary strands wound around each other in a double helix. The strands are antiparallel; the bases of each strand face the interior and hydrogen-bond to their complements on the other strand.
- ▶ In order to replicate, a DNA strand divides and an enzyme called DNA polymerase creates the complement of each of the divided strands, thereby making two copies of the original DNA molecule.
- ▶ To synthesize proteins, the section of DNA that codes for that gene unravels. Messenger RNA (mRNA) is synthesized as a copy of the gene. The mRNA joins with ribosomes, structures that “read” the mRNA code and synthesize the correct sequence of amino acids.

## Key Learning Outcomes

CHAPTER OBJECTIVES	ASSESSMENT
Recognizing and Working with the Basic Structures of Lipids (22.2) 	Exercises 31–34
Recognizing and Working with the Basic Structures of Carbohydrates (22.3)	Exercises 37–40
Identifying Chiral Carbon Atoms in Carbohydrates (22.3)	Example 22.1 For Practice 22.1 Exercises 41, 42, 86
Drawing Structures for Amino Acids and Peptide Bonds (22.4)	Example 22.2 For Practice 22.2 Exercises 49–58
Recognizing Levels of Protein Structure (22.5) 	Exercises 59–62
Recognizing Nucleic Acids and Nucleotides (22.6)	Exercises 63, 64

## EXERCISES

## Review Questions

- What is biochemistry? What significant advances in biochemistry have helped diabetics?
- What is a lipid? What roles do lipids play in living organisms?
- What is a fatty acid? Draw the general structure of a fatty acid.
- What effect do double bonds have within the hydrocarbon chain of a fatty acid?
- What are triglycerides? Draw a general structure of a triglyceride.
- Explain the difference, both in terms of structure and in terms of properties, between a saturated fat and an unsaturated fat.
- Describe the basic structure of phospholipids and glycolipids. What functions do these lipids have in living organisms?
- What is a steroid? List some functions of steroids.
- What are carbohydrates? What role do they play in living organisms?
- How do monosaccharides and disaccharides differ? Aldoses and ketoses?
- How do simple and complex carbohydrates differ?
- How do cellulose, starch, and glycogen differ? Describe the function of each.
- What roles do proteins play in living organisms? List specific examples.
- Describe the basic structure of an amino acid. How are amino acids linked together to form proteins?
- How do the properties of the R groups in amino acids relate to the properties of proteins?
- Why are amino acids chiral?
- Draw the structure of a neutral amino acid and its dipolar ion.
- Draw the structure of any two amino acids, showing how they link together to form a dipeptide.
- Why is protein structure important?
- How do fibrous proteins and globular proteins differ?
- Describe the various levels of protein structure (primary, secondary, tertiary, and quaternary).
- What types of interactions or bonds maintain each of the structures listed in the previous problem?
- Describe the secondary structures known as  $\alpha$ -helix and  $\beta$ -pleated sheet.
- What is the function of nucleic acids in living organisms?
- What is the general structure of a nucleic acid?
- The bases in nucleic acids are *complementary*. What does this mean?
- What is a codon? A gene? A chromosome?
- Do most cells contain complete copies of an organism's DNA? Do most cells express all of the genes contained in their DNA?
- Explain the mechanism by which DNA is replicated.
- Explain the mechanism by which proteins are synthesized from the information contained within DNA.

## Problems by Topic

## Lipids

31. Determine whether or not each molecule is a lipid. If the molecule is a lipid, indicate the kind of lipid. If it is a fatty acid or a triglyceride, classify it as saturated or unsaturated.

32. Determine whether or not each molecule is a lipid. If the molecule is a lipid, state the kind of lipid. If it is a fatty acid or a triglyceride, classify it as saturated or unsaturated.

**33.** Determine whether or not each molecule is a fatty acid. If it is a fatty acid, classify it as saturated, monounsaturated, or polyunsaturated.

**34.** Which fatty acid is most likely to be a solid at room temperature?

35. Draw structures showing the reaction of glycerol with linoleic acid to form the triglyceride trilinolein. Would you expect this triglyceride to be a fat or an oil?

36. Draw structures showing the reaction of glycerol with myristic acid to form the triglyceride trimyristin. Would you expect this triglyceride to be a fat or an oil?

## Carbohydrates

**37.** Determine whether or not each structure is a carbohydrate. If the molecule is a carbohydrate, classify it as a monosaccharide, disaccharide, or trisaccharide.

**38.** Determine whether or not each structure is a carbohydrate. If the molecule is a carbohydrate, classify it as a monosaccharide, disaccharide, or trisaccharide.

**a.**

**b.**

C.

d.

39. Classify each saccharide as an aldose or a ketose. Also classify each as a triose, tetrose, pentose, and so on.

40. Classify each saccharide as an aldose or a ketose. Also classify each as a triose, tetrose, pentose, and so on.

41. How many chiral carbon atoms are in each of the structures in Problem 39?
42. How many chiral carbon atoms are in each of the structures in Problem 40?
43. Draw structures for the straight-chain and ring forms of glucose.
44. Draw structures for the straight-chain and ring forms of fructose.

45. Draw the products that result from the hydrolysis of the carbohydrate pictured on the right.

46. Draw the products that result from the hydrolysis of the carbohydrate pictured on the right.

47. Draw the structure of sucrose. Label the glucose and fructose rings in this disaccharide.
48. Lactose is a disaccharide of glucose and galactose. Draw the structure of lactose.

## Amino Acids and Proteins

49. Draw each amino acid in its dipolar ion form.  
a. Thr      b. Ala      c. Leu      d. Lys
50. Draw each amino acid in its dipolar ion form.  
a. Val      b. Phe      c. Tyr      d. Cys
51. Draw the structures of the two enantiomers of alanine.
52. Draw the structures of the two enantiomers of cysteine.
53. How many different tripeptides can form from serine, glycine, and cysteine? List the amino acid sequence of each one.
54. How many dipeptides can form from leucine and serine? List the amino acid sequence for each one.
55. Draw the reaction by which serine and tyrosine form a peptide bond.
56. Draw the reaction by which valine and asparagine form a peptide bond.
57. Draw a structure for each tripeptide.  
a. Gln-Met-Cys      b. Ser-Leu-Cys      c. Cys-Leu-Ser
58. Draw a structure for each tetrapeptide.  
a. Ser-Ala-Leu-Cys      b. Gln-Met-Cys-Gly  
c. Gly-Cys-Met-Gln
59. A phenylalanine amino acid on a protein strand undergoes hydrophobic interactions with another phenylalanine amino acid that is 26 amino acid units away. The resulting fold in the protein is an example of which kind of structure? (primary, secondary, tertiary, or quaternary)
60. An amino acid on a protein strand forms a hydrogen bond to another amino acid that is four amino acid units away. The next amino acid on the chain does the same, hydrogen-bonding to an amino acid that is four amino acids away from it. This pattern repeats itself over a significant part of the protein chain. The resulting pattern in the protein is an example of which kind of structure? (primary, secondary, tertiary, or quaternary)
61. The amino acid sequence in one section of a protein is shown here. It represents which kind of structure? (primary, secondary, tertiary, or quaternary)  
-Lys-Glu-Thr-Ala-Ala-Ala-Lys-Phe-Glu-

62. A dimeric protein is composed of two individual chains of amino acids. The way these two chains fit together is an example of which kind of structure? (primary, secondary, tertiary, or quaternary)

## Nucleic Acids

63. Determine whether or not each structure is a nucleotide. For each nucleotide, identify the base as A, T, C, or G.

64. Determine whether or not each structure is a nucleotide. For each nucleotide, identify the base as A, T, C, or G.

65. Draw the structures of the two purine bases in nucleic acids.
66. Draw the structures of the three pyrimidine bases in nucleic acids.
67. Draw the DNA strand that is complementary to the DNA strand shown here.

68. Draw the DNA strand that is complementary to the DNA strand shown here.

69. A monomeric protein contains 154 amino acids. How many codons code for these amino acids? How many nucleotides?
70. A dimeric protein contains 142 amino acids in one strand and 148 in the other. How many codons code for these amino acids? How many nucleotides?

## Cumulative Problems

71. Determine the class of biochemical compound that contains each type of linkage.
- peptide bonds
  - glycosidic linkage
  - ester linkage
72. Name the type of polymer associated with each monomer.
- nucleotide
  - amino acid
  - saccharide
73. What is the difference between a codon and a nucleotide? A codon and a gene?
74. What is the difference between a fatty acid and a triglyceride? A triglyceride and a phospholipid?
75. The amino acid alanine has the condensed structural formula shown here:

Determine the VSEPR geometry about each internal atom and make a three-dimensional sketch of the molecule.

76. The amino acid serine has the condensed structural formula shown here:

Determine the VSEPR geometry about each internal atom and make a three-dimensional sketch of the molecule.

77. Which amino acids in Table 22.3 are most likely to be involved in hydrophobic interactions?
78. Sickle-cell anemia is caused by a genetic defect that substitutes valine for glutamic acid at one position in two of the four chains of the hemoglobin protein. The result is a decrease in the water solubility of hemoglobin. Examine the structures of valine and glutamic acid and explain why this occurs.

79. Determining the amino acid sequence in a protein usually involves treating the protein with various reagents that break up the protein into smaller fragments that can be individually sequenced. Treating a particular 11-amino acid polypeptide with one reagent produced the fragments:

Treating the same polypeptide with a different reagent produced the fragments:

What is the amino acid sequence of the polypeptide?

80. Treating a particular polypeptide with one reagent (as described in the previous problem) produced the fragments:

Treating the same polypeptide with a different reagent produced the fragments:

What is the amino acid sequence of the polypeptide?

81. Naturally occurring D-glucose is one of a pair of enantiomers. Its mirror image is L-glucose. Draw the two cyclic six-membered isomers of L-glucose that differ in the configuration around C1 and indicate which is  $\alpha$  and which is  $\beta$ .
82. Calculate the mass percent of phosphorus in a strand of DNA that consists of equal amounts of each of the four N-bases.
83. The double helical structure of DNA disrupts on heating but reforms on cooling. Use thermodynamic reasoning to account for these observations.
84. From the structural formula of cholesterol shown on page 1034, determine (a) the composition, and (b) the number of chiral centers.

## Challenge Problems

85. One way to fight viral infections is to prevent a virus from replicating its DNA. Without DNA replication, the virus cannot multiply. Some viral drug therapies cause the introduction of *fake* nucleotides into cells. When the virus uses one of these fake nucleotides in an attempt to replicate its DNA, the fake nucleotide doesn't work and viral DNA replication is halted. For example, azidothymidine (AZT), a drug used to fight the human immunodeficiency virus (HIV) that causes AIDS, results in the introduction of the following fake thymine-containing nucleotide into cells. Examine the structures of the real nucleotide and the AZT fake nucleotide. Propose a mechanism for how this fake nucleotide might halt DNA replication.

86. Draw each molecule and identify the chiral centers within them.
- ribose
  - galactose
  - 5-deoxyribose (*Hint*: The 5 indicates that the oxygen is removed from the 5th carbon.)
87. Glucose transport across the red blood cell membranes (erythrocyte membrane) is a well-studied system. One laboratory project obtained the data shown here for glucose transport.

[Glucose] <sub>outside</sub> (mM)	Rate of Glucose Entry (μM/min)
0.5	12
1.0	19
2.0	27
3.0	32
4.0	35

The kinetics of glucose transport through the membrane follows the Michaelis–Menten equation:

$$V_0 = \frac{V_{\max}[\text{glucose}]}{K_t + [\text{glucose}]}$$

$V_0$  = rate of glucose entry

$V_{\max}$  = maximum rate (the point at which addition of glucose has no effect on the rate)

$K_t$  = transport constant

The Michaelis–Menten equation can be rearranged so that a plot  $1/V_0$  versus  $1/[\text{glucose}]$  produces a straight line. Rearrange the equation and plot the data in order to determine  $K_t$  and  $V_{\max}$  for glucose transport across the erythrocyte membrane.

88. Eukaryotic DNA is equipped with special ends called telomers. Telomers are made up of hexanucleotide sequences that repeat at the ends of the DNA. For example, human DNA features repeating AGGGTT sequences. Functionally, telomers protect the ends of chromosomes from being treated as a broken piece of DNA in need of repair. Interestingly, telomers are cut off each time the DNA is replicated, indicating a possible cellular clock that allows only a certain number of cellular replications. Telomerase is the enzyme that catalyzes the synthesis of telomers. Telomerase is present in limited quantities within certain cells such as fetal tissue, adult male germ cells, and stem cells. It is also found in over 85% of tumor cells. Researchers speculate that the telomerase activity may be linked to cancer. Propose an explanation for why telomerase activity could be associated with cancer and speculate on ways in which cancer treatments in the future may capitalize on research on this enzyme.
89. Write the major equilibrium that is established in a solution of glycine at pH = 2 and at pH = 10. The  $pK_a$  of the COOH group is 2.3 and the  $pK_a$  of the  $NH_3^+$  group is 9.6. Determine the relative concentrations of each member of the relevant conjugate acid–base pair at pH = 2 and pH = 10. Calculate the pH at which glycine is neutral.

## Conceptual Problems

90. How many different tetrapeptides can form from four different amino acids?
91. Could the genetic code have been based on just three bases and three-base codons? Explain why or why not. (Assume that the code must accommodate 20 different amino acids.)
92. The genetic code is random, which means that a particular codon could have coded for a different amino acid. The genetic

code is also nearly universal, meaning that it is the same code in nearly all organisms (and in the few where it differs, it does so only slightly). If scientists ever find life on another planet, they will be curious to know its genetic code. What would a completely different genetic code indicate about the origin of the life forms? What would a genetic code identical to terrestrial life indicate?

## Questions for Group Work

Discuss these questions with the group and record your consensus answer.

93. Compare and contrast cornstarch with cotton balls, which are made of almost pure cellulose. Include at least three ways in which they are similar and three ways in which they are different. Mention aspects you have observed in daily life and aspects on the molecular scale.
94. With group members acting as atoms, molecules, or molecular fragments, act out the formation of a peptide bond.
95. Describe how a common object or toy (e.g., a train, building blocks, or beads on a string) could represent a protein. Describe how amino acids and peptide bonds are represented in your analogy. Also describe the representation of primary, secondary, tertiary, and quaternary structure in your analogy.
96. Use the tabulated key to decipher the mRNA encoded message. Group members may split up the message and decode separate parts, but each part must be decoded by at least two group members (to prevent errors). Describe how the process your group uses to decode the message is significant for biochemistry.

Codon	Amino Acid	Codon	Amino Acid	Codon	Amino Acid	Codon	Amino Acid
UUC	A	ACU	H	GAC	O	GGC	V
CUA	B	GCG	I	GAA	P	UGA	W
AUU	C	UAC	J	UGU	Q	UAA	X
AUG	D	CAU	K	UGG	R	UAG	Y
GUC	E	CAG	L	CGC	S	GGU	Z
UCC	F	AAC	M	AGU	T		
CCG	G	AAG	N	AGG	U		

CUAGCGGACAUUACUGUCAACGCGCGCAGUUGGUAG  
GCGCGC UUCAACUUCGGUGCGAAGCCG!

97. Working individually, draw an accurate structure for one of the following (don't tell other group members which one you choose): a monosaccharide, a disaccharide, a polysaccharide, a fatty acid, a triglyceride, a steroid, an amino acid, or a dipeptide. After each group member has completed drawing a structure, take turns showing your structure to the group. How many group members can correctly identify the structure you drew? How many of your group members' structures can you correctly identify?

## Data Interpretation and Analysis

### Digestion of Lactose by the Lactase Enzyme

98. Lactose is a disaccharide sugar present in milk. Lactose is composed of two monosaccharides, galactose and glucose, that are joined together by a  $\beta$ -glycosidic bond. The  $\beta$ -glycosidic bond forms between the hydroxyl group on C-1 of galactose and C-4 of glucose.

When lactose is digested, the glycosidic bond between galactose and glucose is hydrolyzed. The enzyme responsible for hydrolyzing lactose is *lactase*, which is found in the small intestine. Millions of people lack sufficient levels of lactase, and as a result, they experience lactose intolerance. If lactose is not hydrolyzed, it remains in the intestines. Bacteria in the gut ferment the lactose, causing many unpleasant symptoms such as indigestion, cramping, and gas. Fortunately, commercial preparations can enable lactose-intolerant individuals to consume and digest milk products without discomfort.

Use the information provided to answer the following questions:

- a. Draw the structure of lactose. (The structures of galactose and glucose are shown on page 1037 with their carbon numbering scheme.)

**FIGURE a**  
**Lactase Activity and pH**  
[Source: *European Journal of Biochemistry*, Vol. 114, p. 653–661 (1981).]

- b. Lactase enzyme activity, like most enzymes, is sensitive to pH. Figure a illustrates how lactase activity is affected by the pH of a solution. Based on the data in Figure a, what can you conclude about the pH of the small intestine?
- c. A glutamic acid in the active site of lactase is suspected to be involved in the catalytic mechanism. Draw the structure of the glutamic acid side chain in the ionization state that likely exists when lactase is most catalytically active.

## Answers to Conceptual Connections

### Peptides

- 22.1 Six possible tripeptides can form from these three amino acids. They are (1) Ser-Gly-Ala; (2) Gly-Ala-Ser; (3) Ala-Ser-Gly; (4) Ala-Gly-Ser; (5) Ser-Ala-Gly; (6) Gly-Ser-Ala. Notice that bonding the amino acids in reverse order results in a different molecule because the N-terminal and the C-terminal ends reside on different amino acids. For example, in Ser-Gly-Ala, the N-terminal amino acid is Ser (conventionally drawn on the

left) and the C-terminal side is Ala. In Ala-Gly-Ser, in contrast, the N-terminal amino acid is Ala and the C-terminal one is Ser.

### The Genetic Code

- 22.2 The number of unique two-base sequences of four bases is  $4^2 = 16$ . The number of unique three-base sequences of four bases is  $4^3 = 64$ . A two-base system could code for 16 amino acids, and a three-base system could code for 64 amino acids.

# Chemistry of the Nonmetals

What one learns in chemistry is that Nature wrote all the rules of structuring; man does not invent chemical structuring rules; he only discovers the rules. All the chemist can do is find out what Nature permits, and any substances that are thus developed or discovered are inherently natural.

—R. BUCKMINSTER FULLER (1895–1983)

**KEY LEARNING OUTCOMES 1095**

In these last few chapters, we explore the descriptive chemistry of the nonmetals and metals. These descriptions are part of a branch of chemistry called inorganic chemistry. We begin our exploration of descriptive inorganic chemistry by looking at the chemistry of some of the main-group elements. The main-group elements are grouped together because their valence electrons occupy only *s* or *p* orbitals; however, their properties vary greatly. The main-group elements include metals, nonmetals, and metalloids and they may be solids, liquids, or gases at room temperature. This great diversity of properties, bonding, and structures of all the main-group elements cannot be adequately described in a single chapter. Therefore, this chapter focuses on only a few main-group elements (silicon, boron, carbon, nitrogen, phosphorus, oxygen, sulfur, and the halogens) and their compounds in an effort to illustrate the diversity within the group.

▲ Scientists have been able to synthesize carbon nanotubes that have an insulating boron nitride sheath. These structures are like electrical wires 100,000 times thinner than a human hair.

## 23.1 Insulated Nanowires

In 1991, scientists discovered carbon nanotubes, the long, thin, hollow cylinders of carbon atoms that we discussed in Section 12.6. In the late 1990s, scientists discovered that they could make similar tubes from boron nitride. Boron nitride contains BN units that are isoelectronic (having the same number of electrons) with carbon in the sense that each BN unit contains eight valence electrons, or four per atom (just like carbon). The size and electronegativity of a carbon atom are also almost equal to the average of those properties for a boron atom and a nitrogen atom (Table 23.1). As a result, BN forms a number of structures that are similar to those formed by carbon, including nanotubes.

TABLE 23.1 Properties of BN and C

Element	Atomic Radius (pm)	Ionization Energy (kJ/mol)	Electronegativity
 B  N BN	85 77.5 average 70	800 1101 average 1402	2 2.5 average 3
 C	77	1086	2.5

**▲ FIGURE 23.1 Boron Nitride Nanotube** The model represents an insulating BN nanotube filled with a conducting carbon nanotube.

An important difference between boron nitride nanotubes and carbon nanotubes is their conductivity. Carbon nanotubes conduct electrical current, but boron nitride tubes act as insulators. In 2003, scientists were able to combine these two sorts of nanotubes into one structure: a conducting carbon nanotube with an insulating boron nitride sheath, shown in Figure 23.1. The result is an insulated conducting wire that is 100,000 times thinner than a human hair. Such thin wires may someday be used in computers and other electronic devices, allowing these devices to continue to become smaller and more efficient.

The more we learn about the structures and reactivities of known materials, the better equipped we are to discover new materials and applications. Even though it may seem that most inorganic compounds have already been discovered and analyzed, new materials, with immense impacts on our society, are constantly being discovered. As Buckminster Fuller stated in this chapter's opening quote, we continue to find “what Nature permits.” In some cases, what nature permits turns out to be extremely useful to society.

## 23.2 The Main-Group Elements: Bonding and Properties

We identify the **main-group elements** by their electron configurations. In this chapter, we focus on groups 3A–7A, the major part of the *p* block in the periodic table. The *p* orbitals fill incrementally across any row of this section of the periodic table; they contain from one electron in group 3A to five electrons in group 7A (the halogens). The physical properties of the elements, such as atomic size and electronegativity, also change across each period, and this affects their reactivity and the types of compounds they form.

1A																8A

The vast range in elemental properties, from those of metallic elements such as thallium and lead that have very low electronegativities of 1.8 and 1.9 (respectively) to those of the nonmetallic elements such as oxygen and fluorine that have the highest electronegativities of 3.5 and 4.0 (respectively), results in the great chemical diversity of the elements in the *p* block. These elements include metals, alloys, simple covalent compounds, enormous covalent network compounds, simple binary ionic compounds, and complex chain and layered ionic compounds.

## Major Divisions of the Periodic Table

[illegible]

## 23.3 Silicates: The Most Abundant Matter in Earth's Crust

The most abundant elements in Earth's crust are oxygen (45–50% by mass) and silicon (about 28% by mass). The few other elements that individually comprise more than 1% of the crust's mass are aluminum, iron, calcium, magnesium, sodium, and potassium (Figure 23.2▼), and most of these are found in silicon and oxygen compounds. In order to understand the matter on Earth's surface, we must understand silicon and oxygen compounds.

► **FIGURE 23.2 Major Elements in Earth's Crust** The major components of Earth's crust are oxygen and silicon. Only a few other elements compose more than 1% of the crust each.

A rock is a heterogeneous mixture that may contain one or more minerals.

**Silicates** are covalent atomic solids (see Section 12.6) that contain silicon, oxygen, and various metal atoms. Rocks, clays, and soils contain silicates. Their great diversity illustrates a theme that we have encountered since Chapter 1 of this book: the properties of substances are determined by their atomic and molecular structures. The structures of silicates determine their properties—and since these structures are varied, their properties are also varied. Some silicates form strong three-dimensional materials, whereas others break into sheets, and still others are highly fibrous. Let's examine more closely several of these structures.

▲ **FIGURE 23.3  $\text{SiO}_4$  Tetrahedron** In a  $\text{SiO}_4$  tetrahedron, silicon occupies the center of the tetrahedron and one oxygen atom occupies each corner.

### Quartz

Recall from Chapter 12 that silicon and oxygen form a network covalent structure in which a silicon atom bonds to four oxygen atoms, forming a tetrahedral shape with the silicon atom in the middle and the four oxygen atoms at the corners of the tetrahedron (Figure 23.3◀). As we examined in Chapter 12, the silicon atom bonds to each oxygen atom with a single covalent sigma bond. Recall that the silicon atom in this structure bonds to four oxygen atoms and obtains a complete octet. However, each oxygen atom is one electron short of an octet, so each O atom forms a second covalent bond to a different Si atom, forming the three-dimensional structure of **quartz**. Quartz has a formula unit of  $\text{SiO}_2$  and is generally called **silica**. Each Si atom is in a tetrahedron surrounded by four O atoms, and each O atom acts as a bridge connecting the corners of two tetrahedrons (Figure 23.4▼).

### Aluminosilicates

**Aluminosilicates** are a family of compounds in which aluminum atoms substitute for silicon atoms in some of the lattice sites of the silica structure. Since the aluminum ion has only three valence electrons (in contrast to the four valence electrons of silicon), a  $\text{SiO}_2$  unit becomes  $\text{AlO}_2^-$  upon substitution of aluminum. The negative charge is balanced by a positive counterion. A common group of aluminosilicates is the feldspars. The mineral albite is a feldspar. A **mineral** is a homogeneous, crystalline substance that naturally occurs in the Earth's crust. In albite, one-fourth of the Si atoms are replaced by Al atoms.  $\text{Na}^+$  ions provide the necessary balancing positive charge. The formula for albite is  $\text{Na}(\text{AlSi}_3\text{O}_8)$ , but it may be written as  $\text{Na}(\text{AlO}_2)(\text{SiO}_2)_3$  to illustrate the substitution of Al for Si.

◀ **FIGURE 23.4 Structure of Quartz** In the quartz structure, each Si atom is in a tetrahedron surrounded by four O atoms, and each O atom is a bridge connecting the corners of two tetrahedrons.

### Example 23.1 Determining the Composition of an Aluminosilicate

Write the formula for anorthite, a crystal in which Al atoms substitute for one-half of the Si atoms and the charge is balanced by  $\text{Ca}^{2+}$  ions.

#### SOLUTION

The  $\text{AlO}_2^-$  unit substitutes for one-half of the  $\text{SiO}_2$  units; therefore, the formula has equal numbers of  $\text{AlO}_2^-$  and  $\text{SiO}_2$  units. You must balance every  $\text{AlO}_2^-$  ion in the formula by a corresponding positive charge. Since  $\text{Ca}^{2+}$  has a 2+ charge, it can balance two  $\text{AlO}_2^-$  units. Thus, the formula for anorthite is  $\text{Ca}(\text{Al}_2\text{Si}_2\text{O}_8)$  or  $\text{Ca}(\text{AlO}_2)_2(\text{SiO}_2)_2$ .

**FOR PRACTICE 23.1** Orthoclase is a crystal in which  $\text{Al}^{3+}$  substitutes for one-fourth of the  $\text{Si}^{4+}$  ions.  $\text{K}^+$  ions balance the charge. Write the formula for orthoclase.

## Individual Silicate Units, Silicate Chains, and Silicate Sheets

In many silicate compounds, the oxygen atoms are not connected to two silicon atoms to form the neutral compound that is found in quartz. Instead, the oxygen atoms gain electrons from metal atoms and form polyatomic anions, such as  $\text{SiO}_4^{4-}$ . The positively charged metal ions then bond to the negatively charged silicon oxide. In these minerals, the  $\text{SiO}_4$  tetrahedrons occur singly, in chains, or in sheets.

When a tetrahedron occurs singly (not bonded to other tetrahedrons), it forms the  $\text{SiO}_4^{4-}$  polyatomic anion (which has four extra electrons that satisfy the octet rule for the four oxygen atoms). These types of silicates are **orthosilicates** (or nesosilicates) and require cations that have a total charge of 4+ to neutralize the negative charge. The cations can be of a single metal, such as  $\text{Zn}^{2+}$  in  $\text{Zn}_2\text{SiO}_4$  (the mineral willemite), or they can be a mixture of different metals, such as the family of crystals called olivines  $[(\text{Mg}, \text{Fe})_2\text{SiO}_4]$  where the  $\text{Mg}^{2+}$  and  $\text{Fe}^{2+}$  ions can exist in variable proportions, providing a total charge of 4+. All of these compounds are held together by ionic bonding between the metal cations and  $\text{SiO}_4^{4-}$  polyatomic anions.

The silicate tetrahedrons can also form structures called **pyrosilicates** (or sorosilicates) in which two tetrahedrons share one corner (Figure 23.5▶), forming the disilicate ion, which has the formula  $\text{Si}_2\text{O}_7^{6-}$ . This group requires cations that balance the 6− charge on  $\text{Si}_2\text{O}_7^{6-}$ . Again, these cations can be the same metal ions or a mixture of different metal ions. For example, in the mineral hardystonite ( $\text{Ca}_2\text{ZnSi}_2\text{O}_7$ ), two  $\text{Ca}^{2+}$  ions and one  $\text{Zn}^{2+}$  ion provide the 6+ charge.

The silicon tetrahedron also forms structures called **pyroxenes** (or inosilicates) in which many of the tetrahedrons bond together creating chains (Figure 23.6▶). The formula unit for these chains is the  $\text{SiO}_3^{2-}$  unit, and the repeating unit in the structure is two formula units ( $\text{Si}_2\text{O}_6^{4-}$ ). Two of the oxygen atoms are bonded to two silicon atoms (and thus to two other tetrahedrons) at two of the four corners of each tetrahedron. The silicate chains are held together by ionic bonding to

Formula unit:  $\text{Si}_2\text{O}_7^{6-}$

▶ **FIGURE 23.5 Pyrosilicate Structure** In pyrosilicates, the silicate tetrahedrons share one corner, forming  $\text{Si}_2\text{O}_7^{6-}$  units. Pyrosilicates are also called sorosilicates.

Formula unit:  $\text{SiO}_3^{2-}$

▶ **FIGURE 23.6 Pyroxene Structure**

In pyroxenes, chains of silicate tetrahedrons form. Pyroxenes are also called inosilicates.

► **FIGURE 23.7 Amphibole Structure**

Amphiboles contain double chains of silica tetrahedrons.

▲ The fibrous texture of asbestos results from the silicate double chains of the amphibole structure.

▲ The flaky texture of mica is due to silicate sheets of the phyllosilicate structure.

metal cations, which lie between the chains. For example, in the crystal diopside,  $\text{CaMg}(\text{SiO}_3)_2$ ,  $\text{Ca}^{2+}$  and  $\text{Mg}^{2+}$  ions bond with the silicate chains.

Some silicate structures have *double chains* in which half of the tetrahedrons of one chain are bonded to tetrahedrons in another chain through oxygen atoms. The minerals with double silicate chains are called amphiboles, and the repeating unit in the crystal is  $\text{Si}_4\text{O}_{11}^{6-}$  (Figure 23.7▲). Half of the tetrahedrons are bonded by two of the four corner O atoms, and half of the tetrahedrons are bonded by three of the four corners, joining the two chains together. The bonding within the double chains is very strong, but the bonding between the double chains is not so strong. This structure often results in fibrous minerals such as asbestos. An example of an asbestos-type mineral is tremolite,  $\text{Ca}_2(\text{OH})_2\text{Mg}_5(\text{Si}_4\text{O}_{11})_2$ . In this crystal, hydroxide ions bonded to some of the metal cations help balance the charge between the cations and the anionic silicate chains.

When three of the four oxygen atoms are bonded between the silicate tetrahedrons, the sheet structure shown in Figure 23.8▼ results. These compounds are called phyllosilicates and have a formula unit of  $\text{Si}_2\text{O}_5^{2-}$ . Sheets of tetrahedral silicates are bonded together by metal cations that lie between the sheets. For example, the mineral *talc*,  $\text{Mg}_3(\text{Si}_2\text{O}_5)_2(\text{OH})_2$ , is a phyllosilicate. The weak interactions between silicate sheets give talc its slippery feel (this is similar to the way the weak interactions between sheets of carbon atoms give graphite its slippery feel). Table 23.2 summarizes the different kinds of silicate structures.

◀ **FIGURE 23.8 Phyllosilicate Structure**

In phyllosilicates, three of the four oxygens are bonded to two silicon atoms, forming sheets of silica tetrahedrons.

**TABLE 23.2** Types of Silicate Structures

Tetrahedrons	Shared Vertices	Formula Unit	Si : O Ratio	Class Name	Example
Single tetrahedron	0	$\text{SiO}_4^{4-}$	1 : 4	Orthosilicates, nesosilicates	Olivine, $\text{Mg}_2\text{SiO}_4$
Double tetrahedron	1	$\text{Si}_2\text{O}_7^{6-}$	2 : 7	Pyrosilicates, sorosilicates	Hardystonite, $\text{Ca}_2\text{ZnSi}_2\text{O}_7$
Single chain	2	$\text{SiO}_3^{2-}$	1 : 3	Pyroxenes, inosilicates	Jadeite, $\text{NaAl}(\text{SiO}_3)_2$
Double chain	2 and 3	$\text{Si}_4\text{O}_{11}^{6-}$	4 : 11	Amphiboles	Tremolite, $\text{Ca}_2(\text{OH})_2\text{Mg}_5(\text{Si}_4\text{O}_{11})_2$
Sheet	3	$\text{Si}_2\text{O}_5^{2-}$	2 : 5	Phyllosilicates	Talc, $\text{Mg}_3(\text{Si}_2\text{O}_5)_2(\text{OH})_2$
Network covalent	4	$\text{SiO}_2$	1 : 2	Silicas, tectosilicates	Quartz, $\text{SiO}_2$
Network covalent	4	$\text{AlSi}_3\text{O}_8^-$ or $\text{Al}_2\text{Si}_2\text{O}_8^{2-}$	Variable	Feldspars	Albite, $\text{NaAlSi}_3\text{O}_8$

**Example 23.2** Composition and Charge Balance of Silicates

The silicate chrysotile is an amphibole with the formula  $\text{Mg}_6\text{Si}_4\text{O}_{11}(\text{OH})_x$ . Use charge balancing to calculate the value of  $x$  in the formula.

**SOLUTION**

The silicate unit for amphiboles is  $\text{Si}_4\text{O}_{11}^{6-}$ . The formula has six  $\text{Mg}^{2+}$  ions for a total charge of 12+. To balance, you need to add another 6− charge to the 6− charge for the silicate. Therefore, add six  $\text{OH}^-$  ions to the formula for chrysotile, giving a formula of  $\text{Mg}_6\text{Si}_4\text{O}_{11}(\text{OH})_6$ .

**FOR PRACTICE 23.2** Use charge balancing to calculate how many hydroxide ions there are in the formula of the mineral pyrophyllite,  $\text{Al}_2(\text{Si}_2\text{O}_5)_2(\text{OH})_x$ .

**Procedure for...****Predicting Types of Silicate Structure and Accounting for Charge Balance**

Determine the ratio of Si to O in the formula.

Match the Si : O ratio to the type of silicate in Table 23.2.

Determine the total anion charge.

Determine the total cation charge and show that it matches the total anion charge.

**Example 23.3****Predicting Silicate Structures**

Predict the silicate structure for the mineral spudomene,  $\text{LiAlSi}_2\text{O}_6$ , and show that the formula is charge neutral.

**SOLUTION**

Si : O = 1 : 3

A 1 : 3 ratio is a single chain, a pyroxene (or inosilicate).

Each  $\text{SiO}_3$  group has a charge of 2−, and there are two groups per formula, so the total anion charge is 4−.

The  $\text{Li}^+$  cation has a 1+ charge and the  $\text{Al}^{3+}$  cation has a 3+ charge for a total of 4+, which matches the anion charge.

**FOR PRACTICE 23.3** Predict the silicate structure for the mineral phenakite,  $\text{Be}_2\text{SiO}_4$ , and show that the formula is charge neutral.

**Example 23.4****Predicting Silicate Structures**

Predict the silicate structure for the mineral thortveitite,  $\text{Sc}_2\text{Si}_2\text{O}_7$ , and show that the formula is charge neutral.

**SOLUTION**

Si : O = 2 : 7

A 2 : 7 ratio is a double tetrahedron, a pyrosilicate (or sorosilicate).

Each  $\text{Si}_2\text{O}_7$  group has a charge of 6−, and there is one group per formula, so the total anion charge is 6−.

Each scandium cation has a charge of 3+ for a total of 6+, which matches the anion charge.

**FOR PRACTICE 23.4** Predict the silicate structure for the mineral diopside,  $\text{CaMgSi}_2\text{O}_6$ , and show that the formula is charge neutral.

## 23.4 Boron and Its Remarkable Structures

The group 3A elements each have a filled  $s$  sublevel and one electron in the  $p$  sublevel. This electron configuration prevents these main-group elements, especially boron, from easily attaining a full octet. Most of the elements in group 3A are metals; however, because of its small size and higher electronegativity, boron behaves as a semimetal. These characteristics endow boron with some special properties and result in a wide array of structures not common to most elements.

**▲ FIGURE 23.9 B<sub>12</sub> Icosahedron**  
An icosahedron contains 20 triangular faces that are connected at 12 vertices. Elemental boron forms several different structures, each based on the basic icosahedral unit.

### Elemental Boron

The structure of elemental boron is complex. Boron has at least five different allotropes (different structures with the same elemental composition). The structure of each allotrope is based on an icosahedron (Figure 23.9), a geometrical shape, containing 20 triangular faces joined at 12 vertices, that is very roughly spherical. Twelve boron atoms occupy the 12 vertices. Each different allotrope connects the icosahedrons in different ways. They all have boron atoms outside the icosahedrons that bridge the icosahedrons together.

Boron is rare in Earth's crust, making up less than 0.001% by mass. Yet because it is highly concentrated at various deposits around the world, it can be mined in large quantities. The largest deposit occurs at a mine in Boron, California, which has operated continuously for over 135 years. Naturally occurring boron always occurs in compounds, and it is almost always bonded to oxygen. Among the major sources of boron are the sodium borates, which include borax,  $\text{Na}_2[\text{B}_4\text{O}_5(\text{OH})_4] \cdot 8 \text{H}_2\text{O}$ , and kernite,  $\text{Na}_2[\text{B}_4\text{O}_6(\text{OH})_2] \cdot 3 \text{H}_2\text{O}$ . Another major source of boron is calcium borate, or colemanite,  $\text{Ca}_2\text{B}_6\text{O}_{11} \cdot 5 \text{H}_2\text{O}$ . In all of these compounds, boron is bonded in polyatomic anions.

The primary use for boron today is in glass manufacture. Recall from Section 12.7 that adding boron oxide to silicon oxide glass alters the thermal expansion of the glass, which is important for glassware intended for heating. When glass is heated, the outer edge of the glass warms and expands more quickly than the inner edge, creating stress that can result in cracking. Adding boron oxide to glass reduces its thermal expansion, allowing the glass (called borosilicate glass or Pyrex) to be heated without cracking.

Elemental boron is also used in the nuclear energy industry. Boron readily absorbs neutrons and is used in the control rods of nuclear reactors. When the nuclear reaction needs to be slowed down, the rods are inserted into the reactor to absorb the neutrons (see Section 20.7).

### Boron–Halogen Compounds: Trihalides

Boron forms many covalently bonded compounds in which boron atoms bond to each other. In some ways, these compounds are similar to those in which carbon covalently bonds to itself; however, the structures are different because boron is less electronegative and has only three valence electrons. Recall from earlier in this section that elemental boron has a tendency to form polyhedral cluster structures. Boron also tends to form electron-deficient compounds (compounds in which boron lacks an octet).

Boron halides have the general formula  $\text{BX}_3$  and have a trigonal planar structure:

The bonds in the boron trihalides are stronger and shorter than a typical single bond, which we can explain using valence bond theory and hybridization. The boron atom uses  $sp^2$  hybridized orbitals to form sigma bonds with the three halogen atoms. Because boron's three valence electrons are used to form the sigma bonds, the third  $p$  orbital of boron is an empty orbital that is perpendicular to the trigonal plane of the molecule. Each halogen atom has a filled  $p$  orbital, also perpendicular to the trigonal plane of the molecule. The empty  $p$  orbital on the boron atom can overlap with the full  $p$  orbitals on

the halogens, forming a coordinate-covalent-type second bond. In  $\text{BCl}_3$ , for example, the boron and chlorine are joined by bonds resembling a double bond. Like normal double bonds, the boron–chlorine bond is shorter and stronger than a single bond.

The boron trihalides are strong Lewis acids. For example,  $\text{BF}_3$  reacts with  $\text{NH}_3$  according to the following Lewis acid–base reaction:

Boron trihalides act as Lewis acids in many organic reactions, such as those in which alcohols or acids are converted into esters. In water, the trihalides hydrolyze to form acidic solutions according to these reactions:

## Boron–Oxygen Compounds

Boron forms very strong bonds with oxygen in structures that contain trigonal  $\text{BO}_3$  structures. The formula for the crystalline structure of boron and oxygen is  $\text{B}_2\text{O}_3$ . In this compound, the trigonal  $\text{BO}_3$  structures hook together to form interlocking  $\text{B}_6\text{O}_6$  hexagonal rings (Figure 23.10 ▶). Each hexagonal ring has a boron atom at each of its six corners and an oxygen atom in the middle of each of the six sides. The compound  $\text{B}_2\text{O}_3$  melts at  $450^\circ\text{C}$ . If the molten  $\text{B}_2\text{O}_3$  cools quickly, it forms a glass (an amorphous solid). The glass still contains many interlocking  $\text{B}_6\text{O}_6$  hexagonal rings but lacks the long-range order of the crystal. Molten boron oxide dissolves many metal oxides and silicon oxide to form glasses of many different compositions.

▲ **FIGURE 23.10**  $\text{B}_2\text{O}_3$  Structure  
Crystalline  $\text{B}_2\text{O}_3$  consists of  $\text{BO}_3$  trigonal structures that form hexagonal rings of  $\text{B}_6\text{O}_6$ .

## Boron–Hydrogen Compounds: Boranes

Compounds composed of boron and hydrogen, called **boranes**, form many unique cluster, cagelike, and netlike structures. The **closo-boranes** have the formula  $\text{B}_n\text{H}_n^{2-}$  and form fully closed polyhedrons with triangular sides; Figure 23.11 ▼ shows two of these structures. A boron atom, with an attached hydrogen atom, occupies each of the vertices in the polyhedrons. The *closo*-borane with the formula  $\text{B}_{12}\text{H}_{12}^{2-}$  forms the full icosahedral shape that elemental boron does, but it includes added hydrogen atoms.

If the borane polyhedron is missing one or more boron atoms, extra hydrogen atoms attach to the structure to make the borane neutral. Researchers have identified over 35 structurally different neutral boranes, ranging from  $\text{B}_2\text{H}_6$  to  $\text{B}_{20}\text{H}_{26}$ . We classify these neutral boranes on the basis of their different chemical formulas. The **nido-boranes**, named from the Latin word for *nest*, have the formula  $\text{B}_n\text{H}_{n+4}$ . They consist of a cage of

◀ **FIGURE 23.11** *closo*-Borane Structures  
*closo*-Borane structures form closed polyhedrons with triangular faces. In this figure, each sphere represents a BH unit.  $\text{B}_6\text{H}_6^{2-}$  has an octahedral (square bipyramidal) shape.  $\text{B}_7\text{H}_7^{2-}$  has a pentagonal bipyramidal shape.

► FIGURE 23.12 *nido-* and *arachno-*

**Boranes** The *nido*-borane structure forms a cage missing one boron atom from a corner. The *arachno*-borane structure forms a web missing more than one boron from a corner.

boron atoms missing one corner. The **arachno-boranes**, named from the Greek word for *spiderweb*, have the formula  $B_nH_{n+6}$ . They consist of a cage of boron atoms that is missing two or three corners. Figure 23.12▲ shows examples of a *nido*- and an *arachno*-borane.

Boranes not only form interesting structures, but they are also valuable as catalysts in organic reactions. For example, adding an alkene to a diborane forms an alkane bonded to the boron atom. The alkane can be cleaved (split) from the boron, resulting in a net hydrogenation reaction such as the one shown here that can be carried out under mild (lower temperature) conditions:

## 23.5 Carbon, Carbides, and Carbonates

The group 4A elements exhibit the most versatile bonding of all elements. As we saw in Chapters 12 and 21, carbon has the ability to bond with other carbon atoms and with a few other elements to form a great variety of organic compounds. These compounds are the molecules of life, which we examined in Chapter 22. The different forms of elemental crystalline carbon were covered in Chapter 12 (see Section 12.6). Here we focus on amorphous carbon and those compounds of carbon that are known as *inorganic* (rather than organic).

### Amorphous Carbon

Carbon occurs naturally in noncrystalline forms. Noncrystalline **coal** forms from the decomposition of ancient plant material that has been buried for millions of years, during which time it undergoes a process called carbonization. The carbonization reaction, which occurs under high pressure in the presence of water and the absence of air, removes most of the hydrogen and oxygen (which are lost as volatile gases such as methane and water) from the original organic compounds that composed the plant. The resulting coal contains a mixture of various hydrocarbons and carbon-rich particles. It is extensively mined and employed as an energy source throughout the world. Coal types are classified by the amount of carbon and other elements that they contain, as shown in Table 23.3.

Among the types of coal listed in Table 23.3, anthracite has the highest carbon content and consequently yields the most energy per mass when burned. Bituminous coal also contains a relatively high amount of carbon but has in addition high levels of sulfur, which results in increased formation of sulfur oxides when bituminous coal is burned. Sulfur oxides are the pollutants that create acid rain (see Sections 3.6 and 16.12).

Heating coal in the absence of air forms a solid called **coke** that is composed mainly of carbon and ash. Coke is used in the steel industry for the reduction of iron ore to iron.

In a blast furnace, the carbon in the coke is oxidized to form carbon monoxide, which reduces the iron in iron oxide according to these reactions:

Heating wood in the absence of air produces **charcoal**. Like coal, charcoal contains a high amount of amorphous free carbon and is a common fuel for outdoor cooking grills. Charcoal retains the general overall shape of the original wood, but the process creates many voids, resulting in a much lower density. The voids within charcoal create high surface area that makes the charcoal useful for filtration. The impurities in a liquid or gas adsorb (or stick) on the charcoal surface as the liquid or gas flows through the pores in the charcoal.

Very fine carbon particles with high surface areas are called **activated carbon**, or *activated charcoal*. The large surface area of the particles, greater than  $10^3 \text{ m}^2/\text{g}$ , makes activated carbon particles extremely efficient at adsorbing other molecules onto their surfaces. Activated carbon is made by heating amorphous carbon in steam, which breaks the grains into smaller sizes and removes any other materials adsorbed on the surface. Activated carbon is used to filter impurities from gas and as a decolorizing agent, removing impurities that discolor organic products such as sugar or wheat flour.

**TABLE 23.3** Approximate Composition of the Main Types of Coal

Type of Coal	Free C (mol %)	Total C (mol %)	H (mol %)	O (mol %)	S (mol %)
Lignite	22	71	4	23	1
Bituminous	60	80	6	8	5
Anthracite	88	93	3	3	1

**Soot** is an amorphous form of carbon that forms during the incomplete combustion of hydrocarbons; its presence is indicated by blue or black smoke. Toxic carbon monoxide also forms in the process:

**Carbon black**, a fine, powdered form of carbon, is a component of soot. Each day, over a million tons of carbon black, a strengthener for rubber tires, is used in manufacturing. The black color of automobile tires is due to the several kilograms of carbon black within each tire, accounting for over 25% of the mass of the typical tire.

## Carbides

Binary compounds composed of carbon combined with less electronegative elements are **carbides**. We classify carbides into three general categories: ionic, covalent, and metallic. All types of carbides have some shared properties; they are extremely hard materials with high melting points.

### Ionic Carbides

Compounds composed of carbon and a low-electronegativity metal such as an alkali metal or an alkaline earth metal are **ionic carbides**. Most ionic carbides contain the dicarbide ion,  $\text{C}_2^{2-}$ , commonly called the *acetylide ion*. For example, calcium carbide has the formula  $\text{CaC}_2$  and a structure similar to that of  $\text{NaCl}$  (Figure 23.13►, on the next page).

Calcium carbide forms by the reaction of calcium oxide with coke in an electric furnace:

▲ Automobile tires are black because of the carbon black that is added to strengthen the tires and maintain flexibility.

► **FIGURE 23.13 Calcium Carbide Structure**

In the NaCl-type structure for  $\text{CaC}_2$ , the dicarbide ions are in the positions of the chloride ions, making the structure slightly noncubic.

Ionic carbides react with water, forming acetylene. For example, sodium carbide reacts with water according to the reaction shown here:

In the past, calcium carbide was used as a source of acetylene (which is highly flammable) for lighting. The solid  $\text{CaC}_2$  reacts with water, releasing acetylene gas, which was burned in applications such as automobile headlights and lamps for mines. Transporting solid calcium carbide was more convenient and safer than transporting the flammable gas.

### CONCEPTUAL CONNECTION 23.1

**Carbide Formulas** Predict the formula for potassium carbide.

### Covalent Carbides

Compounds composed of carbon and low-electronegativity *nonmetals* or *metalloids* are **covalent carbides**. The most important covalent carbide is silicon carbide ( $\text{SiC}$ ), a very hard material. Over 500,000 tons of silicon carbide are produced annually, mostly for use as an abrasive material in the cutting and polishing of metals. In a process analogous to the formation of calcium carbide, silicon carbide forms by the reaction of silicon oxide with coke at high temperatures:

A gem-quality form of  $\text{SiC}$ , called *moissanite*, has also been developed. Moissanite is described as being more brilliant than all other gems, including diamonds. Yet moissanite costs much less than diamond and is consequently sold as a diamond substitute (like the more common diamond substitute cubic zirconia,  $\text{ZrO}_2$ ). Moissanite was first identified in small particles at the Diablo Canyon meteorite impact crater in Arizona and is sometimes advertised as “a gift from the stars.”

### Metallic Carbides

Compounds composed of carbon and metals that have a metallic lattice with holes small enough to fit carbon atoms are **metallic carbides**. Metallic carbides retain many metallic properties, such as high electrical conductivity, but they are stronger, harder, and less malleable than their corresponding metals. Adding carbon to steel, for example,

▲ This micrograph shows cementite (dark regions) in steel.

increases its hardness by forming regions of cementite ( $\text{Fe}_3\text{C}$ ) in the steel matrix. Tungsten carbide ( $\text{WC}$ ) is a metallic carbide used in cutting tools.

## Carbon Oxides

Carbon forms two stable oxides, carbon monoxide and carbon dioxide. Earth's atmosphere contains about 0.04% carbon dioxide by volume. Plants use atmospheric carbon dioxide to produce sugars during photosynthesis:

Carbon dioxide returns to the atmosphere via animal respiration, plant and animal decay, and (in modern history) fossil fuel combustion. Because carbon dioxide is highly soluble in water, the oceans of the world act as a reservoir for  $\text{CO}_2$ , keeping the amount of  $\text{CO}_2$  in the atmosphere generally stable. As we saw in Section 6.10, however, the increase in the combustion of fossil fuels in the last century has increased the amount of  $\text{CO}_2$  in the atmosphere by about 38%.

Recall from Section 11.8 that  $\text{CO}_2$  has a triple point at  $-57^\circ\text{C}$  and 5.1 atm. At atmospheric pressure, therefore, the liquid phase of  $\text{CO}_2$  does not exist. Solid carbon dioxide sublimates directly to the gas phase when heated, which is why solid  $\text{CO}_2$  is called “dry ice.”

Carbon monoxide ( $\text{CO}$ ) is a colorless, odorless, and tasteless gas. The boiling point of carbon monoxide is  $-192^\circ\text{C}$  at atmospheric pressure, and  $\text{CO}$  is only very slightly soluble in water. Carbon monoxide is toxic because it interferes with the ability of hemoglobin to bind oxygen. Unlike carbon dioxide, which is very stable, carbon monoxide is relatively reactive and can be used as a reducing agent.

For example, carbon monoxide reacts with oxygen and metal oxides to form carbon dioxide:

Carbon monoxide also reduces many nonmetals, producing compounds with the reduced form of the nonmetal:

The product of the first reaction listed is phosgene ( $\text{COCl}_2$ ), also known as carbonyl chloride, a poisonous gas that was used in World War I as a chemical weapon. Phosgene is now an important industrial chemical used in the production of polycarbonates. The product of the second reaction, carbonyl sulfide ( $\text{COS}$ ), is a fungicide (a substance that kills fungi).

## Carbonates

When carbon dioxide dissolves in water, it forms carbonic acid ( $\text{H}_2\text{CO}_3$ ). As a weak acid, carbonic acid partially ionizes into hydrogen carbonate (or bicarbonate) and carbonate:

Recall from Section 13.4 that the solubility of carbon dioxide, like that of other gases, increases with increasing pressure. Carbon dioxide under high pressure carbonates soft drinks. Under most conditions, less than 0.5% of the dissolved carbon dioxide reacts with water to form carbonic acid. This leaves most of the carbon dioxide as dissolved gas molecules, so the soft drink does not acquire much of a sour acidic taste.

The hydrated crystal of sodium carbonate,  $\text{Na}_2\text{CO}_3 \cdot 10 \text{H}_2\text{O}$ , is known as **washing soda**. Heating washing soda releases the waters of hydration, forming the stable anhydrous sodium carbonate,  $\text{Na}_2\text{CO}_3$ . All of the alkali metal ions form stable carbonates that remain

▲ Alka-Seltzer™ contains sodium bicarbonate mixed with citric acid and aspirin. When put in water, the acid and carbonate react.

stable even when heated. The carbonates all make basic solutions when added to water because the carbonate ions readily ionize water (as described more fully in Section 16.8):

Sodium bicarbonate ( $\text{NaHCO}_3$ ) is *baking soda*. When heated, baking soda gives off carbon dioxide gas, which is why its use in baking helps raise dough:

Baking *powder* is a mixture of  $\text{NaHCO}_3$  and an acid. The two components of the mixture are kept from reacting by a starch filler. When water is added to the mixture, however, the two components dissolve and react, producing the carbon dioxide that forms pockets of gas in baked products. You can perform a simple test to determine if baking powder is still good (that is, whether the acid has not already slowly reacted with the sodium bicarbonate) by pouring some boiling water over a small sample of the baking powder. If the hot water produces bubbles, then the baking powder is still active. Alka-Seltzer is another common consumer product that employs sodium bicarbonate, in this case mixed with citric acid and aspirin. When immersed in water, the acid and carbonate react to produce carbon dioxide, creating the familiar fizz.

## CONCEPTUAL CONNECTION 23.2

**Carbonate Solubility** As we saw in Chapter 4, the carbonates of metal ions other than group 1A are insoluble in water. Which action would increase their solubility?

- (a) adding acid to the solution
- (b) adding base to the solution
- (c) increasing the amount of the solid carbonate in the solution

## 23.6 Nitrogen and Phosphorus: Essential Elements for Life

The group 5A elements range from nonmetallic nitrogen and phosphorus to metallic bismuth. Both nitrogen and phosphorus are nonmetals; they do not conduct electricity, and they form acidic oxides. Both have  $s^2p^3$  electron configurations, and yet their chemical properties are very different. Phosphorus is much larger and less electronegative; it also has  $d$  orbitals available for bonding.

### Elemental Nitrogen and Phosphorus

Nitrogen was identified in 1772 and phosphorus in 1669. Elemental nitrogen is a diatomic gas that composes about 78% of Earth's atmosphere by volume (see Section 5.6). To obtain elemental nitrogen, air is cooled below  $-196^\circ\text{C}$ , which causes it to liquefy. When the liquid air is warmed slightly, the nitrogen boils off, leaving liquid oxygen (which boils at the higher temperature of  $-183^\circ\text{C}$ ). Passing the vaporized gas over hot copper metal purifies the nitrogen by removing residual oxygen (which reacts with the copper to form  $\text{CuO}$ ). Nitrogen gas can also be separated from the other atmospheric gases by passing air through certain silicate materials called *zeolites*, which have channels of just the right diameter to separate gas molecules of different size. Some mineral sources for nitrogen are saltpeter ( $\text{KNO}_3$ ) and Chile saltpeter ( $\text{NaNO}_3$ ).

As we first saw in Section 9.5, nitrogen molecules have a triple bond between the two N atoms. The strength of the triple bond makes  $\text{N}_2$  very stable, and attempts to break the bond have not been commercially successful. When nitrogen gas is heated

with oxygen or hydrogen, nitric oxide (NO) or ammonia (NH<sub>3</sub>), respectively, form with low yields. When nitrogen gas is heated with active metals, metal nitrides form. Aside from this, however, nitrogen gas is relatively unreactive.

The stability of elemental nitrogen makes it useful in creating a protective atmosphere to prevent oxidation in many industrial processes. For example, industrial furnaces employ a nitrogen atmosphere to anneal (hold at elevated temperature below the melting point) products made of metal, and chemical reactions sensitive to oxygen are carried out in a nitrogen atmosphere. Nitrogen is also used to preserve a variety of foods.

Elemental phosphorus was first isolated by accident from urine when Henning Brand (1630–1710), a physician and alchemist from Hamburg, Germany, was distilling urine in an ill-informed attempt to obtain gold from the golden liquid. The elemental form of phosphorus that Brand obtained instead was a white, waxy, flammable solid called **white phosphorus**. White phosphorus is highly toxic to humans. For over a hundred years, urine was the main source for elemental phosphorus. Today, however, phosphorus is obtained from a calcium phosphate mineral called apatite, [Ca<sub>3</sub>(PO<sub>4</sub>)<sub>2</sub>]. The mineral is heated with sand and coke in an electric furnace:

White phosphorus consists of P<sub>4</sub> molecules in a tetrahedral shape, with the phosphorus atoms at the corners of the tetrahedron (Figure 23.14▶). The bond angles between the three P atoms on any one face of the tetrahedron are small (60°) and strained, making the P<sub>4</sub> molecule unstable and reactive. White phosphorus spontaneously burns in air; it is normally stored under water to prevent contact with air.

When heated to about 300 °C in the absence of air, white phosphorus slightly changes its structure to a different allotrope called **red phosphorus**, which is amorphous. The general structure of red phosphorus is similar to that of white phosphorus, except that one of the bonds between two phosphorus atoms in the tetrahedron is broken (Figure 23.15▼). The two phosphorus atoms link to other phosphorus atoms, making chains that vary in structure.

▲ **FIGURE 23.14 White Phosphorus**  
The small bond angle of 60° between the phosphorus atoms at the corners of the tetrahedron puts a great strain on the structure and makes the P<sub>4</sub> molecule unstable.

▼ **FIGURE 23.15 Red Phosphorus**  
Red phosphorus consists of chains of phosphorus atoms that form amorphous structures.

Red phosphorus is neither as reactive nor as toxic as white phosphorus, and even though it is also flammable, it can be stored in air. Red phosphorus is used commercially in applications such as match heads. Rubbing a match head onto a surface produces enough heat (through friction) to ignite the phosphorus. Most strike-anywhere matches feature the phosphorus compound tetraphosphorus trisulfide (P<sub>4</sub>S<sub>3</sub>) and an oxidizing agent, potassium chlorate (KClO<sub>3</sub>).

A third allotrope of phosphorus is **black phosphorus**. Black phosphorus is obtained by heating white phosphorus under pressure. This form of phosphorus is the most thermodynamically stable form, and therefore the least reactive. Black phosphorus has a layered structure similar to that of graphite.

**TABLE 23.4** Oxidation States of Various Nitrogen Compounds

Nitrogen-Containing Compound	Oxidation State
NH <sub>3</sub>	-3
N <sub>2</sub> H <sub>4</sub>	-2
H <sub>2</sub> NOH	-1
HN <sub>3</sub>	- $\frac{1}{3}$
N <sub>2</sub>	0
N <sub>2</sub> O	+1
NO	+2
N <sub>2</sub> O <sub>3</sub> , NF <sub>3</sub>	+3
NO <sub>2</sub> , N <sub>2</sub> O <sub>4</sub>	+4
N <sub>2</sub> O <sub>5</sub> , HNO <sub>3</sub>	+5

**FIGURE 23.16** Hydrazine and Hydrogen Peroxide Hydrazine forms a structure similar to hydrogen peroxide with an N—N bond in the place of the O—O bond.

## Nitrogen Compounds

Nitrogen, with a valence electron configuration of  $2s^2 2p^3$ , can gain three electrons or lose five electrons to obtain an octet. Nitrogen forms many covalent compounds with oxidation states from -3 to +5, as shown in Table 23.4.

### Nitrogen Hydrides

The most common nitrogen hydride is **ammonia** (NH<sub>3</sub>), the strong-smelling compound in which nitrogen displays its lowest oxidation state (-3). Ammonia is important to humans because it reacts with sulfuric acid (or phosphoric acid) to produce ammonium salts for fertilizers:

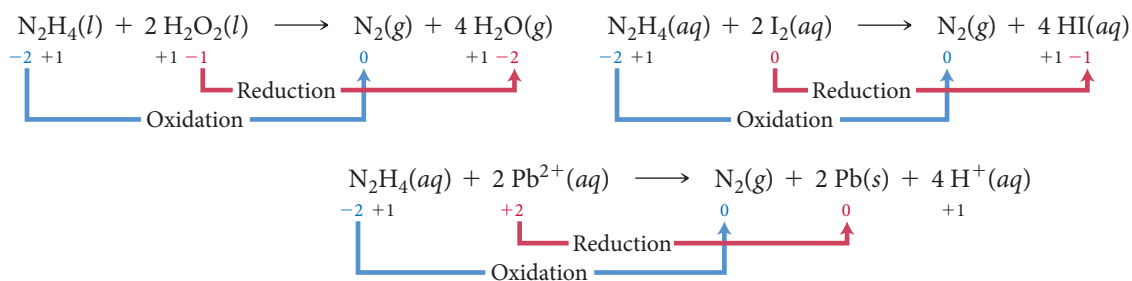

For hundreds of years, natural biological materials such as animal manure were used as nitrogen-containing fertilizers. In the 1800s, however, the nitrogen-bearing nitrate mineral NaNO<sub>3</sub> was discovered in Chile (and named Chile saltpeter). This nitrate mineral became an important source of fertilizer and made the country of Chile very wealthy. However, because Chile saltpeter was a limited source, chemists were continually striving to develop a new source.

The obvious *unlimited* source of nitrogen is the atmosphere, but the strong triple bond in elemental nitrogen renders it unusable by plants. In order to be used as fertilizer, elemental nitrogen has to be *fixed*, which means that it has to be converted into a nitrogen-containing compound such as NH<sub>3</sub>. However, the direct reaction of nitrogen gas with hydrogen gas to form ammonia is very slow and produces low yields of ammonia under normal conditions:

In the early 1900s, German chemist Fritz Haber studied the equilibrium conditions for this reaction and showed that high pressures and lower temperatures favored the product. Carrying out the reaction at a higher pressure, and using a catalyst to increase the reaction rate, the industrial process for producing ammonia from nitrogen gas and hydrogen gas—now called the **Haber-Bosch process**—became practical by the mid-1930s. This process is the main industrial process for making ammonia and fixing nitrogen for many uses, including fertilizers and explosives.

**Hydrazine** (N<sub>2</sub>H<sub>4</sub>) is another nitrogen and hydrogen compound in which nitrogen has a negative oxidation state (-2). Hydrazine is the nitrogen analog of hydrogen peroxide; it has a bond between nitrogen atoms that is similar to the bond between oxygen atoms in hydrogen peroxide (Figure 23.16). Hydrazine, like hydrogen peroxide, is a colorless liquid. However, while hydrogen peroxide is a powerful oxidizing agent, hydrazine is a powerful reducing agent, as shown in the following reactions:

The oxidation state of each atom appears directly below its symbol. Notice that in each reaction, nitrogen is oxidized and causes the reduction of the other reactant.

**Hydrogen azide** (HN<sub>3</sub>) is a nitrogen and hydrogen compound with a higher nitrogen-to-hydrogen ratio than ammonia or hydrazine. Ammonia and hydrazine are both basic:

Hydrogen azide, by contrast, is acidic, ionizing in water to form the azide ion ( $\text{N}_3^-$ ):

The  $\text{N}_3^-$  ion can be represented with the resonance structures shown here (formal charges indicated in red):

Since the rightmost structure has the least amount of formal charge, it contributes most to the hybrid structure.

Hydrogen azide is thermodynamically unstable compared to its constituent elements and reacts explosively to produce hydrogen and nitrogen gas:

The sodium azide salt is a stable solid at room temperature, but at elevated temperatures, or with a spark, it quickly forms elemental sodium and nitrogen gas:

The large volume of  $\text{N}_2$  gas that forms from a small volume of  $\text{NaN}_3(s)$  is the basis for airbags in automobiles. However, pure sodium azide also forms liquid sodium, which is dangerous because of its high reactivity. Therefore, other components, such as  $\text{KNO}_3$  and  $\text{SiO}_2$  are added to the mixture in airbags to react with the liquid sodium:

The overall reaction produces the large volume of nitrogen gas required to fill an automobile airbag quickly, along with harmless potassium and sodium silicates.

## Nitrogen Oxides

Under certain conditions, especially high temperatures, nitrogen is oxidized by oxygen to form a number of different oxides. For example, during lightning storms, nitrogen monoxide (NO) gas forms in the upper atmosphere:

Other nitrogen oxides, such as nitrogen dioxide and dinitrogen trioxide, form from the further oxidation of nitrogen monoxide:

All nitrogen oxides are thermodynamically unstable and eventually decompose into their constituent elements or react to form more stable compounds. However, many of these reactions are kinetically slow, so some nitrogen oxides persist for long periods of time.

The most important nitrogen oxide, because of its significance in biological systems, is probably nitrogen monoxide (NO), also called nitric oxide. In 1987, nitrogen monoxide was named molecule of the year by the journal *Science* because of several discoveries related to its biological functions. For example, NO helps control blood pressure through blood vessel dilation, it is important in memory and digestion, and it plays major roles in inducing male erections and female uterine contractions. The ability to adjust NO levels is a key role of the medications that treat erectile dysfunction (such as Viagra).

Earlier in this section, we learned that lightning forms NO in the atmosphere. In Sections 3.6 and 16.12 we saw that NO and  $\text{NO}_2$ , formed as by-products of fossil fuel combustion, are among the important precursors of acid rain. Nitrogen monoxide and nitrogen dioxide are both reactive free radicals (they contain unpaired electrons). At low temperature, two  $\text{NO}_2$  molecules dimerize to form  $\text{N}_2\text{O}_4$ , pairing their two lone electrons. If  $\text{N}_2\text{O}_4$  is heated, it decomposes back to  $\text{NO}_2$ . Consequently, the equilibrium between  $\text{NO}_2$  and  $\text{N}_2\text{O}_4$  is highly temperature-dependent, as we saw in Section 15.9:

Dinitrogen monoxide ( $\text{N}_2\text{O}$ ), also called nitrous oxide, is a good oxidizing agent. It can support the combustion of active metals:

Dinitrogen monoxide is unstable when heated, decomposing into nitrogen and oxygen gas:

Dinitrogen monoxide (often referred to as “nitrous” or laughing gas) is used as an anesthetic by dentists and to pressurize food dispensers (such as whipped-cream dispensers). Commercially,  $\text{N}_2\text{O}$  is produced by the decomposition of ammonium nitrate:

### Nitric Acid, Nitrates, and Nitrides

Nitric acid is an important commercial product of nitrogen. In an electric furnace, nitric acid forms from nitrogen and oxygen gas:

This reaction is thermodynamically favored, but it is kinetically slow. (What would happen to our atmosphere if this reaction were thermodynamically *and* kinetically favored?) Because of the slow speed of this reaction, a more efficient process, called the **Ostwald process**, is used to commercially produce nitric acid.

The first step of the Ostwald process involves passing ammonia gas over hot metal gauze at 600–700 °C to form NO gas. The gauze is made of metals such as platinum and rhodium that are good catalysts for this reaction:

Next, additional oxygen is added to oxidize the NO to  $\text{NO}_2$  gas, which is then passed through a water spray to form nitric acid:

These steps are similar to the natural process that forms acid rain from NO and  $\text{NO}_2$  gas in the atmosphere. The NO gas made during this last step can be recycled back to form more  $\text{NO}_2$  and eventually more  $\text{HNO}_3$ .

Nitric acid is a strong acid that completely ionizes in water. Concentrated nitric acid is 70% nitric acid by mass, or 16 M. A small fraction of the  $\text{HNO}_3$  in a bottle of concentrated nitric acid will react with water to form  $\text{NO}_2$ , a reddish brown gas that, in small amounts, gives the acid its characteristic pale yellow color:

The main commercial uses of nitric acid are in the production of fertilizers and explosives. Over a million tons of ammonium nitrate fertilizer is produced annually by the reaction between ammonia and nitric acid:

Besides being a good fertilizer, ammonium nitrate and some other nitrates are also good explosives. Ammonium nitrate explodes according to the following reaction:

Metal nitrates are responsible for the various colors seen in fireworks displays. The different metal ions emit different colors as the nitrate explodes in air. For example, copper nitrate produces a green-colored light according to the reaction:

As we learned in Chapter 4, nitrates are very soluble in water. For reactions that need soluble metal cations, a nitrate compound is a good source for the cation without interference from the anion.

Nitrites are compounds containing the nitrite ion ( $\text{NO}_2^-$ ). Sodium nitrite is used as a food preservative because it kills *Clostridium botulinum* bacteria, the cause of botulism, and because it keeps meat from discoloring when the meat is exposed to air. Consumers have voiced concerns over this practice, both because it hides the true age of the meat and because the nitrites can react with amines in the meat to form compounds called nitrosamines, which are suspected cancer-causing agents. However, no evidence exists to support the idea that nitrites at levels currently used in meats increase cancer risk in humans.

## Phosphorus Compounds

Phosphorus has a valence electron configuration of  $3s^23p^3$ , similar to that of nitrogen. Phosphorus also forms many compounds, with oxidation states ranging from  $-3$  through  $+5$ . The most stable compounds have the  $+5$  oxidation state.

### Phosphine

**Phosphine** ( $\text{PH}_3$ ) is a colorless, poisonous gas that smells like decaying fish. In phosphine, phosphorus has an oxidation state of  $-3$ . Since phosphorus is less electronegative than nitrogen, phosphine is less polar than ammonia. Phosphine forms from the hydrolysis of metal phosphides:

The disproportionation of white phosphorus in a basic solution can also produce phosphine:

When heated, phosphine decomposes to phosphorus and hydrogen:

Like ammonia, phosphine can form phosphonium compounds such as  $\text{PH}_4\text{Cl}$  and  $\text{PH}_4\text{I}$ . Unlike ammonia, phosphine is not basic in aqueous solution.

Disproportionation is a reaction in which an element is both reduced and oxidized during the same reaction. In this equation the phosphorus in  $\text{P}_4$  is both oxidized and reduced. Phosphorus has an oxidation number of 0 in  $\text{P}_4$  and is reduced to  $-3$  in  $\text{PH}_3$  and oxidized to  $+5$  in  $\text{H}_2\text{PO}_4^-$ .

### Phosphorus Halides

When phosphorus reacts with the halogens, it forms phosphorus halides, the most important of which generally have the formulas  $\text{PX}_3$  and  $\text{PX}_5$ :

Phosphorus halides react with water to form phosphoric acid and the corresponding hydrogen halide. For example,  $\text{PCl}_3$  reacts with water:

Reaction of  $\text{PCl}_3$  with oxygen at room temperature forms phosphorus oxychloride:

Other phosphorus oxyhalides form as a result of the reactions of  $\text{POCl}_3$  with metal fluorides or iodides:

The phosphorus halides and oxyhalides are important compounds in organic chemistry and serve as starting materials for the production of many phosphorus-containing compounds. Many of the key compounds in pesticides, oil additives, fire retardants for clothing, and surfactants (agents that act at surfaces), for example, are commercially made from phosphorus oxyhalides.

### Phosphorus Oxides

White phosphorus reacts directly with oxygen to form phosphorus oxides, as in the reaction shown here:

The product depends upon the amount of oxygen. Tetraphosphorus hexaoxide,  $\text{P}_4\text{O}_6(\text{s})$ , forms when oxygen is limited, and tetraphosphorus decaoxide,  $\text{P}_4\text{O}_{10}(\text{s})$ , forms when greater amounts of oxygen are available.

Phosphorus oxides form interesting cage structures (Figure 23.17▼). We can visualize the  $\text{P}_4\text{O}_6$  structure as a tetrahedron with a phosphorus atom at each of the vertices and an oxygen atom between each pair of phosphorus atoms. The  $\text{P}_4\text{O}_{10}$  structure has four additional oxygen atoms bonded to each phosphorus atom at the vertices of each tetrahedron.

▲ **FIGURE 23.17** Tetraphosphorus Hexaoxide and Decaoxide,  $\text{P}_4\text{O}_6$  and  $\text{P}_4\text{O}_{10}$  The  $\text{P}_4\text{O}_6$  structure has the P atoms at the corners of a tetrahedron and the O atoms on the edges. The  $\text{P}_4\text{O}_{10}$  structure has O atoms also bonded to the P atoms at the corners.

### Phosphoric Acid and Phosphates

Phosphoric acid and phosphates are among the most important phosphorus-containing compounds. Phosphoric acid is a colorless solid that melts at  $42^\circ\text{C}$ . Concentrated phosphoric acid is 85% phosphoric acid by mass, or 14.7 M. Phosphoric acid is produced from the oxidation of white phosphorus to tetraphosphorus decaoxide (see previous reaction), which is then reacted with water:

This method produces a very pure phosphoric acid. A less pure product forms from the reaction of calcium phosphate (a mineral source of phosphate) with concentrated sulfuric acid:

One direct use of phosphoric acid is rust removal. In steel production, thick steel slabs must be heated and rolled into thinner ones. During this process, the hot steel is exposed to air, which oxidizes the surface. To remove this rust, the thin steel sheets pass through phosphoric or hydrochloric acid baths, which dissolve the rust from the metal.

A major use of phosphoric acid is fertilizer production. In the past, phosphorus-containing materials such as fish, bones, and bat guano were used as fertilizer. Sulfuric acid decomposes bones to make phosphorus compounds that are more readily taken up by plants. Today many different phosphorus compounds have been developed specifically as fertilizers for various types of plants.

Detergent manufacturers use sodium phosphate compounds as additives. Compounds such as sodium pyrophosphate ( $\text{Na}_4\text{P}_2\text{O}_7$ ) and sodium tripolyphosphate ( $\text{Na}_5\text{P}_3\text{O}_{10}$ ) remove metal ions such as  $\text{Ca}^{2+}$  and  $\text{Mg}^{2+}$  from hard water, increasing the effectiveness of the detergent and preventing scum rings on sinks and tubs. However, phosphate compounds in detergents are being replaced by other compounds because of ecological problems—primarily the overfertilization of algae in bodies of water—associated with the phosphates.

Phosphoric acid and phosphates are also important chemicals in the food industry. Phosphoric acid is a soft drink additive. At a low concentration, phosphoric acid is non-toxic and adds a tart, acidic taste to soft drinks. It also prevents bacterial growth in the soda. Table 23.5 summarizes the uses of phosphates in the food industry.

**TABLE 23.5** Uses of Phosphates in the Food Industry

Phosphoric acid, $\text{H}_3\text{PO}_4$	Flavor agent in soda, yeast nutrient
Sodium dihydrogen phosphate (also sodium phosphate monobasic), $\text{NaH}_2\text{PO}_4$	Emulsifier, pH buffering agent
Sodium hydrogen phosphate (also sodium phosphate dibasic), $\text{Na}_2\text{HPO}_4$	Baking powder, fermentation auxiliary
Sodium hexametaphosphate, $(\text{NaPO}_3)_6$	Preservative, pH buffering agent
Sodium trimetaphosphate, $(\text{NaPO}_3)_3$	Starch modifier, juice dispersant
Iron(III) pyrophosphate nonahydrate, $\text{Fe}_4(\text{P}_2\text{O}_7)_3 \cdot 9 \text{H}_2\text{O}$	Nutritional supplement
Sodium monofluorophosphate, $\text{Na}_2\text{PO}_3\text{F}$	Fluoride source for toothpaste
Pyrophosphate, $\text{P}_2\text{O}_7^{4-}$	Tartar control for toothpaste

## 23.7 Oxygen

The group 6A elements have an  $s^2p^4$  valence electron configuration and a strong attraction for electrons. They obtain a full octet by gaining only two more electrons. Because of its small size, oxygen is a much stronger oxidizing agent than the rest of the group 6A elements. Oxygen has the second highest electronegativity of any element (3.5), while the rest of the 6A elements range from 2.5 to 2.0. Because of its high abundance (almost half the mass of Earth's crust is composed of oxygen) and its high reactivity, oxygen occurs in many common compounds, including metal oxides, carbonates, silicates, hydrates, and water. Oxygen is also critical for life; the oxidation of biomolecules by oxygen provides energy for most living systems on Earth.

### Elemental Oxygen

Oxygen exists naturally as a colorless, odorless, diatomic, nonpolar gas. It condenses to a pale blue liquid at  $-183^\circ\text{C}$ . Oxygen is slightly soluble in water (0.04 g in 1 L or 0.001 M at  $25^\circ\text{C}$ ). This rather low concentration of oxygen is enough to support life in aquatic environments. A few types of living systems that dwell deep in the ocean near vents that exude sulfur-containing fumes base their life processes on sulfur chemistry rather than oxygen chemistry.

Today, about 21% of Earth's atmosphere is composed of  $\text{O}_2$ , but this was not always the case. Earth's early atmosphere was reducing (rather than oxidizing) and contained hydrogen, methane, ammonia, and carbon dioxide. About 2.7 billion years ago, cyanobacteria (blue-green algae) began to convert the carbon dioxide and water to oxygen by photosynthesis. It took hundreds of millions of years to reach the current oxygen levels.

Joseph Priestley (1733–1804), an English scientist and minister, is credited with discovering oxygen. In 1774, he isolated oxygen by focusing sunlight on mercury(II) oxide and collecting the gas that was released as the red powder oxide formed liquid mercury. He tested the gas by using it to make a candle burn more brightly. He carried out a number of experiments with oxygen over the years, including bravely breathing his new-found gas. Antoine Lavoisier (1743–1794) is credited with recognizing that oxygen is necessary for combustion. He described combustion as the reaction of a substance with oxygen (and not the loss of a substance). These discoveries and explanations were important steps in the development of modern chemistry.

Oxygen is one of the most abundantly produced industrial chemicals. The major production method is the *fractionation* of air. Fractionation involves cooling air until its components liquefy. Then the air is warmed, and components such as  $\text{N}_2$  and Ar are separated out, leaving oxygen behind. Most commercial oxygen is stored and transported as a gas in tanks under high pressure. Another method for the production of oxygen is the electrolysis of water. Passing an electric current through water containing a small amount of an electrolyte produces hydrogen gas at the cathode and oxygen gas at the

▲ Black smokers are vents found under the ocean that provide energy based on sulfur chemistry for life dwelling near the vents.

anode (see Section 19.8). Because of the large amount of electricity needed, however, electrolysis is not a cost-efficient method for oxygen production:

In the laboratory, oxygen can be produced by heating and decomposing metal oxides and other oxygen-containing compounds. The oxides of mercury, silver, and gold lose all their oxygen when heated, while the oxides of other metals, such as barium, lose only some of their oxygen:

Metal nitrates and chlorates also yield oxygen when heated. A catalyst, such as manganese oxide or iron oxide, can make these reactions very fast and dangerous:

## Uses for Oxygen

The greatest industrial use for oxygen is the enrichment of the air in a blast furnace for the conversion of high-carbon iron to steel. Large quantities of oxygen are also used in oxyhydrogen or oxyacetylene torches for the cutting of metals. In addition, oxygen is used to create artificial air for use underwater, during high-altitude travel, and in safety equipment.

Oxygen plays an important role in the treatment of a number of medical conditions, such as acute and chronic lung diseases and heart disorders. Generally, patients use masks or nasal catheters to receive oxygen from a tank of compressed oxygen. However, portable oxygen concentrators have been developed that use molecular sieves to separate and concentrate oxygen from air. Hyperbaric oxygen therapy is the application of high oxygen levels to patients with skin wounds, such as those with skin grafts or hard-to-heal wounds associated with diabetes. The high oxygen level kills anaerobic bacteria that can infect such wounds.

## Oxides

As a strong oxidizing agent, oxygen reacts with most other elements to form oxides. We classify oxides according to the oxidation state of oxygen in the oxide (Table 23.6). The type of oxide that forms depends on the size and charge of the metal. Regular oxides are more stable for the smaller ions with a higher charge. Superoxides are more stable for the larger ions with a smaller charge.

**TABLE 23.6** Types of Oxides

Class	Ion	Oxidation State of O	Example
Oxide	$\text{O}^{2-}$	-2	$\text{Li}_2\text{O}$ , $\text{MgO}$
Peroxide	$\text{O}_2^{2-}$	-1	$\text{Na}_2\text{O}_2$ , $\text{BaO}_2$
Superoxide	$\text{O}_2^-$	$-\frac{1}{2}$	$\text{RbO}_2$ , $\text{CsO}_2$

Oxygen also reacts with many nonmetals to form covalent compounds. Many of these nonmetals form several different binary oxides. For example, we have already seen that carbon forms  $\text{CO}$  and  $\text{CO}_2$  and that nitrogen forms  $\text{N}_2\text{O}$ ,  $\text{NO}$ ,  $\text{N}_2\text{O}_3$ ,  $\text{NO}_2$ ,  $\text{N}_2\text{O}_4$ , and  $\text{N}_2\text{O}_5$ .

## Ozone

**Ozone** ( $\text{O}_3$ ), an allotrope of oxygen, is a toxic blue diamagnetic gas with a strong odor. People can detect the smell at levels as low as 0.01 ppm, and the odor is often noticed in electrical storms or near electrical equipment because the gas forms from  $\text{O}_2$  by an

electrical discharge. Ozone is denser than  $\text{O}_2$  and condenses to a deep blue liquid at  $-112^\circ\text{C}$ . Ozone is naturally made by the irradiation of  $\text{O}_2$  with ultraviolet light in the upper atmosphere:

Ozone is also produced by passing  $\text{O}_2$  gas through an electric field. The volume of gas decreases as the  $\text{O}_2$  is converted to  $\text{O}_3$ . Ozone is produced industrially by the electrolysis of cold concentrated sulfuric acid.

Thermodynamically unstable, ozone decomposes spontaneously to oxygen:

Ozone is used commercially as a strong oxidizing agent. For example, ozone can oxidize  $\text{NO}_2$  to  $\text{N}_2\text{O}_5$  or  $\text{PbS}$  to  $\text{PbSO}_4$ :

Ozone kills bacteria and is an environmentally safe replacement for chlorine in water-purification plants because the only by-product is  $\text{O}_2$ . However, since ozone naturally decomposes, it must constantly be replenished, an economic drawback that limits its use.

The air we breathe contains ozone because it forms as a by-product of fossil fuel combustion. Since it is a strong oxidizing agent, it is a harmful substance. In the lower atmosphere, ozone damages the lungs and skin, stings the eyes, and damages most plant and animal tissues. Ozone also reacts with many types of plastic and rubber materials, causing them to become brittle and to crack.

As we also saw in Section 6.10, the layer of ozone in the upper atmosphere plays an important role in the absorption of harmful ultraviolet radiation from the sun. It absorbs the UV radiation and breaks apart to  $\text{O}_2$  and  $\text{O}$ . This oxygen atom will often react with another  $\text{O}_2$  molecule to re-form as ozone. During this cycle, each ozone molecule absorbs many ultraviolet photons. Recall from Section 3.9 that the ozone layer has been depleted by chlorofluorocarbons (CFCs). However, legislation has banned CFCs in the hope that their reduction will help the ozone layer to recover.

## 23.8 Sulfur: A Dangerous but Useful Element

Like oxygen, sulfur is a nonmetal that belongs to the 6A family. However, sulfur's  $3p$  orbitals extend farther out from the nucleus than do oxygen's  $2p$  orbitals. Consequently, sulfur is larger and is a much weaker oxidizing agent than oxygen. Unlike oxygen, which forms compounds with *only* negative oxidation states, sulfur forms compounds with both negative and positive oxidation states. Sulfur, selenium, and tellurium generally form covalent compounds with +4 or +6 oxidation states, forming anions only when bonding with highly electropositive metals. Sulfur is also much less abundant than oxygen, yet it still composes about 0.06% of the mass of Earth's crust.

### Elemental Sulfur

Elemental sulfur occurs in a few natural deposits, mostly deep underground in the Gulf Coast area of the United States and in eastern Europe. These deposits are believed to have formed as a by-product of anaerobic bacteria that decomposed sulfur-containing minerals over many years. The **Frasch process**, which allows us to recover sulfur from the earth, is diagrammed in Figure 23.18. Superheated water and compressed air are forced down long pipes into the sulfur deposits. The hot water melts the sulfur, which is pushed up to the surface along with

▲ **FIGURE 23.18 The Frasch Process** The Frasch process extracts molten sulfur from the ground by forcing superheated water into beds of deposited solid sulfur.

▲ **FIGURE 23.19 Sulfur Deposits** Some sulfur deposits can also be found at Earth's surface where volcanic activity has brought the element to the surface.

▲ **FIGURE 23.20 Quenching Liquid Sulfur** When hot liquid sulfur is poured into cold water, the sulfur quenches into an amorphous solid.

▲ Molten sulfur below 150 °C (left) and nearing 180 °C (right).

the hot water through a third pipe. Some sulfur deposits also occur at Earth's surface—often in hot springs—where volcanic activity has made the sulfur accessible (Figure 23.19▲).

Sulfur has several allotropes; the most common naturally occurring allotrope of sulfur is composed of an  $S_8$  ring structure called cyclooctasulfur. Most of the different allotropes have ring structures with rings ranging in size from  $S_6$  to  $S_{20}$ . When heated above its melting point of 112 °C, cyclooctasulfur forms a straw-yellow liquid with low viscosity. Above 150 °C, the rings begin to break, and the sulfur becomes a darker, more viscous liquid as the broken rings entangle one another. The color is darkest at 180 °C when the liquid becomes very viscous and pours very slowly, as can be seen in the accompanying photo. Above this temperature, however, the intermolecular forces between the  $S_8$  chains weaken, and the liquid becomes less viscous again. If the hot liquid is poured into cold water, the sulfur will quench into an amorphous solid (Figure 23.20▲). Initially, this amorphous material is flexible like a plastic, but it hardens into a brittle solid.

The Frasch process, while important, provides less than one-third of the world's sulfur; sulfur is a by-product of a number of other industrial processes and is thus recovered from them. For example, dihydrogen monosulfide ( $H_2S$ ), which is commonly called hydrogen sulfide, is a component of natural gas. The  $H_2S$  is separated from the other components by passing the gas through organic solvents such as ethanolamine. The  $H_2S$  dissolves in the organic solvent:

The  $H_2S$  is recovered and oxidized to elemental sulfur through a two-step process—the **Claus process**—that accounts for over 50% of all sulfur produced:

The third major source of sulfur production is metal sulfide minerals, such as the mineral iron(II) disulfide (also known as iron pyrite). Roasting iron pyrite in the absence of air causes the sulfur to disproportionate (react with itself) to form iron(II) sulfide and elemental sulfur:

Alternatively, the metal sulfide can be roasted in air to oxidize the metal sulfide. The sulfur is then removed as sulfur dioxide:

## Hydrogen Sulfide and Metal Sulfides

Hydrogen sulfide, a component of natural gas, is toxic and forms by the reactions of anaerobic bacteria on organic substances. Rotting vegetation and bogs are natural sources of  $\text{H}_2\text{S}$  for the atmosphere. Fortunately, we can detect the odor of  $\text{H}_2\text{S}$  (a rotten egg smell) at concentrations as low as 0.02 ppm, which pose no threat to our health. Levels as low as 10 ppm can cause nausea, and 100 ppm can cause death. The smell of  $\text{H}_2\text{S}$  becomes more difficult to detect at high levels because  $\text{H}_2\text{S}$  also has an anesthetic effect that dulls the sense of smell. Consequently, the sudden onset of strong  $\text{H}_2\text{S}$  odor is a reason to move quickly to fresh air.

It might initially seem that hydrogen sulfide ( $\text{H}_2\text{S}$ ) would share chemical properties with water ( $\text{H}_2\text{O}$ ), but it does not. Water has a larger bond angle ( $104.5^\circ$ ) than hydrogen sulfide ( $92.5^\circ$ ) and is much more polar. Because of its polarity, water forms strong hydrogen bonds, whereas hydrogen sulfide does not. In addition, the  $\text{O}-\text{H}$  bond is much stronger than the  $\text{S}-\text{H}$  bond. These differences result in a far lower boiling point and greater reactivity for hydrogen sulfide compared to water. Water is a stable molecule in the presence of air and oxygen. Hydrogen sulfide burns in air, reacting with oxygen to form elemental sulfur or sulfur oxides.

### Example 23.5 Balancing of and Assigning Oxidation States to Sulfur Reactions

Write a balanced equation for the reaction of  $\text{O}_2$  and  $\text{H}_2\text{S}$  to form elemental S (in the form of  $\text{S}_8$ ). Identify the change of the oxidation state for S.

#### SOLUTION

Write the skeletal equation. The products are elemental  $\text{S}_8$  and  $\text{H}_2\text{O}$ .

Since hydrogen is initially balanced, balance S first, followed by H and O.

Assign oxidation states to each element (see Section 4.9).

The oxidation state of S changes from  $-2$  in  $\text{H}_2\text{S}$  to  $0$  in  $\text{S}_8$ ; therefore, S is oxidized.

**FOR PRACTICE 23.5** Write a balanced equation for the reaction of oxygen with  $\text{H}_2\text{S}$  to form  $\text{SO}_2$ . Identify the change of the oxidation state for S.

**TABLE 23.7** Common Metal Sulfides

Sulfide	Formula	Common Name	$K_{\text{sp}}$ (at $25^\circ\text{C}$ )
Iron(II) sulfide	$\text{FeS}_2$	Pyrite	$3.72 \times 10^{-19}$
Zinc sulfide	$\text{ZnS}$	Sphalerite	$2.0 \times 10^{-25}$
Lead(II) sulfide	$\text{PbS}$	Galena	$9.04 \times 10^{-29}$
Mercury(II) sulfide	$\text{HgS}$	Cinnabar	$1.6 \times 10^{-54}$

Hydrogen sulfide forms from the reactions of metal sulfides with hydrochloric acid:

Only a few of the metal sulfides, those with group 1A and 2A metals and Al, are very soluble in water. Some common metal sulfides and their solubility product constants are listed in Table 23.7. The low solubility of these sulfides allows the use of  $\text{H}_2\text{S}$  as a good analytical method to determine whether metal ions are present in a solution. Sodium sulfide is used to precipitate toxic metals from industrial waste sources.

Metal sulfides have a number of industrial uses, mostly because they are toxic to bacteria. For example,  $\text{SeS}_2$  is a shampoo additive that kills bacteria and controls dandruff, and  $\text{As}_2\text{S}_3$  kills parasites.

## Sulfur Dioxide

Sulfur dioxide is another toxic sulfur compound. Under standard conditions, it is a colorless, dense gas that has an acidic taste. The acidic taste results from the reaction of the gas with the water in your mouth:

Sulfur dioxide forms naturally during volcanic activity when sulfides oxidize in the high volcanic temperatures. Sulfur dioxide is also a pollutant that forms during many industrial processes, such as coal and oil combustion and metal extraction. As we have seen, when the sulfur dioxide is emitted into the air, it reacts with oxygen and water to produce acid rain:

Sulfuric acid as a pollutant is destructive to plants, animals, and man-made structures (see Section 16.12).

To prevent the release of  $\text{SO}_2$  into the atmosphere, industrial processes “scrub” their emissions to remove the  $\text{SO}_2$ . The exhaust gas flows through stacks lined with calcium carbonate that, when heated, capture sulfur oxides in the form of calcium sulfate dust:

The  $\text{CaSO}_4$  dust is collected and disposed of. New uses for the tons of waste  $\text{CaSO}_4$ , such as discarded fireproof insulation, are needed.

One use for  $\text{SO}_2$  capitalizes on its toxicity. Food producers spray fruits and other vegetation with a solution containing  $\text{SO}_2$  to kill mold and preserve the fruit. As a result, the fruits and vegetables can be shipped throughout the world, making it possible for inhabitants of the Northern Hemisphere to enjoy summer fruits (from the Southern Hemisphere) in the winter.

## Sulfuric Acid

The most important use of sulfur and its compounds is the production of sulfuric acid. In fact, sulfuric acid is the most abundantly produced chemical in the world because it is a strong acid, a strong oxidizing agent, and a good dehydrating agent. It is also plentiful and inexpensive. Sulfuric acid is used in fertilizers, color dyes, petrochemicals, paints, plastics, explosives, battery, steel, and detergent industries, to name just a few.

Pure  $\text{H}_2\text{SO}_4$  melts at  $10.4^\circ\text{C}$  and boils at  $337^\circ\text{C}$ . At room temperature, it is an oily, dense liquid. Sulfuric acid reacts vigorously and exothermically with water. Pure or concentrated  $\text{H}_2\text{SO}_4$  must be added to water slowly to avoid rapid heating, boiling, and splattering:

The strong attraction between sulfuric acid and water makes sulfuric acid a very strong dehydrating agent. As shown in Figure 23.21, its affinity for water is strong enough to decompose some organic materials, such as sucrose:

Sulfuric acid is produced industrially by a method known as the **contact process**, developed in the early twentieth century. In this method, elemental sulfur is first heated in air to form  $\text{SO}_2$  gas, which is then heated in contact with a  $\text{V}_2\text{O}_5$  catalyst to form  $\text{SO}_3$  gas:

**▲ FIGURE 23.21 Dehydration of Sucrose** Sulfuric acid dehydrates sucrose by removing the hydrogen and oxygen as water molecules and leaving carbon behind. The porous carbon foam forms because the reaction is very exothermic.

The  $\text{SO}_3$  gas is absorbed into concentrated sulfuric acid, producing a dense form of sulfuric acid called oleum,  $\text{H}_2\text{S}_2\text{O}_7$ , which produces  $\text{H}_2\text{SO}_4$  when dissolved in water:

As we have already seen, sulfuric acid is used in fertilizer production, which consumes a significant amount of the sulfuric acid produced.

## 23.9 Halogens: Reactive Elements with High Electronegativity

The halogens are all one electron short of a noble gas electron configuration. They are the most electronegative elements in their respective periods and are therefore very reactive. They do not naturally occur in their elemental form. The source of most of the halogens (except fluorine) is the dissolved salts present in seawater. The major sources for fluorine are several different minerals, including fluorspar ( $\text{CaF}_2$ ) and fluoroapatite [ $\text{Ca}_{10}\text{F}_2(\text{PO}_4)_6$ ].

We have already seen some of the properties of the halogens, especially those that exhibit periodic trends, in Section 8.9. For example, the atomic radius of the halogens increases regularly from fluorine to iodine, as shown in Table 23.8. Due partly to its small size, fluorine has the highest electronegativity of all elements and is always found in oxidation states of  $-1$  or  $0$ . The other halogens can be found with oxidation states ranging from  $-1$  to  $+7$ . The positive oxidation states occur when a halogen bonds to more electronegative elements such as fluorine or oxygen.

**TABLE 23.8** Selected Properties of the Halogens

Element	Melting Point ( $^{\circ}\text{C}$ )	Boiling Point ( $^{\circ}\text{C}$ )	Atomic Radius (pm)	Electronegativity
Fluorine	$-219$	$-188$	72	4.0
Chlorine	$-101$	$-34$	99	3.0
Bromine	$-7$	60	113	2.8
Iodine	114	185	133	2.5

### Example 23.6 Determining the Oxidation State of Halogens in Compounds

Calculate the oxidation state of Cl in each compound.

- (a)  $\text{ClO}_3^-$       (b)  $\text{HClO}$       (c)  $\text{Cl}_2$

#### SOLUTION

- (a) For  $\text{ClO}_3^-$ , each O atom has an oxidation state of  $-2$  for a total of  $-6$  for all three O atoms. Therefore, the Cl atom has to have an oxidation state of  $+5$  for the sum of the oxidation states to equal the charge of the ion ( $5 - 6 = -1$ ).
- (b) For  $\text{HClO}$ , the O atom has an oxidation state of  $-2$ , and the H atom has an oxidation state of  $+1$ . Therefore the Cl atom has to have an oxidation state of  $+1$  to have a neutral charge ( $1 + 1 - 2 = 0$ ).
- (c) For  $\text{Cl}_2$ , the Cl atoms are in their elemental state, so they have an oxidation state of  $0$ .

**FOR PRACTICE 23.6** Calculate the oxidation state of Cl in  $\text{ClO}_4^-$  and  $\text{Cl}^-$ .

## Elemental Fluorine and Hydrofluoric Acid

Fluorine is the most reactive element and forms binary compounds with all elements except He, Ne, and Ar. Fluorine even forms compounds with some of the noble gases, producing compounds such as  $\text{XeF}_2$ ,  $\text{XeF}_6$ , and  $\text{XeOF}_4$ . The high reactivity of fluorine is related to several factors. First, the  $\text{F}-\text{F}$  bond is among the weakest halogen-halogen bonds, as shown in Table 23.9. In order for a halogen to react with other substances, the halogen-halogen bond must break. The energy required to break that bond is small for  $\text{F}_2$ , so the resulting reaction is more exothermic. Second, the small size of fluorine results in a high lattice energy for the ionic compounds that it forms. The high lattice energy means the compounds are very stable.

**TABLE 23.9** Comparison of Halogen  $\text{X}-\text{X}$  Bond Energy

Halogen	$\text{F}-\text{F}$	$\text{Cl}-\text{Cl}$	$\text{Br}-\text{Br}$	$\text{I}-\text{I}$
Bond energy (kJ/mol)	159	243	193	151

The high reactivity of fluorine is illustrated by its ability to burn (or quickly oxidize) many substances, such as iron and sulfur, that do not readily burn with oxygen:

Fluorine gas even reacts with asbestos and glass, two materials commonly used as containers for reactive substances. Consequently, fluorine is normally held in metal containers made of iron, copper, or nickel. These metals also initially react with fluorine, but then a thin layer of the product coats the surface of the metal, protecting the underlying metal from further reaction.

Elemental fluorine is produced from the electrolysis of hydrofluoric acid, forming  $\text{F}_2$  and  $\text{H}_2$  gases:

Gaseous hydrogen fluoride can be obtained from the reaction of the mineral fluorspar ( $\text{CaF}_2$ ) with sulfuric acid:

In its solid form, HF has a crystal structure that contains zigzag chains of alternating H and F atoms. In aqueous solutions, HF is a weak acid ( $K_a = 3.5 \times 10^{-4}$  for HF at 298 K). Like all anions in aqueous solution, the  $\text{F}^-$  ions from ionized HF are solvated by water molecules. However, the  $\text{F}^-$  ions can also associate with other HF molecules to form  $\text{HF}_2^-$ .

The structure of  $\text{HF}_2^-$ , shown here, is unique because it contains a bridging hydrogen atom (a hydrogen atom that essentially forms two bonds):

Hydrofluoric acid is a strong oxidizing agent and reacts with glass according to the following reactions:

or:

As a result, hydrofluoric acid cannot be held in a glass container and is generally stored in plastic. The ability of HF to react with glass makes it useful in etching glass. The parts of the glass to be etched are left exposed, and the rest of the surface is masked with a nonreactive substance such as plastic. The surface is then exposed to hydrofluoric acid

and the nonmasked glass etches away, leaving the desired pattern. Hydrofluoric acid is particularly dangerous because it quickly penetrates into tissues, damaging internal organs and bones. Direct exposure of just 2% of body surface area to concentrated hydrofluoric acid can be fatal.

## Elemental Chlorine

Historically, the primary source for chlorine has been seawater. Electrolysis of NaCl in seawater produces Cl<sub>2</sub> gas and H<sub>2</sub> gas:

Today, much Cl<sub>2</sub> gas is produced and collected as a by-product of the various metal processing methods, such as in the reduction of metal chlorides to form metals:

## Halogen Compounds

Halogens form ionic compounds with most metals, they form covalent compounds with many nonmetals, and they can bond with other halogens to form interhalogen compounds. Here we look at some of the compounds halogens form.

### Interhalogen Compounds

Covalent compounds composed of two different halogens are known as **interhalogen compounds** or *interhalides*. The general formula of these compounds is AB<sub>*n*</sub>, where A is the larger halogen, B is the smaller halogen, and *n* is 1, 3, 5, or 7. The smaller halogens surround the larger halogen in the AB<sub>3</sub> compounds. The only known AB<sub>5</sub> compounds contain fluorine as the smaller halogen (because the other halogens are too large for five of them to fit around another halogen). The compound IF<sub>7</sub> is the only known interhalogen compound with *n* = 7. The large size of the iodine atom allows seven small fluorine atoms to surround it. The interhalides can be formed by reacting the elemental halogens with one another. Interhalide polyatomic ions, such as ICl<sub>2</sub><sup>+</sup> and ICl<sub>4</sub><sup>−</sup>, also exist.

### Example 23.7 Formation of Interhalogen Compounds

Write the balanced equation for the formation of ClF<sub>3</sub> gas from the elemental halogens.

#### SOLUTION

The unbalanced reaction is:

At least two ClF<sub>3</sub> molecules form from each Cl<sub>2</sub> molecule; therefore, add a 2 before ClF<sub>3</sub> and then a 3 before F<sub>2</sub>. The balanced equation is:

**FOR PRACTICE 23.7** Write a balanced equation for the formation of IF<sub>5</sub> gas from the elemental halogens.

The geometry of the interhalides can be predicted from the valence shell electron pair repulsion model (VSEPR). Because the halogens do not form double or triple bonds, the shapes of these compounds are relatively straightforward to determine, as shown in Examples 23.8 and 23.9.

## Procedure for...

<b>Determining the Shape of Interhalogen Compounds</b>	<b>Example 23.8</b> <b>Molecular Shapes of Interhalogen Compounds</b> Determine the molecular geometry of $\text{IBr}_2^-$ .	<b>Example 23.9</b> <b>Molecular Shapes of Interhalogen Compounds</b> Determine the molecular geometry of $\text{IF}_7$ .
Identify the central atom.	<b>SOLUTION</b> I	<b>SOLUTION</b> I
Draw the Lewis structure (see Section 9.5).	$\left[ \text{:}\ddot{\text{Br}}-\ddot{\text{I}}-\ddot{\text{Br}}\text{:} \right]^-$	
Count the number of bonds and lone pairs on the central atom.	The I atom has two bonds and three lone pairs for a total of five electron groups.	The I atom has seven bonds on the central atom for a total of seven electron groups.
Determine the electron geometry from the number of electron groups (see Section 10.4).	With five electron groups, the electron geometry is <i>trigonal bipyramidal</i> .	With seven electron groups, the electron geometry is <i>pentagonal bipyramidal</i> .
Determine the molecular shape from the number of bonds and lone pairs.	With two bonds the molecular geometry is <i>linear</i> because the three lone pairs occupy equatorial positions. 	With seven bonds, the molecular geometry is also <i>pentagonal bipyramidal</i> . 
	<b>FOR PRACTICE 23.8</b> Determine the electron geometry and molecular geometry of $\text{ICl}_2^+$ .	<b>FOR PRACTICE 23.9</b> Determine the electron geometry and molecular geometry of $\text{BrF}_5$ .

The only industrially useful interhalide is  $\text{ClF}_3$ , employed in the nuclear energy industry to produce  $\text{UF}_6(\text{g})$ , which is used to separate  $^{235}\text{U}$  (<1% of naturally occurring uranium) from  $^{238}\text{U}$ . Uranium ores react with gaseous hydrogen fluoride to form  $\text{UF}_4(\text{s})$ , which reacts with  $\text{ClF}_3(\text{g})$  to form the gaseous uranium compound:

Because of the difference in mass between the two isotopes,  $^{238}\text{UF}_6$  effuses more slowly than  $^{235}\text{UF}_6$  (see Section 5.9 for a description of effusion). The mixture of gases is allowed to flow through barriers with very small pores. Since  $^{235}\text{UF}_6$  effuses more quickly, the initial flow of gas that exits the pores is enriched in  $^{235}\text{UF}_6$ . By repeating the process, the two isotopes can be nearly completely separated.

### Halogen Oxides

Most halogen oxides are unstable, and many are explosive. A unique halogen oxide is  $\text{OF}_2$ ; oxygen usually has a negative oxidation state in its compounds but has a +2 oxidation state in  $\text{OF}_2$  (due to the high electronegativity of fluorine).

A number of different chlorine oxides are known, including  $\text{Cl}_2\text{O}$ ,  $\text{ClO}_2$ ,  $\text{Cl}_2\text{O}_6$ , and  $\text{Cl}_2\text{O}_7$ . Chlorine dioxide is a powerful oxidizing agent used to bleach flour and wood pulp (to make white paper). Because  $\text{ClO}_2$  is explosive, the gas is diluted with  $\text{CO}_2$  or  $\text{N}_2$  for safety. Some water treatment plants use  $\text{ClO}_2$  for water disinfection in place of  $\text{Cl}_2$ .  $\text{ClO}_2$  is produced by the oxidation of sodium chlorite with  $\text{Cl}_2$  or by the reduction of sodium chlorate with hydrochloric acid:

### Example 23.10 Identifying Changes in Oxidation States

Identify the change of oxidation state for Cl in the production of chlorine dioxide from sodium chlorite. Identify the oxidizing agent and the reducing agent.

#### SOLUTION

First determine the oxidation state of Cl in each compound.

The Cl in the  $\text{NaClO}_2$  was oxidized from +3 to +4 by the oxidizing agent  $\text{Cl}_2$ , which was reduced from 0 to -1 by the reducing agent  $\text{NaClO}_2$ .

**FOR PRACTICE 23.10** Identify the change of oxidation state for Cl in the production of chlorine dioxide from sodium chlorate. Identify the oxidizing agent and the reducing agent.

## Self-Assessment Quiz

- Q1.** An aluminosilicate is composed of a crystal in which Al atoms substitute for three-fourths of the Si atoms in the silica structure. The negative charge of the  $\text{AlO}_2^-$  groups is balanced by  $\text{Na}^+$  ions. What is the formula of the aluminosilicate?
- a)  $\text{Na}(\text{AlSi}_3\text{O}_8)$                       b)  $\text{Na}_2(\text{Al}_2\text{Si}_2\text{O}_8)$   
c)  $\text{Na}_3(\text{Al}_3\text{SiO}_8)$                       d)  $\text{NaSiO}_2$
- Q2.** Use charge balance to determine  $x$  in the formula for the sorosilicate bertrandite,  $\text{Be}_4\text{Si}_2\text{O}_7(\text{OH})_x$ .
- a) 1                      b) 2                      c) 3                      d) 4
- Q3.** Which element is important in the manufacturing of glassware intended for heating?
- a) carbon                      b) nitrogen  
c) phosphorus                      d) boron
- Q4.** Fertilizers commonly contain compounds of which element?
- a) nitrogen                      b) aluminum  
c) fluorine                      d) boron
- Q5.** What is the oxidation state of bromine in the compound  $\text{NaBrO}_3$ ?
- a) +2                      b) -3                      c) -4                      d) +5
- Q6.** What is the molecular geometry of  $\text{ICl}_4^-$ ?
- a) tetrahedral                      b) square planar  
c) octahedral                      d) seesaw
- Q7.** Which element is oxidized in the reaction?
- $$2 \text{CaO}(s) + 2 \text{SO}_2(g) + \text{O}_2(g) \longrightarrow 2 \text{CaSO}_4(s)$$
- a) Ca                      b) O                      c) S  
d) None of the above (no element is oxidized in the reaction)
- Q8.** Which carbon oxide does not exist?
- a) CO                      b)  $\text{CO}_2$                       c)  $\text{CO}_3^{2-}$                       d)  $\text{CO}_4$
- Q9.** Which element is extracted from the ground primarily in its elemental form?
- a) boron                      b) phosphorus  
c) sulfur                      d) fluorine
- Q10.** Which substance forms when carbon dioxide dissolves in water?
- a) CO                      b)  $\text{H}_2\text{CO}$                       c)  $\text{CH}_4$                       d)  $\text{H}_2\text{CO}_3$

Answers: 1. (c) 2. (b) 3. (d) 4. (a) 5. (d) 6. (b) 7. (c) 8. (d) 9. (c) 10. (d)

## Chapter 23 IN REVIEW

### Key Terms

#### Section 23.2

main-group elements (1064)

#### Section 23.3

silicates (1066)  
quartz (1066)  
silica (1066)  
aluminosilicates (1066)  
mineral (1068)  
orthosilicates (1067)  
pyrosilicates (1067)  
pyroxenes (1067)

#### Section 23.4

boranes (1071)  
*closo*-boranes (1071)  
*nido*-boranes (1071)  
*arachno*-boranes (1072)

#### Section 23.5

coal (1072)  
coke (1072)  
charcoal (1073)  
activated carbon (1073)  
soot (1073)  
carbon black (1073)  
carbides (1073)  
ionic carbides (1073)  
covalent carbides (1074)  
metallic carbides (1074)  
washing soda (1075)

#### Section 23.6

white phosphorus (1077)  
red phosphorus (1077)  
black phosphorus (1077)  
ammonia (1078)

Haber-Bosch process (1078)  
hydrazine (1078)  
hydrogen azide (1078)  
Ostwald process (1080)  
phosphine (1081)

#### Section 23.7

ozone (1084)

#### Section 23.8

Frasch process (1085)  
Claus process (1086)  
contact process (1088)

#### Section 23.9

interhalogen compounds (1091)

### Key Concepts

#### Bonding and Properties (23.2)

- ▶ Main-group elements are defined by their electron configurations and their location on the periodic table.
- ▶ The properties of the main-group elements show great diversity. Metals, nonmetals, and metalloids are all found among the main-group elements.
- ▶ Some main-group elements form covalent bonds while others form ionic bonds.

#### The Most Common Matter: Silicates (23.3)

- ▶ Silicates (found in rocks, clays, and soils) are covalent atomic solids that contain silicon, oxygen, and various metal atoms.
- ▶ Silicate structures consist of four oxygen atoms bonded to silicon, forming a negatively charged polyatomic anion with a tetrahedral shape. Various metal ions within the structure balance the charge of the compound.
- ▶ The  $\text{SiO}_4$  tetrahedrons can link to form chains, double chains, sheets, or even extended three-dimensional structures.
- ▶ The properties of the silicates depend on the connections between the silicate tetrahedrons. Because of the wide variety of combinations of tetrahedron connections and the many different metal ions that fit within the structure, an enormous variety of different silicate minerals exist in nature, making the silicate materials the most common structures found on Earth.

#### Boron (23.4)

- ▶ Because of its small size and high electronegativity, boron behaves as a metalloid.
- ▶ The structure of elemental boron consists of icosahedron structures bonded together in various ways.
- ▶ Boron tends to form electron-deficient compounds.
- ▶ Compounds of boron and hydrogen form cluster compounds resembling spheres, cages, and nets.

#### Carbon (23.5)

- ▶ Organic chemistry is based on the chemistry of carbon, and carbon is also very important in many inorganic compounds and applications. Important types of amorphous elemental carbon include carbon black and coke.
- ▶ Important types of inorganic carbon compounds include carbides and carbonates. Carbon can form carbides with metallic, covalent, or ionic properties.
- ▶ Carbon and its oxygen compounds are intimately involved in the functions of life.

#### Nitrogen and Phosphorus (23.6)

- ▶ Nitrogen and phosphorus have been known for over 200 years; both form compounds, with oxidation numbers ranging from  $-3$  up to  $+5$ .
- ▶ Both nitrogen and phosphorus compounds are critical for plant growth; their most important use is as fertilizers. The strong triple bond between nitrogen atoms in  $\text{N}_2$  makes nitrogen from the atmosphere inaccessible to most plants, so ingenious chemical processes have been devised to make nitrogen compounds that are more available to plants.

#### Oxygen (23.7)

- ▶ Oxygen is the most common element on Earth. It is found in the atmosphere as the elemental gas and as many oxide gases.
- ▶ Oxygen is found in ocean water and in Earth's crust as silicate and oxide compounds. Oxygen is a strong oxidizing agent and forms compounds with  $-\frac{1}{2}$ ,  $-1$ , or  $-2$  oxidation states.
- ▶ Ozone,  $\text{O}_3$ , is a helpful molecule in the upper atmosphere, where it absorbs harmful ultraviolet radiation, but it is a harmful molecule at Earth's surface.

**Sulfur (23.8)**

- ▶ More sulfuric acid is produced than any other chemical; most of it is used to make fertilizers. Other uses take advantage of its strong oxidation and dehydration properties.
- ▶ Elemental sulfur has several allotropes ranging from ring structures to chain structures and amorphous materials, depending upon temperature.

**Halogens (23.9)**

- ▶ The halogens are the most electronegative elements, so they are always found as compounds, usually ionic. When the halogens

bond with other electronegative elements, however, they can form covalent compounds.

- ▶ Fluorine has special chemical properties because it is the most electronegative element and is very small, making it a very strong oxidizing agent.
- ▶ Interhalogen compounds are formed between two halogens, with the larger halogen as the central atom of the structure.

## Key Learning Outcomes

CHAPTER OBJECTIVES	ASSESSMENT
Determining the Composition, Charge Balance, and Type of Silicates and Aluminosilicates (23.3)	Examples 23.1, 23.2, 23.3, 23.4 For Practice 23.1, 23.2, 23.3, 23.4 Exercises 15–24
Writing Equations for Reactions and Assigning Oxidation States (23.8, 23.9)	Examples 23.5, 23.6, 23.10 For Practice 23.5, 23.6, 23.10 Exercises 39–42, 51–54, 69–70, 73–74
Formation of Interhalogen Compounds and Their Structures (23.9)	Examples 23.7, 23.8, 23.9 For Practice 23.7, 23.8, 23.9 Exercises 71–72, 76

## EXERCISES

### Review Questions

- Why does BN form compounds similar to those formed by elemental carbon?
- What is the main characteristic that determines whether or not an element is a main-group element?
- Does the metallic characteristic of a main-group element increase or decrease as we move down a family? Explain why.
- Why does silicon form only single bonds with oxygen but carbon, which is in the same family as silicon, forms double bonds with oxygen in many compounds?
- What is the difference between a rock and a mineral?
- Briefly define each term.
  - orthosilicate
  - amphibole
  - pyroxene
  - pyrosilicate
  - feldspar
- Why is boron oxide often added to silica glass?
- Why does boron form electron-deficient bonds? Provide an example.
- Explain why solid  $\text{CO}_2$  is referred to as dry ice.
- Nitric acid and phosphoric acid are two major chemical products of the chemical industry. Describe some of their uses.
- What is the typical concentration of oxygen in dry air?
- Describe how nitrogen can be separated from the other components of air.
- Earth's atmosphere originally did not contain oxygen. Explain how the atmosphere gained oxygen.
- Name a benefit, a hazard, and a useful commercial application of ozone.

### Problems by Topic

**Silicates: The Most Abundant Matter in Earth's Crust**

- Silicon bonds to oxygen to form a tetrahedral shape in both the network covalent silica compound,  $\text{SiO}_2$ , and in ionic silicate compounds. What is the oxidation state of Si in each of these structures?
  - silica compound,  $\text{SiO}_2$
  - orthosilicates,  $\text{SiO}_4^{4-}$
  - pyrosilicates,  $\text{Si}_2\text{O}_7^{6-}$
- What is the oxidation state of Si in each of these structures?
  - pyroxenes,  $\text{SiO}_3^{2-}$
  - amphiboles,  $\text{Si}_4\text{O}_{11}^{6-}$
  - phyllosilicates,  $\text{Si}_2\text{O}_5^{2-}$
- In the orthosilicate garnet, the formula unit has three  $\text{SiO}_4^{4-}$  units and is balanced by  $\text{Ca}^{2+}$  and  $\text{Al}^{3+}$  cations. Determine the formula unit of garnet.
- In the pyroxene kanoite, the formula unit has two  $\text{SiO}_3^{2-}$  units and is balanced by manganese and magnesium ions. Determine the formula unit of kanoite. Assume that the oxidation state of Mn is +2.
- Kaolin is a clay material that is a phyllosilicate. Use charge balancing to determine how many hydroxide ions are in the formula for kaolin,  $\text{Al}_2\text{Si}_2\text{O}_5(\text{OH})_x$ .

20. Tremolite is a double-chain silicate in the amphibole class. Use charge balancing to determine how many hydroxide ions are in the formula for tremolite,  $\text{Ca}_2\text{Mg}_5\text{Si}_8\text{O}_{22}(\text{OH})_x$ .
21. How are the silica tetrahedrons linked for  $\text{ZrSiO}_4$ ? Which class of silicates does this compound belong to?
22. How are the silica tetrahedrons linked for  $\text{CaSiO}_3$ ? Which class of silicates does this compound belong to?
23. Predict the structure and give the charges on the cations in one of the minerals in the hornblende family,  $\text{Ca}_2\text{Mg}_4\text{FeSi}_7\text{AlO}_{22}(\text{OH})_2$ .
24. Predict the structure and label the charges on the cations in the mineral hedenbergite,  $\text{CaFeSi}_2\text{O}_6$ .

### Boron and Its Remarkable Structures

25. A major source of boron is the mineral kernite,  $\text{Na}_2[\text{B}_4\text{O}_5(\text{OH})_4] \cdot 3 \text{H}_2\text{O}$ . Calculate how many grams of boron can be produced from  $1.0 \times 10^3 \text{ kg}$  of a kernite-bearing ore if the ore contains 0.98% kernite by mass and the process has a 65% yield.
26. An uncommon mineral of boron is ulexite,  $\text{NaCaB}_5\text{O}_9 \cdot 8 \text{H}_2\text{O}$ . How many grams of boron can be produced from  $5.00 \times 10^2 \text{ kg}$  of ulexite-bearing ore if the ore contains 0.032% ulexite by mass and the process has an 88% yield?
27. Explain why the bond angles in  $\text{BCl}_3$  and  $\text{NCl}_3$  are different.
28. Explain why the bond between B and Cl in the molecule  $\text{BCl}_3$  is shorter than would be expected for a single B—Cl bond.
29. Predict the number of vertices and faces on each *closo*-borane.  
a.  $\text{B}_6\text{H}_6^{2-}$                       b.  $\text{B}_{12}\text{H}_{12}^{2-}$
30. Predict the number of vertices and faces on each *closo*-borane.  
a.  $\text{B}_4\text{H}_4^{2-}$                       b.  $\text{B}_9\text{H}_9^{2-}$
31. Describe the differences among a *closo*-borane, a *nido*-borane, and an *arachno*-borane.
32. Describe how boron is used in the nuclear industry.

### Carbon, Carbides, and Carbonates

33. Describe the difference between regular charcoal and activated charcoal.
34. Explain why the structure of charcoal allows carbon to act as a good filter while the diamond structure does not.
35. Describe the difference between an ionic carbide and a covalent carbide. Which types of atoms will form these carbides with carbon?
36. Silicon carbide is produced by heating silicone polymers, forming methane gas, hydrogen gas, and silicon carbide. Balance the reaction of heating  $[(\text{CH}_3)_2\text{Si}]_8$  to form silicon carbide.
37. Referring to the phase diagram in Section 11.8, describe what happens to the phase of  $\text{CO}_2$  during each process.  
a. reducing the pressure on solid  $\text{CO}_2$  that is at  $-80^\circ\text{C}$   
b. decreasing the temperature on  $\text{CO}_2$  gas that is held at a pressure of 20 atm  
c. increasing the temperature on solid  $\text{CO}_2$  that is held at a pressure of 0.8 atm
38. Referring to the phase diagram in Section 11.8, describe what happens to the phase of  $\text{CO}_2$  during each process.  
a. reducing the temperature from the critical point  
b. increasing the pressure on  $\text{CO}_2$  gas that is held at a temperature of  $-50^\circ\text{C}$   
c. increasing the temperature on solid  $\text{CO}_2$  that is held at a pressure of 20 atm
39. Predict the products for each reaction and write a balanced equation.  
a.  $\text{CO}(\text{g}) + \text{CuO}(\text{s})$       b.  $\text{SiO}_2(\text{s}) + \text{C}(\text{s})$       c.  $\text{S}(\text{s}) + \text{CO}(\text{g})$

40. Predict the products for each reaction and write a balanced equation.  
a.  $\text{CO}(\text{g}) + \text{Cl}_2(\text{g})$       b.  $\text{CO}_2(\text{g}) + \text{Mg}(\text{s})$       c.  $\text{S}(\text{s}) + \text{C}(\text{s})$
41. Give the oxidation state for carbon in:  
a.  $\text{CO}$                       b.  $\text{CO}_2$                       c.  $\text{C}_3\text{O}_2$
42. Write a balanced reaction for the gas release reaction of Alka-Seltzer, sodium bicarbonate with citric acid,  $\text{C}_6\text{H}_8\text{O}_7$ . (The acid is a triprotic acid and consists of a chain of three carbon atoms, each with a carboxylic acid group,  $\text{COOH}$ .)

### Nitrogen and Phosphorus: Essential Elements for Life

43. Explain the process of fixing nitrogen.
44. Explain why the diatomic nitrogen atom is unusable by most plants. Where do plants get nitrogen?
45. Describe the differences in the allotropes of white and red phosphorus. Explain why red phosphorus is more stable.
46. Describe how red and black phosphorus are made from white phosphorus.
47. Saltpeter and Chile saltpeter are two important mineral sources for nitrogen. Calculate the mass percent of nitrogen in each mineral.
48. Apatite is a main mineral source for the production of phosphorus. Calculate the atomic and mass percent of P in the mineral apatite.
49. Referring to the tables in Appendix IIB, determine whether or not hydrogen azide is stable at room temperature compared to its elements,  $\text{H}_2$  and  $\text{N}_2$ . Is hydrogen azide stable at any temperature?
50. Referring to the tables in Appendix IIB, determine if dinitrogen monoxide is stable at room temperature compared to its elements,  $\text{O}_2$  and  $\text{N}_2$ . Is dinitrogen monoxide stable at any temperature?
51. Predict the products for each reaction and write a balanced equation.  
a.  $\text{NH}_4\text{NO}_3(\text{aq}) + \text{heat}$   
b.  $\text{NO}_2(\text{g}) + \text{H}_2\text{O}(\text{l})$   
c.  $\text{PCl}_3(\text{l}) + \text{O}_2(\text{g})$
52. Predict the products for each reaction and write a balanced equation.  
a.  $\text{NO}(\text{g}) + \text{NO}_2(\text{g})$       b. heating  $\text{PH}_3$       c.  $\text{P}_4(\text{s}) + 5 \text{O}_2(\text{g})$
53. Rank the nitrogen ions from the one with N in the highest oxidation state to the one with N in the lowest.  
 $\text{N}_3^-$ ,  $\text{N}_2\text{H}_5^+$ ,  $\text{NO}_3^-$ ,  $\text{NH}_4^+$ ,  $\text{NO}_2^-$
54. Determine the oxidation state of N in the compounds in the reaction for the formation of nitric acid. Identify the oxidizing agent and the reducing agent.  
$$3 \text{NO}_2(\text{g}) + \text{H}_2\text{O}(\text{l}) \longrightarrow 2 \text{HNO}_3(\text{l}) + \text{NO}(\text{g})$$
55. Draw the Lewis structures for the phosphorus halides  $\text{PCl}_3$  and  $\text{PCl}_5$ . Describe their VSEPR shape.
56. Dinitrogen pentoxide is an ionic compound formed from the ions  $\text{NO}_2^+$  and  $\text{NO}_3^-$ . Give the oxidation state of N in each ion and the VSEPR shape for each of the ions.
57. Ammonium carbonate is produced from the reaction of urea,  $\text{CO}(\text{NH}_2)_2$  with water. Write a balanced equation for this reaction and determine how much urea is needed to produce 23 g of ammonium carbonate.
58. Explain why phosphine,  $\text{PH}_3$ , is less polar than ammonia.
59. Reacting oxygen with white phosphorus can form either  $\text{P}_4\text{O}_6$  or  $\text{P}_4\text{O}_{10}$ . State the conditions that determine which product forms.

60.  $P_4O_{10}$  is one of the most effective drying agents, having the ability to extract water from other molecules. The  $P_4O_{10}$  forms phosphoric acid. Write balanced reactions for the reaction of  $P_4O_{10}$  with:
- a.  $HNO_3$ , forming  $N_2O_5$       b.  $H_2SO_4$ , forming  $SO_3$

### Oxygen

61. Name the major source of the element oxygen and describe how it is produced.
62. Explain why either greatly decreasing or increasing the percentage of oxygen in the atmosphere is dangerous.
63. Identify each compound as an oxide, peroxide, or superoxide.
- a.  $LiO_2$       b.  $CaO$       c.  $K_2O_2$
64. Identify each compound as an oxide, peroxide, or superoxide.
- a.  $MgO$       b.  $Na_2O_2$       c.  $CsO_2$

### Sulfur: A Dangerous but Useful Element

65. Explain why the viscosity of liquid sulfur increases with increasing temperature initially, but then decreases upon further increases in temperature.
66. Sulfur dioxide is a toxic sulfur compound. List one natural source and one industrial source that produce  $SO_2$ .
67. Calculate the maximum mass (in grams) of each metal sulfide that will dissolve in 1.0 L of a solution that is  $5.00 \times 10^{-5} M$  in  $Na_2S$ .
- a.  $PbS$       b.  $ZnS$
68. A coal source contains 1.1% sulfur by mass. If  $2.0 \times 10^4 kg$  of coal is burned and forms oxides, calculate the mass of  $CaSO_4(s)$  that is produced from "scrubbing" the  $SO_2$  pollutant out of the exhaust gas. Assume that all of the sulfur in the coal is converted to calcium sulfate.

69. Write the equation for roasting iron pyrite in the absence of air to form elemental sulfur. Calculate the volume of  $S_2$  gas that can be produced from roasting 5.5 kg of iron pyrite. Assume that all of the sulfur in the iron pyrite is converted to  $S_2$  gas. (Assume STP to calculate the gas volume.)
70. Write an overall reaction from the two steps in the Claus process. Calculate the volume of  $H_2S$  gas needed to produce 1.0 kg of  $S(s)$ . (Assume STP to calculate the gas volume.)

### Halogens

71. Determine the oxidation state of Xe and give the VSEPR structure for each compound.
- a.  $XeF_2$       b.  $XeF_6$       c.  $XeOF_4$
72. Describe the shape of each halogen compound.
- a.  $BrF_4^-$       b.  $IF_3$       c.  $BrO_2^-$       d.  $ClO_4^-$
73. When chlorine is bubbled through a colorless aqueous solution containing bromide ions, the solution turns red and the chlorine is reduced. Write a balanced equation for this reaction and identify the oxidizing and reducing agent.
74. Carbon tetrachloride is produced by passing chlorine gas over carbon disulfide in the presence of a catalyst. The reaction also produces  $S_2Cl_2$ . Write the balanced reaction and identify which element is oxidized and which element is reduced.
75. If 55 g of  $SiO_2(s)$  glass is placed into 111 L of 0.032 M  $HF$ , is there enough  $HF$  to dissolve all of the glass? Determine which substance is the limiting reagent and calculate how much of the other reagent is left if the reaction proceeds to completion.
76. Describe the difference in the types of bonds (single, double, triple) and the shapes of the following two iodine ions:  $ICl_4^-$  and  $IO_4^-$ .

## Cumulative Problems

77. From the compositions of lignite and bituminous coal, calculate the mass of sulfuric acid that could potentially form as acid rain from burning  $1.00 \times 10^2 kg$  of each type of coal.
78. Calculate the volume of  $CO_2$  released from heating and decomposing 88 g of sodium bicarbonate. (Assume standard pressure and temperature.)
79. All of the halogens form oxoacids. The perhalic acids have the general formula of  $HXO_4$ . Explain why  $HClO_4$  is a much stronger acid than  $HIO_4$ .
80. The halogens form oxoacids with different amounts of oxygen. Explain why  $HClO_4$  is a stronger acid than  $HClO_2$ .
81. Determine the ratio of effusion rates of  $HCl$  compared to each gas.
- a.  $Cl_2$   
b.  $HF$   
c.  $HI$
82. Calculate the ratio of effusion rates for each pair of gases.
- a.  $^{238}UF_6$  and  $ClF_3$   
b.  $^{238}UF_6$  and  $^{235}UF_6$
83. Sodium peroxide is a very powerful oxidizing agent. Balance the reaction of sodium peroxide with elemental iron to give sodium oxide and  $Fe_3O_4$ .
84. Sulfur dioxide is a reducing agent. When it is bubbled through an aqueous solution containing  $Br_2$ , a red-colored solution, it reduces the bromine to colorless bromide ions and forms sulfuric acid. Write a balanced equation for this reaction and identify the oxidizing and reducing agent.

85. Using the molecular orbital model for a diatomic molecule, explain the different bond lengths for the ions of oxygen. Also state which ion is diamagnetic.

Ion	O—O Bond Length (pm)
$O_2^+$	112
$O_2$	121
$O_2^-$	133
$O_2^{2-}$	149

86. The *clos*-borane with the formula  $B_6H_6^{2-}$  has the six B atoms at vertices, forming an octahedron structure with eight faces. The formula for the number of sides is  $2n - 4$ , where  $n$  is the number of boron atoms. Determine the number of vertices and faces for each *clos*-borane.
- a.  $B_4H_4^{2-}$       b.  $B_{12}H_{12}^{2-}$
87. Find the amount (in moles) of C—C bonds that must be broken when 1.0 mole of  $C(g)$  is formed from  $C(\text{diamond})$ . Calculate the  $\Delta H$  of sublimation of diamond from the data in Appendix II, Table B. Then do the calculation using the C—C bond energy in Table 9.3. Suggest a reason for the difference between the two values.
88. Breathing air that contains 0.13% CO by volume for 30 minutes will cause death. CO can form by incomplete combustion of carbon-containing compounds. Calculate the minimum volume of octane ( $C_8H_{18}$ , a component of gasoline, which has a density of 0.70 g/mL) that must burn to produce this composition of CO in a garage of volume  $40 m^3$  at 298 K and 1.0 atm.

89. Given that the  $\Delta H_f^\circ$  of 1 M  $\text{H}_2\text{SO}_3$  is  $-633 \text{ kJ}$ , use the data in Appendix II, Table B to calculate the  $\Delta H^\circ$  for the formation of a 1 M solution of  $\text{SO}_2$  in water from  $\text{SO}_2(\text{g})$ .

90. Use the data in Appendix II, Table B to calculate  $\Delta H^\circ$  for the formation of a 1 M solution of  $\text{H}_2\text{SO}_4$  from  $\text{SO}_3(\text{g})$ .

## Challenge Problems

91. Calculate the standard enthalpy of reaction for reducing the different forms of iron oxide to iron metal and  $\text{CO}_2$  from the reaction of the oxide with  $\text{CO}$ . Identify which reaction is the most exothermic per mole of iron and explain why.

- $\text{Fe}_3\text{O}_4$
- $\text{FeO}$
- $\text{Fe}_2\text{O}_3$

92. Balance the equation for the production of acetylene ( $\text{C}_2\text{H}_2$ ) from the reaction of calcium carbide with water. If the acetylene is burned to form water and carbon dioxide, how many kilojoules of energy are produced from the complete reaction of 18 g of calcium carbide?

93. Carbon suboxide,  $\text{C}_3\text{O}_2$ , is a linear molecule with the two oxygen atoms at the end and double bonds between each carbon and oxygen atom.

- Draw the Lewis structure for  $\text{C}_3\text{O}_2$ .
- State the type of hybridization of each carbon atom.
- Calculate the heat of reaction for the reaction of carbon suboxide with water to form malonic acid ( $\text{HO}_2\text{CCH}_2\text{CO}_2\text{H}$ ).  
Hint: Each end of malonic acid has a carbon double bonded to an oxygen and bonded to a hydroxide.

94. Calcium carbonate is insoluble in water. Yet, it dissolves in an acidic solution. Calculate the standard enthalpy, entropy, and Gibbs free energy change for the reaction between solid calcium carbonate and hydrochloric acid. What drives the reaction, the enthalpy change, or the entropy change?

95. When hydrazine is dissolved in water it acts like a base.

- Calculate the  $K_b$  for the overall reaction of hydrazine forming  $\text{N}_2\text{H}_6^{2+}$ .
- Calculate  $K_{a1}$  for  $\text{N}_2\text{H}_5^+$ .
- Calculate the concentration of hydrazine and both cations in a solution buffered at a pH of 8.5 for a solution that was made by dissolving 0.012 mol of hydrazine in 1 L of water.

96. Solid fuel in the booster rockets for spacecraft consists of aluminum powder as the fuel and ammonium perchlorate as the oxidizing agent.

If a rocket launch burns  $2.200 \times 10^3 \text{ kg}$  of aluminum, calculate the energy produced in joules. Calculate the volume of the gas produced assuming it was cooled back to 298 K at 1 atm. The standard enthalpy of formation of solid ammonium perchlorate is  $-295.3 \text{ kJ/mol}$ .

97. Two known compounds have the formula  $\text{H}_2\text{N}_2\text{O}_2$ . One of them is a weak acid and one is a weak base. The acid, called hyponitrous acid, has two  $\text{O}-\text{H}$  bonds. The base, called nitramide, has no  $\text{O}-\text{H}$  bonds. Draw Lewis structures for these compounds. Predict whether the acid is stronger or weaker than nitrous acid and whether the base is stronger or weaker than ammonia.

## Conceptual Problems

98. Explain why fine particles of activated charcoal can absorb more (as a filter) than large briquettes of charcoal.

99. The two major components of the atmosphere are the diatomic molecules of nitrogen and oxygen. Explain why pure nitrogen is used as a protective atmosphere in the laboratory and pure oxygen is much more reactive.

100. Explain why nitrogen can form compounds with many different oxidation numbers.

101. Describe how sodium dihydrogen phosphate can be used as a pH buffering agent.

102. Explain why  $\text{H}_2\text{S}$  has a different bond angle and is much more reactive than  $\text{H}_2\text{O}$ .

103. Explain why fluorine is found only with the oxidation state of  $-1$  or  $0$ , while the other halogens are found in compounds with other oxidation states.

104. Why do some substances burn in fluorine gas even if they do not burn in oxygen gas?

105. Explain why  $\text{SO}_2$  is used as a reducing agent but  $\text{SO}_3$  is not.

106. Explain why the interhalogen molecule  $\text{BrCl}_3$  exists but  $\text{ClBr}_3$  does not.

## Active Classroom Learning

## Questions for Group Work

Discuss these questions with the group and record your consensus answer.

107. Have each group member select a different element from this list: B, C, N, O, and F. Have all group members look up the following values for their elements: valence electron configuration, covalent atomic radius, effective nuclear charge, first ionization energy, and Pauling electronegativity. All members should compare the values for their elements with those of the group. Repeat with O, S, Se, Te, and Po. Account for the trends

you see by referring to quantum mechanical shells. Note and provide a tentative explanation for any exceptions to trends you observe.

108. Provide a detailed chemical description of your birthstone or favorite gem. If two members of the group share a birthstone, have one select another gem, so that no two group members work with the same gem. Is your gem a silicate? What type? Share your findings with your group. Does your group agree on which gem has the most interesting structure?

- 109.** As a group, create a single schematic drawing of a factory that uses the Haber-Bosch process and the Ostwald process to make  $\text{NH}_4\text{NO}_3$  fertilizer. The factory may only take in  $\text{N}_2(\text{g})$ ,  $\text{H}_2(\text{g})$ , and  $\text{O}_2(\text{g})$ . Pass your diagram around the group and have each group member add one step in the process. Where might the factory obtain  $\text{H}_2$ ?
- 110.** Ask each group member to work individually to write out two or three reactions from one section of the chapter. Replace the symbol for the element that is the topic of that section with a blank or an X. Take turns playing “identify the mystery element” as follows. One person shares their reactions (with the blanks) with the group. The person to the right of the person

sharing tries to identify the missing element. If that person can't, the group member to the right tries. Continue until either the element has been identified or all group members have had a chance. The next round starts with the person who was first to guess the element sharing reactions with the group. Continue until all have shared reactions, and all reactions have been correctly identified.

- 111.** Working individually, find a sentence in the chapter that uniquely describes a particular main-group compound. As in the previous question, take turns reading your sentences to the group saying “blank” in place of the name of the compound and giving group members a chance to identify the compound.

## Data Interpretation and Analysis

### Hydrogen Sulfide in Well Water

- 112.** Hydrogen sulfide ( $\text{H}_2\text{S}$ ) smells like rotten eggs, and its smell can be detected at concentrations as low as 0.02 ppm. Well water, which is drawn from underground depths of 30–250 meters (100–800 feet), is commonly contaminated with hydrogen sulfide. The contamination arises from bacterial decomposition of sulfur-containing organic and inorganic matter present in the oxygen-deficient underground environment. Some  $\text{H}_2\text{S}$  gas dissolves in the water that is pumped for drinking supplies, where it is detected by taste at concentrations as low as 0.05 ppm. Municipalities remove  $\text{H}_2\text{S}$  to improve water taste and to prevent the accumulation of toxic  $\text{H}_2\text{S}$  gas within the system.

Table a lists hydrogen sulfide solubility in water when the partial pressure of hydrogen sulfide is 1.00 atm. Table b lists solubility product constant data for common metal sulfides.

Temperature, °C	Mole fraction of hydrogen sulfide in water
15	$2.335 \times 10^{-3}$
20	$2.075 \times 10^{-3}$
25	$1.85 \times 10^{-3}$
30	$1.66 \times 10^{-3}$
35	$1.51 \times 10^{-3}$

**TABLE a** Hydrogen Sulfide Solubility in Water (Partial Pressure of Hydrogen Sulfide = 1.00 atm) [Source: *CRC Handbook of Chemistry and Physics*, 85th Edition]

Sulfide	$K_{\text{sp}}$ (at 25 °C)
copper(II) sulfide	$6 \times 10^{-37}$
iron(II) sulfide	$6 \times 10^{-19}$
lead(II) sulfide	$9.04 \times 10^{-29}$
zinc sulfide	$2.0 \times 10^{-25}$

**TABLE b** Solubility Product Constant Data of Common Metal Sulfides

Use the information provided in the tables to answer the following questions:

- What can you conclude about the temperature dependence of  $\text{H}_2\text{S}$  solubility in water from the data in Table a?
- Suppose that water analysis indicates that your well's water contains 1.8 mg  $\text{H}_2\text{S}$  per liter of well water. Using Henry's law (Chapter 13) and the data in Table a, calculate the partial pressure of  $\text{H}_2\text{S}$ , in atm, that exists above your well water at 30 °C. (Assume the well water is in a closed container.)
- Air containing  $\text{H}_2\text{S}$  at 20 ppm (by volume) and below is considered safe to breathe. Is the air above the solution in part b safe to breathe? (The total pressure is 1.00 atm.)
- A water technician recommends that you treat your well water with hydrogen peroxide,  $\text{H}_2\text{O}_2$ , in order to convert  $\text{H}_2\text{S}$  to sulfate (which does not have an offensive odor or taste), according to the following unbalanced reaction:

What volume of a 3.0% by mass solution of hydrogen peroxide is required to treat 955 liters of your well water? (Assume that no other species are present to react with the  $\text{H}_2\text{O}_2$  and that the density of the hydrogen peroxide solution is 1.0 g/mL.)

- Hydrogen sulfide is a weak diprotic acid that ionizes in water to form hydrogen sulfide ( $\text{HS}^-$ ) and sulfide ( $\text{S}^{2-}$ ). Sulfide dissolved in water can be precipitated as an insoluble metal sulfide, according to the following reaction:

Which metal in Table b most effectively removes hydrogen sulfide from water?

- What volume, in mL, of a 0.500 M solution of the metal ion you chose in part e is required to remove the hydrogen sulfide present in 955 liters of your well water (from part b)?
- What mass, in grams, of the metal sulfide (from part f) precipitates? (Assume 100% yield.)

## Answers to Conceptual Connections

### Carbide Formulas

- 23.1**  $\text{K}_2\text{C}_2$

### Carbonate Solubility

- 23.2** (a) Since the carbonate ion is basic, adding acid to the solution drives the dissolution reaction to the right because the acid reacts with the carbonate ion. (Recall from Section 17.5 that the solubility of an ionic compound with a basic anion increases with increasing acidity.)

# Metals and Metallurgy

The metals are not presented immediately to the hand of man . . . but they are, for the most part, buried in darkness, in the bowels of the earth, where they are so much disguised, by combination and mixture with other substances, that they often appear entirely unlike themselves.

—WILLIAM HENRY (1774–1836)

**KEY LEARNING OUTCOMES 1121**

If you look around your house, classroom, or neighborhood, much of what you see is made of metal or at least has some metal parts. Can you imagine life without metals? Without metals, we would have no skyscrapers, which need the rigid framework of steel beams; no automobiles, which need metal engines and bodies; and no electricity, which needs copper and aluminum wire for transmission. Metallurgy is both a very old and a very new science. We find the roots of metallurgy in the distant past, when our primitive ancestors began to search for and process metals. Of the three prehistoric ages of humankind—the Stone Age, the Bronze Age, and the Iron Age—two are named after our quest for metals. But we do not commonly find metals as elements on Earth; instead we find them in compounds, often scattered within other compounds. The mining, separating, and refining of the vast array of metals is a fairly new science. Many modern metals were not available even as recently as 200 years ago. In the middle of the nineteenth century, gold was cheaper than aluminum because aluminum was so difficult to refine, and titanium, which is important in the aerospace industry, could not even be manufactured. In this chapter, we cover the area of chemistry known as metallurgy.

▲ Oil is sometimes contaminated with vanadium, which is thought to have been the metal used for oxygen transport by some ancient life-forms on Earth.

## 24.1 Vanadium: A Problem and an Opportunity

Companies often seek help from university researchers to solve specific technical problems. In one case, representatives of an oil company sought help from a university's chemistry and engineering departments to address vanadium contamination in oil. Because vanadium is toxic, the U.S. government regulates the quantity of vanadium

▲ Vanadium is a soft white metal.

that can be emitted by industrial processes, and oil companies have to figure out environmentally acceptable ways to remove the vanadium from the oil.

Vanadium is a rare element, making up only about 0.015% of Earth's crust (by mass). It is a soft white metal with high ductility and malleability, which means that it can be easily drawn into narrow wires or rolled into thin sheets. Because of the high reactivity of pure vanadium, this element occurs naturally within compounds (not in its elemental form). However, vanadium compounds are not normally found in the rocks or soils near oil fields, so why does this rare, reactive metal occur in oil? The answer lies in the biology of ancient life-forms. Most modern animals use iron in hemoglobin to transport oxygen through their bloodstreams (see Section 15.1), and a few (such as lobsters) use copper for this function. It appears that some extinct animals used vanadium. Even today, one group of simple marine organisms, the tunicates or sea squirts, are believed to employ vanadium compounds for oxygen transport. The source of vanadium in some crude oil may be the very animals from which the oil was formed.

During refining, crude oil is heated to carry out the reactions that form the different petroleum products. If some of the vanadium-containing oil burns during heating, the vanadium forms vanadate compounds, ionic compounds with vanadium oxide polyatomic ions such as  $\text{VO}_4^{3-}$  and  $\text{VO}_3^-$ . These compounds, which have low melting points, can dissolve the protective oxide coatings on stainless steel containers, causing the steel to corrode and ruining the containers in which the oil is stored. If the vanadium compounds are not removed from the oil before storage, the customer inherits the problem. In addition, vanadium and many of its compounds are toxic, so oil companies cannot simply dump the extracted vanadium compounds into the environment.

The presence of vanadium in crude oil may, however, turn out to be profitable for the oil companies. If vanadium can be economically recovered from oil, then oil could become a major source of vanadium, a valuable metal with several important industrial uses, including the production of iron alloys and sulfuric acid.

The recovery of vanadium from oil involves metallurgy, the topic of this chapter. **Metallurgy** includes all the processes associated with mining, separating, and refining metals and the subsequent production of pure metals and mixtures of metals called *alloys* (which we define in Section 24.4). In this chapter, we explore the general properties and natural distribution of metals; several different categories of metallurgical processes, including pyrometallurgy, hydrometallurgy, electrometallurgy, and powder metallurgy; the structures and alloys formed by metals; and the metallic products and applications for several selected materials.

## 24.2 The General Properties and Natural Distribution of Metals

Metals share several common properties. All metals are opaque (we cannot see through them), and they are good conductors of heat and electricity. They generally have high malleability (the capacity to be bent or hammered into desired forms) and ductility (the capacity to be drawn into wires). We can explain these properties by the bonding theories that we have already examined for metals: the electron sea model and band theory. In the electron sea model, discussed in Section 9.11, each metal atom within a metal sample donates one or more electrons to an *electron sea*, which flows within the metal. In band theory, discussed in Section 12.8, the atomic orbitals of the metal atoms are combined, forming *bands* that are delocalized over the entire crystalline solid; electrons move freely within these bands. The mobile electrons in both of these models endow metals with many of their shared properties.

Each metal, however, is also unique, and even their shared properties may vary within a range. For example, some metals, such as copper, silver, and aluminum, have much higher thermal and electrical conductivities than do other metals. Table 24.1 lists the thermal conductivity and electrical resistivity (a low resistivity corresponds to a high conductivity) of a few metals. Notice that both properties can vary by factors of 10 or more. Most metals are very strong, malleable, and ductile. But lead is a

**TABLE 24.1 Thermal Conductivity and Electrical Resistivity of Several Metals**

Metal	Thermal Conductivity (W/cm · K)	Electrical Resistivity ( $\mu\Omega \cdot \text{cm}$ )
Ag, silver	4.29	1.59
Cu, copper	4.01	1.67
Fe, iron	0.804	9.71
V, vanadium	0.307	24.8

soft, weak metal, and chromium is a brittle metal that will not bend without breaking. When we think about the shared properties of metals, we must allow for a range of properties as well as some unique ones.

Over 75% of the elements in the periodic table are metals, yet metals make up only about 25% of the mass of Earth's crust (see Figure 23.2 for the composition of Earth's crust). Earth's core is thought to be composed of iron and nickel, but because the core is so far from the surface, these metals are not accessible. The most abundant metal on Earth is aluminum, a main-group metal. Several alkali and alkaline earth metals (calcium, sodium, potassium, and magnesium) make up more than 1% of Earth's crust. Iron, which makes up about 5% of the crust, is the only transition metal that accounts for more than 0.1% of the crust. Of the first-row transition metals, titanium, chromium, iron, nickel, copper, and zinc are all plentiful enough to be important industrial materials.

Only a few metals occur naturally as elements, including nickel, copper, palladium, silver, platinum, and gold. Because of their low reactivity, these metals are often called the *noble metals*. They are usually concentrated within mountainous or volcanic regions in small, isolated veins within a rock matrix.

Most of the rest of the metals occur naturally in positive oxidation states within mineral deposits. **Minerals** (as we saw in Chapter 23) are homogeneous, naturally occurring, crystalline inorganic solids. A rock that contains a high concentration of a specific mineral is called an **ore**. Metallurgical processes separate useful minerals from other, unusable material in the ore.

The main sources for the alkali metals are chloride minerals, such as halite (sodium chloride) and sylvite (potassium chloride). Halite occurs in large deposits in sites that were once ancient oceans, or it can be precipitated by evaporating ocean water. The main source for some other metals are oxide minerals, such as hematite ( $\text{Fe}_2\text{O}_3$ ), rutile ( $\text{TiO}_2$ ), and cassiterite ( $\text{SnO}_2$ ). The ores containing these minerals are unevenly distributed throughout Earth. For example, North America has large deposits of hematite but no substantial deposits of cassiterite. Sulfides are the most important minerals for many metals, such as galena ( $\text{PbS}$ ), cinnabar ( $\text{HgS}$ ), sphalerite ( $\text{ZnS}$ ), and molybdenite ( $\text{MoS}_2$ ).

The main mineral source for some other metals can be complex. For example, the primary *mineral* sources for vanadium are vanadinite [ $\text{Pb}_5(\text{VO}_4)_3\text{Cl}$ ] and carnotite [ $\text{K}_2(\text{UO}_2)_2(\text{VO}_4)_2 \cdot 3\text{H}_2\text{O}$ ], which is also a main mineral source for uranium. Vanadium, as we have seen, is also found in crude oil. No specific minerals contain the metal radium. Yet radium sometimes substitutes for uranium within uranium-containing minerals. The small amount of radium that replaces uranium in carnotite is the major source of radium. Tantalum and niobium, named after the Greek god Tantalus and his daughter Niobe, always occur together in mixed deposits of columbite [ $\text{Fe}(\text{NbO}_3)_2$ ] and tantalite [ $\text{Fe}(\text{TaO}_3)_2$ ]. The minerals are mined together, and the elements are later separated by recrystallization (see Section 13.4).

▲ Gold is one of the few metals that can be found as an element in nature, often in veins like the one shown here.

▲ Most NaCl salt is produced by trapping ocean water in shallow basins and letting the water evaporate.

## 24.3 Metallurgical Processes

Mined ores are first physically *separated* into their metal-containing and nonmetal-containing components. Then, the elemental metal is extracted from the compounds in which it is found, a process called **extractive metallurgy**. In this section, we look at several metallurgical processes, including pyrometallurgy, hydrometallurgy, electrometallurgy, and powder metallurgy. After separation and extraction, the metal is **refined**; refining is the process in which the crude material is purified.

### Separation

The first step in processing metal-containing ores is crushing the ore into smaller particles. The particles that contain the minerals are then separated from the undesired material, called **gangue** (pronounced “gang”), usually by physical methods. For example, in some cases, a cyclone of wind is used to lift the gangue away from the metal-containing particles, as shown in Figure 24.1 ▼. If the minerals are magnetic, magnets can separate the minerals. Electrostatic forces can also separate polar minerals from nonpolar gangue.

Sometimes solutions separate the minerals from the gangue, as shown in Figure 24.2 ▼. A *wetting agent* (or detergent) that preferentially attaches to the mineral surfaces is added to a mixture of the mined material and water. Air is blown through the mixture, forming bubbles and a froth. Because they are attached to the wetting agent, the minerals segregate into the froth, where they can be collected. The gangue separates into the solution.

▲ **FIGURE 24.1 Separation by Air** An industrial cyclone separates the crushed light particles of gangue from the heavier metal-bearing particles.

▲ **FIGURE 24.2 Separation by Using a Solution** A wetting agent helps the minerals attach to the froth in a bubbled solution. The minerals in the froth are separated from the gangue remaining in the solution.

### Pyrometallurgy

Once the mineral is separated from the gangue, the elemental metal is extracted from the mineral. Several different techniques can achieve this separation. In **pyrometallurgy**, heat is employed to extract a metal from its mineral. Different heating conditions have different effects on the mineral.

Pyrometallurgy contains the Greek stem *pyro*, meaning fire or heat.

**Calcination** is the heating of an ore in order to decompose it and drive off a volatile product. For example, when carbonate minerals are heated, carbon dioxide is driven off, as shown in these examples:

Many minerals occur in a hydrated form (that is, they contain water). Calcination can also drive off water:

Heating that causes a chemical reaction between the furnace atmosphere (the gases in the furnace) and the mineral is called **roasting**. Roasting is particularly important in processing sulfide ores. The ores are heated in the presence of oxygen, converting the sulfide into an oxide and emitting sulfur dioxide. For example, the roasting of lead(II) sulfide occurs by the reaction:

In some cases, especially with the less active metals such as mercury, roasting the sulfide produces the pure metal:

When roasting forms a liquid product, which makes separation easier, it is called **smelting**. Consider, for example, the smelting of zinc oxide:

The gaseous carbon monoxide separates from the liquid zinc, allowing the metal to be readily recovered. In some cases, a flux must be added to the mixture during smelting to help separate the two materials. The **flux** is a material that will react with the gangue to form a substance with a low melting point. For example, oxides of silicon within gangue can be liquefied by reaction with calcium carbonate according to the reaction:

The waste liquid solution that forms from the flux and gangue is usually a silicate material called a **slag**. The liquid metal and the liquid slag have different densities, and therefore separate. Holes tapped at different heights into the side of the container holding the liquid metal and slag allow the more dense liquid to flow out of the lower tap holes and the less dense liquid to flow out of the higher tap holes.

## Hydrometallurgy

The use of an aqueous solution to extract metals from their ores is **hydrometallurgy**. A hydrometallurgy process is used to obtain gold. Gold occurs in its elemental state, but often as very small particles mixed with other substances. The gold can be separated out of the mixture by selectively dissolving it into solution, a process called **leaching**. In this process, solid gold reacts with sodium cyanide to form a soluble gold complex:

The impurities are filtered out of the solution, and the gold is reduced back to elemental gold with a reactive metal such as zinc:

Leaching has been practiced for many years and often results in the contamination of streams and rivers with cyanide. New alternatives using the thiosulfate ion ( $\text{S}_2\text{O}_3^{2-}$ ) are being investigated to replace leaching.

Different acid, base, and salt solutions are sometimes used to selectively separate out metal-bearing minerals. For example, sulfuric acid is used to separate the copper and

Hydrated compounds are discussed in Section 3.5.

iron from the mineral chalcopyrite,  $\text{CuFeS}_2$ , and a sodium chloride solution is used to separate the lead from the insoluble mineral anglesite,  $\text{PbSO}_4$ :

Hydrometallurgy is often more economical than pyrometallurgy because of the high energy costs associated with the elevated temperatures needed for calcination and roasting.

## Electrometallurgy

See Section 19.8 for a description of electrolysis.

In **electrometallurgy**, electrolysis is used to produce metals from their compounds. For example, the *Hall process* is an electrometallurgical process crucial to aluminum production. The main source of aluminum is bauxite,  $\text{Al}_2\text{O}_3 \cdot n \text{H}_2\text{O}$ . A hydrometallurgical process, the *Bayer process*, separates bauxite from the iron and silicon dioxide with which it is usually found. In this process, the bauxite is heated in a concentrated aqueous  $\text{NaOH}$  solution under high pressure. The aluminum oxide dissolves, leaving the other oxides behind in solid form:

The basic aluminum solution is separated from the oxide solids, and then the aluminum oxide is precipitated out of solution by neutralizing it (recall the pH dependence of the solubility of  $\text{Al}(\text{OH})_3$  from Section 17.8). Calcination of the precipitate at temperatures greater than  $1000^\circ\text{C}$  yields anhydrous alumina ( $\text{Al}_2\text{O}_3$ ). Electrolysis is then used to reduce the aluminum out of the aluminum oxide. Because  $\text{Al}_2\text{O}_3$  melts at such a high temperature (greater than  $2000^\circ\text{C}$ ), however, the electrolysis is not carried out on molten  $\text{Al}_2\text{O}_3$ . Instead, in the Hall process the  $\text{Al}_2\text{O}_3$  is dissolved into molten cryolite ( $\text{Na}_3\text{AlF}_6$ ), and graphite rods are used as electrodes to carry out the electrolysis in the liquid mixture (Figure 24.3▼). The carbon that composes the graphite electrodes is oxidized by the dissolved oxygen ions in the molten salt and converted to carbon dioxide. The aluminum ions dissolved in the molten salt reduce to molten aluminum, which sinks down to the bottom of the cell and is removed:

► **FIGURE 24.3 The Hall Process** The Hall process produces aluminum metal by reducing the aluminum ions in alumina. Graphite electrodes act as reducing agents. Dissolved oxygen ions in the molten cryolite oxidize the carbon in the graphite electrodes to form carbon dioxide.

Another important example of metallurgy is the refinement of copper. The most abundant copper source is the mineral chalcopyrite,  $\text{CuFeS}_2$ . First, the chalcopyrite is converted to  $\text{CuS}$  by roasting. During this process, the iron also forms oxides and sulfides. Silica is added to form an iron silicate slag, which is then removed. The remaining copper(II) sulfide reacts with oxygen to form sulfur dioxide gas and copper metal, but the metal is not very pure. Electrolysis is employed to refine the copper.

◀ **FIGURE 24.4 Copper Electrolysis**

**Cell** Copper is refined by electrolysis. The impure copper is oxidized at the anode and then reduced to form pure metal on the cathode. Many precious metals collect in the sludge at the bottom of the electrolysis cell.

In the electrolysis cell used to refine copper, both the anode and the cathode are made of copper (Figure 24.4▲). The anode is the impure copper (that needs to be refined), and the cathode is a thin sheet of pure copper. As the current flows through the cell, the copper from the anode oxidizes and dissolves in a copper sulfate solution. It then plates out as pure copper on the cathode. The impurities in the copper anode separate from the copper during electrolysis because, even though the more active metals also oxidize from the anode, they stay in solution and do not plate out on the cathode. The less active metals do not oxidize at all and simply fall to the bottom of the cell as the copper is dissolved from the anode. The sludge at the bottom of the electrolysis cell contains many precious metals, including gold and silver. About one-quarter of the silver produced in the United States is from the impurities recovered from the refinement of copper.

## Powder Metallurgy

**Powder metallurgy**, first developed in the 1920s, is used to make metallic components from powdered metal. In powder metallurgy, micron-sized metal particles are pressed together under high pressures to form the desired component. The component is then heated (*sintered*). The sintering process occurs below the melting point of the powder but at a temperature high enough to fuse the metal particles together, strengthening the metal and increasing its density.

Originally, iron powder from mill scrap was used in powder metallurgy. The scrap was primarily iron oxide that would fall off the steel as it was being milled. The iron oxide dust was heated in a hydrogen atmosphere to reduce the oxide to iron particles. Manufacturers called the powdered metal *iron sponge* because numerous holes form in the particles when the oxygen escapes.

In the 1960s, the A. O. Smith Company in the United States introduced a new method for the development of powdered metal, called water atomization. In this method, the pure metal is melted and a small stream of the liquid is allowed to flow from the bottom of the container of molten metal. A high-pressure blast of cold water hits the stream of metal, breaking it into small droplets that quickly solidify. Powdered metal particles made in this way are smoother and more dense than the sponge powder particles from oxide scrap. In addition to powdered iron metal, many copper, bronze, carbide, and brass parts are made with powder metallurgical processes.

Powder metallurgy offers several advantages over traditional casting or milling of metal. For example, waste is almost eliminated because the part can be pressed directly into the desired shape. Intricate teeth on gears and multiple holes can be designed into the press, and therefore do not have to be machined after production. Making cast metal

▲ These metal products were all made by powder metallurgy.

objects from metals with high melting points, such as molybdenum and tungsten, can be difficult because of the high temperatures necessary to melt the metal. Using the powder avoids the need for high temperatures.

## 24.4 Metal Structures and Alloys

We can describe the structures of metals as the closest packing of spheres, first discussed in Section 12.3. Elemental metals generally crystallize in one of the basic types of crystal lattices, including face-centered cubic, body-centered cubic, and hexagonal closest packed. The crystal structure of a metal may change, however, as a function of temperature and pressure. Table 24.2 lists the crystal structures for the 3*d* transition metals.

TABLE 24.2 The Crystal Structures of the 3 <i>d</i> Elements		
Metal	Natural Crystal Structure at Room Temperature and Atmospheric Pressure	Other Crystal Structures at Different Temperatures and Pressures
Sc	Hexagonal closest packed	Face-centered cubic, body-centered cubic
Ti	Hexagonal closest packed	Body-centered cubic above 882 °C
V	Body-centered cubic	
Cr	Body-centered cubic	Hexagonal closest packed
Mn	Alpha complex body-centered cubic form	Beta simple cubic form above 727 °C Face-centered cubic above 1095 °C Body-centered cubic above 1133 °C
Fe	Body-centered cubic	Face-centered cubic above 909 °C Body-centered cubic above 1403 °C
Co	Hexagonal closest packed	Face-centered cubic above 420 °C
Ni	Face-centered cubic	
Cu	Face-centered cubic	
Zn	Hexagonal closest packed	

### Alloys

An **alloy** is a metallic material that contains more than one element. Some alloys are simply solid solutions, whereas others are specific compounds with definite ratios of the component elements. Alloys have metallic properties, but they can consist of either two or more metals or a metal and a nonmetal. We broadly classify alloys as substitutional or interstitial. In a **substitutional alloy**, one metal atom substitutes for another in the crystal structure. The crystal structure may either stay the same upon the substitution, or it may change to accommodate the differences between the atoms. In an **interstitial alloy**, small, usually nonmetallic atoms fit in between the metallic atoms of a crystal. The alloy maintains its metallic properties with these interstitial atoms in the structure.

### Substitutional Alloys

For two metals to form a substitutional alloy, the radii of the two metal atoms must be similar, usually within 15% of each other. For example, the atomic radii of copper and nickel are both 135 pm, and both of the elements form the face-centered cubic structure. Therefore, either metal can easily replace the other in the metal crystal structure.

▲ Copper crystallizes in the face-centered structure shown here.

▲ In a nickel and copper alloy, nickel atoms substitute for some of the copper atoms.

Figure 24.5 is a phase diagram for a copper and nickel alloy. This phase diagram, called a *binary* phase diagram, is different from the diagrams that we discussed in Section 11.8, which show the phases of a pure substance at different pressures and temperatures. This diagram shows the different phases for a mixture at different *compositions* and temperatures. The *x*-axis indicates the composition (in this case, the mole percent of nickel in the alloy, with the left side representing pure copper and the right side representing pure nickel). The *y*-axis indicates the temperature.

Pure copper melts at 1084 °C, as indicated by the change from solid to liquid at 0% nickel. Pure nickel melts at 1455 °C, as indicated by the change from solid to liquid at 100% nickel. The area on the diagram above the line connecting the melting points of copper and nickel represents a liquid solution of the two metals. The area below that line represents a solid solution of the two metals. Any ratios of copper and nickel can form the face-centered cubic structure.

▲ **FIGURE 24.5 Cu–Ni Phase Diagram** Because copper and nickel have similar crystal structures and similar size, together they can form a solid solution. A solution forms at all compositions from pure copper to pure nickel.

### Guidelines for...

Interpreting a Binary Phase Diagram	<b>Example 24.1</b> <b>Determining Alloy Compositions from a Phase Diagram</b> Determine the composition and phase present at point A on Figure 24.5.	<b>Example 24.2</b> <b>Determining Alloy Compositions from a Phase Diagram</b> Determine the composition and phase present at point B on Figure 24.5.
Locate the temperature and composition of the alloy on the binary phase diagram in Figure 24.5.	Point A represents 30 mol % Ni at 1300 °C.	Point B represents 75 mol % Ni at 1100 °C.
Identify the phase.	The point is above the melting point line, so the phase is liquid.	The point is below the melting point line, so the phase is solid.
Identify the amount of copper and nickel in the phase.	This liquid phase is made up of 30 mol % Ni, so it is 70 mol % Cu.	This solid phase is made up of 75 mol % Ni, so it is 25 mol % Cu.
	<b>FOR PRACTICE 24.1</b> Determine the composition and phase present at point C on Figure 24.5.	<b>FOR PRACTICE 24.2</b> Determine the composition and phase present at point D on Figure 24.5.

The phase diagrams of some alloys are more complex. Consider the phase diagram for chromium and vanadium in Figure 24.6, on the next page. Both Cr and V form the body-centered cubic crystal, and the atoms are similar in size. Yet this phase diagram reveals an important difference between this alloy and the Cu and Ni alloy:

► **FIGURE 24.6 Cr–V Phase Diagram** In a binary phase diagram of two metals that form a solid solution, an intermediate composition can have either the highest or lowest melting point. In the chromium and vanadium phase diagram an intermediate composition has the lowest melting point.

the melting temperature does not vary in a uniform way from the lower melting point of Cr to the higher melting point of V. Instead we see that the alloys with intermediate compositions melt at lower temperatures than either pure metal. The lowest melting point is 1750 °C at a composition of 30 mol% vanadium. Solid compositions that melt at temperatures lower than either of the pure metals, as well as compositions that melt at temperatures higher than either of the two metals, are common in these types of alloys.

### Alloys with Limited Solubility

Some alloys are composed of metals that each have different crystal structures. For example, nickel crystallizes in the face-centered cubic structure and chromium in the

body-centered cubic structure. Because of their different structures, these two metals do not form a miscible solid solution at all compositions. At some intermediate composition, the structure has to change from that of one of the metals to that of the other. Figure 24.7 ◀ is the nickel and chromium phase diagram from 700 °C to 1900 °C. Notice that the diagram has two different solid phases: face-centered cubic and body-centered cubic. From pure nickel (0 mol % chromium) to about 40–50 mol % chromium, the structure is face-centered cubic. In this structure, Cr atoms substitute for Ni atoms in the face-centered cubic structure of nickel. However, beyond a certain percentage of chromium (which depends on temperature), that structure is no longer stable. At 700 °C about 40 mol% Cr can fit in the crystal, and at 1200 °C about 50 mol % Cr can fit in. Adding additional Cr beyond these points results in a different phase.

At the other end of the diagram (nearly pure chromium) and at 700 °C, only a small amount of nickel can be substituted into the body-centered cubic structure of the chromium. As the temperature rises to 1300 °C, however, about 20 mol % nickel can be accommodated into the chromium structure. The region in between the two phases is called a **two-phase region**. At these compositions, the two phases (nickel-rich face-centered cubic and chromium-rich body-centered cubic)

exist together. The amount of each phase depends upon the composition of the alloy.

We can determine the composition and relative amounts of the two different phases that coexist in a two-phase region from a phase diagram. Point A on Figure 24.7 in the Cr–Ni phase diagram represents 50% composition at 700 °C, and both phases are present. Some of the Cr atoms have substituted into the nickel-rich face-centered cubic structure, but there is too much Cr to all fit into the crystal. The leftover Cr atoms form the chromium-rich body-centered cubic structure with a small number of Ni atoms in the crystal.

▲ **FIGURE 24.7 Cr–Ni Phase Diagram** Because chromium and nickel form solids with crystal structures that differ from each other, an alloy mixture of the two metals does not form a solid solution at all compositions. A two-phase region exists at compositions between the possible compositions of the two different structures. In the two-phase region, both crystal structures coexist in equilibrium.

The two crystals that exist at point A are (1) the nickel-rich face-centered cubic structure with 40 mol % Cr; and (2) the chromium-rich body-centered cubic structure with 5 mol % Ni. The 50% composition on the phase diagram has just slightly more Cr atoms than can fit into the nickel structure. Thus, most of the crystals in the two-phase region are the nickel-rich face-centered cubic structure with only a small amount of the chromium-rich body-centered cubic structure, as determined by a method called the *lever rule*. The **lever rule** states that in a two-phase region, whichever phase is closer to the composition of the alloy is the more abundant phase. In this example, the 50 mol % Cr composition on the phase diagram is closer to the 40 mol % Cr composition of the nickel-rich face-centered cubic phase than the 95 mol % Cr composition of the chromium-rich body-centered cubic phase, so more face-centered cubic crystals are present than body-centered cubic crystals.

### Guidelines for...

Interpreting the Phases and Compositions in a Binary Phase Diagram as Described by the Lever Rule	Example 24.3	Example 24.4
	Alloy Compositions in a Solid Solution with Limited Solubility	Alloy Compositions in a Solid Solution with Limited Solubility
	Determine the composition, relative amounts, and phases present at point B on Figure 24.7.	Determine the composition, relative amounts, and phases present at point C on Figure 24.7.
	Point B represents 80 mol % Cr at 1100 °C.	Point C represents 20 mol % Cr at 1100 °C.
	Point B is located in the two-phase region, consisting of the nickel-rich face-centered cubic structure and the chromium-rich body-centered cubic structure.	Point C is located in the one-phase region of the nickel-rich face-centered cubic structure.
Locate the temperature and composition of the alloy on the binary phase diagram.		
Identify the phases.		
Identify the amount of Ni and Cr in the phases.	The nickel-rich face-centered cubic structure has 45 mol % Cr and 55 mol % Ni, and the chromium-rich body-centered cubic structure has 90 mol % Cr and 10 mol % Ni.	The nickel-rich face-centered cubic structure at this point has 20 mol % Cr and 80 mol % Ni.
Identify the relative amounts of the phases.	At a composition of 80 mol % Cr, the composition is closer to the Cr-rich body-centered cubic phase, so there is more of this phase than there is of the Ni-rich face-centered cubic phase.	There is only one phase. It is 100 mol % of the Ni face-centered cubic phase.
	<b>FOR PRACTICE 24.3</b> Determine the composition, relative amounts, and phases present at point D on Figure 24.7.	<b>FOR PRACTICE 24.4</b> Determine the composition, relative amounts, and phases present at point E on Figure 24.7.

## Interstitial Alloys

Recall that in contrast to substitutional alloys, where one metal atom substitutes for another in the lattice, interstitial alloys contain atoms of one kind that fit into the holes, or interstitial sites, of the crystal structure of the other metal. In metals with the interstitial elements hydrogen, boron, nitrogen, or carbon, the alloy that results retains its metallic properties.

Octahedral hole

▲ **FIGURE 24.8 Octahedral Holes in Closest-Packed Crystals**

Octahedral holes are found in a closest-packed structure. In the closest-packed structure, the octahedral hole is surrounded by six atoms.

Closest-packed crystal structures have two different types of holes between the atoms in the crystalline lattice. An **octahedral hole**, shown in Figure 24.8 ◀, exists in the middle of six atoms on two adjacent closest-packed sheets of metal atoms. The hole is located directly above the center of three closest-packed metal atoms in one sheet and below the three metal atoms in the adjacent sheet. This configuration of metal atoms is identical to a regular octahedral configuration that consists of four atoms in a square plane with one atom above and one atom below the square.

We can calculate the size of an octahedral hole by determining the size of a hole on a square of four atoms in a plane (Figure 24.9 ◀). Any of the four corners of the square is the  $90^\circ$  angle of a right triangle formed from the adjacent two sides and the diagonal line that runs across the center of the square. According to the Pythagorean theorem, the length of the diagonal line ( $c$ ) is related to the length of the sides ( $a$  and  $b$ ) as follows:

$$c^2 = a^2 + b^2 \quad [24.1]$$

If we let  $r_m$  equal the metal atom radius, the lengths of the sides are  $2r_m$ . We can then substitute  $2r_m$  for both  $a$  and  $b$ :

$$\begin{aligned} c^2 &= (2r_m)^2 + (2r_m)^2 \\ c^2 &= 8r_m^2 \\ c &= 2.828r_m \end{aligned} \quad [24.2]$$

We can see from Figure 24.9 that the length of the diagonal ( $c$ ) is twice the radius of the atoms plus twice the radius of the hole:

$$c = 2r_m + 2r_{\text{hole}} \quad [24.3]$$

Combining Equations 24.2 and 24.3, we get the important result:

$$\begin{aligned} 2.828r_m &= 2r_m + 2r_{\text{hole}} \\ 0.828r_m &= 2r_{\text{hole}} \\ r_{\text{hole}} &= 0.414r_m \end{aligned} \quad [24.4]$$

The octahedral hole, surrounded by six metal atoms, has a radius that is 41.4% of the metal atom radius. By contrast, the hole in the center of a cube in the *simple cubic* structure has a radius that is 73% of the metal atom radius. The *number* of octahedral holes in a closest-packed structure is equal to the number of metal atoms.

The second type of interstitial hole in a closest-packed structure is a **tetrahedral hole** (first introduced in Section 12.5), which forms directly above the center point of three closest-packed metal atoms in one plane and below a fourth metal atom located directly above the center point in the adjacent plane (Figure 24.10 ▼). The number of tetrahedral holes in a closest-packed structure is equal to *twice* the number of metal atoms. Because this hole is surrounded by only four atoms, the hole is smaller than the octahedral interstitial hole. We can apply geometric considerations similar to those used previously for the octahedral hole to determine that the tetrahedral hole has a radius that is 23% of the metal atom radius.

Tetrahedral hole

▲ **FIGURE 24.10 A Tetrahedral Hole in a Closest-Packed Crystal** Tetrahedral holes are found in a closest-packed structure. The tetrahedral hole is surrounded by four of the atoms in the closest-packed structure.

▲ **FIGURE 24.9 A Different View of an Octahedral Hole** An octahedral hole can be viewed as the area in the middle of a square plane of atoms, with one additional atom above the hole and one additional atom below the hole, accounting for the six close atoms. The diagonal of the square is equal to the radius of the two corner atoms plus the diameter of the hole. The Pythagorean theorem relates the length of the diagonal to the lengths of the sides of the square.

**TABLE 24.3** Formulas of Several Interstitial Alloys

Compound	Type of Interstitial Hole Occupied	Fraction of Holes Occupied	Formula
Titanium carbide	Octahedral	All	TiC
Molybdenum nitride	Octahedral	One-half	Mo <sub>2</sub> N
Tungsten nitride	Octahedral	One-half	W <sub>2</sub> N
Manganese nitride	Octahedral	One-quarter	Mn <sub>4</sub> N
Palladium hydride	Tetrahedral	One-quarter	Pd <sub>2</sub> H
Titanium hydride	Tetrahedral	All	TiH <sub>2</sub>

Interstitial alloys form when small nonmetallic atoms fit within the octahedral or tetrahedral holes of the crystalline lattice of the metal. The formulas for these alloys depend both on the type of hole occupied by the nonmetallic atom and on the fraction of holes occupied. For example, titanium and carbon form an alloy with a closest-packed structure for titanium in which all of the octahedral holes are filled with carbon atoms. Since the number of octahedral holes in a closest-packed structure is equal to the number of atoms in the structure, the ratio of carbon atoms to titanium atoms is 1:1 and the corresponding formula is TiC. In the compound formed between molybdenum and nitrogen, by contrast, only one-half of the octahedral holes in the closest-packed structure of Mo are filled with N. Therefore, the formula for this compound is Mo<sub>2</sub>N. Table 24.3 lists the formulas and relative number of holes filled for several different interstitial alloys.

**Interstitial Alloys** An interstitial alloy contains a nonmetal (X) that occupies one-eighth of the tetrahedral holes of the closest-packed structure of the metal (M). What is its formula?

## 24.5 Sources, Properties, and Products of Some of the 3d Transition Metals

In this section we examine major sources, interesting properties, and important products of several of the 3d transition metals, specifically, titanium, chromium, manganese, cobalt, copper, nickel, and zinc. We also survey the different metallurgical methods used to separate and refine them. The variety of uses for these metals reflects their varied structures and properties.

### Titanium

Titanium is the ninth most abundant element in Earth's crust and the fourth most abundant metal. Titanium was discovered in 1791, but the pure metal was not isolated until 1910. The principal minerals of titanium are rutile (TiO<sub>2</sub>) and ilmenite (FeTiO<sub>3</sub>). Another source of titanium is coal ash, the residue from burned coal. Black shiny ilmenite is found in granite deposits along the North Atlantic coast, often within silica sand. The mineral ilmenite is magnetic due to the presence of Fe<sup>2+</sup> ions, so it can be separated with a magnet from the nonmagnetic silica. The separated mineral is heated in the presence of carbon under an atmosphere of chlorine gas, forming TiCl<sub>4</sub>, a volatile gas that can be isolated:

The TiCl<sub>4</sub> gas is reacted with hot magnesium metal turnings (shaved pieces of magnesium), forming elemental titanium—a solid sponge material:

Titanium is very reactive, readily oxidizing in the presence of oxygen and even nitrogen. Consequently, the elemental titanium is **arc-melted**—a method in which the solid metal is melted with an arc (an electrical discharge) from a high-voltage electric source in a controlled atmosphere to prevent oxidation—and then collected in a water-cooled copper pot. Because of titanium's high reactivity, any further processing must be done in a protective atmosphere of an inert gas, such as Ar, to prevent oxidation.

Despite its reactivity, solid titanium is highly resistant to corrosion in air, acid, and seawater because it quickly reacts with oxygen to form an oxide that coats the surface, preventing further oxidation of the underlying metal. Consequently, titanium is often used in the production of ship components such as propeller shafts and rigging. Titanium is also very strong and light; it is stronger than steel and less than half as dense. It is denser than aluminum but twice as strong. For these reasons, titanium is used in the airline industry for the production of jet engine parts. When titanium is alloyed with 5% aluminum and trace amounts of Fe, Cr, and Mo, the resulting metal retains its strength under higher temperature.

The most common use of titanium, however, is as titanium(IV) oxide ( $\text{TiO}_2$ ), which forms a clear crystal but a brilliant white powder. Most white paints include  $\text{TiO}_2$ , which is far less toxic than  $\text{PbO}_2$ , which was used in older paints. Titanium(IV) oxide is made by reacting sulfuric acid with ilmenite, which dissolves the titanium into solution:

Neutralizing the solution with strong base forms titanium(IV) oxide:

Calcination of the oxide dries it to form  $\text{TiO}_2$  rutile crystals. Large rutile crystals are sometimes used as gems because they resemble diamonds.

▲ **FIGURE 24.11** Chromium Compounds  
Chromium compounds tend to be brightly colored.

## Chromium

The name *chromium* comes from the Greek root *chroma*, which means color. The different compounds of chromium are brightly colored (Table 24.4; Figure 24.11 ◀). The main ore source of chromium is chromite,  $\text{FeCr}_2\text{O}_4$ . No appreciable sources of chromium ores exist in the United States. Chromium metal is produced by reducing chromium ore with aluminum:

Metallic chromium is a white, hard, lustrous, and brittle metal. The metal readily dissolves in acids such as hydrochloric acid and sulfuric acid, but it does not dissolve in concentrated nitric acid (because nitric acid forms an oxide on the surface of the chromium that resists further reaction). The primary use of chromium is in the production of steel alloys called *stainless steels*. Reducing chromite with carbon produces ferrochrome, an alloy that is added to steel:

**TABLE 24.4** The Colors of Various Chromium Compounds

Compound	Color
Chromates ( $\text{CrO}_4^{2-}$ )	Yellow
Chromium(II) iodide	Red-brown
Chromium(III) iodide	Green-black
Chromium(II) chloride	White
Chromium(III) chloride	Violet
Dichromates ( $\text{Cr}_2\text{O}_7^{2-}$ )	Orange
Chromium(III) oxide	Deep green
Chrome alum	Purple
Chromium(VI) oxychloride ( $\text{CrO}_2\text{Cl}_2$ )	Dark red
Chromium(II) acetate	Red

The chromium reacts with any oxygen in the steel to protect the iron from rusting. Chromium compounds were also used extensively in metal coatings, such as paints because the chromium helps to rustproof the underlying metal, and in wood preservatives because these compounds kill many of the bacteria and molds that rot wood. Chromium compounds are finding less use today, however, because of their toxicity and potential carcinogenicity. Nonetheless, because of their great corrosion resistance, chromate coatings are still used on large outdoor steel structures such as bridges, and chromate paints are used to mark streets (on the pavement) and on street signs.

Because chromium has the electron configuration  $[\text{Ar}] 4s^1 3d^5$ , with six orbitals available for bonding, it can have oxidation states from +1 to +6. Low-oxidation-state chromium exists primarily as the *cation* in salt compounds such as  $\text{Cr}(\text{NO}_3)_3$  and  $\text{CrCl}_3$ . High-oxidation-state chromium occurs within the polyatomic *anions* of salts. The most important compounds with chromium in the +6 oxidation state are the chromates and dichromates. In an acidic solution (below pH 6), the orange-red dichromate ion  $\text{Cr}_2\text{O}_7^{2-}$  is more stable. In more basic solutions (above pH 6), the yellow chromate ion  $\text{CrO}_4^{2-}$  dominates. Adding acid to a solution containing the chromate ion produces the dichromate ion:

The chromate ion has a tetrahedral arrangement of oxygen atoms around a chromium atom. The dichromate ion has one bridging oxygen between the two tetrahedrons surrounding the chromium ions:

The high-oxidation-state chromates and dichromates are very strong oxidizing agents (that is, they are easily reduced). Consequently, they are used as coatings on other metal surfaces to prevent oxidation. The chromates react with the atoms on the surface of the other metals, forming a strongly bonded gel-like film. The film is nonmetallic and bonds very effectively with paint and resins that are applied over the film. We can see evidence of the oxidizing power of dichromate in the ability of ammonium dichromate to sustain combustion without any additional oxygen. Once ignited, ammonium dichromate burns with visible flames, giving off a smoke of green chromium oxide dust:

## Manganese

Manganese, with the electron configuration  $[\text{Ar}] 4s^2 3d^5$ , exhibits a wide range of oxidation states, from +1 to +7. The most common natural sources of manganese are pyrolusite ( $\text{MnO}_2$ ), hausmannite ( $\text{Mn}_3\text{O}_4$ ), and rhodochrosite ( $\text{MnCO}_3$ ) minerals. Calcination of rhodochrosite produces manganese(IV) oxide:

The manganese(IV) oxide or pyrolusite minerals can react with active metals such as Al or Na to produce the elemental metal:

▲ Ammonium dichromate does not require additional oxygen to burn.

Pyrolusite, however, is often found as an impure mineral, containing mixtures of  $\text{MnO}$  and  $\text{Fe}_2\text{O}_3$ . Heating the mineral in the presence of carbon can reduce the mineral, forming an alloy of manganese and iron called ferromanganese:

Ferromanganese generally contains about 5–6% carbon and is used as an alloying material in steel production. Manganese is added to steel alloys to change the physical properties of the steel. For example, manganese makes the steel easier to deform at high temperatures. Adding manganese to steel helps the rolling and forging steps of steel production. Steel alloys containing about 12% manganese are used in military armor and industrial applications such as bulldozer blades. Manganese also strengthens copper, aluminum, and magnesium alloys.

Manganese is a reactive metal that dissolves in most acids. When heated in the presence of air, it forms the various manganese oxides, including  $\text{MnO}$ ,  $\text{Mn}_3\text{O}_4$ , and  $\text{MnO}_2$ . When heated in pure oxygen, the high-oxidation-state oxide  $\text{Mn}_2\text{O}_7$  also forms. At high-oxidation states, the manganese compounds are good oxidizing agents. Dissolving  $\text{MnO}_2$  into a solution of hydrochloric acid oxidizes the chloride and produces chlorine gas:

The permanganate ion ( $\text{MnO}_4^-$ ) has an oxidation state of +7 for Mn and is also an important oxidizing agent. The permanganate ion can even oxidize hydrogen peroxide, which is itself used as an oxidizing agent:

The compound  $\text{MnO}_2$  is a glass additive. By itself,  $\text{MnO}_2$  is either a brown or black crystal, depending on the degree of hydration. Yet, when added to a silica glass, it imparts a pink color to the glass. The pink color is useful because it counteracts the green color often seen in glass, which is due to small concentrations of impure iron oxides. In other words,  $\text{MnO}_2$  is added to glass to “decolorize” it. Old manganese-containing glass that has been exposed to UV light for over 100 years develops a slight purple tint. This purple color is due to the oxidation of  $\text{MnO}_2$  to Mn(VII) oxides.

## Cobalt

Cobalt ore is often found within the ores of other metals, such as iron, nickel, lead, and silver. Cobalt's most common ores are sulfide minerals, such as cobaltite ( $\text{CoAsS}$ ), which is collected as a by-product in the extraction processes of the other metal ores. No large deposits of cobalt ores occur in the United States, but surveys indicate that there are cobalt-rich deposits in the Pacific Ocean near the Hawaiian Islands.

Cobalt, like iron and nickel, is **ferromagnetic** and is important in the production of magnets. The atoms in ferromagnetic materials contain unpaired electrons like the paramagnetic materials described in Section 8.7. In ferromagnetic materials, however, these electrons can all align with their spins oriented in the same direction, creating a permanent magnetic field.

Magnets are increasingly important in industrial and military applications. In the United States, concerns have arisen over the lack of domestic sources of cobalt for these applications. New and stronger magnetic materials that do not require cobalt have been developed, but these require neodymium, which is found mostly in China.

Cobalt is also an important additive for high-strength steels. Carbaloy, a mixture composed primarily of cobalt metal with grains of tungsten carbide, is a very tough material. The strength of the cobalt and the hardness of the carbides make carbaloy a good material for industrial cutting and abrasion. Cobalt also forms many compounds with brilliant blue colors and is used in making pigments and inks. Cobalt compounds are essential for health because cobalt is the metal in vitamin  $\text{B}_{12}$ , which prevents anemia.

## Copper

Copper, which can be found in its elemental form, was one of the first elements to be isolated and used by humans—copper products have been known for over 10,000 years. Ancient civilizations used copper to form tools. The earliest known artifacts produced by the smelting of copper are at a site in Tepe Yahya, Iran, dating from about 3800 B.C.E. The discovery of **bronze**, a copper and tin alloy, improved tool making because copper's bronze alloys are stronger, and they resist wear and corrosion better than pure copper.

The most important copper ores are chalcopyrite ( $\text{CuFeS}_2$ ) and malachite [ $\text{Cu}_2(\text{OH})_2\text{CO}_3$ ]. Copper ores often occur near deposits of elemental copper, providing early humans with an easy way to locate copper ores. The electrometallurgical production of pure copper from chalcopyrite is described in Section 24.3.

The high natural abundance and generally high concentration of copper and copper ores make copper an economical choice for many industrial applications. Today over 40% of copper products are made from recycled copper. The ease and low cost of recycling copper have allowed copper to remain an important industrial metal.

The high conductivity of copper is second only to that of silver, making copper the most important metal for electrical wires. Along with iron in steel, copper is now among the most widely used metals; it is used in electrical motors and devices, the electrical wiring that snakes through the walls of houses, and the electrical transmission network linking power sources to homes and industries all over the world. Because of its high heat conductivity, copper is also used as a heat exchange material—for example, in car radiators. In addition, copper is used to make pipes for water distribution. Copper pipes can be readily connected to each other with watertight seals by soldering. Copper displaced lead for use as water pipes because of the toxicity of lead. Today, because of its lower price and lighter weight, plastic is used for many water pipes.

Copper has a distinctive reddish color that can be polished to a beautiful metallic luster; it has been used in architecture, as a decorative metal in jewelry, and as a material for sculpture. Copper composes the decorative sheathings on many domes and rooftop art works. When exposed to the atmosphere and rain, copper can oxidize, forming a number of different compounds, such as malachite and brochantite ( $\text{Cu}_4\text{SO}_4(\text{OH})_6$ ), which have beautiful blue or green colors. Copper roofing shingles can be purchased as polished copper sheets or as sheets that have already been oxidized and exhibit a beautiful weathered *patina* (a coating that comes with age and use). Chemical compounds speed up the aging process and produce the desired patina, which takes 20 or more years to develop naturally.

Even though copper has many useful properties, it is not a very strong metal; therefore, alloys of copper with improved strength have been developed. Bronze was one of the first alloys ever produced. This alloy of copper and tin has been used for thousands of years because it could be made even in the low heat of a Stone Age campfire. **Brass**, another widely used alloy, contains copper and zinc. Many brass and bronze alloys also contain other metals to achieve certain physical properties. Some of the most important applications of bronze and brass are for plumbing fixtures, bearings, and art decorations. In addition, the tendency of brass and bronze alloys (unlike those of iron) not to spark when struck makes them useful in applications where sparks could be dangerous.

## Nickel

Most of the world's nickel comes from deposits in Ontario, Canada. These deposits are believed to have formed from a meteorite impact (most meteorites have high nickel content). The nickel occurs as a sulfide compound mixed with copper and iron sulfides. To produce nickel, sulfides are roasted in air to form metal oxides, and then they are reduced to the elemental metals with carbon. The metal mixture is heated in the presence of carbon monoxide, forming nickel carbonyl, which has a boiling point of  $43^\circ\text{C}$  and can be collected as a gas:

▲ Copper is used in a variety of applications.

▲ Copper wiring is used to conduct electricity in wires.

When the nickel carbonyl is heated past 200 °C, it decomposes back to nickel metal and carbon monoxide. This method of refining nickel is the *Mond process*.

Nickel metal is fairly unreactive and resistant to corrosion, characteristics that it shares with platinum and palladium. Consequently, nickel is used as an alloying metal in the production of stainless steels. Many nickel alloys are used for applications where corrosion resistance is important. For example, the alloy Monel contains 72% Ni, 25% Cu, and 3% Fe and is resistant to reaction with most chemicals. Monel does not react even with fluorine gas at room temperature. Nickel-steel alloys are used for armor plates, and elemental nickel is often plated onto other metals as a protective coating.

## Zinc

Elemental zinc was officially discovered in Europe in 1746 when calamine (zinc silicate) was reduced with charcoal to produce the metal. However, zinc had been used for many hundreds of years before this discovery because zinc ores and copper ores were used to form copper-zinc brass alloys. The main sources of zinc are ores composed of sphalerite (ZnS), smithsonite (ZnCO<sub>3</sub>), and an oxide mixture of zinc, iron, and manganese called franklinite. These ores are roasted to form the oxides of the metals and then reduced with carbon to produce the elemental metals.

Zinc combines with many different metals to form useful alloys. As we have discussed, the combination of zinc and copper produces the brass family of alloys. The combination of zinc and nickel with copper produces alloys with a silver color called *German* or *silver brass*. Zinc is also used in solder alloys with low melting points.

*Galvanizing* a steel object (such as a nail) involves dipping the object into a molten bath of zinc. The zinc, which is more reactive than the iron in steel, preferentially oxidizes, forming a tough protective coating. Zinc compounds are also used to coat steel before applying other coatings. The zinc compounds, such as zinc phosphate, adhere strongly to the steel surface, forming rough crystals onto which other coatings, such as paint, adhere very well. If a painted steel surface is scratched, the underlying exposed metal is susceptible to rust, but the added zinc ions prevent this by migrating toward the defect and forming a protective zinc oxide coating.

Zinc and zinc compounds have generally been considered safe. Zinc additives in coatings have replaced many of the chromium and lead additives (both of which are toxic) that were previously used. Today, however, even zinc additives in coatings are being studied for environmental hazards. In Europe, all substances that contain zinc compounds must be labeled as potential pollutants of environmental water. More environmentally safe organic compounds have been developed to replace the metallic anticorrosion additives, but these compounds are more expensive to produce. Opportunities abound for chemists to develop needed products that are both environmentally safe and economically viable.

▲ Zinc phosphate adheres strongly to steel surfaces, forming rough crystals onto which other coatings, such as paint, can be applied.

## Self-Assessment Quiz

**Q1.** Which metal is naturally found in its elemental state?

- a) gold
- b) titanium
- c) chromium
- d) iron

**Q2.** Which reaction is an example of pyrometallurgy?

- a)  $\text{Ti}^{4+}(\text{aq}) + 4\text{OH}^{-}(\text{aq}) \rightarrow \text{TiO}_2(\text{s}) + 2\text{H}_2\text{O}(\text{l})$
- b)  $2\text{MnCO}_3(\text{s}) + \text{O}_2(\text{g}) \xrightarrow{\text{heat}} 2\text{MnO}_2(\text{s}) + 2\text{CO}_2(\text{g})$
- c)  $\text{Ni}(\text{s}) + 4\text{CO}(\text{g}) \rightarrow \text{Ni}(\text{CO})_4(\text{g})$
- d)  $3\text{MnO}_2(\text{s}) + 4\text{Al}(\text{s}) \rightarrow 3\text{Mn}(\text{s}) + 2\text{Al}_2\text{O}_3(\text{s})$

**Q3.** Based on the data shown here, which pair of metals is likely to form a substitutional alloy?

Metal	Atomic Radius	Crystal Structure
Sc	162 pm	Hexagonal closet packed
W	135 pm	Body-centered cubic
Cu	128 pm	Face-centered cubic
Cr	128 pm	Body-centered cubic

- a) Sc and W
- b) Cu and Cr
- c) Cu and Sc
- d) Cr and W

- Q4.** Two metals, A and B, form a substitutional alloy with the binary phase diagram shown here. What is the melting point of the alloy at a composition that is 75% A and 25% B?

- a) 1000 °C  
b) 1300 °C  
c) 1450 °C  
d) 2000 °C
- Q5.** Two metals, A and B, form a substitutional alloy with the binary phase diagram shown here. Determine the composition and relative amounts of the two phases present at 50% composition and 1500 °C.

- a) The A-rich bcc phase is 80% A and 20% B; the B-rich fcc phase is 37% A and 63% B; the mixture contains more of the A-rich fcc phase.  
b) The A-rich bcc phase is 20% A and 80% B; the B-rich fcc phase is 63% A and 37% B; the mixture contains more of the B-rich fcc phase.  
c) The A-rich bcc phase is 50% A and 50% B; the B-rich fcc phase is 50% A and 50% B; the mixture contains equal amounts of both phases.  
d) The A-rich bcc phase is 80% A and 20% B; the B-rich fcc phase is 37% A and 63% B; the mixture contains more of the B-rich fcc phase.

- Q6.** An interstitial alloy contains a nonmetal (X) that occupies one-fourth of the octahedral holes in the closet-packed lattice of the metal (M). What is the formula for the alloy?

- a)  $M_4X$   
b)  $MX_4$   
c)  $M_2X$   
d)  $MX_2$

- Q7.** Which metal is commonly used to make electrical wires?

- a) zinc  
b) cobalt  
c) manganese  
d) copper

- Q8.** Which metal is commonly used to make parts for aircraft engines?

- a) zinc  
b) titanium  
c) nickel  
d) silver

- Q9.** Calculate the mass percent of chromium in the mineral chromite ( $FeCr_2O_4$ ).

- a) 83.97%  
b) 46.46%  
c) 86.78%  
d) 36.13%

- Q10.** What is a common use for zinc?

- a) galvanization of steel  
b) lightweight aircraft parts  
c) paint pigments  
d) production of magnets

## Chapter 24 IN REVIEW

### Key Terms

#### Section 24.1

metallurgy (1102)

#### Section 24.2

minerals (1103)

ore (1103)

#### Section 24.3

extractive metallurgy (1104)

refining (1104)

gangue (1104)

pyrometallurgy (1104)

calcination (1105)

roasting (1105)

smelting (1105)

flux (1105)

slag (1105)

hydrometallurgy (1105)

leaching (1105)

electrometallurgy (1106)

powder metallurgy (1107)

#### Section 24.4

alloy (1108)

substitutional alloy (1108)

interstitial alloy (1108)

two-phase region (1110)

lever rule (1111)

octahedral hole (1112)

tetrahedral hole (1112)

#### Section 24.5

arc-melting (1114)

ferromagnetic (1116)

bronze (1117)

brass (1117)

### Key Concepts

#### General Properties (24.2)

- ▶ Metals have many common physical properties, such as high conductivity of electricity and heat and high malleability and ductility. These properties vary among the different metals.

#### Natural Distribution of Metals (24.2)

- ▶ Metals are unevenly distributed throughout Earth's crust. All the metals together compose about 25% of the mass of Earth's crust, but just a few key metals are abundant enough to each individually compose more than 1% of the crust.
- ▶ Few metals exist naturally in their elemental state; most are found in ores, rocks that contain a high concentration of metal-containing minerals.
- ▶ Most metal-containing minerals are oxides, sulfides, chlorides, carbonates, or more complex compounds.

#### Metallurgical Processes (24.3)

- ▶ To be useful, metals have to be separated from the gangue, the unusable part of the ores, reduced to elemental metals and refined to be more pure.
- ▶ Extractive metallurgy is the general term for the processes, such as pyrometallurgy, hydrometallurgy, and electrometallurgy, that separate metal from ore.
- ▶ A method of forming metal components from micron-sized metal particles is powder metallurgy.

#### Phase Diagrams (24.4)

- ▶ Elemental metals tend to crystallize in three crystalline structures: face-centered cubic, body-centered cubic, and hexagonal closest packed.
- ▶ When two types of metal atoms bond together, they form an alloy.
- ▶ A binary phase diagram is a graphical representation of the phases and crystal types of alloys present at different compositions and temperatures.
- ▶ If the two metals in an alloy are similar in size and have the same crystal structure, they tend to form a miscible solid solution, which means that they can form an alloy at any composition ratio. If the two metals are dissimilar in size or crystal structure, the solubility of one atom in the other's crystal structure is often limited. At certain compositions two different crystals can coexist in equilibrium; this is called a two-phase region. The lever rule determines which phase is present in a greater proportion.

#### Types of Alloys (24.4)

- ▶ There are two different types of alloys, substitutional and interstitial.
- ▶ A substitutional alloy is a mixture in which one type of metal atom replaces another type of metal atom in the crystal structure.
- ▶ In an interstitial alloy, one type of atom (either a metal or non-metal) fits into the holes within the crystal structure of the metal. Interstitial alloys can be made with different atoms filling different fractions of the different types of holes.

### Key Equations and Relationships

#### Lever Rule (24.4)

In a two-phase region on a phase diagram, two different crystal structures coexist in equilibrium. Whichever phase has a composition closer to the overall composition of the alloy is the phase present in the larger relative amount.

## Key Learning Outcomes

### CHAPTER OBJECTIVES

Using a Phase Diagram to Determine the Composition, Relative Amounts, and Phases Present (24.4)

Determining the Composition of an Interstitial Alloy from the Occupancy of the Interstitial Holes (24.4)

### ASSESSMENT

Examples 24.1, 24.2, 24.3, 24.4 For Practice 24.1, 24.2, 24.3, 24.4 Exercises 35–38

Exercises 41, 42

## EXERCISES

### Review Questions

- Why is vanadium present in oil from some sources?
- List three categories of metallurgical processes.
- Why is Ni not considered a common metal even though it composes over 2% of the total mass of Earth and only Fe and Mg have a higher percent composition of Earth's total mass?
- Metal elements are found in both minerals and ores. Describe the difference between a mineral and an ore.
- Ores contain minerals and gangue. Describe the difference between a mineral and gangue.
- Calcination, roasting, and smelting are three pyrometallurgical processes. Compare and contrast the processes.
- What compound has been historically used to leach gold from gold ores? Why is this process being discontinued?
- Name three advantages of making metal components from the powder metallurgical process.
- Describe the difference between body-centered cubic and face-centered cubic structures.
- Describe the difference between a substitutional alloy and an interstitial alloy.
- Why was copper one of the first metals that humans used?
- Describe why bronze was one of the first alloys that humans used.
- Both brass and bronze contain copper. Describe the difference between these two alloys.
- List the properties of copper that make it appropriate for electric wires and the properties that make it appropriate for water pipes.

### Problems by Topic

#### The General Properties and Natural Distribution of Metals

- Describe three typical properties of metals.
- Describe whether each property is generally higher or lower for metals compared to nonmetals.
  - thermal conductivity
  - electrical resistivity
  - transparency
  - ductility
- List four metal elements that each individually compose more than 1% of Earth's crust.
- List four metals that occur as elements in their natural state.
- List the name and formula of one important mineral source for each of these metals: Fe, Hg, V, and Nb.
- List the name and formula of one important mineral source for each of these metals: Ti, Zn, U, and Ta.

#### Metallurgical Processes

- Two ores of magnesium are  $\text{MgCO}_3$  and  $\text{Mg}(\text{OH})_2$ . Write balanced equations for the calcination of these two minerals to form  $\text{MgO}$ .

- Two ores of copper are  $\text{CuO}$  and  $\text{CuS}$ . Write balanced equations for the roasting of  $\text{CuO}$  with C to form Cu metal and the roasting of  $\text{CuS}$  with  $\text{O}_2$  to form  $\text{CuO}$ .

- Give the definition of a flux and identify the flux in the reaction.

- Give the definition of a slag and identify the slag in the reaction.

- Provide a general description of how hydrometallurgy is used to extract metals from ores.
- Provide a general description of how electrometallurgy is used to extract metals from ores.
- How is  $\text{Al}_2\text{O}_3$  separated from other oxides using the Bayer process? What soluble form of aluminum forms from  $\text{Al}_2\text{O}_3$  during the Bayer process?
- When copper is purified using an electrochemical cell, which electrode has the pure copper and which electrode has the impure copper? Explain how gold is obtained from this process.

29. Describe the difference between sponge powdered iron and water-atomized powdered iron.
30. Describe the difference in the processing of sponge powdered iron and water-atomized powdered iron.

### Metal Structures and Alloys

31. Determine the composition of each vanadium alloy.
- One-half of the V atoms are replaced by Cr atoms.
  - One-fourth of the V atoms are replaced by Fe atoms.
  - One-fourth of the V atoms are replaced by Cr atoms, and one-fourth of the V atoms are replaced by Fe atoms.
32. Determine the composition of each cobalt alloy.
- One-third of the Co atoms are replaced by Zn atoms.
  - One-eighth of the Co atoms are replaced by Ti atoms.
  - One-third of the Co atoms are replaced by Zn atoms, and one-sixth of the Co atoms are replaced by Ti atoms.
33. Referring to Table 24.2, explain why you might expect Cr and Fe to form miscible alloys.
34. Referring to Table 24.2, explain why you might expect Co and Cu to not form miscible alloys.
35. Determine the composition and phases present at points A and B on the Cr-Fe phase diagram.

36. Determine the composition and phase present at points C and D on the Cr-Fe phase diagram (see Problem 35 for diagram).
37. Determine the composition, relative amounts, and phases present at points A and B on the Co-Cu phase diagram.

38. Determine the composition, relative amounts, and phases present at points C and D on the Co-Cu phase diagram (see Problem 37 for phase diagram).

39. The elements Mn and Si are added to steel to improve its properties in electric motors, and some C is often found as a detrimental impurity. Which of these elements fills interstitial holes in the Fe lattice, and which substitutes for the Fe in the lattice?
40. The elements Si and P are added to steel to improve its properties in electric motors, and some N is often found as a detrimental impurity. Which of these elements fills interstitial holes in the Fe lattice, and which substitutes for the Fe in the lattice?
41. Determine the formula for each interstitial alloy.
- Nitrogen occupies one-half of the octahedral sites of a closest-packed Mo structure.
  - Hydrogen occupies all of the tetrahedral sites of a Cr closest-packed structure.
42. Determine the formula for each interstitial alloy.
- Nitrogen occupies one-fourth of the octahedral sites of a closest-packed Fe structure.
  - Hydrogen occupies one-half of the tetrahedral sites of a Ti closest-packed structure.

### Sources, Properties, and Products of Some of the 3d Transition Metals

43. Identify the metal found in each mineral.
- sphalerite
  - malachite
  - hausmannite
44. Name at least one important mineral that is a source for each metal.
- Fe
  - Co
  - Cr
45. Calculate the heat of reaction ( $\Delta H_{\text{rxn}}^\circ$ ) for the calcination of rhodochrosite. ( $\Delta H_f^\circ$  for rhodochrosite is  $-894.1 \text{ kJ/mol}$ .)
46. The extraction of Mn from pyrolusite with aluminum produces pure Mn metal and  $\text{Al}_2\text{O}_3$ . Calculate the heat of reaction ( $\Delta H_{\text{rxn}}^\circ$ ).
47. Describe the effects of adding Cr to steel and give a use for chromium-steel alloys.
48. Describe the effects of adding Mn to steel and give a use for manganese-steel alloys.
49. Calculate the mole percent and mass percent of Ti in the minerals rutile and ilmenite.
50. Calculate the mole percent and mass percent of Mn in the minerals pyrolusite and rhodochrosite.
51. Why is it important to use an inert atmosphere to surround the metal when arc-melting titanium?
52. Titanium is a very reactive metal. Explain why titanium has a high corrosion resistance to seawater and can be used for the production of ship components.
53. Which compound of Ti is the most important industrial product of titanium metal? Describe an application for this compound.
54. Describe how Zn is used to protect the surface of steel products. What is the name of this process?
55. Describe the Bayer process.
56. Describe the Mond process.
57. Which metals are found in carballoy steel?
58. Which metals are found in Monel steel?

## Cumulative Problems

59. After  $2.0 \times 10^4$  kg of an ore that contains 0.051% ilmenite is mined, the percent yield from extracting and refining the metals from the mineral is 87% for the iron and 63% for the titanium. Calculate the mass of iron and titanium produced from the ore.
60. Calculate the mass of aluminum metal that is needed to produce Cr metal from  $5.00 \times 10^2$  g of chromite. Calculate how many grams of Cr metal are produced from  $5.00 \times 10^2$  g of chromite.
61. How many lattice atoms surround a tetrahedral hole and an octahedral hole in a closest-packed structure? Describe which hole site is larger and explain why.
62. Explain why the crystal structure and atomic size of the two elements are important factors in a two-component phase diagram.
63. Why does Mn form compounds with higher oxidation states than Cr?
64. Why is  $\text{MnO}_2$  added to silica glass?
65. Co, Fe, and Ni are ferromagnetic. What is the difference between ferromagnetic and paramagnetic?
66. Is the chromate ion or dichromate ion more stable in an acidic solution? Which ion has a higher Cr:O ratio? Which ion has a higher oxidation state for Cr?
67. The first ionization energies of iron, cobalt, nickel, and the first three platinum metals are all about the same, but the first ionization energies of osmium, iridium, and platinum are substantially greater. Suggest an explanation for this observation.
68. Although both the Group IA and IB metals have a half-filled *s* subshell, the IB metals have markedly higher first ionization energies, densities, and melting points, and markedly lower second and third ionization energies than the corresponding IA metals. Explain these observations.

## Challenge Problems

69. Iron powder is placed into a tall cylinder-shaped die and pressed from the top and bottom to make a cylinder-shaped pressed part with a height of 5.62 cm and a radius of 4.00 cm. The density of the iron powder before it was pressed was 2.41 g/mL. The density of a pressed iron part is 6.85 g/mL. The density of pure solid iron is 7.78 g/mL.
  - a. Calculate the original height of the powder before it was pressed.
  - b. Calculate the theoretical height of the pressed component if it could be pressed to the same density of pure iron.
  - c. What percentage of the pressed iron part is composed of voids between the iron particles?
70. When a part is made by pressing together powdered metal, no metal is wasted. In contrast, metal is typically scrapped after a metal part is cut from a solid metal plate. If a circular part with a diameter of 10.0 cm is made from an original shape of a square with a side length of 10.0 cm, calculate the percentage of the metal that is thrown away as scrap. If the circular shape also has a circular hole with a diameter of 6.0 cm, calculate the percentage of the metal that is thrown away as scrap.
71. Hydrogen can be in both the octahedral and tetrahedral holes for lanthanum. Determine the percentage of the holes that are filled if the formula is  $\text{LaH}_{2.76}$ .
72. Tin exists in two allotropic forms. Gray tin has a diamond structure, and white tin has a close-packed structure. Predict which allotrope is (a) denser, (b) a conductor of electricity. Predict the valence electronic configuration of tin in each allotrope.
73. Find the equilibrium constant at 298 K for the reaction.
 
$$[\text{Ag}(\text{CN})_2]^{-}(\text{aq}) + \text{Cu}(\text{s}) \rightleftharpoons [\text{Cu}(\text{CN})_2]^{-}(\text{aq}) + \text{Ag}(\text{s})$$
 The  $K_f$  for  $[\text{Cu}(\text{CN})_2]^{-} = 1.0 \times 10^{24}$  and the rest of the data needed are in Appendix II.
74. Find the equilibrium constant at 298 K for the reaction.
 
$$2 [\text{Cu}(\text{NH}_3)_2]^{+}(\text{aq}) \rightleftharpoons [\text{Cu}(\text{NH}_3)_4]^{2+}(\text{aq}) + \text{Cu}(\text{s})$$
 The  $K_f$  for  $[\text{Cu}(\text{NH}_3)_2]^{+} = 6.3 \times 10^{10}$  and the rest of the data needed are in Appendix II.
75. Propose a chemical procedure to extract cobalt from the mineral cobaltite,  $\text{CoAsS}$ . What are some of the hazards of such a procedure?

## Conceptual Problems

76. Why are metals such as Ni and Co economical to mine and use in industrial processes, even though they have a very low natural abundance in Earth's crust?
77. Explain why metals such as Au and Ag are found in their elemental states in nature, but metals like Na and Ca are always found in compounds in nature.
78. What allows some pairs of metals to form alloys that have the same structure at any composition, while other pairs of metals form alloys with structures that depend on the relative composition of the two metals?

## Questions for Group Work

Discuss these questions with the group and record your consensus answer.

79. Assign each element in the first row of the transition metals, scandium through zinc, to a group member. Have each group member look up on the Internet or in a reputable chemistry reference book the electrical resistivity for his or her element(s). Agree on the units and temperature. As a group, prepare a graph of resistivity versus atomic number. What is the general trend in resistivity as the atomic number increases? What atomic properties might account for this trend? Are there any notable exceptions?
80. Create a table comparing and contrasting pyrometallurgy, hydrometallurgy, and electrometallurgy. Include a definition, an application or two, and any relevant notes for each type of metallurgy. Once your table is complete, pass it around your group asking each group member to read one cell from your table. Have other group members take turns trying to identify the type of metallurgy from the fact that is read aloud.
81. Would you expect an alloy of iron and vanadium to be substitutional or interstitial? Explain your choice. Create a phase diagram for the binary alloy of iron and vanadium based on the tabulated data provided.

% V	Melting Point
0	1530
20	1480
40	1470
60	1560
80	1720
100	1900

82. Assign each group member a different interstitial alloy from Table 24.3. Each group member should look up a few interesting facts for his or her alloy, including how it is used. Present findings, along with a description of each alloy's structure, to the group.
83. Working individually, create a fill-in-the-blank question by re-writing a characteristic sentence or chemical reaction from Section 24.5, but leaving out the name of the metal focused on in the content selected. Take turns sharing questions with the rest of the group. Take turns in the group trying to fill in the blank with the correct metal.

## Data Interpretation and Analysis

### Soldering with Tin–Lead Alloys

84. Alloys of tin and lead are common solders. A *solder* is a metal alloy that melts at a relatively low temperature and connects two or more metal pieces. The technique of soldering is commonly used by plumbers to fuse copper water pipes and by electricians to affix electrical components to printed circuit boards. Table a lists tensile strength and hardness data for pure tin, pure lead, and two tin–lead alloys. *Tensile strength* is the maximum stress a material that is being stretched or pulled can withstand before breaking. *Hardness* on the Brinell Scale is a measure of a substance's resistance to indentation

when subjected to impact by a steel ball (the higher the number the greater the hardness).

The tin–lead phase diagram in Figure a contains a *eutectic point*—a point on the phase diagram representing the lowest melting point. The eutectic composition has a sharp melting transition. All other compositions of tin–lead melt over a range of temperatures, beginning at the *solidus* line (the line separating the solid phase and the liquid–solid region) and ending at the *liquidus* line (the line separating the liquid phase and the liquid–solid region). Between these lines, a mixture of liquid and solid

◀ **FIGURE a** Tin–Lead Phase Diagram.

exists. This mixture is described as “pasty” because it can be worked into an optimal shape around the connection point of the two base metal pieces.

Substance	Tensile Strength, MPa	Hardness (Brinell Scale)
Pure tin	13.2	4
Pure lead	12.3	4
63% tin-37% lead (mass%)	51.5	17
50% tin-50% lead (mass%)	41.2	14

**TABLE a** Strength and Hardness of Tin, Lead, and Tin-Lead alloys

Use the information provided to answer the following questions:

- Based on the data provided in Table a, explain why tin-lead alloys are better solders than pure tin or pure lead.
- Based on the phase diagram shown in Figure a, do tin and lead form a miscible solid solution at all compositions?
- According to the phase diagram, what are the melting points of pure tin and pure lead?
- What composition of tin and lead constitutes a eutectic mixture, and what is the melting point of the eutectic mixture?
- Why is a 63% tin/37% lead (mass %) alloy commonly used for electrical soldering projects?
- What is the melting range of a 50% tin/50% lead (mass %) alloy?

## Answers to Conceptual Connections

### Interstitial Alloys

- 24.1**  $M_4X$ . Because there are twice as many tetrahedral holes as metal atoms in a closest-packed structure, and one-eighth of them are occupied by nonmetal atoms, there must be one-quarter as many nonmetal atoms as metal atoms.

# Transition Metals and Coordination Compounds

**“Chemistry must become the astronomy of the molecular world.”**

—ALFRED WERNER (1866–1919)

**25.1 The Colors of Rubies and Emeralds 1127**

**25.2 Properties of Transition Metals 1128**

**25.3 Coordination Compounds 1132**

**25.4 Structure and Isomerization 1137**

**25.5 Bonding in Coordination Compounds 1142**

**25.6 Applications of Coordination Compounds 1147**

**KEY LEARNING OUTCOMES 1152**

In this chapter, we examine the chemistry of the transition metals and an important class of transition metal compounds called coordination compounds. We will see that coordination compounds form all of the types of isomers that we have studied so far, as well as some new types. In our examination of the transition metals, we draw on much of what we learned in Chapters 7 and 8 about electronic structure and periodicity. We also briefly revisit valence bond theory to understand bonding in coordination compounds, but we quickly shift to a different theory—called crystal field theory—that better explains many of the properties of these compounds. Transition metals and coordination compounds are important, not only because of their interesting chemistry, but because of their numerous applications. Coordination compounds are the basis for a number of therapeutic drugs, chemical sensors, and coloring agents. In addition, many biological molecules contain transition metals that bond in ways that are similar to coordination compounds. For example, the oxygen-carrying site on hemoglobin is an iron ion bonded partly to an amino acid in the hemoglobin molecule and partly to a flat molecule called a porphyrin. An oxygen molecule reversibly bonds to the iron and is transported throughout the body by blood flow.

▲ The color of ruby is caused by a splitting of the d-orbital energy levels in  $\text{Cr}^{3+}$  by the host crystal.

## 25.1 The Colors of Rubies and Emeralds

Rubies are deep red and emeralds are brilliant green, yet the color of both gemstones is caused by the same ion,  $\text{Cr}^{3+}$ . The difference lies in the crystal that hosts the ion. Rubies are crystals of aluminum oxide ( $\text{Al}_2\text{O}_3$ ) in which about 1% of the  $\text{Al}^{3+}$  ions are replaced by  $\text{Cr}^{3+}$  ions. Emeralds, by contrast, are crystals of beryllium aluminum silicate

▲ **Ruby and Emerald** The red color of ruby and the green color of emerald are both caused by  $\text{Cr}^{3+}$ .

$[\text{Be}_3\text{Al}_2(\text{SiO}_3)_6]$  in which a similar percentage of the  $\text{Al}^{3+}$  ions is replaced by  $\text{Cr}^{3+}$ . The embedded  $\text{Cr}^{3+}$  ion is red in the aluminum oxide crystal but green in the beryllium aluminum silicate crystal. Why?

The answer to this question lies in the effect that the host crystal has on the energies of the atomic orbitals in  $\text{Cr}^{3+}$ . Atoms in the crystal create a field around the ion—sometimes called the *crystal field*—that splits the five normally degenerate  $d$  orbitals into two or more levels. The color of each gemstone is caused by electron transitions between these levels. In rubies, the crystal field is stronger (and the corresponding splitting of the  $d$  orbitals greater) than it is in emeralds. Recall from Chapter 7 that the color of a substance depends on the colors *absorbed* by that substance, which in turn depends on the energy differences between the orbitals involved in the absorption. The greater splitting in ruby results in a greater energy difference between the  $d$  orbitals of  $\text{Cr}^{3+}$ , and consequently the absorption of a different color of light than in emerald.

The colors of several other gemstones are also caused by the splitting of the  $d$  orbitals in transition metal ions embedded within host crystals. For example, the red in garnet, which has  $\text{Mg}_3\text{Al}_2(\text{SiO}_4)_3$  as a host crystal, and the yellow-green of peridot, which has  $\text{Mg}_2\text{SiO}_4$  as a host crystal are both caused by electron transitions between  $d$  orbitals in  $\text{Fe}^{2+}$ . Similarly, the blue in turquoise, which has  $[\text{Al}_6(\text{PO}_4)_4(\text{OH})_8 \cdot 4\text{H}_2\text{O}]^{2-}$  as a host crystal, is due to transitions between the  $d$  orbitals in  $\text{Cu}^{2+}$ .

In this chapter, we examine the properties of the transition metals and their ions more closely. We also examine the properties of coordination compounds in some detail. We first discussed this common type of transition metal compound in Chapter 17 (see Section 17.8). In a coordination compound, bonds to a central metal ion split the  $d$  orbitals much as they are split in the crystals of gemstones. The theory that explains the splitting and the corresponding colors is **crystal field theory**, which we also explore in this chapter.

▲ **Garnet, Peridot, and Turquoise** The red in garnet and the yellow-green of peridot are both caused by  $\text{Fe}^{2+}$ . The blue of turquoise is caused by  $\text{Cu}^{2+}$ .

## 25.2 Properties of Transition Metals

Transition metals, the elements in the  $d$  block of the periodic table, are a study in similarities and differences. When we compare their properties with the varied properties of the main-group elements, they seem markedly similar. For example, almost all transition metals have moderate to high densities, good electrical conductivity, high melting points, and moderate to extreme hardness. Their similar properties are related to their similar electron configurations: they all have electrons in  $d$  orbitals that can be involved in metallic bonding. In spite of their similarities, however, each element is also unique, and the transition metals exhibit a wide variety of chemical behavior. Before we examine some of their periodic properties, let's review the electron configurations of these elements, first discussed in Chapter 8.

### Electron Configurations

Recall from Section 8.4 that, as we move to the right across a row of transition elements, electrons are added to  $(n - 1)d$  orbitals (where  $n$  is the row number in the periodic table and also the quantum number of the highest occupied principal level). For example, as we move across the fourth-period transition metals, electrons are added to the  $3d$  orbitals, as Table 25.1 shows.

In general, the ground state electron configuration for the first two rows of transition elements is [noble gas]  $ns^2(n-1)d^x$  and for the third and fourth rows it is [noble gas]  $ns^2(n-2)f^{14}(n-1)d^x$ , where  $x$  ranges from 1 to 10. Recall from Section 8.4, however, that because the  $ns$  and  $(n-1)d$  sublevels are close in energy, many exceptions occur. For example, in the first transition series of the  $d$  block, the outer configuration is  $4s^23d^x$  with two exceptions: Cr is  $4s^13d^5$  and Cu is  $4s^13d^{10}$ . This behavior is related to the closely spaced  $3d$  and  $4s$  energy levels and the stability associated with a half-filled or completely filled  $d$  sublevel.

Recall from Section 8.7 that the transition metals form ions by losing electrons from the  $ns$  orbital *before* losing electrons from the  $(n-1)d$  orbitals. For example,  $\text{Fe}^{2+}$  has an electron configuration of  $[\text{Ar}] 3d^6$  because it has lost both of the  $4s$  electrons to form the  $2+$  charge. Examples 25.1 and 25.2 review the steps in writing electron configurations for transition metals and their ions.

**TABLE 25.1** First-Row Transition Metal Orbital Occupancy

	4s	3d				
Sc	$\uparrow\downarrow$	1				
Ti	$\uparrow\downarrow$	1	1			
V	$\uparrow\downarrow$	1	1	1		
Cr	1	1	1	1	1	1
Mn	$\uparrow\downarrow$	1	1	1	1	1
Fe	$\uparrow\downarrow$	$\uparrow\downarrow$	1	1	1	1
Co	$\uparrow\downarrow$	$\uparrow\downarrow$	$\uparrow\downarrow$	1	1	1
Ni	$\uparrow\downarrow$	$\uparrow\downarrow$	$\uparrow\downarrow$	$\uparrow\downarrow$	1	1
Cu	1	$\uparrow\downarrow$	$\uparrow\downarrow$	$\uparrow\downarrow$	$\uparrow\downarrow$	$\uparrow\downarrow$
Zn	$\uparrow\downarrow$	$\uparrow\downarrow$	$\uparrow\downarrow$	$\uparrow\downarrow$	$\uparrow\downarrow$	$\uparrow\downarrow$

### Procedure for...

<b>Writing Electron Configurations</b>	<b>Example 25.1</b> <b>Writing Electron Configurations for Transition Metals</b> Write the ground state electron configuration for Zr.	<b>Example 25.2</b> <b>Writing Electron Configurations for Transition Metals</b> Write the ground state electron configuration for $\text{Co}^{3+}$ .
	<b>SOLUTION</b> <div style="text-align: center;">[Kr]</div>	<b>SOLUTION</b> <div style="text-align: center;">[Ar]</div>
	Identify the noble gas that precedes the element and write it in square brackets.  Count down the periods to determine the outer principal quantum level—this is the quantum level for the $s$ orbital. Subtract one to obtain the quantum level for the $d$ orbital. If the element is in the third or fourth transition series, include $(n-2)f^{14}$ electrons in the configuration.	Co is in the fourth period, so the orbitals used are:  <div style="text-align: center;">[Ar] <math>4s3d</math></div>
	Count across the row to see how many electrons are in the neutral atom and fill the orbitals accordingly.	Co has nine more electrons than Ar.  <div style="text-align: center;">[Ar] <math>4s^23d^7</math></div>
	For an ion, remove the required number of electrons, first from the $s$ and then from the $d$ orbitals.	$\text{Co}^{3+}$ has three fewer electrons than the Co atom. <div style="text-align: center;">[Ar] <math>4s^03d^6</math> or [Ar] <math>3d^6</math></div>
	<b>FOR PRACTICE 25.1</b> Write the ground state electron configuration for Os.	<b>FOR PRACTICE 25.2</b> Write the ground state electron configuration for $\text{Nb}^{2+}$ .

**▲ FIGURE 25.1 Trends in Atomic Radius** With the exception of a decrease in radius from the first to the second element, there is only a small variation in atomic radius across a row. There is a small and expected increase in radius from the first to the second transition row but virtually no difference in radius from the second to the third.

electrons than the second row. The reason that the third transition row elements are not larger is because 14 of the 32 electrons are in a  $(n - 2)f$  sublevel, and while electrons in  $f$  orbitals are in lower principal quantum levels, they are not very effective at shielding the outer electrons from nuclear charge. Consequently, the outer electrons are held more tightly by the nucleus, offsetting the typical increase in size between the periods—an effect called the **lanthanide contraction**.

## Atomic Size

As we discussed in Section 8.6, for main-group elements, the size of atoms decreases across a period and increases down a column. For transition metals, however, there is little variation in size across a row (other than for the first two elements in each transition metal row, such as Sc and Ti in the first row), as Figure 25.1 ◀ illustrates. The reason for the difference is that, across a row of transition elements, the number of electrons in the outermost principal energy level (highest  $n$  value) is nearly constant. As another proton is added to the nucleus with each successive element, another electron is added as well, but the electron goes into an  $n - 1$  orbital. The number of outermost electrons thus stays the same, and the electrons experience a roughly constant effective nuclear charge as we move across the row, keeping the radii approximately constant.

Looking down a group, we see a small but expected increase in size from the first transition metal row to the second, but the size of elements in the third row is about the same as it is for those in the second row. This pattern is also different from that of the main-group elements, especially when we consider that in any given column, the third transition row has 32 more elec-

trons than the second row. The reason that the third transition row elements are not larger is because 14 of the 32 electrons are in a  $(n - 2)f$  sublevel, and while electrons in  $f$  orbitals are in lower principal quantum levels, they are not very effective at shielding the outer electrons from nuclear charge. Consequently, the outer electrons are held more tightly by the nucleus, offsetting the typical increase in size between the periods—an effect called the **lanthanide contraction**.

## CONCEPTUAL CONNECTION 25.1

**Atomic Size** Which element has the larger atomic radius, Fe or W?

**▲ FIGURE 25.2 Trends in First Ionization Energy** First ionization energy generally increases across a row, following the main-group trend. However, in contrast to the main-group trend, the third transition row has a higher ionization energy than the first and second rows.

## Ionization Energy

The first ionization energies of transition elements follow the expected main-group periodic trend and slowly increase across a row (Figure 25.2 ◀), but the increase is smaller than for main-group elements. As we move down a group, we see that the third transition row generally has a higher ionization energy than do the first two rows, a trend counter to that observed in the main-group elements. In the transition elements the charge of the nucleus increases substantially from one row to the next, but there is only a small increase in atomic size between the first and second rows, and no increase in size between the second and third row. The outer electrons are therefore held more tightly in the third transition row than in the first two rows.

## Electronegativity

The electronegativity values of the transition metals, like their ionization energies, follow the main-group trend and slowly increase across a row, as shown in Figure 25.3. The increase is smaller than the increase that occurs in the main-group elements, but we expect that given the similarity in the sizes of the atoms. The trend in electronegativity values down a group (or column) is another example of the transition metals behaving differently from the main-group elements. The electronegativity values generally increase from the first transition row to the second, but there is no further increase for the third row. In the main-group elements, in contrast, we see a *decrease* in electronegativity as we move down a group. The difference is again caused by the relatively small change in atomic size as we move down a column for the transition elements, accompanied by a large increase in nuclear charge. One of the heaviest metals, gold (Au), is also the most electronegative metal. Its electronegativity value (EN = 2.4) is even higher than that of some nonmetals (EN of P is 2.1), and compounds of an  $\text{Au}^-$  ion have been observed.

◀ **FIGURE 25.3 Trends in Electronegativity**

The electronegativity of the transition elements generally increases across a row, following the main-group trend. However, in contrast to the main-group trend, electronegativity increases from the first transition row to the second. There is little electronegativity difference between the second and third transition rows.

## Oxidation States

Unlike main-group metals, which tend to exhibit only one oxidation state, the transition metals often exhibit a variety of oxidation states (Figure 25.4). The highest oxidation state for a transition metal is +7 for manganese (Mn). The electron configuration of manganese in this oxidation state corresponds to the loss of all the electrons in the 4s and 3d orbitals, leaving a noble gas electron configuration ([Ar]). This is the same configuration we see for all of the highest oxidation states of the elements to the left of Mn. To the right of manganese, the oxidation states are all lower, mostly +2 or +3. A +2 oxidation state for a transition metal is not surprising, as 4s electrons are readily lost.

Metals in high oxidation states, such as +7, exist only when the metal is bound to a highly electronegative element such as oxygen; they do not exist as bare ions.

◀ **FIGURE 25.4 First-Row Transition Metal Oxidation States**

The transition metals exhibit many more oxidation states than the main-group elements. These oxidation states range from +7 to +1.

## 25.3 Coordination Compounds

We discussed at the end of Chapter 17 that transition metals tend to form *complex ions*. A **complex ion** contains a central metal ion bound to one or more *ligands*. A **ligand** is a Lewis base (or electron donor) that forms a bond with the metal. When a complex ion combines with one or more *counterions* (ions of opposite charge that are not acting as ligands), the resulting neutral compound is a **coordination compound**.

▲ **Complex Ion and Coordination Compound** A coordination compound contains a complex ion and corresponding counterions. The complex ion contains a central metal atom coordinated to several ligands. The compound shown here is  $[\text{Co}(\text{NH}_3)_6]\text{Cl}_3$ .

The first coordination compounds were discovered in the early eighteenth century, but their nature was not understood until nearly 200 years later. Swiss chemist Alfred Werner (1866–1919) studied coordination compounds extensively—especially a series of cobalt(III) compounds with ammonia. The formulas for these compounds were then written as  $\text{CoCl}_3 \cdot 6 \text{NH}_3$ ,  $\text{CoCl}_3 \cdot 5 \text{NH}_3$  and,  $\text{CoCl}_3 \cdot 4 \text{NH}_3$ . In 1893, Werner proposed that the central metal ion has two types of interactions that he named **primary valence** and **secondary valence**. The primary valence is the oxidation state on the central metal atom, and the secondary valence is the number of molecules or ions directly bound to the metal atom, called the **coordination number**. In  $\text{CoCl}_3 \cdot 6 \text{NH}_3$  the primary valence is +3, and it was discovered that the ammonia molecules are directly bound to the central cobalt, giving a coordination number of 6. Today we write the formula of this compound as  $[\text{Co}(\text{NH}_3)_6]\text{Cl}_3$  to better represent the coordination compound as the combination of a complex ion,  $\text{Co}(\text{NH}_3)_6^{3+}$ , and three  $\text{Cl}^-$  counterions.

We write the formulas of the other cobalt(III) compounds studied by Werner as  $[\text{Co}(\text{NH}_3)_5\text{Cl}]\text{Cl}_2$  and  $[\text{Co}(\text{NH}_3)_4\text{Cl}_2]\text{Cl}$ . In these two cases, the complex ions are  $\text{Co}(\text{NH}_3)_5\text{Cl}^{2+}$  (with two  $\text{Cl}^-$  counterions) and  $\text{Co}(\text{NH}_3)_4\text{Cl}_2^+$  (with one  $\text{Cl}^-$  counterion), respectively. With this series of compounds, Werner demonstrated that the  $\text{Cl}^-$  can replace  $\text{NH}_3$  in the secondary valence. In other words,  $\text{Cl}^-$  can act as a counterion, or it can bond directly to the metal as part of the complex ion.

The complex ion itself contains the metal ion in the center and the ligands—which can be neutral molecules or ions—arranged around it. We can think of the metal–ligand complex as a Lewis acid–base adduct (see Section 16.11) because the bond is formed

when the ligand donates a pair of electrons to an empty orbital on the metal. For example, consider the reaction between the silver ion and ammonia:

A bond of this type, which we first encountered in Section 10.6, is often referred to as a **coordinate covalent bond**. Ligands are therefore good Lewis bases and have at least one pair of electrons to donate to, and bond with, the central metal ion. Table 25.2 contains a number of common ligands.

**TABLE 25.2** Common Ligands

Name	Lewis diagram
Water	$\text{H}-\ddot{\text{O}}-\text{H}$
Ammonia	$\begin{array}{c} \text{H}-\ddot{\text{N}}-\text{H} \\   \\ \text{H} \end{array}$
Chloride ion	$[\text{:}\ddot{\text{Cl}}\text{:}]^-$
Carbon monoxide	$\text{:C}\equiv\text{O:}$
Cyanide ion	$[\text{:C}\equiv\text{N:}]^-$
Thiocyanate ion	$[\text{:}\ddot{\text{S}}=\text{C}=\ddot{\text{N}}\text{:}]^-$
Oxalate ion (ox)	$\left[ \begin{array}{cc} \ddot{\text{O}} & \ddot{\text{O}} \\    &    \\ \text{C} & - & \text{C} \\ / & \backslash \\ \ddot{\text{O}} & \ddot{\text{O}} \end{array} \right]^{2-}$
Ethylenediamine (en)	$\begin{array}{cccc} & \text{H} & \text{H} & \\ &   &   & \\ \text{H}-\ddot{\text{N}} & -\text{C}- & \text{C}- & \ddot{\text{N}}-\text{H} \\ &   &   & \\ & \text{H} & \text{H} & \end{array}$
Ethylenediaminetetraacetate (EDTA)	$\left[ \begin{array}{ccccc} & \text{:O:} & & \text{:O:} & \\ &    & &    & \\ \text{:}\ddot{\text{O}}\text{:}-\text{CCH}_2 & & \text{CH}_2\text{C}-\ddot{\text{O}}\text{:}^- & & \\ & \backslash & & / & \\ & \text{NCH}_2\text{CH}_2\text{N} & & & \\ & / & & \backslash & \\ \text{:}\ddot{\text{O}}\text{:}-\text{CCH}_2 & & \text{CH}_2\text{C}-\ddot{\text{O}}\text{:}^- & & \\ &    & &    & \\ & \text{:O:} & & \text{:O:} & \end{array} \right]^{4-}$

Ligands that donate only one electron pair to the central metal are **monodentate**. Some ligands have the ability to donate two pairs of electrons (from two different atoms) to the metal; these are **bidentate**. Examples of bidentate ligands include the oxalate ion (abbreviated ox) and the ethylenediamine molecule (abbreviated en) shown here. The ethylenediamine ligand bonded to  $\text{Co}^{3+}$  is shown in Figure 25.5(a) ▼.

Some ligands, called **polydentate** ligands, can donate even more than two electron pairs (from more than two atoms) to the metal. The most common polydentate ligand is the ethylenediaminetetraacetate ion ( $\text{EDTA}^{4-}$ ) shown here:

The EDTA ligand wraps itself completely around the metal, donating up to six pairs of electrons (Figure 25.5b ▼). A complex ion that contains either a bidentate or polydentate ligand is a **chelate** (pronounced “key-late”), and the coordinating ligand is known as a **chelating agent**.

A survey of many coordination compounds shows that coordination numbers can vary from as low as 2 to as high as 12. The most common coordination numbers are 6, as occurs in  $[\text{Co}(\text{NH}_3)_6]^{3+}$ , and 4, as occurs in  $[\text{PdCl}_4]^{2-}$ . Coordination numbers greater than 6 are rarely observed for the first-row transition metals. Typically, only 1+ metal ions have a coordination number as low as 2, as occurs in  $[\text{Ag}(\text{NH}_3)_2]^+$ . Odd coordination numbers exist, but they are rare.

► **FIGURE 25.5** Bidentate and Polydentate Ligands Coordinated to  $\text{Co(III)}$  (a) Ethylenediamine is a bidentate ligand; (b) EDTA is a hexadentate ligand.

#### Bidentate and Polydentate Ligands Coordinated to $\text{Co(III)}$

The common geometries of complex ions, shown in Table 25.3, depend in part on their coordination number. A coordination number of 2 results in a linear geometry, and a coordination number of 6 results in an octahedral geometry. A coordination number of 4 can have either a tetrahedral geometry or a square planar geometry, depending on the number of  $d$  electrons in the metal ion. Metal ions with a  $d^8$  electron configuration (such as  $[\text{PdCl}_4]^{2-}$ ) exhibit square planar geometry, and metal ions with a  $d^{10}$  electron configuration (such as  $[\text{Zn}(\text{NH}_3)_4]^{2+}$ ) exhibit tetrahedral geometry.

**TABLE 25.3 Common Geometries of Complex Ions**

Coordination Number	Shape	Model	Example
2	Linear		$[\text{Ag}(\text{NH}_3)_2]^+$
4	Square planar		$[\text{PdCl}_4]^{2-}$
4	Tetrahedral		$[\text{Zn}(\text{NH}_3)_4]^{2+}$
6	Octahedral		$[\text{Fe}(\text{H}_2\text{O})_6]^{3+}$

## Naming Coordination Compounds

To name coordination compounds, we follow a series of general rules based on the system originally proposed by Werner. As with all salts (see Section 3.5), the name of the cation goes before the name of the anion.

Guidelines for Naming Complex Ions	Examples
<p><b>1.</b> Name the ligands.</p> <ul style="list-style-type: none"> <li>Name neutral ligands as molecules with the following notable exceptions: <ul style="list-style-type: none"> <li><math>\text{H}_2\text{O}</math> (aqua)</li> <li><math>\text{NH}_3</math> (ammine)</li> <li><math>\text{CO}</math> (carbonyl)</li> </ul> </li> <li>Name anionic ligands with the name of the ion plus an ending modified as follows: <ul style="list-style-type: none"> <li><i>-ide</i> becomes <i>-o</i></li> <li><i>-ate</i> becomes <i>-ato</i></li> <li><i>-ite</i> becomes <i>-ito</i></li> </ul> </li> </ul>	<p><math>\text{NH}_2\text{CH}_2\text{CH}_2\text{NH}_2</math> is ethylenediamine.</p> <p><math>\text{H}_2\text{O}</math> is aqua.</p> <p><math>\text{Cl}^-</math> is chloro.</p> <p><math>\text{SO}_4^{2-}</math> is sulfato.</p> <p><math>\text{SO}_3^{2-}</math> is sulfito.</p>
Table 25.4 lists the names of some common ligands.	
<p><b>2.</b> List the names of the ligands in alphabetical order before the name of the metal cation.</p>	<p>Ammine (<math>\text{NH}_3</math>) is listed before chloro (<math>\text{Cl}^-</math>), which is listed before nitrito (<math>\text{NO}_2^-</math>).</p>

—Continued on the next page

Guidelines for Naming Complex Ions	Examples
<p><b>3.</b> Use a prefix to indicate the number of ligands (when there is more than one of a particular type): <i>di-</i> (2), <i>tri-</i> (3), <i>tetra-</i> (4), <i>penta-</i> (5), or <i>hexa-</i> (6).</p> <p>If the name of the ligand already contains a prefix, such as ethylenediamine, place parentheses around the ligand name and use <i>bis-</i> (2), <i>tris-</i> (3), or <i>tetrakis-</i> (4) to indicate the number.</p> <p>Prefixes do not affect the order in which you list the ligands.</p>	<p>Trichloro indicates three <math>\text{Cl}^-</math> ligands. Tetraammine indicates four <math>\text{NH}_3</math> ligands.</p> <p>Tris(ethylenediamine) indicates three ethylenediamine ligands.</p>
<p><b>4.</b> Name the metal.</p> <p><b>a.</b> When the complex ion is a cation, use the name of the metal followed by the oxidation state written with a roman numeral.</p> <p><b>b.</b> If the complex ion is an anion, drop the ending of the metal and add <i>-ate</i> followed by the oxidation state written with a Roman numeral. Some metals use the Latin root with the <i>-ate</i> ending. Table 25.5 lists the names for some common metals in anionic complexes.</p>	<p>In cations:</p> <p><math>\text{Co}^{3+}</math> is cobalt(III). <math>\text{Pt}^{2+}</math> is platinum(II). <math>\text{Cu}^+</math> is copper(I).</p> <p>In anions:</p> <p><math>\text{Co}^{3+}</math> is cobaltate(III). <math>\text{Pt}^{2+}</math> is platinate(II). <math>\text{Cu}^+</math> is cuprate(I).</p>
<p><b>5.</b> Write the entire name of the complex ion by listing the ligands first followed by the metal.</p>	<p><math>[\text{Pt}(\text{NH}_3)_2\text{Cl}_4]^{2-}</math> is diamminetetrachloroplatinate(II). <math>[\text{Co}(\text{NH}_3)_6]^{3+}</math> is hexaamminecobalt(III).</p>

TABLE 25.4 Names and Formulas of Common Ligands	
Ligand	Name in Complex Ion
<b>Anions</b>	
Bromide, $\text{Br}^-$	Bromo
Chloride, $\text{Cl}^-$	Chloro
Hydroxide, $\text{OH}^-$	Hydroxo
Cyanide, $\text{CN}^-$	Cyano
Nitrite, $\text{NO}_2^-$	Nitro
Oxalate, $\text{C}_2\text{O}_4^{2-}$ (ox)	Oxalato
Ethylenediaminetetraacetate ( $\text{EDTA}^{4-}$ )	Ethylenediaminetetraacetato
<b>Neutral molecules</b>	
Water, $\text{H}_2\text{O}$	Aqua
Ammonia, $\text{NH}_3$	Ammine
Carbon monoxide, CO	Carbonyl
Ethylenediamine (en)	Ethylenediamine

TABLE 25.5 Names of Common Metals when Found in Anionic Complex Ions	
Metal	Name in Anionic Complex
Chromium	Chromate
Cobalt	Cobaltate
Copper	Cuprate
Gold	Aurate
Iron	Ferrate
Lead	Plumbate
Manganese	Manganate
Molybdenum	Molybdate
Nickel	Nickelate
Platinum	Platinate
Silver	Argentate
Tin	Stannate
Zinc	Zincate

When we write the *formula* of a complex ion, we write the symbol for the metal first, followed by neutral molecules and then anions. If there is more than one anion or neutral molecule acting as a ligand, we list them in alphabetical order based on the chemical symbol.

**Procedure for...**

<b>Naming Coordination Compounds</b>	<b>Example 25.3</b> <b>Naming Coordination Compounds</b> Name the following compound: $[\text{Cr}(\text{H}_2\text{O})_5\text{Cl}]\text{Cl}_2$ .	<b>Example 25.4</b> <b>Naming Coordination Compounds</b> Name the following compound: $\text{K}_3[\text{Fe}(\text{CN})_6]$ .
Identify the cation and anion and first name the simple ion (i.e., not the complex one).	<b>SOLUTION</b> $[\text{Cr}(\text{H}_2\text{O})_5\text{Cl}]^{2+}$ is a complex cation. $\text{Cl}^-$ is chloride.	<b>SOLUTION</b> $\text{K}^+$ is potassium. $[\text{Fe}(\text{CN})_6]^{3-}$ is a complex anion.
Give each ligand a name and list them in alphabetical order.	$\text{H}_2\text{O}$ is aqua. $\text{Cl}^-$ is chloro.	$\text{CN}^-$ is cyano.
Name the metal ion.	$\text{Cr}^{3+}$ is chromium(III).	$\text{Fe}^{3+}$ is ferrate(III) because the complex is anionic.
Name the complex ion by adding prefixes to indicate the number of each ligand followed by the name of each ligand followed by the name of the metal ion.	$[\text{Cr}(\text{H}_2\text{O})_5\text{Cl}]^{2+}$ is pentaquachlorochromium(III).	$[\text{Fe}(\text{CN})_6]^{3-}$ is hexacyanoferrate(III).
Name the compound by writing the name of the cation before the anion. The only space is between ion names.	$[\text{Cr}(\text{H}_2\text{O})_5\text{Cl}]\text{Cl}_2$ is pentaquachlorochromium(III) chloride.	$\text{K}_3[\text{Fe}(\text{CN})_6]$ is potassium hexacyanoferrate(III).
	<b>FOR PRACTICE 25.3</b> Name the following compound: $[\text{Mn}(\text{CO})(\text{NH}_3)_5]\text{SO}_4$ .	<b>FOR PRACTICE 25.4</b> Name the following compound: $\text{Na}_2[\text{PtCl}_4]$ .

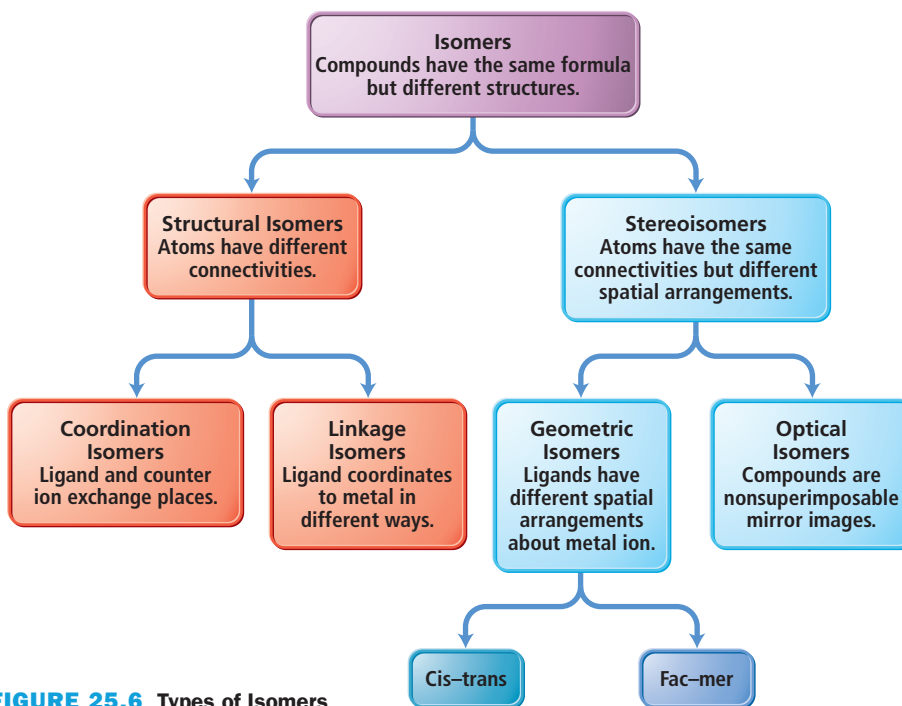

## 25.4 Structure and Isomerization

Isomerism is common in coordination compounds. We broadly divide the isomerism observed in coordination compounds into two categories. Each category has subcategories, as shown in Figure 25.6►, on the next page. In **structural isomers**, atoms are connected to one another in different ways, whereas in **stereoisomers**, atoms are connected in the same way but the ligands have a different spatial arrangement about the metal atom.

### Structural Isomerism

We subdivide the broad category of structural isomers into two types: coordination isomers and linkage isomers. **Coordination isomers** occur when a coordinated ligand exchanges places with the uncoordinated counterion. For example, two different compounds have the general formula  $\text{Co}(\text{NH}_3)_5\text{BrCl}$ . In one of them, the bromine coordinates to the metal and chloride is a counterion, pentaamminebromocobalt(II) chloride,  $[\text{Co}(\text{NH}_3)_5\text{Br}]\text{Cl}$ ; in the other one, the chlorine coordinates to the metal and bromide is the counterion, pentaamminechlorocobalt(II) bromide,  $[\text{Co}(\text{NH}_3)_5\text{Cl}]\text{Br}$ .

**Linkage isomers** have ligands that can coordinate to the metal in different orientations. For example, the nitrite ion ( $\text{NO}_2^-$ ) has a lone pair on the N atom as well as lone pairs on the O atoms—either of the two atoms can form coordinate covalent bonds with the metal. When the nitrite ion coordinates through the N atom, it is a *nitro* ligand and

► **FIGURE 25.6** Types of Isomers

is represented as  $\text{NO}_2^-$ , but when it coordinates through the O atom, it is a *nitrito* ligand and is usually represented as  $\text{ONO}^-$ . An example of linkage isomerization can be seen in the yellow-orange complex ion pentaamminenitrocobalt(III),  $[\text{Co}(\text{NH}_3)_5\text{NO}_2]^{2+}$ , which contrasts with the red-orange complex ion pentaamminenitritocobalt(III),  $[\text{Co}(\text{NH}_3)_5\text{ONO}]^{2+}$ , as shown in Figure 25.7. Table 25.6 lists other ligands capable of linkage isomerization.

► **FIGURE 25.7** Linkage Isomers

In  $[\text{Co}(\text{NH}_3)_5\text{NO}_2]^{2+}$ , the  $\text{NO}_2$  ligand bonds to the central metal atom through the nitrogen atom. In  $[\text{Co}(\text{NH}_3)_5\text{ONO}]^{2+}$ , the  $\text{NO}_2$  ligand bonds through the oxygen atoms. The different isomers have different colors.

TABLE 25.6 Ligands Capable of Linkage Isomerization

## Stereoisomerism

We can also subdivide the broad category of stereoisomers into two types: geometric isomers and optical isomers. **Geometric isomers** result when the ligands bonding to the metal have a different spatial arrangement. One type of geometric isomerism, as we saw in Section 21.5, is cis-trans isomerism, which in complex ions occurs in square planar complexes of the general formula  $\text{MA}_2\text{B}_2$  or octahedral complexes of the general formula  $\text{MA}_4\text{B}_2$ . For example, cis-trans isomerism occurs in the square planar complex  $\text{Pt}(\text{NH}_3)_2\text{Cl}_2$ . Figure 25.8(a) shows the two distinct ways in which the ligands can be oriented around the metal. In one complex, the  $\text{Cl}^-$  ligands are next to each other on one side of the molecule—this is the cis isomer. In the other complex, the  $\text{Cl}^-$  ligands are on opposite sides of the molecule—this is the trans isomer.

Geometric isomerism also exists in the octahedral complex ion  $[\text{Co}(\text{NH}_3)_4\text{Cl}_2]^+$ . As shown in Figure 25.8(b), the ligands arrange themselves around the metal in two ways, one with the  $\text{Cl}^-$  ligands on the same side (the cis isomer) and another with the  $\text{Cl}^-$  ligands

◀ **FIGURE 25.8** Cis-trans Isomerism

**(a)** Cis-trans isomerism in square planar  $\text{Pt}(\text{NH}_3)_2\text{Cl}_2$ . In the cis isomer, the  $\text{Cl}^-$  ligands are next to each other on one side of the molecule. In the trans isomer, the  $\text{Cl}^-$  ligands are on opposite sides of the molecule. **(b)** Cis-trans isomerism in octahedral  $[\text{Co}(\text{NH}_3)_4\text{Cl}_2]^+$ . In the cis isomer, the  $\text{Cl}^-$  ligands are on the same side. In the trans isomer, the  $\text{Cl}^-$  ligands are on opposite sides.

on opposite sides of the metal (the trans isomer). Note that cis-trans isomerism does not occur in tetrahedral complexes because all bond angles around the metal are  $109.5^\circ$ , and each corner of a tetrahedron is considered to be adjacent to all three other corners.

Another type of geometric isomerism is fac-mer isomerism, which occurs in octahedral complexes of the general formula  $\text{MA}_3\text{B}_3$ . For example, in  $\text{Co}(\text{NH}_3)_3\text{Cl}_3$ , the ligands arrange themselves around the metal in two ways (Figure 25.9). In the fac isomer the three  $\text{Cl}^-$  ligands are all on one side of the molecule and make up one face of the octahedron (fac is short for facial). In the mer isomer the three ligands form an arc around the middle of the octahedron (mer is short for meridian).

► **FIGURE 25.9** Fac-Mer Isomerism in  $\text{Co}(\text{NH}_3)_3\text{Cl}_3$  In the fac isomer, all three  $\text{Cl}^-$  ligands are on one side of the molecule and make up one face of the octahedron. In the mer isomer, the three ligands inscribe an arc around the middle (or meridian) of the octahedron.

## Procedure for...

Identifying and Drawing Geometric Isomers	<b>Example 25.5</b> <b>Identifying and Drawing Geometric Isomers</b> Draw the structures and label the type of all the isomers of $[\text{Co}(\text{en})_2\text{Cl}_2]^+$ .	<b>Example 25.6</b> <b>Identifying and Drawing Geometric Isomers</b> Draw the structures and label the type for of the isomers of $[\text{Ni}(\text{CN})_2\text{Cl}_2]^{2-}$ .
Identify the coordination number and the geometry around the metal.	<b>SOLUTION</b> The ethylenediamine (en) ligand is bidentate, so each occupies two coordination sites. Each $\text{Cl}^-$ is monodentate, occupying one site. The total coordination number is 6, so this must be an octahedral complex.	<b>SOLUTION</b> All the ligands are monodentate, so the total coordination number is 4. $\text{Ni}^{2+}$ is a $d^8$ electronic configuration, so we expect a square planar complex.
Identify if this is cis-trans or fac-mer isomerism.	With ethylenediamine occupying four sites and $\text{Cl}^-$ occupying two sites, it fits the general formula $\text{MA}_4\text{B}_2$ , leading to cis-trans isomers.	Square planar complexes can only have cis-trans isomers.
Draw and label the two isomers.	<div style="display: flex; justify-content: space-around; margin-top: 5px;"> <span>Cis</span> <span>Trans</span> </div>	<div style="display: flex; justify-content: space-around; margin-top: 5px;"> <span>Cis</span> <span>Trans</span> </div>
	<b>FOR PRACTICE 25.5</b> Draw the structures and label the type of all the isomers of $[\text{Cr}(\text{H}_2\text{O})_3\text{Cl}_3]^+$ .	<b>FOR PRACTICE 25.6</b> Draw the structures and label the type of all the isomers of $[\text{Co}(\text{NH}_3)_2\text{Cl}_2(\text{ox})]^-$ .

The second category of stereoisomerism is optical isomerism. Recall from Section 21.3 that **optical isomers** are nonsuperimposable mirror images of one another. If you hold your right hand up to a mirror, the image in the mirror looks like your left hand.

No matter how you rotate or flip your left hand, you cannot superimpose it on your right hand. Molecules or ions that exhibit this quality are *chiral*. The isomers are *enantiomers*, and they exhibit the property of optical activity (the rotation of polarized light). The complex ion  $[\text{Co}(\text{en})_3]^{3+}$  is nonsuperimposable on its mirror image, so it is a chiral complex (Figure 25.10▼).

◀ **FIGURE 25.10** Optical Isomerism in  $[\text{Co}(\text{en})_3]^{3+}$  The mirror images of  $[\text{Co}(\text{en})_3]^{3+}$  are not superimposable. (The connected nitrogen atoms represent the ethylenediamine ligand.)

### Example 25.7 Recognizing and Drawing Optical Isomers

Determine whether the cis or trans isomers in Example 25.5 are optically active (demonstrate optical isomerism).

#### SOLUTION

Draw the trans isomer of  $[\text{Co}(\text{en})_2\text{Cl}_2]^+$  and its mirror image. Check to see if they are superimposable by rotating one isomer  $180^\circ$ .

In this case the two are identical, so there is no optical activity.

—Continued on the next page

Continued—

Draw the cis isomer and its mirror image. Check to see if they are superimposable by rotating one isomer 180°.

**FOR PRACTICE 25.7** Determine whether the fac or mer isomers of  $[\text{Cr}(\text{H}_2\text{O})_3\text{Cl}_3]^+$  are optically active.

The previous examples demonstrate optical isomerism in octahedral complexes. Tetrahedral complexes can also exhibit optical isomerism, but only if all four coordination sites are occupied by different ligands. Square planar complexes do not normally exhibit optical isomerism as they are superimposable on their mirror images.

## 25.5 Bonding in Coordination Compounds

The bonding in complex ions and coordination compounds can be described by valence bond theory, which helps us to understand the geometries of the complex ions. However,

other properties of complex ions, such as their colors and their magnetic properties, require a different model called crystal field theory. We examine both models in this section.

Geometry	Hybridization	Orbitals
Linear	$sp$	
Tetrahedral	$sp^3$	
Square planar	$dsp^2$	
Octahedral	$d^2sp^3$	

**▲ FIGURE 25.11 Common Hybridization Schemes in Complex Ions** We can deduce the valence bond model hybridization schemes from the geometry of the complex ion.

### Valence Bond Theory

Recall from Section 10.6 that according to valence bond theory, a coordinate covalent bond is the overlap between a completely filled atomic orbital and an empty atomic orbital. In complex ions, the filled orbital is on the ligand, and the empty orbital is on the metal ion. The metal ion orbitals are hybridized according to the geometry of the complex ion. The common hybridization schemes are shown in Figure 25.11. An octahedral complex ion requires six empty orbitals in an octahedral arrangement on the metal ion. A full set of  $d^2sp^3$  hybrid orbitals results in the exact orbitals needed for this geometry. A set of  $sp^3$  hybrid orbitals results in a tetrahedral arrangement of orbitals, a set of  $dsp^2$  hybrid

orbitals results in a square planar arrangement, and a set of  $sp$  hybrid orbitals results in a linear arrangement of orbitals. In each case, the coordinate covalent bond is formed by the overlap between the orbitals on the ligands and the hybridized orbitals on the metal ion.

## Crystal Field Theory

Crystal field theory (CFT) is a bonding model for transition metal complexes that helps us to understand their colors and magnetic properties. To illustrate the basic principles of CFT, we examine the central metal atom's  $d$  orbitals in an octahedral complex.

### Octahedral Complexes

The basic premise of CFT is that complex ions form because of attractions between the electrons on the ligands and the positive charge on the metal ion. However, the electrons on the ligands also repel the electrons in the *unhybridized* metal  $d$  orbitals. CFT focuses on these repulsions. Figure 25.12 shows how the ligand positions superimpose on the  $d$  orbitals in an octahedral complex. Notice that the ligands in an octahedral complex are located in the same space as the lobes of the  $d_{x^2-y^2}$  and  $d_{z^2}$  orbitals. The repulsions *between* electron pairs in the ligands and any potential electrons in the  $d$  orbitals result in an increase in the energies of these orbitals. In contrast, the  $d_{xy}$ ,  $d_{xz}$ , and  $d_{yz}$  orbitals lie *between* the axes and have nodes directly on the axes, which results in less repulsion and lower energies for these three orbitals. In other words, the  $d$  orbitals—which are degenerate in the bare metal ion—are split into higher- and lower-energy levels because of the spatial arrangement of the ligands (Figure 25.13). The difference in energy between these split  $d$  orbitals is known as the crystal field splitting energy ( $\Delta$ ). The magnitude of the splitting depends on the particular complex. In **strong-field complexes**, the splitting is large, and in **weak-field complexes**, the splitting is small.

Ligands overlap with orbital lobes, resulting in strong repulsions.

Ligands come in between orbital lobes, resulting in weak repulsions.

**▲ FIGURE 25.12 Relative Positions of  $d$  Orbitals and Ligands in an Octahedral Complex** The ligands in an octahedral complex (represented here as spheres of negative charge) interact most strongly with the  $d_{z^2}$  and  $d_{x^2-y^2}$  orbitals.

**▲ FIGURE 25.13  $d$  Orbital Splitting in an Octahedral Field** The otherwise degenerate  $d$  orbitals are split into two energy levels by the ligands in an octahedral complex ion.

▲ **FIGURE 25.14** Colors of Complex Ions

(a) The complex ion  $[\text{Fe}(\text{CN})_6]^{3-}$  forms a deep red solution, and (b)  $[\text{Ni}(\text{NH}_3)_6]^{2+}$  is blue.

### The Color of Complex Ions and Crystal Field Strength

We discussed in the opening section of this chapter that transition metals in host crystals often show brilliant colors because of the crystal field splitting of their  $d$  orbitals. Solutions of complex ions display brilliant colors because of similar splittings. For example, an  $[\text{Fe}(\text{CN})_6]^{3-}$  solution is deep red, and an  $[\text{Ni}(\text{NH}_3)_6]^{2+}$  solution is blue (Figure 25.14 ◀).

Recall from Chapter 7 that the color of an object is related to the absorption of light energy by its electrons. If a substance absorbs all of the visible wavelengths, it appears black. If it transmits (or reflects) all the wavelengths (absorbs no light), it appears colorless. A substance appears to be a particular color if it absorbs some visible light but also transmits (or reflects) the wavelengths associated with that color. A substance also appears to be a given color if it transmits (or reflects) most wavelengths but absorbs the *complementary color* on a color wheel (Figure 25.15 ▼). For example, a substance that absorbs green light (the complement of red) will appear red. A solution of  $[\text{Ti}(\text{H}_2\text{O})_6]^{3+}$  is purple because it absorbs strongly between 490 and 580 nm, the yellow-green region of the visible spectrum (Figure 25.16(a) ▼).

The easiest way to measure the energy difference between the  $d$  orbitals in a complex ion is to use spectroscopy to determine the wavelength of light absorbed when an electron makes a transition from the lower-energy  $d$  orbitals to the higher-energy ones. With that information we can calculate the crystal field splitting energy,  $\Delta$ :

$$E_{\text{photon}} = h\nu = \frac{hc}{\lambda} = \Delta$$

Consider the  $[\text{Ti}(\text{H}_2\text{O})_6]^{3+}$  absorption spectrum shown in Figure 25.16(b) ▼. The maximum absorbance is at 498 nm. Using this wavelength, we calculate  $\Delta$ :

$$\Delta = \frac{hc}{\lambda} = \frac{(6.626 \times 10^{-34} \text{ J} \cdot \text{s})(3.00 \times 10^8 \text{ m/s})}{(498 \text{ nm} \times 1 \times 10^{-9} \text{ m/nm})}$$

$$\Delta = 3.99 \times 10^{-19} \text{ J}$$

This energy corresponds to a single  $[\text{Ti}(\text{H}_2\text{O})_6]^{3+}$  ion. We can convert to kilojoules per mole:

$$\Delta = \left(3.99 \times 10^{-19} \frac{\text{J}}{\text{ion}}\right) \left(6.02 \times 10^{23} \frac{\text{ion}}{\text{mol}}\right) \left(1 \frac{\text{kJ}}{1000 \text{ J}}\right) = 240 \text{ kJ/mol}$$

▲ **FIGURE 25.15** The Color Wheel Colors across from one another on the color wheel are said to be complementary. A substance that absorbs a color on the wheel will appear to be its complementary color.

▲ **FIGURE 25.16** The Color and Absorption Spectrum of  $[\text{Ti}(\text{H}_2\text{O})_6]^{3+}$  (a) A solution containing  $[\text{Ti}(\text{H}_2\text{O})_6]^{3+}$  is purple. (b) The absorption spectrum of  $[\text{Ti}(\text{H}_2\text{O})_6]^{3+}$  extends across the green-yellow region of the spectrum.

**Example 25.8** Crystal Field Splitting Energy

The complex ion  $[\text{Cu}(\text{NH}_3)_6]^{2+}$  is blue in aqueous solution. Estimate the crystal field splitting energy (in kJ/mol) for this ion.

**SOLUTION**

Begin by consulting the color wheel to determine approximately which wavelength is being absorbed.	Because the solution is blue, you can deduce that orange light is absorbed since orange is the complementary color to blue.
Estimate the absorbed wavelength.	The color orange ranges from 580 to 650 nm, so you can estimate the average wavelength as 615 nm.
Calculate the energy corresponding to this wavelength, using $E = hc/\lambda$ . This energy corresponds to $\Delta$ .	$E = \frac{(6.626 \times 10^{-34} \text{ J} \cdot \text{s})(3.00 \times 10^8 \text{ m/s})}{(615 \text{ nm})(1 \times 10^{-9} \text{ m/nm})}$ $E = 3.23 \times 10^{-19} \text{ J} = \Delta$
Convert J/ion into kJ/mol.	$E = \frac{(3.23 \times 10^{-19} \text{ J/ion})(6.02 \times 10^{23} \text{ ion/mol})}{(1000 \text{ J/kJ})}$ $\Delta = 195 \text{ kJ/mol}$

**FOR PRACTICE 25.8** The complex ion  $[\text{Co}(\text{NH}_3)_5\text{NO}_2]^{2+}$  is yellow. Estimate the crystal field splitting energy (in kJ/mol) for this ion.

The magnitude of the crystal field splitting in a complex ion—and, therefore whether it is a strong-field or a weak-field complex—depends in large part on the ligands attached to the central metal ion. Spectroscopic studies of various ligands attached to the same metal allow us to arrange different ligands in order of their ability to split the  $d$  orbitals. This list is known as the *spectrochemical series* and is arranged from ligands that result in the largest  $\Delta$  to those that result in the smallest:

typically strong-field ligands

typically weak-field ligands

Ligands that produce large values of  $\Delta$  are *strong-field ligands*, and those that give small values of  $\Delta$  are *weak-field ligands*.

The metal ion also has an effect on the magnitude of  $\Delta$ . If we examine different metal ions with the same ligand, we find that  $\Delta$  increases as the charge on the metal ion increases. The greater charge on the metal draws the ligands closer, causing greater repulsion with the  $d$  orbitals and therefore a larger  $\Delta$ . An example of this behavior occurs in the complex ions between  $\text{NH}_3$  (a ligand in the middle of the spectrochemical series) and the +2 or +3 oxidation states of cobalt. Hexaamminecobalt(II) ion,  $[\text{Co}(\text{NH}_3)_6]^{2+}$ , has a weak crystal field (small  $\Delta$ ) and hexaamminecobalt(III) ion,  $[\text{Co}(\text{NH}_3)_6]^{3+}$ , has a strong field (large  $\Delta$ ).

**Weak- and Strong-Field Ligands** Two ligands, A and B, form complexes with a particular metal ion. When the metal ion complexes with ligand A, the resulting solution is red. When the metal ion complexes with ligand B, the resulting solution is yellow. Which of the two ligands produces the larger  $\Delta$ ?

CONCEPTUAL  
CONNECTION 25.2

**Magnetic Properties**

The strength of the crystal field can affect the magnetic properties of a transition metal complex. Recall that, according to Hund's rule, electrons occupy degenerate orbitals singly as long as an empty orbital is available. When the energies of the  $d$  orbitals are split

Recall from Section 8.7 that a paramagnetic species contains unpaired electrons and a diamagnetic one does not.

by ligands, the lower-energy orbitals fill first. Once they are half-filled, the next electron can either: (1) pair with an electron in one of the lower-energy half-filled orbitals by overcoming the electron–electron repulsion associated with having two electrons in the same orbital; or (2) go into an empty orbital of higher energy by overcoming the energy difference between the orbitals—in this case, the crystal field splitting energy,  $\Delta$ . The magnitude of  $\Delta$  compared to the electron–electron repulsions determines which of these two actually occurs.

We can compare two iron(II) complexes to see the difference in behavior under strong- and weak-field conditions.  $[\text{Fe}(\text{CN})_6]^{4-}$  is known to be diamagnetic, and  $[\text{Fe}(\text{H}_2\text{O})_6]^{2+}$  is known to be paramagnetic. Both of these complexes contain  $\text{Fe}^{2+}$ , which has an electron configuration of  $[\text{Ar}] 3d^6$ . In the case of  $[\text{Fe}(\text{CN})_6]^{4-}$ ,  $\text{CN}^-$  is a strong-field ligand that generates a large  $\Delta$ , so it takes more energy to occupy the higher-energy level than it does to pair the electrons in the lower-energy level. The result is that all six electrons are paired and the compound is diamagnetic, as shown in the accompanying figure in the margin.

In  $[\text{Fe}(\text{H}_2\text{O})_6]^{2+}$ ,  $\text{H}_2\text{O}$  is a weak-field ligand that generates a small  $\Delta$ , so the electron pairing energy is greater than  $\Delta$ . Consequently, the first five electrons occupy the five  $d$  orbitals singly and only the sixth pairs up, resulting in a paramagnetic compound with four unpaired electrons, as shown in the accompanying figure in the margin.

In general, complexes with strong-field ligands have fewer unpaired electrons relative to the free metal ion and are therefore called **low-spin complexes**. Complexes with weak-field ligands, by contrast, have the same number of unpaired electrons as the free metal ion and are **high-spin complexes**.

When we examine the orbital diagrams of the  $d^1$  through  $d^{10}$  metal ions in octahedral complexes, we find that only  $d^4$ ,  $d^5$ ,  $d^6$ , and  $d^7$  metal ions have low- and high-spin possibilities. Since there are three lower-energy  $d$  orbitals, the  $d^1$ ,  $d^2$ , and  $d^3$  metal ions always have unpaired electrons, independent of  $\Delta$ . In the  $d^8$ ,  $d^9$ , and  $d^{10}$  metal ions, the three lower-energy orbitals are completely filled, so the remaining electrons fill the two higher orbitals (as expected according to Hund's rule), also independent of  $\Delta$ .

## Procedure for...

### Determining the Number of Unpaired Electrons in Octahedral Complexes

Begin by determining the charge and number of  $d$  electrons on the metal.

Look at the spectrochemical series to determine whether the ligand is a strong-field or a weak-field ligand.

Decide if the complex is high- or low-spin and draw the electron configuration.

### Example 25.9

#### High- and Low-Spin Octahedral Complexes

How many unpaired electrons are there in the complex ion  $[\text{CoF}_6]^{3-}$ ?

#### SOLUTION

The metal is  $\text{Co}^{3+}$  and has a  $d^6$  electronic configuration.

$\text{F}^-$  is a weak-field ligand, so  $\Delta$  is relatively small.

Weak-field ligands yield high-spin configurations.

### Example 25.10

#### High- and Low-Spin Octahedral Complexes

How many unpaired electrons are there in the complex ion  $[\text{Co}(\text{NH}_3)_5\text{NO}_2]^{2+}$ ?

#### SOLUTION

The metal is  $\text{Co}^{3+}$  and has a  $d^6$  electronic configuration.

$\text{NH}_3$  and  $\text{NO}_2^-$  are both strong-field ligands, so  $\Delta$  is relatively large.

Strong-field ligands yield low-spin configurations.

Count the unpaired electrons.	This configuration has four unpaired electrons.	This configuration has no unpaired electrons.
	<b>FOR PRACTICE 25.9</b> How many unpaired electrons are there in the complex ion $[\text{FeCl}_6]^{3-}$ ?	<b>FOR PRACTICE 25.10</b> How many unpaired electrons are there in the complex ion $[\text{Co}(\text{CN})_6]^{4-}$ ?

### Tetrahedral and Square Planar Complexes

So far, we have examined the  $d$  orbital energy changes only for octahedral complexes, but transition metal complexes can have other geometries, such as tetrahedral and square planar. We use crystal field theory to determine the  $d$  orbital splitting pattern for these geometries as well. For a tetrahedral complex, the  $d$  orbital splitting pattern is the opposite of the octahedral splitting pattern: three  $d$  orbitals ( $d_{xy}$ ,  $d_{xz}$ , and  $d_{yz}$ ) are higher in energy, and two  $d$  orbitals ( $d_{x^2-y^2}$  and  $d_{z^2}$ ) are lower in energy (Figure 25.17▼). Almost all tetrahedral complexes are high-spin because of reduced ligand-metal interactions. The  $d$  orbitals in a tetrahedral complex interact with only four ligands, as opposed to six in the octahedral complex, so the value of  $\Delta$  is generally smaller.

**FIGURE 25.17** Splitting of  $d$  Orbitals by a Tetrahedral Ligand Geometry In tetrahedral complexes, the splitting of the  $d$  orbitals has a pattern that is the opposite of the octahedral splitting pattern. The  $d_{xy}$ ,  $d_{yz}$ , and  $d_{xz}$  orbitals are higher in energy than the  $d_{z^2}$  and  $d_{x^2-y^2}$  orbitals.

A square planar complex gives us the most complex splitting pattern of the three geometries (Figure 25.18▼). As we discussed previously, square planar complexes occur in  $d^8$  metal ions, such as  $\text{Pt}^{2+}$ ,  $\text{Pd}^{2+}$ ,  $\text{Ir}^+$ , or  $\text{Au}^{3+}$ , and they are low-spin in nearly all cases.

**FIGURE 25.18** Splitting of  $d$  Orbitals by a Square Planar Ligand Geometry Square planar complexes produce the  $d$  orbital energy pattern shown here.

## 25.6 Applications of Coordination Compounds

Coordination compounds are found in living systems, in industry, and even in household products. Recall from Chapter 24 how silver and gold metals are extracted from their respective ores using cyanide complexes and how nickel metal is extracted by forming the gaseous carbonyl complex,  $\text{Ni}(\text{CO})_4$ . In this section, we describe a few additional applications of coordination compounds.

▲ **FIGURE 25.19** Chemical Analysis with  $\text{SCN}^-$  (a) Blue indicates  $\text{Co}^{2+}$ . (b) Red indicates  $\text{Fe}^{3+}$ .

## Chelating Agents

In Section 25.3, we introduced the chelating agent ethylenediaminetetraacetate ion ( $\text{EDTA}^{4-}$ ). This ligand has lone pairs on six different donor atoms that can interact with a metal ion to form very stable metal complexes. EDTA is used to treat victims of heavy metal poisoning such as lead poisoning. The patient is given  $[\text{Ca}(\text{EDTA})]^{2-}$  and because the lead complex ( $K_f = 2 \times 10^{18}$ ) is more stable than the calcium complex ( $K_f = 4 \times 10^{10}$ ), the lead displaces the calcium. The body excretes the lead complex and leaves behind the calcium, which is nontoxic (and is in fact a nutrient).

## Chemical Analysis

Some ligands are selective in their binding, preferring specific metal ions; these ligands can be used in chemical analysis. For example, dimethylglyoxime ( $\text{dmg}$ ) is used to chemically analyze a sample for  $\text{Ni}^{2+}$  or  $\text{Pd}^{2+}$ . In the presence of  $\text{Ni}^{2+}$ , an insoluble red precipitate forms, and in the presence of  $\text{Pd}^{2+}$ , an insoluble yellow precipitate forms. Similarly, the  $\text{SCN}^-$  ligand is used to test for  $\text{Co}^{2+}$  or  $\text{Fe}^{3+}$ . In the presence of  $\text{Co}^{2+}$  a blue solution forms, and in the presence of  $\text{Fe}^{3+}$  a deep red solution forms (Figure 25.19 ◀).

## Coloring Agents

Because of the wide variety of colors found in coordination complexes, they are often used as coloring agents. For example, a commercially available agent, iron blue, is a mixture of the hexacyano complexes of iron(II) and iron(III). Iron blue is used in ink, paint, cosmetics (eye shadow), and blueprints.

## Biomolecules

Living systems contain many molecules based on metal complexes. Hemoglobin (involved in oxygen transport), cytochrome c (involved in electron transport), carbonic anhydrase (involved in respiration), and chlorophyll (involved in photosynthesis) all have coordinated metal ions that are critical to their structure and function. Table 25.7 summarizes the biological significance of many of the other first-row transition metals.

**TABLE 25.7** Transition Metals and Some of Their Functions in the Human Body

Transition Metal	Biological Function
Chromium	Works with insulin to control utilization of glucose
Manganese	Fat and carbohydrate synthesis
Molybdenum	Involved in hemoglobin synthesis
Iron	Oxygen transport
Copper	Involved in hemoglobin synthesis
Zinc	Involved in cell reproduction and tissue growth; part of more than 70 enzymes; assists in the utilization of carbohydrate, protein, and fat

## Hemoglobin and Cytochrome C

In hemoglobin and in cytochrome c, an iron complex called a heme is connected to a protein, as shown in the figure below. A heme is an iron ion coordinated to a flat,

polydentate ligand called a porphyrin (Figure 25.20▼). The porphyrin ligand has a planar ring structure with four nitrogen atoms that can coordinate to the metal ion. Different porphyrins have different substituent groups connected around the outside of the ring.

◀ **FIGURE 25.20 Porphyrin** A porphyrin has four nitrogen atoms that can coordinate to a central metal atom.

In hemoglobin, the iron complex is octahedral, with the four nitrogen atoms of the porphyrin in a square planar arrangement around the metal. A nitrogen atom from a nearby amino acid of the protein occupies the fifth coordination site, and either  $O_2$  or  $H_2O$  occupies the last coordination site (Figure 25.21▶). In the lungs, where the oxygen content is high, the hemoglobin

Hemoglobin is discussed in Section 15.1.

▶ **FIGURE 25.21 Hemoglobin** In hemoglobin, the iron complex is octahedral, with the four nitrogen atoms of the porphyrin in a square planar arrangement around the metal. A nitrogen atom from a nearby amino acid of the protein occupies the fifth coordination site, and either  $O_2$  or  $H_2O$  occupies the last coordination site.

Hemoglobin

Heme structure

▲ **FIGURE 25.22 Chlorophyll**  
Chlorophyll, involved in photosynthesis in plants, contains magnesium coordinated to a porphyrin.

coordinates to an  $O_2$  molecule. The oxygen-rich hemoglobin is carried by the bloodstream to areas throughout the body that are depleted in oxygen, where oxygen is released and replaced by a water molecule. The hemoglobin then travels back to the lungs to repeat the cycle.

### Chlorophyll

Chlorophyll, shown in Figure 25.22 ◀, is another porphyrin-based biomolecule. In chlorophyll the porphyrin is not surrounded by a protein, and the coordinated metal is magnesium (which is not a transition metal). Chlorophyll is essential for photosynthesis process performed by plants, in which light energy from the sun is converted to chemical energy to fuel the plant's growth.

### Carbonic Anhydrase

In carbonic anhydrase, the zinc ion is bound in a tetrahedral complex, with three of the coordination sites occupied by nitrogen atoms from surrounding amino acids and the fourth site available to bind a water molecule (Figure 25.23 ▼). Carbonic anhydrase catalyzes the reaction between water and  $CO_2$  in respiration:

▲ **FIGURE 25.23 Carbonic Anhydrase** Carbonic anhydrase contains a zinc ion that is bound in a tetrahedral complex, with three of the coordination sites occupied by nitrogen atoms from surrounding amino acids. The fourth site is available to bind a water molecule.

A water molecule alone is not acidic enough to react with a  $CO_2$  molecule at a sufficient rate. When the water molecule is bound to the zinc ion in carbonic anhydrase, the positive charge on the metal draws electron density from the  $O-H$  bond and the  $H_2O$  becomes more acidic—sufficiently so to readily lose a proton. The resulting bound  $OH^-$  easily reacts with a  $CO_2$  molecule, and the reaction is much faster than the uncatalyzed version.

### Drugs and Therapeutic Agents

In the mid-1960s, researchers found that the platinum(II) complex *cis*- $[Pt(NH_3)_2Cl_2]$ , known as cisplatin, is an effective anticancer agent (Figure 25.24 ◀). Interestingly, the closely related geometric isomer *trans*- $[Pt(NH_3)_2Cl_2]$  has little or no effect on cancer tumors. Cisplatin is believed to function by attaching itself to the cancer cell's DNA and replacing the  $Cl^-$  ligands with donor atoms from the DNA strands. The *cis* arrangement of the  $Cl^-$  ligands corresponds to the geometry required to bind to the DNA strands. The *trans* isomer, though closely related, cannot bind properly due to the arrangement of the  $Cl^-$  ligands and is therefore not an effective agent. Cisplatin and other closely related platinum(II) complexes are still used today in chemotherapy for certain types of cancer and are among the most effective anticancer agents available for these cases.

▲ **FIGURE 25.24 Cisplatin**  
Cisplatin is an effective anticancer agent.

## Self-Assessment Quiz

- Q1.** What is the electron configuration of the  $\text{Cu}^+$  ion?
- a)  $[\text{Ar}]4s^23d^9$                       b)  $[\text{Ar}]4s^23d^8$   
 c)  $[\text{Ar}]4s^13d^9$                       d)  $[\text{Ar}]4s^03d^{10}$
- Q2.** Which metal has the highest first ionization energy?
- a) Ti                      b) Mn                      c) Ru                      d) Au
- Q3.** What is the name of the compound  $[\text{CoCl}(\text{NH}_3)_5]\text{Cl}_2$ ?
- a) pentaamminetrichlorocobalt(III) chloride  
 b) pentaamminechlorocobalt(III) chloride  
 c) pentaamminechlorocobalt(II) chloride  
 d) pentaamminetrichlorocobalt(II) chloride
- Q4.** What is the formula of hexaaquamanganese(II) sulfate?
- a)  $[\text{Mn}(\text{OH})_6]\text{SO}_4$                       b)  $[\text{Mn}(\text{H}_2\text{O})_6]\text{SO}_4$   
 c)  $[\text{Mn}(\text{H}_2\text{O})_6]_2\text{SO}_4$                       d)  $[\text{Mn}_2(\text{H}_2\text{O})_6]\text{SO}_4$
- Q5.** Which complex ion can exhibit geometric isomerism? Assume that M is the metal ion, A and B are ligands, and the geometry is octahedral.
- a)  $[\text{MA}_6]^{2+}$                       b)  $[\text{MA}_5\text{B}]^{2+}$   
 c)  $[\text{MA}_4\text{B}_2]^{2+}$                       d)  $[\text{MA}_3\text{B}_3]^{2+}$
- Q6.** Pick the optical isomer of the complex ion represented here:

- Q7.** According to valence bond theory, what is the hybridization of the central metal ion in an octahedral complex ion?
- a)  $sp$                       b)  $sp^3$                       c)  $dsp^2$                       d)  $d^2sp^3$
- Q8.** Estimate the crystal field splitting energy (in kJ/mol) for a complex ion that is red in solution.
- a) 228 kJ/mol  
 b) 171 kJ/mol  
 c)  $2.84 \times 10^{-19}$  kJ/mol  
 d)  $3.79 \times 10^{-19}$  kJ/mol
- Q9.** Use crystal field theory to determine the number of unpaired electrons in the complex ion  $[\text{Fe}(\text{CN})_6]^{4-}$ .
- a) 0                      b) 2                      c) 3                      d) 4
- Q10.** Which complex ion is diamagnetic?
- a)  $[\text{Cr}(\text{H}_2\text{O})_4\text{Cl}_2]^+$                       b)  $[\text{Fe}(\text{H}_2\text{O})_6]^{2+}$   
 c)  $[\text{Co}(\text{NH}_3)_6]^{3+}$                       d)  $[\text{CoCl}_6]^{3-}$

Answers: 1. (d) 2. (d) 3. (b) 4. (b) 5. (c) 6. (b) 7. (d) 8. (a) 9. (a) 10. (c)

## Chapter 25 IN REVIEW

### Key Terms

#### Section 25.1

crystal field theory (1128)

#### Section 25.2

lanthanide contraction (1130)

#### Section 25.3

complex ion (1132)

ligand (1132)

coordination compound (1132)

primary valence (1132)

secondary valence (1132)

coordination number (1132)

coordinate covalent bond (1133)

monodentate (1134)

bidentate (1134)

polydentate (1134)

chelate (1134)

chelating agent (1134)

#### Section 25.4

structural isomers (1137)

stereoisomers (1137)

coordination isomers (1137)

linkage isomers (1137)

geometric isomers (1139)

optical isomers (1140)

#### Section 25.5

strong-field complex (1143)

weak-field complex (1143)

low-spin complex (1146)

high-spin complex (1146)

## Key Concepts

### Electron Configurations (25.2)

- ▶ As we move across a row of transition elements, electrons add to the  $(n - 1)d$  orbitals, resulting in a general electron configuration for the first- and second-row transition elements of [noble gas]  $ns^2(n - 1)d^x$  and for the third and fourth rows of [noble gas]  $ns^2(n - 2)f^{14}(n - 1)d^x$ , where  $x$  ranges from 1 to 10.
- ▶ A transition element forms a cation by losing electrons from the  $ns$  orbitals before losing electrons from the  $(n - 1)d$  orbitals.

### Periodic Trends (25.2)

- ▶ The variations in atomic size, ionization energy, and electronegativity across a row in the periodic table are similar to those of main-group elements (although the trends are less pronounced and less regular). As we move down a group, however, atomic size increases from the first row to the second but stays roughly constant from the second row to the third because of the lanthanide contraction. This contraction results in ionization energy and electronegativity trends as we move down a column that are opposite of the main-group elements.

### Composition and Naming of Coordination Compounds (25.3)

- ▶ A coordination compound is composed of a complex ion and a counterion.
- ▶ A complex ion contains a central metal ion bound to one or more ligands. The number of ligands directly bound to the metal ion is the coordination number.
- ▶ The ligand forms a coordinate covalent bond to the metal ion by donating a pair of electrons to an empty orbital on the metal.
- ▶ Ligands that donate a single pair of electrons are monodentate. A ligand that donates two pairs of electrons is bidentate, and a ligand that donates more than two pairs is polydentate.

- ▶ In naming coordination compounds, we use the name of the cation followed by the name of the anion. To name a complex ion, we use the guidelines outlined in Section 25.3.

### Types of Isomers (25.4)

- ▶ We broadly divide the isomerism observed in coordination compounds into two categories: structural isomers, in which atoms are connected differently to one another, and stereoisomers, in which atoms are connected in the same way but the ligands have a different spatial arrangement about the metal atom.
- ▶ Structural isomers are either coordination isomers (a coordinated ligand exchanges places with an uncoordinated counterion) or linkage isomers (a particular ligand has the ability to coordinate to the metal in different ways).
- ▶ Stereoisomers are either geometric isomers (the ligands bonded to the metal have a different spatial arrangement relative to each other, leading to cis-trans or fac-mer isomers) or optical isomers (nonsuperimposable mirror images).

### Crystal Field Theory (25.5)

- ▶ Crystal field theory is a bonding model for transition metal complex ions. The model describes how the degeneracy of the  $d$  orbitals is broken by the repulsive forces between the electrons on the ligands around the metal ion and the  $d$  orbitals in the metal ion.
- ▶ The energy difference between the split  $d$  orbitals is the crystal field splitting energy ( $\Delta$ ). The magnitude of  $\Delta$  depends in large part on the ligands bound to the metal.
- ▶ Octahedral complexes with a  $d^4$ ,  $d^5$ ,  $d^6$ , or  $d^7$  metal ion can have two possible electronic configurations with different numbers of unpaired electrons. The first, called high-spin, has the same number of unpaired electrons as the free metal ion and is usually the result of a weak crystal field. The second, called low-spin, has fewer unpaired electrons than the free metal ion and is usually the result of a strong crystal field.

## Key Equations and Relationships

### Crystal Field Splitting Energy (25.5)

$$\Delta = hc/\lambda \text{ (where } \lambda \text{ is the wavelength of maximum absorption)}$$

## Key Learning Outcomes

CHAPTER OBJECTIVES	ASSESSMENT
Writing Electronic Configurations for Transition Metals and Their Ions (25.2)	Examples 25.1, 25.2 For Practice 25.1, 25.2 Exercises 19–20, 57, 58
Naming Coordination Compounds (25.3)	Examples 25.3, 25.4 For Practice 25.3, 25.4 Exercises 23–28
Recognizing and Drawing Geometric Isomers (25.4)	Examples 25.5, 25.6 For Practice 25.5, 25.6 Exercises 5–40, 61–62
<div style="display: flex; justify-content: space-around; align-items: center;"> <div style="text-align: center;"> <p>Fac</p>  </div> <div style="text-align: center;"> <p>Mer</p>  </div> </div>	
Recognizing and Drawing Optical Isomers (25.4)	Example 25.7 For Practice 25.7 Exercises 39–40, 61–62

## Calculating Crystal Field Splitting Energy (25.5)

## Example 25.8 For Practice 25.8 Exercises 43–46

## Recognizing and Predicting High-Spin and Low-Spin Octahedral Complex Ions (25.5)

## Examples 25.9, 25.10 For Practice 25.9, 25.10 Exercises 49–52, 65

## EXERCISES

## Review Questions

- When a transition metal atom forms an ion, which electrons are lost first?
- Explain why transition metals exhibit multiple oxidation states instead of a single oxidation state (like most of the main-group metals).
- Why is the +2 oxidation state so common for transition metals?
- Explain why atomic radii of elements in the third row of the transition metals are no larger than those of elements in the second row.
- Gold is the most electronegative transition metal. Explain.
- Briefly define each term.
  - coordination number
  - ligand
  - bidentate and polydentate
  - complex ion
  - chelating agent
- Using the Lewis acid–base definition, how would you categorize a ligand? How would you categorize a transition metal ion?
- Explain the differences between each pair of isomer types.
  - structural isomer and stereoisomer
  - linkage isomer and coordination isomer
  - geometric isomer and optical isomer
- Which complex ion geometry has the potential to exhibit cis–trans isomerism: linear, tetrahedral, square planar, octahedral?
- How can you tell whether a complex ion is optically active?
- Explain the differences between weak-field and strong-field metal complexes.
- Explain why compounds of  $\text{Sc}^{3+}$  are colorless, but compounds of  $\text{Ti}^{3+}$  are colored.
- Explain why compounds of  $\text{Zn}^{2+}$  are white, but compounds of  $\text{Cu}^{2+}$  are often blue or green.
- Explain the differences between high-spin and low-spin metal complexes.
- Why are almost all tetrahedral complexes high-spin?
- Many transition metal compounds are colored. How does crystal field theory account for this?

## Problems by Topic

## Properties of Transition Metals

- Write the ground state electron configuration for each atom and ion pair.
  - $\text{Ni}$ ,  $\text{Ni}^{2+}$
  - $\text{Mn}$ ,  $\text{Mn}^{4+}$
  - $\text{Y}$ ,  $\text{Y}^{+}$
  - $\text{Ta}$ ,  $\text{Ta}^{2+}$
- Write the ground state electron configuration for each atom and ion pair.
  - $\text{Zr}$ ,  $\text{Zr}^{2+}$
  - $\text{Co}$ ,  $\text{Co}^{2+}$
  - $\text{Tc}$ ,  $\text{Tc}^{3+}$
  - $\text{Os}$ ,  $\text{Os}^{4+}$
- Determine the highest possible oxidation state for each element.
  - $\text{V}$
  - $\text{Re}$
  - $\text{Pd}$
- Which first-row transition metal(s) has the following highest possible oxidation state?
  - +3
  - +7
  - +4

## Coordination Compounds

- Determine the oxidation state and coordination number of the metal ion in each complex ion.
  - $[\text{Cr}(\text{H}_2\text{O})_6]^{3+}$
  - $[\text{Co}(\text{NH}_3)_3\text{Cl}_3]^{-}$
  - $[\text{Cu}(\text{CN})_4]^{2-}$
  - $[\text{Ag}(\text{NH}_3)_2]^{+}$
- Determine the oxidation state and coordination number of the metal ion in each complex ion.
  - $[\text{Co}(\text{NH}_3)_5\text{Br}]^{2+}$
  - $[\text{Fe}(\text{CN})_6]^{4-}$
  - $[\text{Co}(\text{ox})_3]^{4-}$
  - $[\text{PdCl}_4]^{2-}$
- Name each complex ion or coordination compound.
  - $[\text{Cr}(\text{H}_2\text{O})_6]^{3+}$
  - $[\text{Cu}(\text{CN})_4]^{2-}$
  - $[\text{Fe}(\text{NH}_3)_5\text{Br}]\text{SO}_4$
  - $[\text{Co}(\text{H}_2\text{O})_4(\text{NH}_3)(\text{OH})]\text{Cl}_2$
- Name each complex ion or coordination compound.
  - $[\text{Cu}(\text{en})_2]^{2+}$
  - $[\text{Mn}(\text{CO})_3(\text{NO}_2)_3]^{2+}$
  - $\text{Na}[\text{Cr}(\text{H}_2\text{O})_2(\text{ox})_2]$
  - $[\text{Co}(\text{en})_3][\text{Fe}(\text{CN})_6]$
- Write the formula for each complex ion or coordination compound.
  - hexaamminechromium(III)
  - potassium hexacyanoferrate(III)
  - ethylenediaminedithiocyanatocopper(II)
  - tetraaquaplatinum(II) hexachloroplatinate(IV)
- Write the formula for each complex ion or coordination compound.
  - hexaaquanickel(II) chloride
  - pentacarbonylchloromanganese(I)
  - ammonium diaquatetrabromovanadate(III)
  - tris(ethylenediamine)cobalt(III) trioxalatoferrate(III)

27. Write the formula and the name of each complex ion.
- a complex ion with  $\text{Co}^{3+}$  as the central ion and three  $\text{NH}_3$  molecules and three  $\text{CN}^-$  ions as ligands
  - a complex ion with  $\text{Cr}^{3+}$  as the central ion and a coordination number of 6 with ethylenediamine ligands
28. Write the formula and the name of each complex ion or coordination compound.
- a complex ion with four water molecules and two  $\text{ONO}^-$  ions connected to an  $\text{Fe(III)}$  ion
  - a coordination compound made of two complex ions: one a complex of  $\text{V(III)}$  with two ethylenediamine molecules and two  $\text{Cl}^-$  ions as ligands and the other a complex of  $\text{Ni(II)}$  having a coordination number of 4 with  $\text{Cl}^-$  ions as ligands

### Structure and Isomerism

29. Draw two linkage isomers of  $[\text{Mn}(\text{NH}_3)_5(\text{NO}_2)]^{2+}$ .
30. Draw two linkage isomers of  $[\text{PtCl}_3(\text{SCN})]^{2-}$ .
31. Write the formulas and names for the coordination isomers of  $[\text{Fe}(\text{H}_2\text{O})_6]\text{Cl}_2$ .
32. Write the formulas and names for the coordination isomers of  $[\text{Co}(\text{en})_3][\text{Cr}(\text{ox})_3]$ .
33. Which complexes exhibit geometric isomerism?
- $[\text{Cr}(\text{NH}_3)_5(\text{OH})]^{2+}$
  - $[\text{Cr}(\text{en})_2\text{Cl}_2]^+$
  - $[\text{Cr}(\text{H}_2\text{O})(\text{NH}_3)_3\text{Cl}_2]^+$
  - $[\text{Pt}(\text{NH}_3)\text{Cl}_3]^-$
  - $[\text{Pt}(\text{H}_2\text{O})_2(\text{CN})_2]$
34. Which complexes exhibit geometric isomerism?
- $[\text{Co}(\text{H}_2\text{O})_2(\text{ox})_2]^-$
  - $[\text{Co}(\text{en})_3]^{3+}$
  - $[\text{Co}(\text{H}_2\text{O})_2(\text{NH}_3)_2(\text{ox})]^+$
  - $[\text{Ni}(\text{NH}_3)_2(\text{en})]^{2+}$
  - $[\text{Ni}(\text{CO})_2\text{Cl}_2]$
35. If W, X, Y, and Z are different monodentate ligands, how many geometric isomers are there for each ion?
- square planar  $[\text{NiWXYZ}]^{2+}$
  - tetrahedral  $[\text{ZnWXYZ}]^{2+}$
36. How many geometric isomers are there for each species?
- $[\text{Fe}(\text{CO})_3\text{Cl}_3]$
  - $[\text{Mn}(\text{CO})_2\text{Cl}_2\text{Br}_2]^+$
37. Draw the structures and label the type for all the isomers of each ion.
- $[\text{Cr}(\text{CO})_3(\text{NH}_3)_3]^{3+}$
  - $[\text{Pd}(\text{CO})_2(\text{H}_2\text{O})\text{Cl}]^+$
38. Draw the structures and label the type for all the isomers of each species.
- $[\text{Fe}(\text{CO})_4\text{Cl}_2]^+$
  - $[\text{Pt}(\text{en})\text{Cl}_2]$
39. Determine if either isomer of  $[\text{Cr}(\text{NH}_3)_2(\text{ox})_2]^-$  is optically active.
40. Determine if either isomer of  $[\text{Fe}(\text{CO})_3\text{Cl}_3]$  is optically active.

### Bonding in Coordination Compounds

41. Draw the octahedral crystal field splitting diagram for each metal ion.
- $\text{Zn}^{2+}$
  - $\text{Fe}^{3+}$  (high- and low-spin)
  - $\text{V}^{3+}$
  - $\text{Co}^{2+}$  (high-spin)
42. Draw the octahedral crystal field splitting diagram for each metal ion.
- $\text{Cr}^{3+}$
  - $\text{Cu}^{2+}$
  - $\text{Mn}^{3+}$  (high- and low-spin)
  - $\text{Fe}^{2+}$  (low-spin)
43. The  $[\text{CrCl}_6]^{3-}$  ion has a maximum in its absorption spectrum at 735 nm. Calculate the crystal field splitting energy (in kJ/mol) for this ion.

44. The absorption spectrum of the complex ion  $[\text{Rh}(\text{NH}_3)_6]^{3+}$  has maximum absorbance at 295 nm. Calculate the crystal field splitting energy (in kJ/mol) for this ion.
45. Three complex ions of cobalt(III),  $[\text{Co}(\text{CN})_6]^{3-}$ ,  $[\text{Co}(\text{NH}_3)_6]^{3+}$ , and  $[\text{CoF}_6]^{3-}$ , absorb light at wavelengths of (in no particular order) 290 nm, 440 nm, and 770 nm. Match each complex ion to the appropriate wavelength absorbed. What color would you expect each solution to be?
46. Three bottles of aqueous solutions are discovered in an abandoned lab. The solutions are green, yellow, and purple. It is known that three complex ions of chromium(III) were commonly used in that lab:  $[\text{Cr}(\text{H}_2\text{O})_6]^{3+}$ ,  $[\text{Cr}(\text{NH}_3)_6]^{3+}$ , and  $[\text{Cr}(\text{H}_2\text{O})_4\text{Cl}_2]^+$ . Determine the likely identity of each of the colored solutions.
47. The  $[\text{Mn}(\text{NH}_3)_6]^{2+}$  ion is paramagnetic with five unpaired electrons. The  $\text{NH}_3$  ligand is usually a strong field ligand. Is  $\text{NH}_3$  acting as a strong field ligand in this case?
48. The complex  $[\text{Fe}(\text{H}_2\text{O})_6]^{2+}$  is paramagnetic. Is the  $\text{H}_2\text{O}$  ligand inducing a strong or weak field?
49. How many unpaired electrons would you expect for each complex ion?
- $[\text{RhCl}_6]^{3-}$
  - $[\text{Co}(\text{OH})_6]^{4-}$
  - cis*- $[\text{Fe}(\text{en})_2(\text{NO}_2)_2]^+$
50. How many unpaired electrons would you expect for each complex ion?
- $[\text{Cr}(\text{CN})_6]^{4-}$
  - $[\text{MnF}_6]^{4-}$
  - $[\text{Ru}(\text{en})_3]^{2+}$
51. How many unpaired electrons would you expect for the complex ion  $[\text{CoCl}_4]^{2-}$  if it is a tetrahedral shape?
52. The complex ion  $[\text{PdCl}_4]^{2-}$  is known to be diamagnetic. Use this information to determine if it is a tetrahedral or square planar structure.

### Applications of Coordination Compounds

53. What structural feature do hemoglobin, cytochrome c, and chlorophyll have in common?
54. Identify the central metal atom in each complex.
- hemoglobin
  - carbonic anhydrase
  - chlorophyll
  - iron blue
55. Hemoglobin exists in two predominant forms in our bodies. One form, known as oxyhemoglobin, has  $\text{O}_2$  bound to the iron and the other, known as deoxyhemoglobin, has a water molecule bound instead. Oxyhemoglobin is a low-spin complex that gives arterial blood its red color, and deoxyhemoglobin is a high-spin complex that gives venous blood its darker color. Explain these observations in terms of crystal field splitting. Would you categorize  $\text{O}_2$  as a strong- or weak-field ligand?
56. Carbon monoxide and the cyanide ion are both toxic because they bind more strongly than oxygen to the iron in hemoglobin (Hb).

Calculate the equilibrium constant value for this reaction:

Does the equilibrium favor reactants or products?

## Cumulative Problems

57. Recall from Chapter 8 that Cr and Cu are exceptions to the normal orbital filling, resulting in a  $[\text{Ar}] 4s^1 3d^x$  configuration. Write the ground state electron configuration for each species.
- Cr,  $\text{Cr}^+$ ,  $\text{Cr}^{2+}$ ,  $\text{Cr}^{3+}$
  - Cu,  $\text{Cu}^+$ ,  $\text{Cu}^{2+}$
58. Most of the second row transition metals do not follow the normal orbital filling pattern. Five of them—Nb, Mo, Ru, Rh, and Ag—have a  $[\text{Kr}] 5s^1 4d^x$  configuration and Pd has a  $[\text{Kr}] 4d^{10}$  configuration. Write the ground state electron configuration for each species.
- Mo,  $\text{Mo}^+$ , Ag,  $\text{Ag}^+$
  - Ru,  $\text{Ru}^{3+}$
  - Rh,  $\text{Rh}^{2+}$
  - Pd,  $\text{Pd}^+$ ,  $\text{Pd}^{2+}$
59. Draw the Lewis diagrams for each ligand. Indicate the lone pair(s) that may be donated to the metal. Indicate any you expect to be bidentate or polydentate.
- $\text{NH}_3$
  - $\text{SCN}^-$
  - $\text{H}_2\text{O}$
60. Draw the Lewis diagrams for each ligand. Indicate the lone pair(s) that may be donated to the metal. Indicate any you expect to be bidentate or polydentate.
- $\text{CN}^-$
  - bipyridyl (bipy), which has the following structure:

- $\text{NO}_2^-$
61. List all the different formulas for an octahedral complex made from a metal (M) and three different ligands (A, B, and C). Describe any isomers for each complex.
62. Amino acids, such as glycine (gly), form complexes with the trace metal ions found in the bloodstream. Glycine, whose

structure is shown here, acts as a bidentate ligand coordinating with the nitrogen atom and one of the oxygen atoms.

Draw all the possible isomers of:

- square planar  $[\text{Ni}(\text{gly})_2]$
  - tetrahedral  $[\text{Zn}(\text{gly})_2]$
  - octahedral  $[\text{Fe}(\text{gly})_3]$
63. Oxalic acid solutions remove rust stains. Draw a complex ion that is likely responsible for this effect. Does it have any isomers?
64. W, X, Y, and Z are different monodentate ligands.
- Is the square planar  $[\text{NiWXYZ}]^{2+}$  optically active?
  - Is the tetrahedral  $[\text{ZnWXYZ}]^{2+}$  optically active?
65. Hexacyanomanganate(III) ion is a low-spin complex. Draw the crystal field splitting diagram with electrons filled in appropriately. Is this complex paramagnetic or diamagnetic?
66. Determine the color and approximate wavelength absorbed most strongly by each solution.
- blue solution
  - red solution
  - yellow solution
67. Draw the structures of all the geometric isomers of  $[\text{Ru}(\text{H}_2\text{O})_2(\text{NH}_3)_2\text{Cl}_2]^+$ . Draw the mirror images of any that are chiral.
68. A 0.32 mol amount of  $\text{NH}_3$  is dissolved in 0.47 L of a 0.38 M silver nitrate solution. Calculate the equilibrium concentrations of all species in the solution.

## Challenge Problems

69. When a solution of  $\text{PtCl}_2$  reacts with the ligand trimethylphosphine,  $\text{P}(\text{CH}_3)_3$ , two compounds are produced. The compounds share the same elemental analysis: 46.7% Pt; 17.0% Cl; 14.8% P; 17.2% C; 4.34% H. Determine the formula, draw the structure, and give the systematic name for each compound.
70. Draw a crystal field splitting diagram for a trigonal planar complex ion. Assume the plane of the molecule is perpendicular to the z axis.
71. Draw a crystal field splitting diagram for a trigonal bipyramidal complex ion. Assume the axial positions are on the z axis.
72. Explain why  $[\text{Ni}(\text{NH}_3)_4]^{2+}$  is paramagnetic, while  $[\text{Ni}(\text{CN})_4]^{2-}$  is diamagnetic.
73. Sulfide ( $\text{S}^{2-}$ ) salts are notoriously insoluble in aqueous solution.
- Calculate the molar solubility of nickel(II) sulfide in water.  
 $K_{\text{sp}}(\text{NiS}) = 3 \times 10^{-16}$
  - Nickel(II) ions form a complex ion in the presence of ammonia with a formation constant ( $K_f$ ) of  $2.0 \times 10^8$ :  
 $\text{Ni}^{2+} + 6 \text{NH}_3 \rightleftharpoons [\text{Ni}(\text{NH}_3)_6]^{2+}$ . Calculate the molar solubility of NiS in 3.0 M  $\text{NH}_3$ .
  - Explain any differences between the answers to parts a and b.
74. Calculate the solubility of  $\text{Zn}(\text{OH})_2(\text{s})$  in 2.0 M NaOH solution. (Hint: you must take into account the formation of  $[\text{Zn}(\text{OH})_4]^{2-}$ , which has a  $K_f = 2 \times 10^{15}$ ).
75. Halide complexes of metal M of the form  $[\text{MX}_6]^{3-}$  are found to be stable in aqueous solution. But it is possible that they undergo rapid ligand exchange with water (or other ligands) that is not detectable because the complexes are less stable. This property is referred to as their *lability*. Suggest an experiment to measure the lability of these complexes that does not employ radioactive labels.
76. The  $K_f$  for  $[\text{Cu}(\text{en})_2]^{2+}$  is much larger than the one for  $[\text{Cu}(\text{NH}_3)_4]^{2+}$ . This difference is primarily an entropy effect. Explain why and calculate the difference between the  $\Delta S^\circ$  values at 298 K for the complete dissociation of the two complex ions. (Hint: the value of  $\Delta H$  is about the same for both systems.)
77. When solid  $\text{Cd}(\text{OH})_2$  is added to a solution of 0.10 M NaI, some of it dissolves. Calculate the pH of the solution at equilibrium.

## Conceptual Problems

**78.** Two ligands, A and B, both form complexes with a particular metal ion. When the metal ion complexes with ligand A, the solution is green. When the metal ion complexes with ligand B, the solution is violet. Which of the two ligands results in the largest  $\Delta$ ?

**79.** Which element has the higher ionization energy, Cu or Au?

**80.** The complexes of  $\text{Fe}^{3+}$  have magnetic properties that depend on whether the ligands are strong or weak field. Explain why this observation supports the idea that electrons are lost from the 4s orbital before the 3d orbitals in the transition metals.

### Active Classroom Learning

## Questions for Group Work

Discuss these questions with the group and record your consensus answer.

**81.** Choose a row of the transition metals in the periodic table. Have each group member look up and graph (where appropriate) a separate trend for the elements in that row, choosing from electron configuration, atomic size, ionization energy, and electronegativity. Each member should present a graph to the group and describe the general trend and any notable exceptions. If possible, form new groups made up of individuals who researched the same property for different rows of the periodic table.

**82.** Have each group member write down the names and formulas for two coordination compounds. Taking turns, show each formula to the group and have the rest of the group name the compound, with each member contributing one step in the process. Once all group members have had their formulas named, repeat the process by showing each formula name to the group and having group members determine the correct formula.

**83.** Working individually, draw a pair of coordination compounds that are isomers. Take turns showing your drawings to the group

and having them identify the type of isomerism and the reasons your drawing demonstrates that type of isomerism. If your group misidentifies your type of isomerism, rather than telling them the correct answer right away, point out the part of the structure that prevents it from being the type of isomerism they thought it was.

**84.** Divide the electron configurations  $d^1$  through  $d^{10}$  among the group members so that every configuration is assigned to at least two group members. Working individually, draw the orbital diagram for the configurations assigned to you, including both high-spin and low-spin diagrams where possible. Present your diagrams to your group. Combine everyone's diagrams into one set for the group.

**85.** Working individually, review one of the applications of coordination complexes. Without referring to the text or mentioning the key words in the heading of the subsection, describe the application you reviewed. As group members each describe the application they reviewed, take turns attempting to identify the key words from the heading of the subsection they are describing.

## Data Interpretation and Analysis

### Qualitative Test for $\text{Fe}^{3+}$ Ions in Solution

**86.** Many aqueous solutions of complex ions display brilliant colors that depend on the identities of the metal ion and ligand(s). Some ligands bind selectively to certain metal ions, producing complex ions with characteristic colors. These distinctive complex ions serve as qualitative indicators of the presence of particular metal ions. For example,  $\text{Fe}^{3+}$  is identified by the rapid formation of the intensely colored pentaquathio-cyanatoiron(III) complex ion,  $[\text{Fe}(\text{H}_2\text{O})_5\text{SCN}]^{2+}$ , when thiocyanate,  $\text{SCN}^-$ , is added to a solution containing hexaquaairon(III),  $[\text{Fe}(\text{H}_2\text{O})_6]^{3+}$ , according to the following chemical equation:

The absorption spectrum of an aqueous solution of  $[\text{Fe}(\text{H}_2\text{O})_5\text{SCN}]^{2+}$  is shown in Figure a.

**▲ FIGURE a** Absorption Spectrum of  $[\text{Fe}(\text{H}_2\text{O})_5\text{SCN}]^{2+}$

Use the information provided to answer the following questions:

- a. Determine the color of the aqueous solution of  $[\text{Fe}(\text{H}_2\text{O})_5\text{SCN}]^{2+}$  based on the spectrum shown in Figure a.
- b. Calculate the crystal field splitting energy,  $\Delta$ , of  $[\text{Fe}(\text{H}_2\text{O})_5\text{SCN}]^{2+}$ , in kJ/mol.
- c. The hexaaquairon(III) complex ion,  $[\text{Fe}(\text{H}_2\text{O})_6]^{3+}$ , produces a pale violet aqueous solution. Is the crystal field splitting energy,  $\Delta$ , of  $[\text{Fe}(\text{H}_2\text{O})_6]^{3+}$  smaller or larger than the  $\Delta$  of  $[\text{Fe}(\text{H}_2\text{O})_5\text{SCN}]^{2+}$ ?
- d. On the basis of your answers to parts b and c, compare the crystal field strengths of water and thiocyanate ligands.
- e. The complex ion hexacyanoferrate(III),  $[\text{Fe}(\text{CN})_6]^{3-}$ , is red in aqueous solution. What can you conclude about the relative crystal field splitting energies of  $[\text{Fe}(\text{CN})_6]^{3-}$  and  $[\text{Fe}(\text{H}_2\text{O})_5\text{SCN}]^{2+}$ ?

## Answers to Conceptual Connections

### Atomic Size

- 25.1** The element W has the larger radius because it is in the third transition row and Fe is in the first. Atomic radii increase from the first to the second transition row and stay roughly constant from the second to the third.

### Weak- and Strong-Field Ligands

- 25.2** Ligand B forms a yellow solution, which means that the complex absorbs in the violet region. Ligand A forms a red solution, which means that the complex absorbs in the green. Since the violet region of the electromagnetic spectrum is of shorter wavelength (higher energy) than the green region, ligand B produces a higher  $\Delta$ .

# APPENDIX I Common Mathematical Operations in Chemistry

## A. Scientific Notation

A number written in scientific notation consists of a **decimal part**, a number that is usually between 1 and 10, and an **exponential part**, 10 raised to an **exponent**,  $n$ :

$$1.2 \times 10^{-10}$$

Each of the following numbers is written in both scientific and decimal notation:

$$1.0 \times 10^5 = 100,000 \quad 1.0 \times 10^{-5} = 0.000010$$

$$6.7 \times 10^3 = 6700 \quad 6.7 \times 10^{-3} = 0.0067$$

A positive exponent ( $n$ ) means 1 multiplied by 10  $n$  times:

$$10^0 = 1$$

$$10^1 = 1 \times 10$$

$$10^2 = 1 \times 10 \times 10 = 100$$

$$10^3 = 1 \times 10 \times 10 \times 10 = 1000$$

A negative exponent ( $-n$ ) means 1 divided by 10  $n$  times:

$$10^{-1} = \frac{1}{10} = 0.1$$

$$10^{-2} = \frac{1}{10 \times 10} = 0.01$$

$$10^{-3} = \frac{1}{10 \times 10 \times 10} = 0.001$$

To convert a number to scientific notation, we move the decimal point to obtain a number between 1 and 10 and then multiply by 10 raised to the appropriate power. For example, to write 5983 in scientific notation, we move the decimal point to the left three places to get 5.983 (a number between 1 and 10) and then multiply by 1000 to make up for moving the decimal point:

$$5983 = 5.983 \times 1000$$

Since 1000 is  $10^3$ , we write:

$$5983 = 5.983 \times 10^3$$

We can do this in one step by counting how many places we move the decimal point to obtain a number between 1 and 10 and then writing the decimal part multiplied by 10 raised to the number of places we moved the decimal point:

$$5983 = 5.983 \times 10^3$$

If the decimal point is moved to the left, as in the previous example, the exponent is positive. If the decimal is moved to the right, the exponent is negative:

$$0.00034 = 3.4 \times 10^{-4}$$

To express a number in scientific notation:

1. Move the decimal point to obtain a number between 1 and 10.
2. Write the result from step 1 multiplied by 10 raised to the number of places you moved the decimal point.
  - The exponent is positive if you moved the decimal point to the left.
  - The exponent is negative if you moved the decimal point to the right.

Consider the following additional examples:

$$290,809,000 = 2.90809 \times 10^8$$

$$0.000000000070 \text{ m} = 7.0 \times 10^{-11} \text{ m}$$

## Multiplication and Division

To multiply numbers expressed in scientific notation, multiply the decimal parts and add the exponents:

$$(A \times 10^m)(B \times 10^n) = (A \times B) \times 10^{m+n}$$

To divide numbers expressed in scientific notation, divide the decimal parts and subtract the exponent in the denominator from the exponent in the numerator:

$$\frac{(A \times 10^m)}{(B \times 10^n)} = \left(\frac{A}{B}\right) \times 10^{m-n}$$

Consider the following example involving multiplication:

$$\begin{aligned}(3.5 \times 10^4)(1.8 \times 10^6) &= (3.5 \times 1.8) \times 10^{4+6} \\ &= 6.3 \times 10^{10}\end{aligned}$$

Consider the following example involving division:

$$\begin{aligned}\frac{(5.6 \times 10^7)}{(1.4 \times 10^3)} &= \left(\frac{5.6}{1.4}\right) \times 10^{7-3} \\ &= 4.0 \times 10^4\end{aligned}$$

## Addition and Subtraction

To add or subtract numbers expressed in scientific notation, rewrite all the numbers so that they have the same exponent, then add or subtract the decimal parts of the numbers. The exponents remained unchanged:

$$\begin{array}{r} A \times 10^n \\ \pm B \times 10^n \\ \hline (A \pm B) \times 10^n \end{array}$$

Notice that the numbers *must have* the same exponent. Consider the following example involving addition:

$$\begin{array}{r} 4.82 \times 10^7 \\ + 3.4 \times 10^6 \\ \hline \end{array}$$

First, express both numbers with the same exponent. In this case, you rewrite the lower number and perform the addition as follows:

$$\begin{array}{r} 4.82 \times 10^7 \\ + 0.34 \times 10^7 \\ \hline 5.16 \times 10^7 \end{array}$$

Consider the following example involving subtraction:

$$\begin{array}{r} 7.33 \times 10^5 \\ - 1.9 \times 10^4 \\ \hline \end{array}$$

First, express both numbers with the same exponent. In this case, you rewrite the lower number and perform the subtraction as follows:

$$\begin{array}{r} 7.33 \times 10^5 \\ - 0.19 \times 10^5 \\ \hline 7.14 \times 10^5 \end{array}$$

## Powers and Roots

To raise a number written in scientific notation to a power, raise the decimal part to the power and multiply the exponent by the power:

$$\begin{aligned} (4.0 \times 10^6)^2 &= 4.0^2 \times 10^{6 \times 2} \\ &= 16 \times 10^{12} \\ &= 1.6 \times 10^{13} \end{aligned}$$

To take the  $n$ th root of a number written in scientific notation, take the  $n$ th root of the decimal part and divide the exponent by the root:

$$\begin{aligned} (4.0 \times 10^6)^{1/3} &= 4.0^{1/3} \times 10^{6/3} \\ &= 1.6 \times 10^2 \end{aligned}$$

## B. Logarithms

### Common (or Base 10) Logarithms

The common or base 10 logarithm (abbreviated log) of a number is the exponent to which 10 must be raised to obtain that number. For example, the log of 100 is 2 because 10 must be raised to the second power to get 100. Similarly, the log of

1000 is 3 because 10 must be raised to the third power to get 1000. The logs of several multiples of 10 are shown here:

$$\log 10 = 1$$

$$\log 100 = 2$$

$$\log 1000 = 3$$

$$\log 10,000 = 4$$

Because  $10^0 = 1$  by definition,  $\log 1 = 0$ .

The log of a number smaller than one is negative because 10 must be raised to a negative exponent to get a number smaller than one. For example, the log of 0.01 is  $-2$  because 10 must be raised to  $-2$  to get 0.01. Similarly, the log of 0.001 is  $-3$  because 10 must be raised to  $-3$  to get 0.001. The logs of several fractional numbers are shown below:

$$\log 0.1 = -1$$

$$\log 0.01 = -2$$

$$\log 0.001 = -3$$

$$\log 0.0001 = -4$$

The logs of numbers that are not multiples of 10 can be computed on your calculator. See your calculator manual for specific instructions.

### Inverse Logarithms

The inverse logarithm or invlog function is exactly the opposite of the log function. For example, the log of 100 is 2 and the inverse log of 2 is 100. The log function and the invlog function undo one another:

$$\log 100 = 2$$

$$\text{invlog } 2 = 100$$

$$\text{invlog}(\log 100) = 100$$

The inverse log of a number is 10 raised to that number:

$$\text{invlog } x = 10^x$$

$$\text{invlog } 3 = 10^3 = 1000$$

The inverse logs of numbers can be computed on your calculator. See your calculator manual for specific instructions.

### Natural (or Base $e$ ) Logarithms

The natural (or base  $e$ ) logarithm (abbreviated ln) of a number is the exponent to which  $e$  (which has the value of 2.71828...) must be raised to obtain that number. For example, the ln of 100 is 4.605 because  $e$  must be raised to 4.605 to get 100. Similarly, the ln of 10.0 is 2.303 because  $e$  must be raised to 2.303 to get 10.0.

The inverse natural logarithm or invln function is exactly the opposite of the ln function. For example, the ln of 100 is

4.605 and the inverse  $\ln$  of 4.605 is 100. The inverse  $\ln$  of a number is simply  $e$  raised to that number:

$$\text{invln } x = e^x$$

$$\text{invln } 3 = e^3 = 20.1$$

The  $\text{invln}$  of a number can be computed on your calculator. See your calculator manual for specific instructions.

## Mathematical Operations Using Logarithms

Because logarithms are exponents, mathematical operations involving logarithms are similar to those involving exponents as follows:

$$\log(a \times b) = \log a + \log b \quad \ln(a \times b) = \ln a + \ln b$$

$$\log \frac{a}{b} = \log a - \log b \quad \ln \frac{a}{b} = \ln a - \ln b$$

$$\log a^n = n \log a \quad \ln a^n = n \ln a$$

## C. Quadratic Equations

A quadratic equation contains at least one term in which the variable  $x$  is raised to the second power (and no terms in which  $x$  is raised to a higher power). A quadratic equation has the following general form:

$$ax^2 + bx + c = 0$$

A quadratic equation can be solved for  $x$  using the quadratic formula:

$$x = \frac{-b \pm \sqrt{b^2 - 4ac}}{2a}$$

Quadratic equations are often encountered when solving equilibrium problems. Here we show how to use the quadratic formula to solve a quadratic equation for  $x$ :

$$3x^2 - 5x + 1 = 0 \quad (\text{quadratic equation})$$

$$\begin{aligned} x &= \frac{-b \pm \sqrt{b^2 - 4ac}}{2a} \\ &= \frac{-(-5) \pm \sqrt{(-5)^2 - 4(3)(1)}}{2(3)} \\ &= \frac{5 \pm 3.6}{6} \end{aligned}$$

$$x = 1.43 \quad \text{or} \quad x = 0.233$$

As you can see, the solution to a quadratic equation usually has two values. In any real chemical system, one of the values can be eliminated because it has no physical significance. (For example, it may correspond to a negative concentration, which does not exist.)

## D. Graphs

Graphs are often used to visually show the relationship between two variables. For example, in Chapter 5 we show

the following relationship between the volume of a gas and its pressure:

**▲ Volume versus Pressure** A plot of the volume of a gas sample—as measured in a J-tube—versus pressure. The plot shows that volume and pressure are inversely related.

The horizontal axis is the  $x$ -axis and is normally used to show the independent variable. The vertical axis is the  $y$ -axis and is normally used to show how the other variable (called the dependent variable) varies with a change in the independent variable. In this case, the graph shows that as the pressure of a gas sample increases, its volume decreases.

Many relationships in chemistry are *linear*, which means that if you change one variable by a factor of  $n$  the other variable will also change by a factor of  $n$ . For example, the volume of a gas is linearly related to the number of moles of gas. When two quantities are linearly related, a graph of one versus the other produces a straight line. For example, the graph below shows how the volume of an ideal gas sample depends on the number of moles of gas in the sample:

**▲ Volume versus Number of Moles** The volume of a gas sample increases linearly with the number of moles of gas in the sample.

A linear relationship between any two variables  $x$  and  $y$  can be expressed by the following equation:

$$y = mx + b$$

where  $m$  is the slope of the line and  $b$  is the  $y$ -intercept. The slope is the change in  $y$  divided by the change in  $x$ :

$$m = \frac{\Delta y}{\Delta x}$$

For the graph above, we can estimate the slope by simply estimating the changes in  $y$  and  $x$  for a given interval. For example, between  $x = 0.4$  mol and  $1.2$  mol,  $\Delta x = 0.80$  mol and we can estimate that  $\Delta y = 18$  L. Therefore the slope is:

$$m = \frac{\Delta y}{\Delta x} = \frac{18 \text{ L}}{0.80 \text{ mol}} = 23 \text{ mol/L}$$

In several places in this book, logarithmic relationships between variables can be plotted in order to obtain a linear relationship. For example, the variables  $[A]_t$  and  $t$  in the following equation are not linearly related, but the natural logarithm of  $[A]_t$  and  $t$  are linearly related:

$$\ln[A]_t = -kt + \ln[A]_0$$

$$y = mx + b$$

A plot of  $\ln[A]_t$  versus  $t$  will therefore produce a straight line with slope  $= -k$  and  $y$ -intercept  $= \ln[A]_0$ .

## APPENDIX II Useful Data

C. Aqueous Equilibrium Constants

1. Dissociation Constants for Acids at 25 °C

Name	Formula	$K_{a1}$	$K_{a2}$	$K_{a3}$
Acetic	HC <sub>2</sub> H <sub>3</sub> O <sub>2</sub>	$1.8 \times 10^{-5}$		
Acetylsalicylic	HC <sub>9</sub> H <sub>7</sub> O <sub>4</sub>	$3.3 \times 10^{-4}$		
Adipic	H <sub>2</sub> C <sub>6</sub> H <sub>8</sub> O <sub>4</sub>	$3.9 \times 10^{-5}$	$3.9 \times 10^{-6}$	
Arsenic	H <sub>3</sub> AsO <sub>4</sub>	$5.5 \times 10^{-3}$	$1.7 \times 10^{-7}$	$5.1 \times 10^{-12}$
Arsenous	H <sub>3</sub> AsO <sub>3</sub>	$5.1 \times 10^{-10}$		
Ascorbic	H <sub>2</sub> C <sub>6</sub> H <sub>6</sub> O <sub>6</sub>	$8.0 \times 10^{-5}$	$1.6 \times 10^{-12}$	
Benzoic	HC <sub>7</sub> H <sub>5</sub> O <sub>2</sub>	$6.5 \times 10^{-5}$		
Boric	H <sub>3</sub> BO <sub>3</sub>	$5.4 \times 10^{-10}$		
Butanoic	HC <sub>4</sub> H <sub>7</sub> O <sub>2</sub>	$1.5 \times 10^{-5}$		
Carbonic	H <sub>2</sub> CO <sub>3</sub>	$4.3 \times 10^{-7}$	$5.6 \times 10^{-11}$	
Chloroacetic	HC <sub>2</sub> H <sub>2</sub> O <sub>2</sub> Cl	$1.4 \times 10^{-3}$		
Chlorous	HClO <sub>2</sub>	$1.1 \times 10^{-2}$		
Citric	H <sub>3</sub> C <sub>6</sub> H <sub>5</sub> O <sub>7</sub>	$7.4 \times 10^{-4}$	$1.7 \times 10^{-5}$	$4.0 \times 10^{-7}$
Cyanic	HCNO	$2 \times 10^{-4}$		
Formic	HCHO <sub>2</sub>	$1.8 \times 10^{-4}$		
Hydrazoic	HN <sub>3</sub>	$2.5 \times 10^{-5}$		
Hydrocyanic	HCN	$4.9 \times 10^{-10}$		
Hydrofluoric	HF	$6.8 \times 10^{-4}$		
Hydrogen chromate ion	HCrO <sub>4</sub> <sup>−</sup>	$3.0 \times 10^{-7}$		
Hydrogen peroxide	H <sub>2</sub> O <sub>2</sub>	$2.4 \times 10^{-12}$		
Hydrogen selenate ion	HSeO <sub>4</sub> <sup>−</sup>	$2.2 \times 10^{-2}$		
Hydrosulfuric	H <sub>2</sub> S	$8.9 \times 10^{-8}$	$1 \times 10^{-19}$	
Hydrotelluric	H <sub>2</sub> Te	$2.3 \times 10^{23}$	$1.6 \times 10^{-11}$	

Name	Formula	$K_{a1}$	$K_{a2}$	$K_{a3}$
Hypobromous	HBrO	$2.8 \times 10^{-9}$		
Hypochlorous	HClO	$2.9 \times 10^{-8}$		
Hypoiodous	HIO	$2.3 \times 10^{-11}$		
Iodic	HIO <sub>3</sub>	$1.7 \times 10^{-1}$		
Lactic	HC <sub>3</sub> H <sub>5</sub> O <sub>3</sub>	$1.4 \times 10^{-4}$		
Maleic	H <sub>2</sub> C <sub>4</sub> H <sub>2</sub> O <sub>4</sub>	$1.2 \times 10^{-2}$	$5.9 \times 10^{-7}$	
Malonic	H <sub>2</sub> C <sub>3</sub> H <sub>2</sub> O <sub>4</sub>	$1.5 \times 10^{-3}$	$2.0 \times 10^{-6}$	
Nitrous	HNO <sub>2</sub>	$4.6 \times 10^{-4}$		
Oxalic	H <sub>2</sub> C <sub>2</sub> O <sub>4</sub>	$6.0 \times 10^{-2}$	$6.1 \times 10^{-5}$	
Paraperiodic	H <sub>5</sub> IO <sub>6</sub>	$2.8 \times 10^{-2}$	$5.3 \times 10^{-9}$	
Phenol	HC <sub>6</sub> H <sub>5</sub> O	$1.3 \times 10^{-10}$		
Phosphoric	H <sub>3</sub> PO <sub>4</sub>	$7.5 \times 10^{-3}$	$6.2 \times 10^{-8}$	$4.2 \times 10^{-13}$
Phosphorous	H <sub>3</sub> PO <sub>3</sub>	$5 \times 10^{-2}$	$2.0 \times 10^{-7}$	
Propanoic	HC <sub>3</sub> H <sub>5</sub> O <sub>2</sub>	$1.3 \times 10^{-5}$		
Pyruvic	HC <sub>3</sub> H <sub>3</sub> O <sub>3</sub>	$4.1 \times 10^{-3}$		
Pyrophosphoric	H <sub>4</sub> P <sub>2</sub> O <sub>7</sub>	$1.2 \times 10^{-1}$	$7.9 \times 10^{-3}$	$2.0 \times 10^{-7}$
Selenous	H <sub>2</sub> SeO <sub>3</sub>	$2.4 \times 10^{-3}$	$4.8 \times 10^{-9}$	
Succinic	H <sub>2</sub> C <sub>4</sub> H <sub>4</sub> O <sub>4</sub>	$6.2 \times 10^{-5}$	$2.3 \times 10^{-6}$	
Sulfuric	H <sub>2</sub> SO <sub>4</sub>	Strong acid	$1.2 \times 10^{-2}$	
Sulfurous	H <sub>2</sub> SO <sub>3</sub>	$1.6 \times 10^{-2}$	$6.4 \times 10^{-8}$	
Tartaric	H <sub>2</sub> C <sub>4</sub> H <sub>4</sub> O <sub>6</sub>	$1.0 \times 10^{-3}$	$4.6 \times 10^{-5}$	
Trichloroacetic	HC <sub>2</sub> Cl <sub>3</sub> O <sub>2</sub>	$2.2 \times 10^{-1}$		
Trifluoroacetic acid	HC <sub>2</sub> F <sub>3</sub> O <sub>2</sub>	$3.0 \times 10^{-1}$		

**2. Dissociation Constants for Hydrated Metal Ions at 25 °C**

Cation	Hydrated Ion	$K_a$
Al <sup>3+</sup>	Al(H <sub>2</sub> O) <sub>6</sub> <sup>3+</sup>	$1.4 \times 10^{-5}$
Be <sup>2+</sup>	Be(H <sub>2</sub> O) <sub>6</sub> <sup>2+</sup>	$3 \times 10^{-7}$
Co <sup>2+</sup>	Co(H <sub>2</sub> O) <sub>6</sub> <sup>2+</sup>	$1.3 \times 10^{-9}$
Cr <sup>3+</sup>	Cr(H <sub>2</sub> O) <sub>6</sub> <sup>3+</sup>	$1.6 \times 10^{-4}$
Cu <sup>2+</sup>	Cu(H <sub>2</sub> O) <sub>6</sub> <sup>2+</sup>	$3 \times 10^{-8}$
Fe <sup>2+</sup>	Fe(H <sub>2</sub> O) <sub>6</sub> <sup>2+</sup>	$3.2 \times 10^{-10}$

Cation	Hydrated Ion	$K_a$
Fe <sup>3+</sup>	Fe(H <sub>2</sub> O) <sub>6</sub> <sup>3+</sup>	$6.3 \times 10^{-3}$
Ni <sup>2+</sup>	Ni(H <sub>2</sub> O) <sub>6</sub> <sup>2+</sup>	$2.5 \times 10^{-11}$
Pb <sup>2+</sup>	Pb(H <sub>2</sub> O) <sub>6</sub> <sup>2+</sup>	$3 \times 10^{-8}$
Sn <sup>2+</sup>	Sn(H <sub>2</sub> O) <sub>6</sub> <sup>2+</sup>	$4 \times 10^{-4}$
Zn <sup>2+</sup>	Zn(H <sub>2</sub> O) <sub>6</sub> <sup>2+</sup>	$2.5 \times 10^{-10}$

**3. Dissociation Constants for Bases at 25 °C**

Name	Formula	$K_b$
Ammonia	NH <sub>3</sub>	$1.76 \times 10^{-5}$
Aniline	C <sub>6</sub> H <sub>5</sub> NH <sub>2</sub>	$3.9 \times 10^{-10}$
Bicarbonate ion	HCO <sub>3</sub> <sup>-</sup>	$2.3 \times 10^{-8}$
Carbonate ion	CO <sub>3</sub> <sup>2-</sup>	$1.8 \times 10^{-4}$
Codeine	C <sub>18</sub> H <sub>21</sub> NO <sub>3</sub>	$1.6 \times 10^{-6}$
Diethylamine	(C <sub>2</sub> H <sub>5</sub> ) <sub>2</sub> NH	$6.9 \times 10^{-4}$
Dimethylamine	(CH <sub>3</sub> ) <sub>2</sub> NH	$5.4 \times 10^{-4}$
Ethylamine	C <sub>2</sub> H <sub>5</sub> NH <sub>2</sub>	$5.6 \times 10^{-4}$
Ethylenediamine	C <sub>2</sub> H <sub>8</sub> N <sub>2</sub>	$8.3 \times 10^{-5}$
Hydrazine	H <sub>2</sub> NNH <sub>2</sub>	$1.3 \times 10^{-6}$
Hydroxylamine	HONH <sub>2</sub>	$1.1 \times 10^{-8}$

Name	Formula	$K_b$
Ketamine	C <sub>13</sub> H <sub>16</sub> ClNO	$3 \times 10^{-7}$
Methylamine	CH <sub>3</sub> NH <sub>2</sub>	$4.4 \times 10^{-4}$
Morphine	C <sub>17</sub> H <sub>19</sub> NO <sub>3</sub>	$1.6 \times 10^{-6}$
Nicotine	C <sub>10</sub> H <sub>14</sub> N <sub>2</sub>	$1.0 \times 10^{-6}$
Piperidine	C <sub>5</sub> H <sub>10</sub> NH	$1.33 \times 10^{-3}$
Propylamine	C <sub>3</sub> H <sub>7</sub> NH <sub>2</sub>	$3.5 \times 10^{-4}$
Pyridine	C <sub>5</sub> H <sub>5</sub> N	$1.7 \times 10^{-9}$
Strychnine	C <sub>21</sub> H <sub>22</sub> N <sub>2</sub> O <sub>2</sub>	$1.8 \times 10^{-6}$
Triethylamine	(C <sub>2</sub> H <sub>5</sub> ) <sub>3</sub> N	$5.6 \times 10^{-4}$
Trimethylamine	(CH <sub>3</sub> ) <sub>3</sub> N	$6.4 \times 10^{-5}$

**4. Solubility Product Constants for Compounds at 25 °C**

Compound	Formula	$K_{sp}$
Aluminum hydroxide	Al(OH) <sub>3</sub>	$1.3 \times 10^{-33}$
Aluminum phosphate	AlPO <sub>4</sub>	$9.84 \times 10^{-21}$
Barium carbonate	BaCO <sub>3</sub>	$2.58 \times 10^{-9}$
Barium chromate	BaCrO <sub>4</sub>	$1.17 \times 10^{-10}$
Barium fluoride	BaF <sub>2</sub>	$2.45 \times 10^{-5}$
Barium hydroxide	Ba(OH) <sub>2</sub>	$5.0 \times 10^{-3}$
Barium oxalate	BaC <sub>2</sub> O <sub>4</sub>	$1.6 \times 10^{-6}$
Barium phosphate	Ba <sub>3</sub> (PO <sub>4</sub> ) <sub>2</sub>	$6 \times 10^{-39}$
Barium sulfate	BaSO <sub>4</sub>	$1.07 \times 10^{-10}$
Cadmium carbonate	CdCO <sub>3</sub>	$1.0 \times 10^{-12}$
Cadmium hydroxide	Cd(OH) <sub>2</sub>	$7.2 \times 10^{-15}$
Cadmium sulfide	CdS	$8 \times 10^{-28}$
Calcium carbonate	CaCO <sub>3</sub>	$4.96 \times 10^{-9}$
Calcium chromate	CaCrO <sub>4</sub>	$7.1 \times 10^{-4}$
Calcium fluoride	CaF <sub>2</sub>	$1.46 \times 10^{-10}$
Calcium hydroxide	Ca(OH) <sub>2</sub>	$4.68 \times 10^{-6}$

Compound	Formula	$K_{sp}$
Calcium hydrogen phosphate	CaHPO <sub>4</sub>	$1 \times 10^{-7}$
Calcium oxalate	CaC <sub>2</sub> O <sub>4</sub>	$2.32 \times 10^{-9}$
Calcium phosphate	Ca <sub>3</sub> (PO <sub>4</sub> ) <sub>2</sub>	$2.07 \times 10^{-33}$
Calcium sulfate	CaSO <sub>4</sub>	$7.10 \times 10^{-5}$
Chromium(III) hydroxide	Cr(OH) <sub>3</sub>	$6.3 \times 10^{-31}$
Cobalt(II) carbonate	CoCO <sub>3</sub>	$1.0 \times 10^{-10}$
Cobalt(II) hydroxide	Co(OH) <sub>2</sub>	$5.92 \times 10^{-15}$
Cobalt(II) sulfide	CoS	$5 \times 10^{-22}$
Copper(I) bromide	CuBr	$6.27 \times 10^{-9}$
Copper(I) chloride	CuCl	$1.72 \times 10^{-7}$
Copper(I) cyanide	CuCN	$3.47 \times 10^{-20}$
Copper(II) carbonate	CuCO <sub>3</sub>	$2.4 \times 10^{-10}$
Copper(II) hydroxide	Cu(OH) <sub>2</sub>	$2.2 \times 10^{-20}$
Copper(II) phosphate	Cu <sub>3</sub> (PO <sub>4</sub> ) <sub>2</sub>	$1.40 \times 10^{-37}$
Copper(II) sulfide	CuS	$1.27 \times 10^{-36}$
Iron(II) carbonate	FeCO <sub>3</sub>	$3.07 \times 10^{-11}$

—(Continued on the next page)

Compound	Formula	$K_{sp}$
Iron(II) hydroxide	$\text{Fe}(\text{OH})_2$	$4.87 \times 10^{-17}$
Iron(II) sulfide	$\text{FeS}$	$3.72 \times 10^{-19}$
Iron(III) hydroxide	$\text{Fe}(\text{OH})_3$	$2.79 \times 10^{-39}$
Lanthanum fluoride	$\text{LaF}_3$	$2 \times 10^{-19}$
Lanthanum iodate	$\text{La}(\text{IO}_3)_3$	$7.50 \times 10^{-12}$
Lead(II) bromide	$\text{PbBr}_2$	$4.67 \times 10^{-6}$
Lead(II) carbonate	$\text{PbCO}_3$	$7.40 \times 10^{-14}$
Lead(II) chloride	$\text{PbCl}_2$	$1.17 \times 10^{-5}$
Lead(II) chromate	$\text{PbCrO}_4$	$2.8 \times 10^{-13}$
Lead(II) fluoride	$\text{PbF}_2$	$3.3 \times 10^{-8}$
Lead(II) hydroxide	$\text{Pb}(\text{OH})_2$	$1.43 \times 10^{-20}$
Lead(II) iodide	$\text{PbI}_2$	$9.8 \times 10^{-9}$
Lead(II) phosphate	$\text{Pb}_3(\text{PO}_4)_2$	$1 \times 10^{-54}$
Lead(II) sulfate	$\text{PbSO}_4$	$1.82 \times 10^{-8}$
Lead(II) sulfide	$\text{PbS}$	$9.04 \times 10^{-29}$
Magnesium carbonate	$\text{MgCO}_3$	$6.82 \times 10^{-6}$
Magnesium fluoride	$\text{MgF}_2$	$5.16 \times 10^{-11}$
Magnesium hydroxide	$\text{Mg}(\text{OH})_2$	$2.06 \times 10^{-13}$
Magnesium oxalate	$\text{MgC}_2\text{O}_4$	$4.83 \times 10^{-6}$
Manganese(II) carbonate	$\text{MnCO}_3$	$2.24 \times 10^{-11}$
Manganese(II) hydroxide	$\text{Mn}(\text{OH})_2$	$1.6 \times 10^{-13}$
Manganese(II) sulfide	$\text{MnS}$	$2.3 \times 10^{-13}$
Mercury(I) bromide	$\text{Hg}_2\text{Br}_2$	$6.40 \times 10^{-23}$
Mercury(I) carbonate	$\text{Hg}_2\text{CO}_3$	$3.6 \times 10^{-17}$
Mercury(I) chloride	$\text{Hg}_2\text{Cl}_2$	$1.43 \times 10^{-18}$
Mercury(I) chromate	$\text{Hg}_2\text{CrO}_4$	$2 \times 10^{-9}$
Mercury(I) cyanide	$\text{Hg}_2(\text{CN})_2$	$5 \times 10^{-40}$

Compound	Formula	$K_{sp}$
Mercury(I) iodide	$\text{Hg}_2\text{I}_2$	$5.2 \times 10^{-29}$
Mercury(II) hydroxide	$\text{Hg}(\text{OH})_2$	$3.1 \times 10^{-26}$
Mercury(II) sulfide	$\text{HgS}$	$1.6 \times 10^{-54}$
Nickel(II) carbonate	$\text{NiCO}_3$	$1.42 \times 10^{-7}$
Nickel(II) hydroxide	$\text{Ni}(\text{OH})_2$	$5.48 \times 10^{-16}$
Nickel(II) sulfide	$\text{NiS}$	$3 \times 10^{-20}$
Silver bromate	$\text{AgBrO}_3$	$5.38 \times 10^{-5}$
Silver bromide	$\text{AgBr}$	$5.35 \times 10^{-13}$
Silver carbonate	$\text{Ag}_2\text{CO}_3$	$8.46 \times 10^{-12}$
Silver chloride	$\text{AgCl}$	$1.77 \times 10^{-10}$
Silver chromate	$\text{Ag}_2\text{CrO}_4$	$1.12 \times 10^{-12}$
Silver cyanide	$\text{AgCN}$	$5.97 \times 10^{-17}$
Silver iodide	$\text{AgI}$	$8.51 \times 10^{-17}$
Silver phosphate	$\text{Ag}_3\text{PO}_4$	$8.89 \times 10^{-17}$
Silver sulfate	$\text{Ag}_2\text{SO}_4$	$1.20 \times 10^{-5}$
Silver sulfide	$\text{Ag}_2\text{S}$	$6 \times 10^{-51}$
Strontium carbonate	$\text{SrCO}_3$	$5.60 \times 10^{-10}$
Strontium chromate	$\text{SrCrO}_4$	$3.6 \times 10^{-5}$
Strontium phosphate	$\text{Sr}_3(\text{PO}_4)_2$	$1 \times 10^{-31}$
Strontium sulfate	$\text{SrSO}_4$	$3.44 \times 10^{-7}$
Tin(II) hydroxide	$\text{Sn}(\text{OH})_2$	$5.45 \times 10^{-27}$
Tin(II) sulfide	$\text{SnS}$	$1 \times 10^{-26}$
Zinc carbonate	$\text{ZnCO}_3$	$1.46 \times 10^{-10}$
Zinc hydroxide	$\text{Zn}(\text{OH})_2$	$3 \times 10^{-17}$
Zinc oxalate	$\text{ZnC}_2\text{O}_4$	$2.7 \times 10^{-8}$
Zinc sulfide	$\text{ZnS}$	$2 \times 10^{-25}$

5. Complex Ion Formation Constants in Water at 25 °C

Complex Ion	$K_f$
$[\text{Ag}(\text{CN})_2]^-$	$1 \times 10^{21}$
$[\text{Ag}(\text{EDTA})]^{3-}$	$2.1 \times 10^7$
$[\text{Ag}(\text{en})_2]^+$	$5.0 \times 10^7$

## APPENDIX III Answers to Selected Exercises

### Chapter 1

33. **a.** theory **b.** observation  
**c.** law **d.** observation

35. Several answers possible.

37. **a.** mixture, homogeneous  
**b.** pure substance, compound  
**c.** pure substance, element  
**d.** mixture, heterogeneous

39. Substance	Pure or Mixture	Type
Aluminum	Pure	Element
Apple juice	Mixture	Homogeneous
Hydrogen peroxide	Pure	Compound
Chicken soup	Mixture	Heterogeneous

41. **a.** pure substance, compound  
**b.** mixture, heterogeneous  
**c.** mixture, homogeneous  
**d.** pure substance, element

43. physical, chemical, physical, physical, physical

45. **a.** chemical **b.** physical  
**c.** physical **d.** chemical

47. **a.** chemical **b.** physical  
**c.** chemical **d.** chemical

49. **a.** physical **b.** chemical **c.** physical

51. **a.** 0 °C **b.** -321 °F  
**c.** -78.3 °F **d.** 310.2 K

53. -62.2 °C, 210.9 K

55. **a.** 1.2 nm **b.** 22 fs **c.** 1.5 Gg **d.** 3.5 ML

57. **a.**  $4.5 \times 10^{-9}$  s **b.**  $1.8 \times 10^{-14}$  s  
**c.**  $1.28 \times 10^{-10}$  m **d.**  $3.5 \times 10^{-5}$  m

59. 1245 kg	$1.245 \times 10^6$ g	$1.245 \times 10^9$ mg
515 km	$5.15 \times 10^6$ dm	$5.15 \times 10^7$ cm
122.355 s	$1.22355 \times 10^5$ ms	0.122355 ks
3.345 kJ	$3.345 \times 10^3$ J	$3.345 \times 10^6$ mJ

61. **a.** 254.998 km **b.**  $2.54998 \times 10^{-1}$  Mm  
**c.**  $254998 \times 10^3$  mm **d.**  $254998 \times 10^2$  cm

63. 10,000 1 cm squares

65. no

67. 1.26 g/cm<sup>3</sup>

69. **a.** 463 g **b.** 3.7 L

71.  $201. \times 10^3$  g

73. **a.** 73.7 mL **b.** 88.2 °C **c.** 647 mL

75. **a.** 1,050,501 **b.** 0.0020  
**c.** 0.000000000000002 **d.** 0.001090

77. **a.** 3 **b.** ambiguous, without more information assume three significant figures  
**c.** 3 **d.** 5

**e.** ambiguous, without more information assume one significant figure

79. **a.** not exact

**c.** not exact

81. **a.** 156.9

**c.** 156.8

83. **a.** 1.84

**c.** 0.500

85. **a.** 41.4

**c.** 73.0

87. **a.** 391.3

**c.** 5.96

89. 0.74 g/mL

91. **a.**  $2.78 \times 10^4$  cm<sup>3</sup>

**c.**  $1.98 \times 10^7$  cm

93. **a.** 60.6 in

**c.** 3.7 qt

95.  $5.0 \times 10^1$  min

97.  $4.0 \times 10^1$  mi/gal

99. **a.**  $1.95 \times 10^{-4}$  km<sup>2</sup>

**c.**  $1.95 \times 10^6$  cm<sup>2</sup>

101. 0.680 mi<sup>2</sup>

103. 0.95 mL

105.  $3.1557 \times 10^7$  s/solar year

107. **a.** extensive

**c.** intensive

**e.** extensive

109. -34 °F

111.  $F = \text{kg}(\text{m}/\text{s}^2) = \text{N}$  (for newton), kN, pN

113. **a.**  $2.2 \times 10^{-6}$  **b.** 0.0159 **c.**  $6.9 \times 10^4$

115. **a.** mass of can of gold =  $1.9 \times 10^4$  g

mass of can of sand =  $3.0 \times 10^3$  g

**b.** Yes, the thief sets off the trap because the can of sand is lighter than the gold cylinder.

117. 22 in<sup>3</sup>

119. 7.6 g/cm<sup>3</sup>

121.  $3.11 \times 10^5$  lb

123.  $3.3 \times 10^2$  km

125.  $6.8 \times 10^{-15}$

127.  $2.4 \times 10^{19}$  km

129. 488 grams

131. 0.661  $\Omega$

133. 0.492

135. 18.2 atm

137. 1 J = 1 kg m<sup>2</sup>/s<sup>2</sup>

$m = \text{kg}$ ,  $v^2 = (\text{m}/\text{s})^2$   $mv = \text{kg m}^2/\text{s}^2$

$P = \text{N}/\text{m}^2 = \text{kg m}/\text{s}^2/\text{m}^2 = \text{kg}/\text{m s}^2$

$V = \text{m}^3$   $PV = \text{kg m}^3/\text{m s}^2 = \text{kg m}^2/\text{s}^2$

139.  $9.0 \times 10^1$  mg CO

141. 13% increase

143. No. Since the container is sealed the atoms and molecules can move around, but they cannot leave. If no atoms or molecules can leave, the mass must be constant.

145. 343 1 cm cubes  
 147. **a.** the dark block **b.** the light-colored block  
**c.** cannot tell  
 149. **a.** law **b.** theory **c.** observation **d.** law  
 155. **a.** ice, 918 kg/m<sup>3</sup>; water, 999.97 kg/m<sup>3</sup>; Ice is less dense, so it floats on liquid water.  
**c.**  $2.44 \times 10^7 \text{ km}^3$

## Chapter 2

29. 13.5 g  
 31. These results are not consistent with the law of definite proportions because sample 1 is composed of 11.5 parts Cl to 1 part C and sample 2 is composed of 9.05 parts Cl to 1 part C. The law of definite proportions states that a given compound always contains exactly the same proportion of elements by mass.  
 33. 23.8 g  
 35. For the law of multiple proportions to hold, the ratio of the masses of O combining with 1 g of O's in the compound should be a small whole number.  
 $0.3369/0.168 = 2.00$   
 37. Sample 1: 1.00 g O<sub>2</sub>/1.00 g S;  
 Sample 2: 1.50 g O<sub>2</sub>/1.00 g S  
 $\text{Sample 2/sample 1} = 1.50/1.00 = 1.50$   
 $3 \text{ O atoms}/2 \text{ O atoms} = 1.5$   
 39. **a.** not consistent  
**b.** consistent: Dalton's atomic theory states that the atoms of a given element are identical.  
**c.** consistent: Dalton's atomic theory states that atoms combine in simple whole-number ratios to form compounds.  
**d.** not consistent  
 41. **a.** consistent: Rutherford's nuclear model states that the atom is largely empty space.  
**b.** consistent: Rutherford's nuclear model states that most of the atom's mass is concentrated in a tiny region called the nucleus.  
**c.** not consistent **d.** not consistent  
 43.  $-2.3 \times 10^{-19} \text{ C}$   
 45.  $9.4 \times 10^{13}$  excess electrons,  $8.5 \times 10^{-17} \text{ kg}$   
 47. **a, b, c**  
 49.  $1.83 \times 10^3 \text{ e}^-$   
 51. **a.** Ag-107 **b.** Ag-109 **c.** U-238 **d.** H-2  
 53. **a.**  $7\frac{1}{2}\text{p}$  and  $7\frac{0}{1}\text{n}$  **b.**  $11\frac{1}{2}\text{p}$  and  $12\frac{0}{1}\text{n}$   
**c.**  $86\frac{1}{2}\text{p}$  and  $136\frac{0}{1}\text{n}$  **d.**  $82\frac{1}{2}\text{p}$  and  $126\frac{0}{1}\text{n}$   
 55.  $6\frac{1}{2}\text{p}$  and  $8\frac{1}{2}\text{n}$ ,  ${}^{14}_6\text{C}$   
 57. **a.**  $28\frac{1}{2}\text{p}$  and  $26\text{e}^-$  **b.**  $16\frac{1}{2}\text{p}$  and  $18\text{e}^-$   
**c.**  $35\frac{1}{2}\text{p}$  and  $36\text{e}^-$  **d.**  $24\frac{1}{2}\text{p}$  and  $21\text{e}^-$   
 59. **a.** 2- **b.** 1+ **c.** 3+ **d.** 1+

Symbol	Ion Formed	Number of Electrons in Ion	Number of Protons in Ion
Ca	Ca <sup>2+</sup>	18	20
Be	Be <sup>2+</sup>	2	4
Se	Se <sup>2-</sup>	36	34
In	In <sup>3+</sup>	46	49

63. **a.** potassium, metal **b.** barium, metal  
**c.** iodine, nonmetal **d.** oxygen, nonmetal  
**e.** antimony, metalloid  
 65. **a** and **b** are main group elements.  
 67. **a.** alkali metal  
**b.** halogen  
**c.** alkaline earth metal  
**d.** alkaline earth metal  
**e.** noble gas  
 69. Cl and F because they are in the same group or family. Elements in the same group or family have similar chemical properties.

73. The fluorine-19 isotope must have a large percent abundance, which would make fluorine produce a large peak at this mass. Chlorine has two isotopes (Cl-35 and Cl-37). The atomic mass is simply the weighted average of these two, which means that there is no chlorine isotope with a mass of 35.45 amu.  
 75. 121.8 amu, Sb  
 77. Br-79 78.92, amu 50.96%  
 79. 152 amu  
 81.  $3.32 \times 10^{24}$  atoms  
 83. **a.** 0.295 mol Ar **b.** 0.0543 mol Zn  
**c.** 0.144 mol Ta **d.** 0.0304 mol Li  
 85.  $2.11 \times 10^{22}$  atoms  
 87. **a.**  $1.01 \times 10^{23}$  atoms **b.**  $6.78 \times 10^{21}$  atoms  
**c.**  $5.39 \times 10^{21}$  atoms **d.**  $5.6 \times 10^{20}$  atoms  
 89. **a.** 36 grams **b.** 0.187 grams

 127. 0.423  
 129. 63.67 g/mol  
 131. 25.06 g/mol

135. If the amu and mole were not based on the same isotope, the numerical values obtained for an atom of material and a mole of material would not be the same. If, for example, the mole were based on the number of particles in C-12 but the amu were changed to a fraction of the mass of an atom of Ne-20, the number of particles and the number of amu that make up one mole of material would no longer be the same. We would no longer have the relationship in which the mass of an atom in amu is numerically equal to the mass of a mole of those atoms in grams.
137. The different isotopes of the same element have the same number of protons and electrons, so the attractive forces between the nucleus and the electrons are constant and there is no difference in the radii of the isotopes. Ions, on the other hand, have a different number of electrons than the parent atom from which they are derived. Cations have fewer electrons than the parent atom. The attractive forces are greater because there is a larger positive charge in the nucleus than the negative charge in the electron cloud. So, cations are smaller than the atom they are derived from. Anions have more electrons than the parent. The electron cloud has a greater negative charge than the nucleus, so the anions have larger radii than the parent.

142. a. yes  
 c. The May process because it produces the least Pb, Cd, and Cu and the smallest amount of total heavy metals.  
 e. 0.148 mg

**133.** 14 g KO<sub>2</sub>. In designing the unit, you would need to consider the theoretical yield and % yield of the reaction, how changing the limiting reactant would affect the reaction, and the stoichiometry between KO<sub>2</sub> and O<sub>2</sub> to determine the mass of KO<sub>2</sub> required to produce enough O<sub>2</sub> for 10 minutes. You might also consider the speed of the reaction and whether or not the reaction produced heat. Additionally, because your body does not use 100% of the oxygen taken in with each breath, the apparatus would only need to replenish the oxygen used. The percentage of oxygen in air is about 20% and the percentage in exhaled air is about 16%, so you can assume that 4% of the air would need to be replenished with oxygen.

**135.** 37.9 g B<sub>5</sub>H<sub>9</sub>

**137. a.** Since the mol ratio of H<sub>2</sub> to NO is 5:2, the 10 mol of H<sub>2</sub> will require 4 mole NO, and H<sub>2</sub> is the limiting reactant. This eliminates answers b and c. Since there is excess NO, this eliminates d, leaving answer a.

**139. a**

- 85.**  $\text{Sr}(s) + \text{I}_2(g) \longrightarrow \text{SrI}_2(s)$
- 87.**  $2\text{Li}(s) + 2\text{H}_2\text{O}(l) \longrightarrow 2\text{Li}^+(aq) + 2\text{OH}^-(aq) + \text{H}_2(g)$
- 89.**  $\text{H}_2(g) + \text{Br}_2(g) \longrightarrow 2\text{HBr}(g)$
- 91.** Br:  $1s^2 2s^2 2p^6 3s^2 3p^6 4s^2 3d^{10} 4p^5$   
 Kr:  $1s^2 2s^2 2p^6 3s^2 3p^6 4s^2 3d^{10} 4p^6$   
 Krypton's outer electron shell is filled, giving it chemical stability. Bromine is missing an electron from its outer shell and subsequently has a high electron affinity. Bromine tends to be easily reduced by gaining an electron, giving the bromide ion stability due to the filled  $p$  subshell that corresponds to krypton's chemically stable electron configuration.
- 93.** V:  $[\text{Ar}] 4s^2 3d^3$   
 $\text{V}^{3+}$ :  $[\text{Ar}] 3d^2$

Both V and  $V^{3+}$  contain unpaired electrons in their  $3d$  orbitals.

- 95.** A substitute for  $K^+$  would need to exhibit a 1+ electric charge and have similar mass and atomic radius.  $Na^+$  and  $Rb^+$  would not be good substitutes because their radii are significantly smaller and larger, respectively. Based on mass,  $Ca^+$  and  $Ar^+$  are the closest to  $K^+$ . Because the first ionization energy of  $Ca^+$  is closest to that of  $K^+$ ,  $Ca^+$  is the best choice for a substitute. The difficulty lies in  $Ca$ 's low second ionization energy, making it easily oxidized.
- 97.** Si, Ge
- 99. a.** N:  $[He] 2s^2 2p^3$ , Mg:  $[Ne] 3s^2$ , O:  $[He] 2s^2 2p^4$ ,  
F:  $[He] 2s^2 2p^5$ , Al:  $[Ne] 3s^2 3p^1$
- b.** Mg, Al, O, F, N
- c.** Al, Mg, O, N, F
- d.** Aluminum's first ionization energy is lower than Mg because its  $3p$  electron is shielded by the  $3s$  orbital. Oxygen's first ionization energy is lower than that of N because its fourth  $2p$  electron experiences electron-electron repulsion by the other electron in its orbital.
- 101.** For main-group elements, atomic radii decrease across a period because the addition of a proton in the nucleus and an electron in the outermost energy level increases  $Z_{eff}$ . This does not happen in the transition metals because the electrons are added to the  $n_{highest} - 1$  orbital and the  $Z_{eff}$  stays roughly the same.
- 103.** Noble gases are exceptionally unreactive due to the stability of their completely filled outer quantum levels and their high ionization energies. The ionization energies of Kr, Xe, and Rn are low enough to form some compounds.
- 105.** 6A:  $ns^2 np^4$ , 7A:  $ns^2 np^5$ , group 7A elements require only one electron to achieve a noble gas configuration. Since group 6A elements require two electrons, their affinity for one electron is less negative because one electron will merely give them an  $np^5$  configuration.
- 107.** 85
- 109. a.** One If By Land (O, Ne, I, F, B, Y, La, Nd)
- b.** Atoms are Fun (N, U, Fe, Ra, S, Mo, Ta backward)

- 113. a.** F      **b.** B      **c.** B      **d.** O
- 115. a.**  $d_{Ar} \approx 2$  g/L,  $d_{Xe} \approx 6.5$  g/L
- b.**  $d_{118} \approx 13$  g/L
- c.** mass =  $3.35 \times 10^{-23}$  g/Ne atom, density of Ne  
atom =  $2.3 \times 10^4$  g/L. The separation of Ne atoms relative to their size is immense.
- d.** Kr:  $2.69 \times 10^{22}$  atoms/L, Ne:  $2.69 \times 10^{22}$  atoms/L.  
It seems Ar will also have  $2.69 \times 10^{22}$  atoms/L.  
 $d_{Ar} = 1.78$  g/L. This corresponds to accepted values.
- 117.** Density increases to the right because, though electrons are added successively across the period, they are added to the  $3d$  subshell, which is not a part of the outermost principal energy level. As a result, the atomic radius does not increase significantly across the period, while mass does.

121. 168, noble gas

123. A relatively high effective nuclear charge is found in gallium with its completed  $3d$  subshell and in thallium with its completed  $4f$  subshell, accounting for the relatively high first ionization energies of these elements.

125. The second electron affinity requires the addition of an electron to something that is already negatively charged. The monoanions of both of these elements have relatively high electron density in a relatively small volume. As we shall see in Chapter 9, the dianions of these elements do exist in many compounds because they are stabilized by chemical bonding.

127. 120, 170

129. Fr, [Rn]  $7s^1$ ,  $>265$ ,  $<376$ ,  $>1.879$ ,  $<29$

a.  $\text{Fr}^+(aq)$ ,  $\text{OH}^-(aq)$ ,  $\text{H}_2(g)$

b.  $\text{Fr}_2\text{O}(s)$

c.  $\text{FrCl}(s)$

131. a. any group 6A element

b. any group 5A element

c. any group 1A element

133. a. true b. true c. false d. true

135. Since Ca has valence electrons of  $4s^2$ , it has a relatively low ionization energy to lose two electrons. F has a highly exothermic electron affinity when gaining one electron but not a second electron because of its  $2s^2 2p^5$  valence electrons. Therefore, calcium and fluoride combine in a 2:1 ratio.

141. a. First ionization energy increases from left to right because effective nuclear charge increases.

c. The first ionization energy of P is about the same as S because the electrons in S are paired in the same orbital, so that even though effective nuclear charge is higher in S, the effect of the repulsion between the paired electrons makes the first ionization energies similar.

e.  $\text{SiF}_4$ ; This support student X's hypothesis, but not student Y's.

43. As the size of the alkaline earth metal ions increases, so does the distance between the metal cations and oxygen anions. Therefore, the magnitude of the lattice energy decreases accordingly because the potential energy decreases as the distance increases.

45. One factor of lattice energy is the product of the charges of the two ions. The product of the ion charges for  $\text{CsF}$  is  $-1$ , while that for  $\text{BaO}$  is  $-4$ . Because this product is four times greater, the lattice energy is also four times greater.

47.  $-708 \text{ kJ/mol}$

49. a.  $\text{H:H}$ , filled duets, 0 formal charge on both atoms

b.  $:\ddot{\text{Cl}}:\ddot{\text{Cl}}:$ , filled octets, 0 formal charge on both atoms

c.  $\ddot{\text{O}}=\ddot{\text{O}}$ , filled octets, 0 formal charge on both atoms

d.  $:\text{N}\equiv\text{N}:$ , filled octets, 0 formal charge on both atoms

55. a. pure covalent

b. polar covalent

c. pure covalent

d. ionic bond

## Chapter 9

structure.

67.  $\text{:O}\equiv\text{C--}\ddot{\text{O}}\text{:}$  does not provide a significant contribution to the resonance hybrid as it has a +1 formal charge on a very electronegative atom (oxygen).

71. N has a formal charge of +1; O has a formal charge of -1.

79.  $\text{H}_3\text{CCH}_3$ ,  $\text{H}_2\text{CCH}_2$ ,  $\text{HCCH}$

81. -128 kJ

83. -614 kJ

89. a.

b.

c.

d.

93. The reaction is exothermic due to the energy released when the  $\text{Al}_2\text{O}_3$  lattice forms.

95.

The fulminate ion is less stable because nitrogen is more electronegative than carbon and should therefore be terminal to accommodate the negative formal charge.

b.

105.  $\Delta H_{\text{rxn}}(\text{H}_2) = -243 \text{ kJ/mol} = -121 \text{ kJ/g}$

$\Delta H_{\text{rxn}}(\text{CH}_4) = -802 \text{ kJ/mol} = -50.0 \text{ kJ/g}$

$\text{CH}_4$  yields more energy per mole, while  $\text{H}_2$  yields more energy per gram.

109.  $\text{Na}^+\text{F}^-$ ,  $\text{Na}^+\text{O}^{2-}$ ,  $\text{Mg}^{2+}\text{F}^-$ ,  $\text{Mg}^{2+}\text{O}^{2-}$ ,  $\text{Al}^{3+}\text{O}^{2-}$

111.  $333 \text{ kJ/mol}$

115.

$$\Delta H_{\text{rxn}} = -172 \text{ kJ}$$

117.  $r_{\text{HCl}} = 113 \text{ pm}$ 

$$r_{\text{HF}} = 84 \text{ pm}$$

These values are close to the accepted values.

119.

121. 126 kJ/mol

123. The oxidation number of the S atoms bonded directly to hydrogen atoms is  $-1$ . The oxidation number of interior S atoms is 0.

125. 536 kJ

127. The compounds are energy rich because a great deal of energy is released when these compounds undergo a reaction that breaks weak bonds and forms strong ones.

129. The theory is successful because it allows us to predict and account for many chemical observations. The theory is limited because electrons cannot be treated as localized "dots."

135. a. The trend in lattice energy mirrors the trend in atomic radius shown in Figure b. The ions with smaller radii have higher (more negative) lattice energies.

c. The lattice energy of  $\text{MnF}_2$  is lower because the ionic radius of  $\text{Mn}^{2+}$  is larger.e.  $\text{VF}_2$  because the  $\text{F}^-$  ion is smaller than the  $\text{Cl}^-$  ion.

## Chapter 10

31. 4

33. a. 4  $e^-$  groups, 4 bonding groups, 0 lone pairb. 5  $e^-$  groups, 3 bonding groups, 2 lone pairsc. 6  $e^-$  groups, 5 bonding groups, 1 lone pair35. a.  $e^-$  geometry: tetrahedral molecular geometry: trigonal pyramidal idealized bond angle:  $109.5^\circ$ , deviationb.  $e^-$  geometry: tetrahedral molecular geometry: bent idealized bond angle:  $109.5^\circ$ , deviationc.  $e^-$  geometry: tetrahedral molecular geometry: tetrahedral idealized bond angle:  $109.5^\circ$ , deviation (due to large size of Cl compared to H)d.  $e^-$  geometry: linear molecular geometry: linear idealized bond angle:  $180^\circ$ 37.  $\text{H}_2\text{O}$  has a smaller bond angle due to lone pair-lone pair repulsions, the strongest electron group repulsion.c. linear,  $\text{F}-\text{I}-\text{F}$ 41. a. linear,  $\text{H}-\text{C}\equiv\text{C}-\text{H}$ 

43. a. The lone pair will cause lone pair-bonding pair repulsions, pushing the three bonding pairs out of the same plane. The correct molecular geometry is trigonal pyramidal.

b. The lone pair should take an equatorial position to minimize  $90^\circ$  bonding pair interactions. The correct molecular geometry is seesaw.

c. The lone pairs should take positions on opposite sides of the central atom to reduce lone pair-lone pair interactions. The correct molecular geometry is square planar.

b. C's: tetrahedral

O: bent

c. O's: bent

47. The vectors of the polar bonds in both  $\text{CO}_2$  and  $\text{CCl}_4$  oppose each other with equal magnitude and sum to 0.49.  $\text{PF}_3$ , polar $\text{SBr}_2$ , nonpolar $\text{CHCl}_3$ , polar $\text{CS}_2$ , nonpolar

51. **a.** polar  
**b.** polar  
**c.** nonpolar

53. **a.** 0  
**b.** 3  
**c.** 1

Expected bond angle = 90°

Valence bond theory is compatible with experimentally determined bond angle of 93.3° without hybrid orbitals.

N:  $sp^3$ bond order  $\text{Be}_2^+ = 1/2$ bond order  $\text{Be}_2^- = 1/2$ 

Both will exist in gas phase.

73. Bonding

Antibonding

bond order =  
0 diamagneticbond order =  
2 diamagnetic

77. a. not stable

c. stable

79.  $\text{C}_2^-$  has the highest bond order, the highest bond energy, and the shortest bond length.

bond order = 3

trigonal planar polar C:  $sp^2$ seesaw polar S:  $sp^3d$ 

(continued on the next page)

**87.**  $\sigma$  bonds: 25

$\pi$  bonds: 4

lone pairs: on O's and N (without methyl group):

$sp^2$  orbitals

on N's (with methyl group):  $sp^3$  orbitals

**89. a.** water soluble

**b.** fat soluble

**c.** water soluble

**d.** fat soluble

bond order = 1

**93.** BrF, unhybridized, linear

BrF<sub>2</sub><sup>−</sup> has two bonds and three lone pairs on the central atom. The hybridization is  $sp^3d$ . The electron geometry is trigonal bipyramidal, with the three lone pairs equatorial. The molecular geometry is linear.

BrF<sub>3</sub> has three bonds and two lone pairs on the central atom. The hybridization is  $sp^3d$ . The electron geometry

is trigonal bipyramidal, with the two lone pairs equatorial. The molecular geometry is T-shaped.

BrF<sub>4</sub><sup>−</sup> has four bonds and two lone pairs on the central atom. The hybridization is  $sp^3d^2$ . The electron geometry is octahedral, with the two lone pairs on the same axis. The molecular geometry is square planar.

BrF<sub>5</sub> has five bonds and one lone pair on the central atom. The hybridization is  $sp^3d^2$ . The electron geometry is octahedral. The molecular geometry is square pyramidal.

**95.** The moments of the two Cl's cancel.

**97. a.** 10

**b.** 14

**c.** 2

**99.** According to valence bond theory, CH<sub>4</sub>, NH<sub>3</sub>, and H<sub>2</sub>O are all  $sp^3$  hybridized. This hybridization results in a tetrahedral electron group configuration with a 109.5° bond angle. NH<sub>3</sub> and H<sub>2</sub>O deviate from this idealized bond angle because their lone electron pairs exist in their own  $sp^3$  orbitals. The presence of lone pairs lowers the tendency for the central atom's orbitals to hybridize. As a result, as lone pairs are added, the bond angle moves further from the 109.5° hybrid angle and closer to the 90° unhybridized angle.

**101.** NH<sub>3</sub> is stable due to its bond order of 3.

**103.** In NO<sub>2</sub><sup>+</sup>, the central N has two electron groups, so the hybridization is  $sp$  and the ONO angle is 180°. In NO<sub>2</sub><sup>−</sup> the central N has three electron groups, two bonds and one lone pair. The ideal hybridization is  $sp^2$ , but the ONO bond angle should close down a bit because of the lone pair. A bond angle around 115° is a good guess. In NO<sub>2</sub> there are three electron groups, but one group is a single electron. Again, the ideal hybridization would be  $sp^2$ , but since one unpaired electron

(continued on the next page)

must be much smaller than a lone pair or even a bonding pair, we predict that the ONO bond angle will spread and be greater than  $120^\circ$ . As a guess, the angle is probably significantly greater than  $120^\circ$ .

- 105.** In addition to the 2s and the three 2p orbitals, one more orbital is required to make five hybrid orbitals. The closest in energy is the 3s orbital. So the hybridization is  $s^2p^3$ . VSEPR predicts trigonal bipyramidal geometry for five identical substituents.

Terminal carbon is tetrahedral, central carbon is trigonal planar, nitrogen is trigonal pyramidal (but resonance structure is trigonal planar).

- 109. a.** This is the best.  
**b.** This statement is similar to **a** but leaves out nonbonding lone-pair electron groups.  
**c.** Molecular geometries are not determined by overlapping orbitals but rather by the number and type of electron groups around each central atom.
- 111.** Lewis theory defines a single bond, double bond, and triple bond as a sharing of two electrons, four electrons, and six electrons, respectively, between two atoms. Valence bond theory defines a single bond as a sigma overlap of two orbitals, a double bond as a single sigma bond combined with a pi bond, and a triple bond as a double bond with an additional pi bond. Molecular orbital theory defines a single bond, double bond, and triple bond as a bond order of 1, 2, or 3, respectively, between two atoms.
- 118. a.** From top to bottom of column:  $109.8^\circ$ ,  $112.4^\circ$ ,  $110.9^\circ$

## Chapter 11

- 35. a.** dispersion  
**b.** dispersion, dipole-dipole, hydrogen bonding  
**c.** dispersion, dipole-dipole  
**d.** dispersion
- 37. a.** dispersion, dipole-dipole  
**b.** dispersion, dipole-dipole, hydrogen bonding

**c.** dispersion

**d.** dispersion

- 39. a, b, c, d.** Boiling point increases with increasing intermolecular forces. The molecules increase in their intermolecular forces as follows: **a**, dispersion forces; **b**, stronger dispersion forces (broader electron cloud); **c**, dispersion forces and dipole-dipole interactions; **d**, dispersion forces, dipole-dipole interactions, and hydrogen bonding.
- 41. a.**  $\text{CH}_3\text{OH}$ , hydrogen bonding  
**b.**  $\text{CH}_3\text{CH}_2\text{OH}$ , hydrogen bonding  
**c.**  $\text{CH}_3\text{CH}_3$ , greater mass, broader electron cloud causes greater dispersion forces
- 43. a.**  $\text{Br}_2$ , smaller mass results in weaker dispersion forces  
**b.**  $\text{H}_2\text{S}$ , lacks hydrogen bonding  
**c.**  $\text{PH}_3$ , lacks hydrogen bonding
- 45. a.** not homogeneous  
**b.** homogeneous, dispersion, dipole-dipole, hydrogen bonding, ion-dipole  
**c.** homogeneous, dispersion  
**d.** homogeneous, dispersion, dipole-dipole, hydrogen bonding
- 47.** Water. Surface tension increases with increasing intermolecular forces, and water can hydrogen-bond while acetone cannot.
- 49.** compound A
- 51.** When the tube is clean, water experiences adhesive forces with glass that are stronger than its cohesive forces, causing it to climb the surface of a glass tube. Water does not experience strong intermolecular forces with oil, so if the tube is coated in oil, the water's cohesive forces will be greater and it will not be attracted to the surface of the tube.
- 53.** The water in the 12-cm dish will evaporate more quickly. The vapor pressure does not change, but the surface area does. The water in the dish evaporates more quickly because the greater surface area allows for more molecules to obtain enough energy at the surface and break free.
- 55.** Water is more volatile than vegetable oil. When the water evaporates, the endothermic process results in cooling.
- 57.** 0.405 L
- 59.**  $91^\circ\text{C}$
- 61.**  $\Delta H_{\text{vap}} = 24.7 \text{ kJ/mol}$ ,  $\text{bp} = 239 \text{ K}$
- 63.** 41 torr
- 65.**  $27.5 \text{ kJ/mol}$
- 67.**  $22.0 \text{ kJ}$
- 69.**  $2.7^\circ\text{C}$
- 71.**  $30.5 \text{ kJ}$
- 73. a.** solid  
**b.** liquid  
**c.** gas  
**d.** supercritical fluid  
**e.** solid/liquid  
**f.** liquid/gas  
**g.** solid/liquid/gas

75.  $\text{N}_2$  has a stable liquid phase at 1 atm.

77. a. 0.027 mmHg b. rhombic  
79. Water has strong intermolecular forces. It is polar and experiences hydrogen bonding.  
81. Water's exceptionally high specific heat capacity has a moderating effect on Earth's climate. Also, its high  $\Delta H_{\text{vap}}$  causes water evaporation and condensation to have a strong effect on temperature.  
83. The general trend is that melting point increases with increasing mass. This is because the electrons of the larger molecules are held more loosely and a stronger dipole moment can be induced more easily. HF is the exception to the rule. It has a relatively high melting point due to hydrogen bonding.  
85. yes, 1.22 g  
87. gas  $\longrightarrow$  liquid  $\longrightarrow$  solid

89. 26 °C

93.  $3.4 \times 10^3$  g  $\text{H}_2\text{O}$

95. a.  $\text{CO}_2(\text{s}) \longrightarrow \text{CO}_2(\text{g})$  at 195 K  
b.  $\text{CO}_2(\text{s}) \longrightarrow$  triple point at 216 K  $\longrightarrow \text{CO}_2(\text{g})$  just above 216 K  
c.  $\text{CO}_2(\text{s}) \longrightarrow \text{CO}_2(\text{l})$  at somewhat above 216 K  $\longrightarrow \text{CO}_2(\text{g})$  at around 250 K  
d.  $\text{CO}_2(\text{s}) \longrightarrow \text{CO}_2(\text{g}) \longrightarrow$  supercritical fluid  
97. Decreasing the pressure will decrease the temperature of liquid nitrogen. Because the nitrogen is boiling, its temperature must be constant at a given pressure. As the pressure decreases, the boiling point decreases, and therefore so does the temperature. If the pressure drops below the pressure of the triple point, the phase change will shift from vaporization to sublimation and the liquid nitrogen will become solid.

99. 70.7 L

101. 0.48 atm

- 103.

105. The water within a container with a larger surface area will evaporate more quickly because there is more surface area for the molecules to evaporate from. Vapor pressure is the pressure of the gas when it is in dynamic equilibrium with the liquid. The vapor pressure is dependent only on the substance and the temperature. The larger the surface area, the more quickly it will reach the dynamic state.  
107. The triple point will be at a lower temperature since the fusion equilibrium line has a positive slope. This means that we will be increasing both temperature and pressure as we travel from the triple point to the normal melting point.  
109. The liquid segment will have the least steep slope because it takes the most kJ/mol to raise the temperature of the phase.  
111. There are substantial intermolecular attractions in the liquid but virtually none in the gas.  
117. a. Molar mass correlates with boiling point for  $\text{H}_2\text{S}$ ,  $\text{H}_2\text{Se}$ , and  $\text{Hg}_2\text{Te}$ , but not for  $\text{H}_2\text{O}$ .  
c. dispersion force  
e. Yes. Since polarizability correlates with the dispersion force and since polarizability increases as boiling point increases, the increasing dispersion force is responsible for the increasing boiling point.

- g.

## Chapter 12

27. 162 pm

29. a. 1                      b. 2                      c. 4

31. 68%

33.  $l = 393 \text{ pm}$ ,  $d = 21.3 \text{ g/cm}^3$ 

35. 134.5 pm

37.  $6.0 \times 10^{23} \text{ atoms/mol}$ 

39. a. atomic

b. molecular

c. ionic

d. atomic

41. LiCl(s). The other three solids are held together by intermolecular forces, while LiCl is held together by stronger coulombic interactions between the cations and anions of the crystal lattice.

43. a.  $\text{TiO}_2(\text{s})$ , ionic solidb.  $\text{SiCl}_4(\text{s})$ , larger, stronger dispersion forcesc.  $\text{Xe}(\text{s})$ , larger, stronger dispersion forces

d. CaO, ions have greater charge and therefore stronger coulombic forces

45.  $\text{TiO}_2$ 47. Cs:  $1(1) = 1$ Cl:  $8(1/8) = 1$ 

1:1

CsCl

Ba:  $8(1/8) + 6(1/2) = 4$ Cl:  $8(1) = 8$ 

4:8 = 1:2

 $\text{BaCl}_2$ 

49. cesium chloride: none of these; barium(II) chloride: fluorite structure

51. face-centered cubic

53. a. nonoxide

b. silicate

c. nonoxide

55. boron oxide,  $\text{B}_2\text{O}_3$ 

57. Ca: +2; Si: +2; O: -2

59. a. Zn(s)

61. 0.807 mol orbitals

63. insulator

65. a. p-type

b. n-type

67. yes, it has sufficient energy

73.  $\text{H}-\text{C}\equiv\text{C}-\text{H}$ 

77. CsCl has a higher melting point than AgI because of its higher coordination number. In CsCl, one anion bonds to eight cations (and vice versa), while in AgI, one anion bonds to only four cations.

79. a.  $4r$ 

$$\text{b. } c^2 = a^2 + b^2 \quad c = 4r, a = l, b = l$$

$$(4r)^2 = l^2 + l^2$$

$$16r^2 = 2l^2$$

$$8r^2 = l^2$$

$$l = \sqrt{8r^2}$$

$$l = 2\sqrt{2}r$$

81. 8 atoms/unit

83. 55.843 g/mol

85.  $2.00 \text{ g/cm}^3$ 

87. body diagonal  $= \sqrt{6}r$ ,  
radius  $= (\sqrt{3} - \sqrt{2})r / \sqrt{2} = 0.2247r$

89. The higher-level electron transitions with their smaller energy gaps would give not off enough energy to create X-rays.

To obtain this structure, the monomer from part a would react in a head-to-head (or tail-to-tail) addition as opposed to the head-to-tail addition that leads to the structure shown in Table 12.3.

93. Because the structure is face-centered cubic, there are therefore four  $\text{C}_{60}$  molecules per unit cell. Thus there must be  $3 \times 4 = 12$  Rb atoms per unit cell, and all sites (tetrahedral and octahedral) are occupied.

95. The liquid must be cooled quickly in order to prevent the formation of an organized crystal structure, and instead achieve an amorphous product.

97. Both structures may be viewed as having essentially a face-centered cubic unit cell with half of the tetrahedral holes filled. Diamond, however, consists of only one type of atom (C) and is covalently bound, whereas zinc blende has  $\text{S}^{2-}$  ions at the face-centered cubic sites and  $\text{Zn}^{2+}$  ions in the tetrahedral holes, and is held together by ionic forces.

99. d. All of the above would likely lead to an increase in electrical conductivity.

105. a. Most of the metals that form hydrides have only one oxidation state.

c. 4.6%

e. heated

## Chapter 13

29. a. hexane, toluene, or  $\text{CCl}_4$ ; dispersion forces  
 b. water, methanol; dispersion, dipole-dipole, hydrogen bonding  
 c. hexane, toluene, or  $\text{CCl}_4$ ; dispersion forces  
 d. water, acetone, methanol, ethanol; dispersion, ion-dipole
31.  $\text{HOCH}_2\text{CH}_2\text{CH}_2\text{OH}$
33. a. water; dispersion, dipole-dipole, hydrogen bonding  
 b. hexane; dispersion  
 c. water; dispersion, dipole-dipole  
 d. water; dispersion, dipole-dipole, hydrogen bonding
35. a. endothermic  
 b. The lattice energy is greater in magnitude than the heat of hydration.

- d. The solution forms because chemical systems tend toward greater entropy.
37.  $-797 \text{ kJ/mol}$
39.  $\Delta H_{\text{soln}} = -6 \times 10^1 \text{ kJ/mol}$ ,  $-7 \text{ kJ}$  of energy evolved
41. unsaturated
43. About 31 g will precipitate.
45. Boiling water releases any  $\text{O}_2$  dissolved in it. The solubility of gases decreases with increasing temperature.
47. As pressure increases, nitrogen will more easily dissolve in blood. To reverse this process, divers should ascend to lower pressures.
49. 1.1 g
51. 1.92 M, 2.0 M, 10.4%
53. 0.340 L
55.  $1.6 \times 10^2 \text{ g}$
57.  $1.4 \times 10^4 \text{ g}$
59. Add water to 7.31 mL of concentrated solution until a total volume of 1.15 L is acquired.
61. a. Add water to 3.73 g KCl to a volume of 100 mL.  
 b. Add 3.59 g KCl to 96.41 g  $\text{H}_2\text{O}$ .  
 c. Add 5.0 g KCl to 95 g  $\text{H}_2\text{O}$ .
63. a. 0.417 M      b. 0.444 M      c. 7.41% by mass  
 d. 0.00794      e. 0.794% by mole
65. 0.89 M
67. 15 M, 0.22
69. The level has decreased more in the beaker filled with pure water. The dissolved salt in the seawater decreases the vapor pressure and subsequently lowers the rate of vaporization.
71. 30.7 torr
73. a.  $P_{\text{hep}} = 24.4 \text{ torr}$ ,  $P_{\text{oct}} = 5.09 \text{ torr}$   
 b. 29.5 torr  
 c. 80.8% heptane by mass, 19.2% octane by mass  
 d. The vapor is richer in the more volatile component.

75.  $P_{\text{chl}} = 51.9 \text{ torr}$ ,  $P_{\text{ace}} = 274 \text{ torr}$ ,  $P_{\text{tot}} = 326 \text{ torr}$ . The solution is not ideal. The chloroform-acetone interactions are stronger than the chloroform-chloroform and acetone-acetone interactions.
77. freezing point (fp) =  $-1.27^\circ\text{C}$ , bp =  $100.349^\circ\text{C}$
79. freezing point (fp) =  $1.0^\circ\text{C}$ , boiling point (bp) =  $82.4^\circ\text{C}$
81.  $1.8 \times 10^2 \text{ g/mol}$
83. 26.1 atm
85.  $6.36 \times 10^3 \text{ g/mol}$
87. a. fp =  $-0.558^\circ\text{C}$ , bp =  $100.154^\circ\text{C}$   
 b. fp =  $-1.98^\circ\text{C}$ , bp =  $100.546^\circ\text{C}$   
 c. fp =  $-2.5^\circ\text{C}$ , bp =  $100.70^\circ\text{C}$
89. 157 g
91. a.  $-0.632^\circ\text{C}$       b. 5.4 atm      c.  $100.18^\circ\text{C}$
93. 2.3
95. 3.4
97. 23.0 torr
99. Chloroform is polar and has stronger solute-solvent interactions than nonpolar carbon tetrachloride.
101.  $\Delta H_{\text{soln}} = 51 \text{ kJ/mol}$ ,  $-8.7^\circ\text{C}$
103.  $2.2 \times 10^{-3} \text{ M/atm}$
105.  $1.3 \times 10^4 \text{ L}$
107. 0.24 g
109.  $-24^\circ\text{C}$
111. a. 1.1% by mass/V      b. 1.6% by mass/V  
 c. 5.3% by mass/V
113. 2.484
115. 0.229 atm
117.  $\chi_{\text{CHCl}_3}(\text{original}) = 0.657$ ,  
 $P_{\text{CHCl}_3}(\text{condensed}) = 0.346 \text{ atm}$
119. 1.74 M
121.  $\text{C}_6\text{H}_{14}\text{O}_2$
123. 12 grams
125.  $6.4 \times 10^{-3} \text{ L}$
127. 22.4% glucose by mass, 77.6% sucrose by mass
129.  $P_{\text{iso}} = 0.131 \text{ atm}$ ,  $P_{\text{pro}} = 0.068 \text{ atm}$ . The major intermolecular attractions are between the OH groups. The OH group at the end of the chain in propyl alcohol is more accessible than the one in the middle of the chain in isopropyl alcohol. In addition, the molecular shape of propyl alcohol is a straight chain of carbon atoms, while that of isopropyl alcohol is a branched chain and is more like a ball. The contact area between two ball-like objects is smaller than that of two chain-like objects. The smaller contact area in isopropyl alcohol means the molecules don't attract each other as strongly as do those of propyl alcohol. As a result of both of these factors, the vapor pressure of isopropyl alcohol is higher.
131. 0.005 M
133.  $\text{Na}_2\text{CO}_3$  0.050 M,  $\text{NaHCO}_3$  0.075 M
135. The water should not be immediately cycled back into the river. As the water was warmed, dissolved oxygen would have been released, since the amount of a gas able to be dissolved into a liquid decreases as the temperature of the liquid increases. As such, the water returned to the river would lack dissolved oxygen if it was still hot. To preserve the dissolved oxygen necessary for the survival of fish and other aquatic life, the water must first be cooled.

137. **b.** NaCl144. **a. i.**  $-2.39^{\circ}\text{C}$ **ii.**  $-2.06^{\circ}\text{C}$ 

Figure c does not show the range of salinities actually present in seawater.

## Chapter 14

25. **a.**  $\text{Rate} = -\frac{1}{2} \frac{\Delta[\text{HBr}]}{\Delta t} = \frac{\Delta[\text{H}_2]}{\Delta t} = \frac{\Delta[\text{Br}_2]}{\Delta t}$

**b.**  $1.8 \times 10^{-3} \text{ M/s}$  **c.**  $0.040 \text{ mol Br}_2$

27. **a.**  $\text{Rate} = -\frac{1}{2} \frac{\Delta[\text{A}]}{\Delta t} = -\frac{\Delta[\text{B}]}{\Delta t} = \frac{1}{3} \frac{\Delta[\text{C}]}{\Delta t}$

**b.**  $\frac{\Delta[\text{B}]}{\Delta t} = -0.0500 \text{ M/s}, \frac{\Delta[\text{C}]}{\Delta t} = 0.150 \text{ M/s}$

29.	$\frac{\Delta[\text{Cl}_2]}{\Delta t}$	$\frac{\Delta[\text{F}_2]}{\Delta t}$	$\frac{\Delta[\text{ClF}_3]}{\Delta t}$	Rate
	$-0.012 \text{ M/s}$	$-0.036 \text{ M/s}$	$0.024 \text{ M/s}$	$0.012 \text{ M/s}$

31. **a.**  $0 \rightarrow 10 \text{ s: Rate} = 8.7 \times 10^{-3} \text{ M/s}$   
 $40 \rightarrow 50 \text{ s: Rate} = 6.0 \times 10^{-3} \text{ M/s}$

**b.**  $1.4 \times 10^{-2} \text{ M/s}$

33. **a. i.**  $1.0 \times 10^{-2} \text{ M/s}$  **ii.**  $8.5 \times 10^{-3} \text{ M/s}$   
**iii.**  $0.013 \text{ M/s}$

35. **a.** first order

**c.**  $\text{Rate} = k[\text{A}]^1, k = 0.010 \text{ s}^{-1}$

37. **a.**  $\text{s}^{-1}$  **b.**  $\text{M}^{-1} \text{s}^{-1}$  **c.**  $\text{M} \cdot \text{s}^{-1}$

39. **a.**  $\text{Rate} = k[\text{A}][\text{B}]^2$

**b.** third order**c.** 2**d.** 4**e.** 1**f.** 8

41. second order,  $\text{Rate} = 5.25 \text{ M}^{-1} \text{s}^{-1} [\text{A}]^2$

43. first order,  $\text{Rate} = 0.065 \text{ s}^{-1} [\text{A}]$

45.  $\text{Rate} = k[\text{NO}_2][\text{F}_2], k = 2.57 \text{ M}^{-1} \text{s}^{-1}$ , second order

47. **a.** zero order**b.** first order**c.** second order

49. second order,  $k = 2.25 \times 10^{-2} \text{ M}^{-1} \text{s}^{-1}$ ,  
 $[\text{AB}] \text{ at } 25 \text{ s} = 0.619 \text{ M}$

51. first order,  $k = 1.12 \times 10^{-2} \text{ s}^{-1}$ ,  $\text{Rate} = 2.8 \times 10^{-3} \text{ M/s}$

53. **a.**  $4.5 \times 10^{-3} \text{ s}^{-1}$

**b.**  $\text{Rate} = 4.5 \times 10^{-3} \text{ s}^{-1} [\text{A}]$

**c.**  $1.5 \times 10^2 \text{ s}$

**d.**  $[\text{A}] = 0.0908 \text{ M}$

55. **a.**  $4.88 \times 10^3 \text{ s}$

**b.**  $9.8 \times 10^3 \text{ s}$

**c.**  $1.7 \times 10^3 \text{ s}$

**d.**  $0.146 \text{ M at } 200 \text{ s}, 0.140 \text{ M at } 500 \text{ s}$

57.  $6.8 \times 10^8 \text{ yr}; 1.8 \times 10^{17} \text{ atoms}$

61.  $17 \text{ s}^{-1}$

63.  $61.90 \text{ kJ/mol}$

65.  $E_a = 251 \text{ kJ/mol}, A = 7.93 \times 10^{11} \text{ s}^{-1}$

67.  $E_a = 23.0 \text{ kJ/mol}, A = 8.05 \times 10^{10} \text{ M}^{-1} \text{s}^{-1}$

69. **a.**  $122 \text{ kJ/mol}$

**b.**  $0.101 \text{ s}^{-1}$

71.  $47.85 \text{ kJ/mol}$

73. **a**

75. The mechanism is valid.

**c.**  $\text{Rate} = k[\text{Cl}_2]^{1/2}[\text{CHCl}_3]$

79. Heterogeneous catalysts require a large surface area because catalysis can only happen at the surface. A greater surface area means greater opportunity for the substrate to react, which results in a faster reaction.

81.  $10^{12}$

83. **a.** first order,  $k = 0.0462 \text{ hr}^{-1}$

**b.** 15 hr

**c.**  $5.0 \times 10^1 \text{ hr}$

85. 0.0531 M/s

87. rate =  $4.5 \times 10^{-4} [\text{CH}_3\text{CHO}]^2$ ,  
 $k = 4.5 \times 10^{-4}$ , 0.37 atm

89. 219 torr

91.  $1 \times 10^{-7}$  s

93.  $1.6 \times 10^2$  seconds

95. a. 2

b.

c. first step

d. exothermic

97. a. 5.41 s

b. 2.2 s for 25%, 5.4 s for 50%

c. 0.28 at 10 s, 0.077 at 20 s

99. a.  $E_a = 89.5$  kJ/mol,  $A = 4.22 \times 10^{11} \text{ s}^{-1}$

b.  $2.5 \times 10^{-5} \text{ M}^{-1} \text{ s}^{-1}$

c.  $6.0 \times 10^{-4} \text{ M/s}$

101. a. No

b. No bond is broken, and the two radicals attract each other.

c. Formation of diatomic gases from atomic gases.

103.  $1.35 \times 10^4$  years

105. a. Both are valid. For both, all steps sum to overall reaction, and the predicted rate law is consistent with experimental data.

b. Buildup of I(g)

107. rate =  $k_2[(k_1/k_{-1})[\text{Br}_2]]^{1/2}[\text{H}_2]$  The rate law is 3/2 order overall.

109. a. 0%

b. 25%

c. 33%

111. 174 kJ

113. a. second order

Rate =  $k_3[\text{CH}_3\text{NC}^*]$

$k_1[\text{CH}_3\text{NC}]^2 = k_2[\text{CH}_3\text{NC}^*][\text{CH}_3\text{NC}]$

$[\text{CH}_3\text{NC}^*] = \frac{k_1}{k_2}[\text{CH}_3\text{NC}]$

Rate =  $k_3 \times \frac{k_1}{k_2}[\text{CH}_3\text{NC}]$

Rate =  $k[\text{CH}_3\text{NC}]$

115. Rate =  $k[\text{A}]^2$

Rate =  $-\frac{d[\text{A}]}{dt}$

$\frac{d[\text{A}]}{dt} = -k[\text{A}]^2$

$2\frac{d[\text{A}]}{[\text{A}]^2} = k dt$

$$\int_{[\text{A}]_0}^{[\text{A}]} -\frac{1}{[\text{A}]^2} d[\text{A}] = \int_0^t k dt$$

$$\left[ \frac{1}{[\text{A}]} \right]_{[\text{A}]_0}^{[\text{A}]} = k[t]_0^t$$

$$\frac{1}{[\text{A}]} - \frac{1}{[\text{A}]_0} = kt$$

$$\frac{1}{[\text{A}]} = kt + \frac{1}{[\text{A}]_0}$$

117. Rate =  $k[\text{CO}][\text{Cl}_2]^3$

119.  $[\text{Cl}_2] = 0.0084$  mol/L,  $[\text{NO}] = 0.017$  mol/L

121. B is first order and A is second order.

B will be linear if you plot  $\ln[\text{B}]$  versus time; A will be linear if you plot  $1/[\text{A}]$  versus time.

125. a. First order; a plot of  $\ln [\% \text{ color}]$  vs. time gives a straight line.

c. Yes. The color is degraded more quickly at warmer temperatures.

e. 38.5 kJ/mol

## Chapter 15

21. a.  $K = \frac{[\text{SbCl}_3][\text{Cl}_2]}{[\text{SbCl}_5]}$

b.  $K = \frac{[\text{NO}]^2[\text{Br}_2]}{[\text{BrNO}]^2}$

c.  $K = \frac{[\text{CS}_2][\text{H}_2]^4}{[\text{CH}_4][\text{H}_2\text{S}]^2}$

d.  $K = \frac{[\text{CO}_2]^2}{[\text{CO}]^2[\text{O}_2]}$

23. The concentration of the reactants will be greater. No, this is not dependent on initial concentrations; it is dependent on the value of  $K_c$ .

25. a. figure v

b. The change in the decrease of reactants and increase of products would be faster.

c. No, catalysts affect kinetics, not equilibrium.

27. a.  $4.42 \times 10^{-5}$ , reactants favored

b.  $1.50 \times 10^2$ , products favored

c.  $1.96 \times 10^{-9}$ , reactants favored

29.  $1.3 \times 10^{-29}$

31. a.  $2.56 \times 10^{-23}$

b.  $1.3 \times 10^{22}$

c. 81.9

33. a.  $K_c = \frac{[\text{HCO}_3^-][\text{OH}^-]}{[\text{CO}_3^{2-}]}$

b.  $K_c = [\text{O}_2]^3$

c.  $K_c = \frac{[\text{H}_3\text{O}^+][\text{F}^-]}{[\text{HF}]}$

d.  $K_c = \frac{[\text{NH}_4^+][\text{OH}^-]}{[\text{NH}_3]}$

35. 136

37. T (K)	$[\text{N}_2]$	$[\text{H}_2]$	$[\text{NH}_3]$	$K_c$
500	0.115	0.105	0.439	$1.45 \times 10^3$
575	0.110	0.249	0.128	9.6
775	0.120	0.140	$4.39 \times 10^{-3}$	0.0584

39. 234 torr  
 41. 18  
 43.  $3.3 \times 10^2$   
 45. 764  
 47. More solid will form.  
 49. Additional solid will not dissolve.  
 51. **a.**  $[A] = 0.20 \text{ M}$ ,  $[B] = 0.80 \text{ M}$   
**b.**  $[A] = 0.33 \text{ M}$ ,  $[B] = 0.67 \text{ M}$   
**c.**  $[A] = 0.38 \text{ M}$ ,  $[B] = 1.2 \text{ M}$   
 53.  $[\text{N}_2\text{O}_4] = 0.0115 \text{ M}$ ,  $[\text{NO}_2] = 0.0770 \text{ M}$   
 55. 0.199 M  
 57.  $1.9 \times 10^{-3} \text{ M}$   
 59. 7.84 torr  
 61. **a.**  $[A] = 0.38 \text{ M}$ ,  $[B] = 0.62 \text{ M}$ ,  $[C] = 0.62 \text{ M}$   
**b.**  $[A] = 0.90 \text{ M}$ ,  $[B] = 0.095 \text{ M}$ ,  $[C] = 0.095 \text{ M}$   
**c.**  $[A] = 1.0 \text{ M}$ ,  $[B] = 3.2 \times 10^{-3} \text{ M}$ ,  
 $[C] = 3.2 \times 10^{-3} \text{ M}$   
 63. **a.** shift left  
**b.** shift right  
**c.** shift right  
 65. **a.** shift right  
**b.** no effect  
**c.** no effect  
**d.** shift left  
 67. **a.** shift right  
**b.** shift left  
**c.** no effect  
 69. Increase temperature  $\longrightarrow$  shift right, decrease  
 temperature  $\longrightarrow$  shift left. Increasing the temperature  
 will increase the equilibrium constant.  
 71. **b, d**  
 73. **a.**  $1.7 \times 10^2$   
**b.**  $\frac{[\text{Hb}-\text{CO}]}{[\text{Hb}-\text{O}_2]} = 0.85$  or 17/20  
 CO is highly toxic, as it blocks  $\text{O}_2$  uptake by  
 hemoglobin. CO at a level of 0.1% will replace  
 nearly half of the  $\text{O}_2$  in blood.  
 75. **a.** 1.68 atm  
**b.** 1.41 atm  
 77. 0.406 g  
 79. **b, c, d**  
 81. 0.0144 atm  
 83.  $3.1 \times 10^2 \text{ g}$ , 20% yield  
 85. 0.12 atm  
 87. 0.72 atm  
 89. 0.017 g  
 91. 0.226  
 93. **a.** 29.3  
**b.** 169 torr  
 95.  $P_{\text{NO}} = P_{\text{Cl}_2} = 429 \text{ torr}$   
 97.  $1.27 \times 10^{-2}$   
 99.  $K_p = 5.1 \times 10^{-2}$   
 101. Yes, because the volume affects  $Q$ .  
 103.  $a = 1$ ,  $b = 2$   
 105.  $K_c = 1$   
 111. **a.** For eqn 1,  $K_p = 0.011$ ; For eqn 2,  $K_p = 91$   
**c.** yes, if the pressure was greater than 100 atm.

## Chapter 16

33. **a.** acid,  $\text{HNO}_3(aq) \longrightarrow \text{H}^+(aq) + \text{NO}_3^-(aq)$   
**b.** acid,  $\text{NH}_4^+(aq) \rightleftharpoons \text{H}^+(aq) + \text{NH}_3(aq)$   
**c.** base,  $\text{KOH}(aq) \longrightarrow \text{K}^+(aq) + \text{OH}^-(aq)$

147. 12.97
149. a.  $\text{pH} < \text{p}K_a$       b.  $\text{pH} > \text{p}K_a$   
 c.  $\text{pH} = \text{p}K_a$       d.  $\text{pH} > \text{p}K_a$
151. b
153. a. no difference  
 b. less soluble  
 c. more soluble
160. a.  $\text{H}_3\text{C}_6\text{H}_5\text{O}_7(aq) + \text{OH}^{-}(aq) \longrightarrow$   
 $\text{H}_2\text{O}(l) + \text{H}_2\text{C}_6\text{H}_5\text{O}_7^{-}(aq)$

- c.  $\text{C}_6\text{H}_5\text{O}_7^{3-}(aq) + \text{H}_3\text{O}^{+}(aq) \longrightarrow$   
 $\text{HC}_6\text{H}_5\text{O}_7^{2-}(aq) + \text{H}_2\text{O}(l)$   
 $\text{HC}_6\text{H}_5\text{O}_7^{2-}(aq) + \text{OH}^{-}(aq) \longrightarrow$   
 $\text{H}_2\text{O}(l) + \text{C}_6\text{H}_5\text{O}_7^{3-}(aq)$
- e. The ratio should be  $[\text{K}_3\text{C}_6\text{H}_5\text{O}_7]/[\text{K}_2\text{HC}_6\text{H}_5\text{O}_7] = 0.41$ ;  
 $[\text{K}_3\text{C}_6\text{H}_5\text{O}_7] = 0.010 \text{ M}$  and  $[\text{K}_2\text{HC}_6\text{H}_5\text{O}_7] = 0.024 \text{ M}$

## Chapter 18

27. a, c
29. System B has the greatest entropy. There is only one energetically equivalent arrangement for System A. However, the particles of System B may exchange positions for a second energetically equivalent arrangement.
31.  $29.2 \text{ J/K}$
33.  $-24.7 \text{ J/K}$
35. a.  $\Delta S > 0$   
 b.  $\Delta S < 0$   
 c.  $\Delta S < 0$   
 d.  $\Delta S < 0$
37. a.  $\Delta S_{\text{sys}} > 0$ ,  $\Delta S_{\text{surr}} > 0$ , spontaneous at all temperatures  
 b.  $\Delta S_{\text{sys}} < 0$ ,  $\Delta S_{\text{surr}} < 0$ , nonspontaneous at all temperatures  
 c.  $\Delta S_{\text{sys}} < 0$ ,  $\Delta S_{\text{surr}} < 0$ , nonspontaneous at all temperatures  
 d.  $\Delta S_{\text{sys}} > 0$ ,  $\Delta S_{\text{surr}} > 0$ , spontaneous at all temperatures
39. a.  $1.29 \times 10^3 \text{ J/K}$   
 b.  $5.00 \times 10^3 \text{ J/K}$   
 c.  $-3.83 \times 10^2 \text{ J/K}$   
 d.  $-1.48 \times 10^3 \text{ J/K}$
41. a.  $-649 \text{ J/K}$ , nonspontaneous  
 b.  $649 \text{ J/K}$ , spontaneous  
 c.  $123 \text{ J/K}$ , spontaneous  
 d.  $-76 \text{ J/K}$ , nonspontaneous
43. a.  $1.93 \times 10^5 \text{ J}$ , nonspontaneous  
 b.  $-1.93 \times 10^5 \text{ J}$ , spontaneous  
 c.  $-3.7 \times 10^4 \text{ J}$ , spontaneous  
 d.  $4.7 \times 10^4 \text{ J}$ , nonspontaneous
45.  $-2.247 \times 10^6 \text{ J}$ , spontaneous
- 47.
- | $\Delta H$ | $\Delta S$ | $\Delta G$            | Low Temperature | High Temperature |
|------------|------------|-----------------------|-----------------|------------------|
| –          | +          | –                     | Spontaneous     | Spontaneous      |
| –          | –          | Temperature dependent | Spontaneous     | Nonspontaneous   |
| +          | +          | Temperature dependent | Nonspontaneous  | Spontaneous      |
| +          | –          | +                     | Nonspontaneous  | Nonspontaneous   |
49. It increases.
51. a.  $\text{CO}_2(g)$ , greater molar mass and complexity  
 b.  $\text{CH}_3\text{OH}(g)$ , gas phase  
 c.  $\text{CO}_2(g)$ , greater molar mass and complexity  
 d.  $\text{SiH}_4(g)$ , greater molar mass  
 e.  $\text{CH}_3\text{CH}_2\text{CH}_3(g)$ , greater complexity  
 f.  $\text{NaBr}(aq)$ , aqueous

- 53. a.** He, Ne, SO<sub>2</sub>, NH<sub>3</sub>, CH<sub>3</sub>CH<sub>2</sub>OH. From He to Ne there is an increase in molar mass; beyond that, the molecules increase in complexity.  
**b.** H<sub>2</sub>O(s), H<sub>2</sub>O(l), H<sub>2</sub>O(g); increase in entropy in going from solid to liquid to gas phase.  
**c.** CH<sub>4</sub>, CF<sub>4</sub>, CCl<sub>4</sub>; increasing entropy with increasing molar mass.
- 55. a.** -120.8 J/K, decrease in moles of gas  
**b.** 133.9 J/K, increase in moles of gas  
**c.** -42.0 J/K, small change because moles of gas stay constant  
**d.** -390.8 J/K, decrease in moles of gas
- 57.** -89.3 J/K, decrease in moles of gas
- 59.**  $\Delta H^\circ_{\text{rxn}} = -1277 \text{ kJ}$ ,  $\Delta S^\circ_{\text{rxn}} = 313.6 \text{ J/K}$ ,  
 $\Delta G^\circ_{\text{rxn}} = -1.370 \times 10^3 \text{ kJ}$ ; yes
- 61. a.**  $\Delta H^\circ_{\text{rxn}} = 57.2 \text{ kJ}$ ,  $\Delta S^\circ_{\text{rxn}} = 175.8 \text{ J/K}$ ,  
 $\Delta G^\circ_{\text{rxn}} = 4.8 \times 10^3 \text{ J/mol}$ ; nonspontaneous, becomes spontaneous at high temperatures  
**b.**  $\Delta H^\circ_{\text{rxn}} = 176.2 \text{ kJ}$ ,  $\Delta S^\circ_{\text{rxn}} = 285.1 \text{ J/K}$ ,  
 $\Delta G^\circ_{\text{rxn}} = 91.2 \text{ kJ}$ ; nonspontaneous, becomes spontaneous at high temperatures  
**c.**  $\Delta H^\circ_{\text{rxn}} = 98.8 \text{ kJ}$ ,  $\Delta S^\circ_{\text{rxn}} = 141.5 \text{ J/K}$ ,  
 $\Delta G^\circ_{\text{rxn}} = 56.6 \text{ kJ}$ ; nonspontaneous, becomes spontaneous at high temperatures  
**d.**  $\Delta H^\circ_{\text{rxn}} = -91.8 \text{ kJ}$ ,  $\Delta S^\circ_{\text{rxn}} = -198.1 \text{ J/K}$ ,  
 $\Delta G^\circ_{\text{rxn}} = -32.8 \text{ kJ}$ ; spontaneous
- 63. a.** 2.8 kJ    **b.** 91.2 kJ    **c.** 56.4 kJ    **d.** -32.8 kJ  
 Values are comparable. The method using  $\Delta H^\circ$  and  $\Delta S^\circ$  can be used to determine how  $\Delta G^\circ$  changes with temperature.
- 65. a.** -72.5 kJ, spontaneous  
**b.** -11.4 kJ, spontaneous  
**c.** 9.1 kJ, nonspontaneous
- 67.** -29.4 kJ
- 69. a.** 19.3 kJ    **b. (i)** 2.9 kJ    **(ii)** -2.9 kJ  
**c.** The partial pressure of iodine is very low.
- 71.** 11.9 kJ
- 73. a.**  $1.48 \times 10^{90}$     **b.**  $2.09 \times 10^{-26}$
- 75. a.** -24.8 kJ    **b.** 0    **c.** 9.4 kJ
- 77. a.**  $1.90 \times 10^{47}$     **b.**  $1.51 \times 10^{-13}$
- 79.**  $\Delta H^\circ = 50.6 \text{ kJ}$      $\Delta S^\circ = 226 \text{ J} \cdot \text{K}$
- 81.** 4.8
- 83. a.** +    **b.** -    **c.** -
- 85. a.**  $\Delta G^\circ = 175.2 \text{ kJ}$ ,  $K = 1.95 \times 10^{-31}$ , nonspontaneous  
**b.** 133 kJ, yes
- 87.** Cl<sub>2</sub>:  $\Delta H^\circ_{\text{rxn}} = -182.1 \text{ kJ}$ ,  $\Delta S^\circ_{\text{rxn}} = -134.4 \text{ J/K}$ ,  
 $\Delta G^\circ_{\text{rxn}} = -142.0 \text{ kJ}$      $K = 7.94 \times 10^{24}$   
 Br<sub>2</sub>:  $\Delta H^\circ_{\text{rxn}} = -121.6 \text{ kJ}$ ,  $\Delta S^\circ_{\text{rxn}} = -134.2 \text{ J/K}$ ,  
 $\Delta G^\circ_{\text{rxn}} = -81.6 \text{ kJ}$      $K = 2.02 \times 10^{14}$   
 I<sub>2</sub>:  $\Delta H^\circ_{\text{rxn}} = -48.3 \text{ kJ}$ ,  $\Delta S^\circ_{\text{rxn}} = -132.2 \text{ J/K}$ ,  
 $\Delta G^\circ_{\text{rxn}} = -8.9 \text{ kJ}$      $K = 37$   
 Cl<sub>2</sub> is the most spontaneous, I<sub>2</sub> is the least. Spontaneity is determined by the standard enthalpy of formation of the dihalogenated ethane. Higher temperatures make the reactions less spontaneous.
- 89. a.** 107.8 kJ  
**b.**  $5.0 \times 10^{-7} \text{ atm}$   
**c.** spontaneous at higher temperatures,  $T = 923.4 \text{ K}$
- 91. a.**  $2.22 \times 10^5$     **b.** 94.4 mol
- 93. a.**  $\Delta G^\circ = -689.6 \text{ kJ}$ ,  $\Delta G^\circ$  becomes less negative  
**b.**  $\Delta G^\circ = -665.2 \text{ kJ}$ ,  $\Delta G^\circ$  becomes less negative  
**c.**  $\Delta G^\circ = -632.4 \text{ kJ}$ ,  $\Delta G^\circ$  becomes less negative  
**d.**  $\Delta G^\circ = -549.3 \text{ kJ}$ ,  $\Delta G^\circ$  becomes less negative
- 95.** With one exception, the formation of any oxide of nitrogen at 298 K requires more moles of gas as reactants than are formed as products. For example, 1 mol of N<sub>2</sub>O requires 0.5 mol of O<sub>2</sub> and 1 mol of N<sub>2</sub>, 1 mol of N<sub>2</sub>O<sub>3</sub> requires 1 mol of N<sub>2</sub> and 1.5 mol of O<sub>2</sub>, and so on. The exception is NO, where 1 mol of NO requires 0.5 mol of O<sub>2</sub> and 0.5 mol of N<sub>2</sub>:
- $$\frac{1}{2} \text{N}_2(\text{g}) + \frac{1}{2} \text{O}_2(\text{g}) \longrightarrow \text{NO}(\text{g})$$
- This reaction has a positive  $\Delta S$  because what is essentially mixing of the N and O has taken place in the product.
- 97.** 15.0 kJ
- 99. a.** Positive, the process is spontaneous. It is slow unless a spark is applied.  
**b.** Positive, although the change in the system is not spontaneous; the overall change, which includes such processes as combustion or water flow to generate electricity, is spontaneous.  
**c.** Positive, the acorn-oak tree system is becoming more ordered, so the processes associated with growth are not spontaneous. But they are driven by spontaneous processes such as the generation of heat by the sun and the reactions that produce energy in the cell.
- 101.** At 18.3 mmHg  $\Delta G = 0$ , at 760 mmHg  
 $\Delta G^\circ = 55.4 \text{ kJ}$
- 103. a.**  $3.24 \times 10^{-3}$   
**b.**  $\text{NH}_3 + \text{ATP} + \text{H}_2\text{O} \longrightarrow \text{NH}_3 - \text{P}_i + \text{ADP}$   
 $\text{NH}_3 - \text{P}_i + \text{C}_5\text{H}_8\text{O}_4\text{N}^- \longrightarrow \text{C}_5\text{H}_9\text{O}_3\text{N}_2 + \text{P}_i + \text{H}_2\text{O}$   
 $\text{NH}_3 + \text{C}_5\text{H}_8\text{O}_4\text{N}^- + \text{ATP} \longrightarrow \text{C}_5\text{H}_9\text{O}_3\text{N}_2 + \text{ADP} + \text{P}_i$   
 $\Delta G^\circ = -16.3 \text{ kJ}$ ,  $K = 7.20 \times 10^2$
- 105. a.** -95.3 kJ/mol. Since the number of moles of reactants and products is the same, the decrease in volume affects the entropy of both equally, so there is no change in  $\Delta G$ .  
**b.** 102.8 kJ/mol. The entropy of the reactants (1.5 mol) is decreased more than the entropy of the product (1 mol). Since the product is relatively more favored at lower volume,  $\Delta G$  is less positive.  
**c.** 204.2 kJ/mol. The entropy of the product (1 mol) is decreased more than the entropy of the reactant (0.5 mol). Since the product is relatively less favored,  $\Delta G$  is more positive.
- 107.**  $\Delta H^\circ = -93 \text{ kJ}$ ,  $\Delta S^\circ = -2.0 \times 10^2 \text{ J/K}$
- 109.**  $\Delta S_{\text{vap}}$  diethyl ether = 86.1 J/mol K,  $\Delta S_{\text{vap}}$  acetone = 88.4 J/mol K,  $\Delta S_{\text{vap}}$  benzene = 87.3 J/mol K,  $\Delta S_{\text{vap}}$  chloroform = 88.0 J/mol K. Because water and ethanol hydrogen bond, they are more ordered in

the liquid and we expect  $\Delta S_{\text{vap}}$  to be more positive.  
 Ethanol  $38600/351.0 = 38600/351.0 = 110 \text{ J/mol K}$ ,  
 $\text{H}_2\text{O} = 40700/373.2 = 109 \text{ J/mol K}$

111. c

113. b

115. c

117.  $\Delta G_{\text{rxn}}^\circ$  is negative and  $\Delta G_{\text{rxn}}$  is positive.

122. a. 121 kJ; endothermic

c. 362 J/K

e. endothermic

## Chapter 19

45. a. 0.93 V

b. 0.41 V

c. 1.99 V

47. a, c, d

51.

53. **b, c** occur spontaneously in the forward direction.

55. aluminum

57. **a.** yes,  $2 \text{ Al}(s) + 6 \text{ H}^+(aq) \longrightarrow 2 \text{ Al}^{3+}(aq) + 3 \text{ H}_2(g)$ **b.** no**c.** yes,  $\text{Pb}(s) + 2 \text{ H}^+(aq) \longrightarrow \text{Pb}^{2+}(aq) + \text{H}_2(g)$ 59. **a.** yes,  $3 \text{ Cu}(s) + 2 \text{ NO}_3^-(aq) + 8 \text{ H}^+(aq) \longrightarrow 3 \text{ Cu}^{2+}(aq) + 2 \text{ NO}(g) + 4 \text{ H}_2\text{O}(l)$ **b.** no61. **a.**  $-1.70 \text{ V}$ , nonspontaneous**b.**  $1.97 \text{ V}$ , spontaneous**c.**  $-1.51 \text{ V}$ , nonspontaneous63. **a**65. **a.**  $-432 \text{ kJ}$       **b.**  $52 \text{ kJ}$       **c.**  $-1.7 \times 10^2 \text{ kJ}$ 67. **a.**  $5.31 \times 10^{75}$       **b.**  $7.7 \times 10^{-10}$       **c.**  $6.3 \times 10^{29}$ 69.  $5.6 \times 10^5$ 71.  $\Delta G^\circ = -7.97 \text{ kJ}$ ,  $E_{\text{cell}}^\circ = 0.041 \text{ V}$ 73. **a.**  $1.04 \text{ V}$       **b.**  $0.97 \text{ V}$       **c.**  $1.11 \text{ V}$ 75.  $1.87 \text{ V}$ 77. **a.**  $0.56 \text{ V}$       **b.**  $0.52 \text{ V}$ **c.**  $[\text{Ni}^{2+}] = 0.003 \text{ M}$ ,  $[\text{Zn}^{2+}] = 1.60 \text{ M}$ 

79.

$$81. \frac{[\text{Sn}^{2+}]_{\text{(ox)}}}{[\text{Sn}^{2+}]_{\text{(red)}}} = 4.2 \times 10^{-4}$$

83. 0.3762

85. 1.038 V

87. **a, c** would prevent the corrosion of iron

89.

minimum voltage = 0.17 V

91. oxidation:  $2 \text{ Br}^-(l) \longrightarrow \text{Br}_2(g) + 2 e^-$ reduction:  $\text{K}^+(l) + e^- \longrightarrow \text{K}(l)$ 93. oxidation:  $2 \text{ Br}^-(l) \longrightarrow \text{Br}_2(g) + 2 e^-$ reduction:  $\text{K}^+(l) + e^- \longrightarrow \text{K}(l)$ 95. **a.** anode:  $2 \text{ Br}^- \longrightarrow \text{Br}_2(l) + 2 e^-$ cathode:  $2 \text{ H}_2\text{O}(l) + 2 e^- \longrightarrow \text{H}_2(g) + 2 \text{ OH}^-(aq)$ **b.** anode:  $2 \text{ I}^-(aq) \longrightarrow \text{I}_2(s) + 2 e^-$ cathode:  $\text{Pb}^{2+}(aq) + 2 e^- \longrightarrow \text{Pb}(s)$ **c.** anode:  $2 \text{ H}_2\text{O}(l) \longrightarrow \text{O}_2(g) + 4 \text{ H}^+(aq) + 4 e^-$ cathode:  $2 \text{ H}_2\text{O}(l) + 2 e^- \longrightarrow \text{H}_2(g) + 2 \text{ OH}^-(aq)$ 

97.

99.  $1.8 \times 10^2 \text{ s}$

101.  $1.2 \times 10^3 \text{ A}$   $E_{\text{cell}} = 0.0725 \text{ V}$ ,  $K = 282$

103.

$[B^{2+}]$	$[A^{2+}]$	$Q$	$E_{\text{cell}}$	$\Delta G_{\text{rxn}}$
1.00	1.0	1.0	0.0725 V	-14.0 kJ
1.00	$1.00 \times 10^{-4}$	$1.00 \times 10^{-4}$	0.191	-36.8 kJ
$1.00 \times 10^{-4}$	1.0	$1.00 \times 10^4$	-0.0458	8.82 kJ
$3.52 \times 10^{-3}$	1.0	284	0	0

107. The drawing should show that several Al atoms dissolve into solution as  $\text{Al}^{3+}$  ions and that several  $\text{Cu}^{2+}$  ions are deposited on the Al surface as solid Cu.

109. a. 68.3 mL
- 
- b. cannot be dissolved
- 
- c. cannot be dissolved

111. 0.25

113. There are no paired reactions that produce more than about 5 or 6 V.

115. a. 2.83 V      b. 2.71 V      c. 16 hr

117. 176 hr

119. 0.71 V

121. a.  $\Delta G^\circ = 461 \text{ kJ}$ ,  $K = 1.4 \times 10^{-81}$   
b.  $\Delta G^\circ = 2.7 \times 10^2 \text{ kJ}$ ,  $K = 2.0 \times 10^{-48}$

125. 51.3%

127.  $\text{pH} = 0.85$

129. 0.83 M

131.  $4.1 \times 10^5 \text{ L}$

133. 435 s

135. 8.39% U

137. The overall cell reaction for both cells is  $2 \text{ Cu}^+(aq) \longrightarrow \text{Cu}^{2+}(aq) + \text{Cu}(s)$ . The difference in  $E^\circ$  is because  $n = 1$  for the first cell and  $n = 2$  for the second cell. For both cells,  $\Delta G^\circ = -35.1 \text{ kJ}$ .

139. a

141.  $\Delta G_{\text{rxn}}^\circ$  is positive and  $E_{\text{cell}}^\circ$  is negative.

147. a.

- c. Any combination in which
- $[\text{Zn}^{2+}]/[\text{Cu}^{2+}] = 0.020$
- will generate a cell potential = 1.15 V.
- 
- e. The
- $\text{Cu}^{2+}$
- concentrations decreases and
- $\text{Zn}^{2+}$
- concentration increases.

## Chapter 20

37. a. stable,  $N/Z$  ratio is close to 1, acceptable for low  $Z$  atoms.

b. not stable,  $N/Z$  ratio is much too high for low  $Z$  atom.

c. not stable,  $N/Z$  ratio is less than 1, much too low.

d. stable,  $N/Z$  ratio is acceptable for this  $Z$ .

39. Sc, V, and Mn, each have odd numbers of protons.

Atoms with an odd number of protons typically have less stable isotopes than those with an even number of protons.

41. a. beta decay

b. positron emission

c. positron emission

d. positron emission

43. a. Cs-125

b. Fe-62

45.  $2.34 \times 10^9 \text{ years}$

47. 0.57 g

49. 10.8 hr

51.  $2.66 \times 10^3 \text{ yr}$

53.  $2.4 \times 10^4 \text{ yr}$

55.  $2.7 \times 10^9 \text{ yr}$

65.  $9.0 \times 10^{13} \text{ J}$

67. a. mass defect = 0.13701 amu binding energy = 7.976 MeV/nucleon

b. mass defect = 0.54369 amu binding energy = 8.732 MeV/nucleon

c. mass defect = 1.16754 amu binding energy = 8.431 MeV/nucleon

69.  $7.228 \times 10^{10} \text{ J/g U-235}$

71.  $7.84 \times 10^{10} \text{ J/g H-2}$

73. radiation: 25 J, fall: 370 J

75. 68 mi

81.  $2.9 \times 10^{21}$  beta emissions, 3700 Ci

83.  $1.6 \times 10^{-5} \text{ L}$

85.  $4.94 \times 10^7 \text{ kJ/mol}$

87. 7.72 MeV

89.  $^{14}\text{N}$

91. 0.15%

93.  $1.24 \times 10^{21}$  atoms

95.  $2.42 \times 10^{-12} \text{ m}$

97.  $-0.7$  MeV, there is no coulombic barrier for collision with a neutron.
99. **a.**  $1.164 \times 10^{10}$  kJ  
**b.**  $0.1299$  g
101. U-235 forms Pb-207 in seven  $\alpha$ -decays and four  $\beta$ -decays, and Th-232 forms Pb-208 in six  $\alpha$ -decays and four  $\beta$ -decays.
103.  $3.0 \times 10^2$  K
105.  ${}^{21}_{9}\text{F} \longrightarrow {}^{21}_{10}\text{Ne} + {}^0_{-1}\text{e}$
107. Nuclide A is more dangerous because the half-life is shorter (18.5 days) and so it decays faster.
109. Iodine is used by the thyroid gland to make hormones. Normally we ingest iodine in foods, especially iodized salt. The thyroid gland cannot tell the difference between stable and radioactive iodine and will absorb both. KI tablets work by blocking radioactive iodine from entering the thyroid. When a person takes KI, the stable iodine in the tablet gets absorbed by the thyroid. Because KI contains so much stable iodine, the thyroid gland becomes “full” and cannot absorb any more iodine—either stable or radioactive—for the next 24 hours.
115. **a.**  $6.0$  h  
**c.** Missing masses (top to bottom):  $0.0301$ ,  $0.0190$ ,  $0.0151$ ; Missing emissions (top to bottom):  $2390$ ,  $1510$ ,  $1200$

## Chapter 21

33. **a.** alkane  
**c.** alkyne
- b.** alkene  
**d.** alkene
35.  $\text{CH}_3\text{—CH}_2\text{—CH}_2\text{—CH}_2\text{—CH}_2\text{—CH}_2\text{—CH}_3$

37. **a.** no      **b.** yes      **c.** yes      **d.** no
39. **a.** enantiomers      **b.** same      **c.** enantiomers
41. **a.** pentane  
**b.** 2-methylbutane  
**c.** 4-isopropyl-2-methylheptane  
**d.** 4-ethyl-2-methylhexane

45. **a.**  $\text{CH}_3\text{CH}_2\text{CH}_3 + 5 \text{O}_2 \longrightarrow 3 \text{CO}_2 + 4 \text{H}_2\text{O}$   
**b.**  $\text{CH}_3\text{CH}_2\text{CH}=\text{CH}_2 + 6 \text{O}_2 \longrightarrow 4 \text{CO}_2 + 4 \text{H}_2\text{O}$   
**c.**  $2 \text{CH}\equiv\text{CH} + 5 \text{O}_2 \longrightarrow 4 \text{CO}_2 + 2 \text{H}_2\text{O}$
47. **a.**  $\text{CH}_3\text{CH}_2\text{Br}$   
**b.**  $\text{CH}_3\text{CH}_2\text{CH}_2\text{Cl}$ ,  $\text{CH}_3\text{CHClCH}_3$   
**c.**  $\text{CHCl}_2\text{Br}$

49.  $\text{CH}_2=\text{CH—CH}_2\text{—CH}_2\text{—CH}_2\text{—CH}_3$   
 $\text{CH}_3\text{—CH}=\text{CH—CH}_2\text{—CH}_2\text{—CH}_3$   
 $\text{CH}_3\text{—CH}_2\text{—CH}=\text{CH—CH}_2\text{—CH}_3$
51. **a.** 1-butene  
**b.** 3,4-dimethyl-2-pentene  
**c.** 3-isopropyl-1-hexene  
**d.** 2,4-dimethyl-3-hexene
53. **a.** 2-butyne  
**b.** 4,4-dimethyl-2-hexyne  
**c.** 3-isopropyl-1-hexyne  
**d.** 3,6-dimethyl-4-nonyne

97. **a.** combustion  
**b.** alkane substitution  
**c.** alcohol elimination  
**d.** aromatic substitution

Can exist as a stereoisomer

Can exist as a stereoisomer

53. 6, Ser-Gly-Cys, Ser-Cys-Gly, Gly-Ser-Cys, Gly-Cys-Ser, Cys-Ser-Gly, Cys-Gly-Ser

59. tertiary

61. primary

63. a. A

b. T

65.

67. A C A T G C G

69. 154 codons, 462 nucleotides

71. a. protein]

b. carbohydrate

c. lipid

73. A codon is composed of three nucleotides. A codon codes for a specific amino acid, while a gene codes for an entire protein.

75.

77. valine, leucine, isoleucine, phenylalanine

79. Gly-Arg-Ala-Leu-Phe-Gly-Asn-Lys-Trp-Glu-Cys

81.

83. As the temperature increases, the favorable entropy for uncoiling a chain becomes dominant. On cooling, the favorable enthalpy of forming hydrogen bonds between paired bases is dominant.

85. When the fake thymine nucleotide is added to the replicating DNA, the chain cannot continue to form because the  $\text{—N=N}^+=\text{NH}$  group on the sugar prevents future phosphate linkages.

87.  $V_{\text{max}} = 47.6$ ,  $K_t = 1.68$

89.  $\text{H}_3\text{N}^+\text{CH}_2\text{COO}^- + \text{H}^+ \rightleftharpoons$

$$\begin{aligned} & (\text{H}_3\text{N}^+\text{CH}_2\text{COOH} [\text{HA}]/[\text{A}^-] = 2, \\ & \text{H}_3\text{N}^+\text{CH}_2\text{COO}^- \rightleftharpoons \text{H}_2\text{NCH}_2\text{COO}^- + \text{H}^+ [\text{HA}]/[\text{A}^-] \\ & = 0.4, \text{pH} = 6.0 \end{aligned}$$

91. A three-base codon codes for a single amino acid. If there are only three bases, there could be 27 different three-base codon arrangements. Therefore, you could theoretically code for the 20 different amino acids needed.

98. a.

c.

## Chapter 23

15. a. +4      b. +4      c. +4

17.  $\text{Ca}_3\text{Al}_2(\text{SiO}_4)_3$ 

19. 4

21. tetrahedrons stand alone, orthosilicates

23. amphibole or double-chain structure;

 $\text{Ca}^{2+}$ ,  $\text{Mg}^{2+}$ ,  $\text{Fe}^{2+}$ ,  $\text{Al}^{3+}$ 

25. 950 g

27.  $\text{NCl}_3$  has a lone pair that  $\text{BCl}_3$  lacks, giving it a trigonal pyramidal shape, as opposed to  $\text{BCl}_3$ 's trigonal planar shape.

29. a. 6 vertices, 8 faces

b. 12 vertices, 20 faces

31. *closo*-Boranes have the formula  $\text{B}_n\text{H}_n^{2-}$  and form fully closed polyhedra, *nido*-boranes have the formula  $\text{B}_n\text{H}_{n+4}$  and consist of a cage missing a corner, and *arachno*-boranes have the formula  $\text{B}_n\text{H}_{n+6}$  and consist of a cage missing two or three corners.

33. Activated charcoal consists of fine particles, rather than a lump of charcoal, and subsequently has a much higher surface area.

35. Ionic carbides are composed of carbon, generally in the form of the carbide ion,  $\text{C}_2^{2-}$ , and low-electronegativity metals, such as the alkali and alkaline earth metals. Covalent carbides are composed of carbon and low-electronegativity nonmetals or metalloids, such as silicon.37. a. solid  $\longrightarrow$  gasb. gas  $\longrightarrow$  liquid  $\longrightarrow$  solidc. solid  $\longrightarrow$  gas39. a.  $\text{CO(g)} + \text{CuO(s)} \longrightarrow \text{CO}_2\text{(g)} + \text{Cu(s)}$ b.  $\text{SiO}_2\text{(s)} + 3 \text{C(s)} \longrightarrow \text{SiC(s)} + 2 \text{CO(g)}$ c.  $\text{S(s)} + \text{CO(g)} \longrightarrow \text{COS(g)}$ 

41. a. +2      b. +4      c. +4/3

43. Fixing nitrogen refers to converting  $\text{N}_2$  to a nitrogen-containing compound.45. White phosphorus consists of  $\text{P}_4$  molecules in a tetrahedral shape with the atoms at the corners of the tetrahedron. This allotrope is unstable because of the strain from the bond angles. Red phosphorus is much more stable because one bond of the tetrahedron is broken, allowing the phosphorus atoms to make chains with bond angles that are less strained.

47. saltpeter: 13.86% N by mass Chile saltpeter: 16.48% N by mass

49.  $\text{HN}_3$  has a positive  $\Delta G_f^\circ$ , meaning that it spontaneously decomposes into  $\text{H}_2$  and  $\text{N}_2$  at room temperature. There are no temperatures at which  $\text{HN}_3$  will be stable.  $\Delta H_f^\circ$  is positive and  $\Delta S_f^\circ$  is negative, so  $\Delta G_f^\circ$  will always be negative.51. a.  $\text{NH}_4\text{NO}_3\text{(aq)} + \text{heat} \longrightarrow \text{N}_2\text{O(g)} + 2 \text{H}_2\text{O(l)}$ b.  $3 \text{NO}_2\text{(g)} + \text{H}_2\text{O(l)} \longrightarrow 2 \text{HNO}_3\text{(l)} + \text{NO(g)}$ c.  $2 \text{PCl}_3\text{(l)} + \text{O}_2\text{(g)} \longrightarrow 2 \text{POCl}_3\text{(l)}$ 53.  $\text{NO}_3^-$ ,  $\text{NO}_2^-$ ,  $\text{N}_3^-$ ,  $\text{N}_2\text{H}_5^+$ ,  $\text{NH}_4^+$ 

55.

Trigonal pyramidal

Trigonal bipyramidal

57.  $\text{CO(NH}_2)_2 + 2 \text{H}_2\text{O} \longrightarrow (\text{NH}_4)_2\text{CO}_3$ 

14 g

59.  $\text{P}_4\text{O}_6$  forms if there is only a limited amount of oxygen available, while  $\text{P}_4\text{O}_{10}$  will form with greater amounts of oxygen.

61. The major source of oxygen is the fractionation of air by which air is cooled and liquefied and oxygen is separated from the other components.

63. a. superoxide      b. oxide      c. peroxide

65. Initially, liquid sulfur becomes less viscous when heated because the  $\text{S}_8$  rings have greater thermal energy, which overcomes intermolecular forces. Above  $150^\circ\text{C}$  the rings break and the broken rings entangle one another, causing greater viscosity.67. a.  $4 \times 10^{-22} \text{ g}$ b.  $4.0 \times 10^{-19} \text{ g}$ 69.  $2 \text{FeS}_2\text{(s)} \xrightarrow{\text{heat}} 2 \text{FeS(s)} + \text{S}_2\text{(g)}$ 

510 L

71. a. +2, linear

b. +6, octahedral

c. +6, square pyramidal

73.  $\text{Cl}_2\text{(g)} + 2 \text{Br}^-\text{(aq)} \longrightarrow 2 \text{Cl}^-\text{(aq)} + \text{Br}_2\text{(l)}$ Oxidizing agent:  $\text{Cl}_2$ Reducing agent:  $\text{Br}^-$ 75. No, there is not enough  $\text{HF}$  to dissolve all of the  $\text{SiO}_2$ .  $\text{HF}$  is the limiting reagent. 1.6 g  $\text{SiO}_2$ .

77. 8 kg from lignite, 40 kg from bituminous

79. Chlorine is much more electronegative than iodine, allowing it to withdraw an electron and ionize in solution much more easily.

81. a.  $\text{rate}_{\text{HCl}}/\text{rate}_{\text{Cl}_2} = 1.395$ b.  $\text{rate}_{\text{HCl}}/\text{rate}_{\text{HF}} = 0.7407$ c.  $\text{rate}_{\text{HCl}}/\text{rate}_{\text{HI}} = 1.873$

83.  $4 \text{Na}_2\text{O}_2 + 3 \text{Fe} \longrightarrow 4 \text{Na}_2\text{O} + \text{Fe}_3\text{O}_4$
85. The bond length of the  $\text{O}_2$  species increases as electrons are added because they are added to the  $\pi^*$  antibonding orbital.  $\text{O}_2^{2-}$  is diamagnetic.
87. 2.0 mol of C—C bonds, 715 kJ/mol,  $6.9 \times 10^2$  kJ/mol. This value calculated from the bond energy is too low because it doesn't include van der Waals attractions between C atoms not directly bonded to each other.
89. -50 kJ/mol
91. a. -13.6 kJ/mol      b. -11.0 kJ/mol  
c. -24.8 kJ/mol  
 $\text{Fe}_2\text{O}_3$  is the most exothermic because it has the highest oxidation state and is therefore able to oxidize the most CO per mol Fe.
93. a.  $\ddot{\text{O}}=\text{C}=\text{C}=\text{C}=\ddot{\text{O}}$       b. *sp*  
c. -92 kJ/mol
95. a.  $7.6 \times 10^{-22}$       b.  $1.2 \times 10^{-8}$   
c.  $[\text{N}_2\text{H}_4] = 0.009 \text{ M}$ ,  $[\text{N}_2\text{H}_5^+] = 0.0025 \text{ M}$ ,  
 $[\text{N}_2\text{H}_6^{2+}] = 7.0 \times 10^{-13} \text{ M}$
97. The acid is  
a.  $\text{HO}-\ddot{\text{N}}=\ddot{\text{N}}-\text{OH}$   
and the base is  
b.  $\text{H}_2\text{N}-\overset{\text{O}}{\parallel}{\text{N}^+}-\text{O}^-$   
The acid is weaker than nitrous acid because of electron donation by resonance in contributing structures such as  
c.  $\text{HO}-\overset{\ominus}{\ddot{\text{N}}}-\ddot{\text{N}}=\overset{\oplus}{\text{O}}\text{H}$   
The base is weaker than ammonia because of electron withdrawal by the electronegative nitro group.
99. The triple bond in nitrogen is much stronger than the double bond in oxygen, so it is much harder to break. This makes it less likely that the bond in nitrogen will be broken.
101. Sodium dinitrogen phosphate ( $\text{NaH}_2\text{PO}_4$ ) can act as a weak base or a weak acid. A buffer can be made by mixing it with either  $\text{Na}_2\text{HPO}_4$  or with  $\text{Na}_3\text{PO}_4$ , depending on the desired pH of the buffer solution.
103. F is extremely small and so there is a huge driving force to fill the octet by adding an electron, giving a -1 oxidation state. Other halogens have access to *d* orbitals, which allows for more hybridization and oxidation state options.
105.  $\text{SO}_3$  cannot be a reducing agent because the oxidation state of S is +6, the highest possible oxidation state for S. Reducing agents need to be able to be oxidized.  $\text{SO}_2$  can be a reducing agent or an oxidizing agent because the oxidation state of S is +4.
112. a. The solubility of  $\text{H}_2\text{S}$  in water decreases as temperature increases.  
c. No  
e. Copper(II)  
f.  $4.8 \times 10^3 \text{ g CuS}$

## Chapter 24

15. Metals are typically opaque, are good conductors of heat and electricity, and are ductile and malleable, meaning they can be drawn into wires and flattened into sheets.
17. aluminum, iron, calcium, magnesium, sodium, potassium
19. Fe: hematite ( $\text{Fe}_2\text{O}_3$ ), magnetite ( $\text{Fe}_3\text{O}_4$ )  
Hg: cinnabar ( $\text{HgS}$ )  
V: vanadite [ $\text{Pb}_5(\text{VO}_4)\text{Cl}$ ], carnotite [ $\text{K}_2(\text{UO}_2)_2(\text{VO}_4)_2 \cdot 3 \text{H}_2\text{O}$ ]  
Nb: columbite [ $\text{Fe}(\text{NbO}_3)_2$ ]
21.  $\text{MgCO}_3(\text{s}) + \text{heat} \longrightarrow \text{MgO}(\text{s}) + \text{CO}_2(\text{g})$   
 $\text{Mg}(\text{OH})_2(\text{s}) + \text{heat} \longrightarrow \text{MgO}(\text{s}) + \text{H}_2\text{O}(\text{g})$
23. The flux is a material that will react with the gangue to form a substance with a low melting point. MgO is the flux.
25. Hydrometallurgy is used to separate metals from ores by selectively dissolving the metal in a solution, filtering out impurities, and then reducing the metal to its elemental form.
27. The Bayer process is a hydrometallurgical process by which  $\text{Al}_2\text{O}_3$  is selectively dissolved, leaving other oxides as solids. The soluble form of aluminum is  $\text{Al}(\text{OH})_4^-$ .
29. Sponge powdered iron contains many small holes in the iron particles due to the escaping of the oxygen when the iron is reduced. Water-atomized powdered iron has much smoother and denser particles as the powder is formed from molten iron.
31. a. 50% Cr, 50% V by moles; 50.5% Cr, 49.5% V by mass  
b. 25% Fe, 75% V by moles; 26.8% Fe, 73.2% V by mass  
c. 25% Cr, 25% Fe, 50% V by moles; 24.8% Cr, 26.6% Fe, 48.6% V by mass
33. Cr and Fe are very close to each other in mass, so their respective atomic radii are probably close enough to form an alloy. Also, they both form body-centered cubic structures.
35. A: solid, 20% Cr, 80% Fe  
B: liquid, 50% Cr, 50% Fe
37. A: solid (20% Co and 80% Cu overall. Two phases; one is the Cu structure with 4% Co, and the other is the Co structure with 7% Cu. There will be more of the Cu structure).  
B: solid (Co structure), 90% Co, 10% Cu
39. C would fill interstitial holes; Mn and Si would substitute for Fe.
41. a.  $\text{Mo}_2\text{N}$       b.  $\text{CrH}_2$
43. a. zinc      b. copper      c. manganese
45. -19.4 kJ/mol
47. When Cr is added to steel, it reacts with oxygen in steel to prevent it from rusting. A Cr steel alloy would be used in any situation where the steel might be easily oxidized, such as when it comes in contact with water.

49. rutile: 33.3% Ti by moles, 59.9% Ti by mass  
 ilmenite: 20.0% Ti by moles, 31.6% Ti by mass
51. Titanium must be arc-melted in an inert atmosphere because the high temperature and flow of electrons would cause the metal to oxidize in a normal atmosphere.
53.  $\text{TiO}_2$  is the most important industrial product of titanium, and it is often used as a pigment in white paint.
55. The Bayer process is a hydrometallurgical process used to separate  $\text{Al}_2\text{O}_3$  from other oxides. The  $\text{Al}_2\text{O}_3$  is selectively dissolved by hot, concentrated  $\text{NaOH}$ . The other oxides are removed as solids, and the  $\text{Al}_2\text{O}_3$  precipitates out of solution when the solution is neutralized.
57. cobalt and tungsten
59. 3.3 kg Fe, 2.0 kg Ti
61. Four atoms surround a tetrahedral hole, and six atoms surround an octahedral hole. The octahedral hole is larger because it is surrounded by a greater number of atoms.
63. Mn has one more electron orbital available for bonding than does chromium.
65. Ferromagnetic atoms, like paramagnetic ones, have unpaired electrons. However, in ferromagnetic atoms, these electrons align with their spin oriented in the same direction, resulting in a permanent magnetic field.
67. The nuclear charge of the last three is relatively high because of the lanthanide series in which the  $4f$  subshell falls between them and the other six metals of the group.
69. **a.** 16.0 cm    **b.** 4.95 cm    **c.** 14%
71. 92%
73.  $5.4 \times 10^7$
75. First, roast to form the oxide.  

$$4 \text{CoAsS}(s) + 9 \text{O}_2(g) \longrightarrow 4 \text{CoO}(s) + 4 \text{SO}_2(g) + \text{As}_4\text{O}_6(s)$$
 Then reduce the oxide with coke.  

$$\text{CoO}(s) + \text{C}(s) \longrightarrow \text{Co}(s) + \text{CO}(g)$$
 The oxides of arsenic are relatively volatile and can be separated, but they are poisonous.
77. Au and Ag are found in elemental form because of their low reactivity. Na and Ca are group 1 and group 2 metals, respectively, and are highly reactive as they readily lose their valence electrons to obtain octets.
84. **a.** Because they are stronger and harder.  
**c.** Tin,  $232^\circ\text{C}$ ; Lead  $328^\circ\text{C}$   
**e.** Because the melting range is neither too sharp nor too broad. It has a pasty range that helps it to set, but then hardens quickly.

## Chapter 25

17. **a.**  $[\text{Ar}] 4s^2 3d^8$ ,  $[\text{Ar}] 3d^8$   
**b.**  $[\text{Ar}] 4s^2 3d^5$ ,  $[\text{Ar}] 3d^3$   
**c.**  $[\text{Kr}] 5s^2 4d^1$ ,  $[\text{Kr}] 5s^1 4d^1$

19. **a.** +5    **b.** +7    **c.** +4
21. **a.** +3, 6    **b.** +2, 6  
**c.** +2, 4    **d.** +1, 2
23. **a.** hexaaquachromium(III)  
**b.** tetracyanocuprate(II)  
**c.** pentaaminebromoiron(III) sulfate  
**d.** aminetetraaquahydroxycobalt(III) chloride
25. **a.**  $[\text{Cr}(\text{NH}_3)_6]^{3+}$   
**b.**  $\text{K}_3[\text{Fe}(\text{CN})_6]$   
**c.**  $[\text{Cu}(\text{en})(\text{SCN})_2]$   
**d.**  $[\text{Pt}(\text{H}_2\text{O})_4][\text{PtCl}_6]$
27. **a.**  $[\text{Co}(\text{NH}_3)_3(\text{CN})_3]$ , triamminetricyanocobalt(III)  
**b.**  $[\text{Cr}(\text{en})_3]^{3+}$ , tris(ethylenediamine)chromium(III)

31.  $[\text{Fe}(\text{H}_2\text{O})_5\text{Cl}]\text{Cl} \cdot \text{H}_2\text{O}$ , pentaquachloroiron(II) chloride monohydrate  
 $[\text{Fe}(\text{H}_2\text{O})_4\text{Cl}_2] \cdot 2 \text{H}_2\text{O}$ , tetraaquadichloroiron(II) dihydrate

33. **b, c, e**

35. **a.** 3

**b.** No geometric isomers.

39. *cis* isomer is optically active

43. 163 kJ/mol

45.  $[\text{Co}(\text{CN})_6]^{3-} \longrightarrow 290 \text{ nm, colorless}$   
 $[\text{Co}(\text{NH}_3)_6]^{3+} \longrightarrow 440 \text{ nm, yellow}$   
 $[\text{CoF}_6]^{3-} \longrightarrow 770 \text{ nm, green}$

47. weak

49. a. 4

b. 3

c. 1

51. 3

53. porphyrin

55. Water is a weak field ligand that forms a high-spin complex with hemoglobin. Because deoxyhemoglobin is a weak field, it absorbs large-wavelength light and appears blue. Oxyhemoglobin is a low-spin complex and absorbs small-wavelength light, so  $\text{O}_2$  must be a strong field ligand.

57. a.  $[\text{Ar}] 4s^1 3d^5$ ,  $[\text{Ar}] 3d^5$ ,  $[\text{Ar}] 3d^4$ ,  $[\text{Ar}] 3d^3$   
 b.  $[\text{Ar}] 4s^1 3d^{10}$ ,  $[\text{Ar}] 3d^{10}$ ,  $[\text{Ar}] 3d^9$

61.  $[\text{MA}_2\text{B}_2\text{C}_2]$  all cis; A trans and B and C cis; B trans and A and C cis; C trans and A and B cis; all trans.

$[\text{MA}_2\text{B}_3\text{C}]$  will have fac-mer isomers.

$[\text{MAB}_2\text{C}_3]$  will have fac-mer isomers.

$[\text{MAB}_3\text{C}_2]$  will have fac-mer isomers.

$[\text{MA}_3\text{B}_2\text{C}]$  will have fac-mer isomers.

$[\text{MA}_2\text{BC}_3]$  will have fac-mer isomers.

$[\text{MA}_3\text{BC}_2]$  will have fac-mer isomers.

$[\text{MABC}_2]$  will have AB cis-trans isomers.

$[\text{MAB}_4\text{C}]$  will have AC cis-trans isomers.

$[\text{MA}_4\text{BC}]$  will have BC cis-trans isomers.

$[\text{MABC}_4]$  will have AB cis-trans isomers.

Only structure 3. is chiral. This is its mirror image.

71.  $d_{z^2}$   
 $d_{x^2-y^2}$  and  $d_{xy}$   
 $d_{xz}$  and  $d_{yz}$

73. a.  $2 \times 10^{-8} \text{ M}$

b.  $6.6 \times 10^{-3} \text{ M}$

c. NiS will dissolve more easily in the ammonia solution because the formation of the complex ion is favorable, removing  $\text{Ni}^{2+}$  ions from the solution and allowing more NiS to dissolve.

75. Prepare a solution that contains both  $[\text{MCl}_6]^{3-}$  and  $[\text{MBr}_6]^{3-}$  and see if any complex ions that contain both Cl and Br form. If they do, it would demonstrate that these complexes are labile.

77. pH = 10.1

79. Au

86. a. red

c. smaller (because it absorbs at longer wavelengths)

e. The crystal fields splitting energies of the two complexes must be similar (because they have the same color).

## APPENDIX IV Answers to In-Chapter Practice Problems

### Chapter 1

- 1.1.** **a.** The composition of the copper is not changing; thus, being hammered flat is a physical change that signifies a physical property.  
**b.** The dissolution and color change of the nickel indicate that it is undergoing a chemical change and exhibiting a chemical property.  
**c.** Sublimation is a physical change indicative of a physical property.  
**d.** When a match ignites, a chemical change begins as the match reacts with oxygen to form carbon dioxide and water. Flammability is a chemical property.
- 1.2.** **a.** 29.8 °C  
**b.** 302.9 K
- 1.3.** 21.4 g/cm<sup>3</sup>. This matches the density of platinum.
- 1.3.** *For More Practice* 4.50 g/cm<sup>3</sup> The metal is titanium.
- 1.4.** The thermometer shown has markings every 1 °F; thus, the first digit of uncertainty is 0.1. The answer is 103.1 °F.
- 1.5.** **a.** Each figure in this number is significant by rule 1: three significant figures.  
**b.** This is a defined quantity that has an unlimited number of significant figures.  
**c.** Both 1's are significant (rule 1), and the interior zero is significant as well (rule 2): three significant figures.  
**d.** Only the two 9's are significant, the leading zeroes are not (rule 3): two significant figures.  
**e.** There are five significant figures because the 1, 4, and 5 are nonzero (rule 1) and the trailing zeroes are after a decimal point so they are significant as well (rule 4).  
**f.** The number of significant figures is ambiguous because the trailing zeroes occur before an implied decimal point (rule 4). Assume two significant figures.
- 1.6.** **a.** 0.381  
**b.** 121.0  
**c.** 1.174

### Chapter 2

- 2.1.** For the first sample:
- $$\frac{\text{mass of oxygen}}{\text{mass of carbon}} = \frac{17.2 \text{ g O}}{12.9 \text{ g C}} = 1.33 \text{ or } 1.33 : 1$$
- For the second sample:
- $$\frac{\text{mass of oxygen}}{\text{mass of carbon}} = \frac{10.5 \text{ g O}}{7.88 \text{ g C}} = 1.33 \text{ or } 1.33 : 1$$
- The ratios of oxygen to carbon are the same in the two samples of carbon monoxide, so these results are consistent with the law of definite proportions.
- 2.2.** Mass of hydrogen to 1 g of oxygen in water/mass of hydrogen to 1 g of oxygen in hydrogen peroxide = 0.125/0.0625 = 2.00.  
The ratio of the mass of hydrogen from one compound to the mass of hydrogen in the other is equal to 2. This is a simple whole number and therefore consistent with the law of multiple proportions.
- 2.3.** **a.** Z = 6, A = 13, <sup>13</sup><sub>6</sub>C

 3.16. 4.0 g O  
 3.16. For More Practice 3.60 g C  
 3.17.  $\text{CH}_2\text{O}$   
 3.18.  $\text{C}_{13}\text{H}_{18}\text{O}_2$   
 3.19.  $\text{C}_6\text{H}_6$   
 3.19. For More Practice  $\text{C}_2\text{H}_8\text{N}_2$   
 3.20.  $\text{C}_2\text{H}_5$   
 3.21.  $\text{C}_2\text{H}_4\text{O}$   
 3.22.  $\text{SiO}_2(\text{s}) + 3 \text{C}(\text{s}) \longrightarrow \text{SiC}(\text{s}) + 2 \text{CO}(\text{g})$   
 3.23.  $2 \text{C}_2\text{H}_6(\text{g}) + 7 \text{O}_2(\text{g}) \longrightarrow 4 \text{CO}_2(\text{g}) + 6 \text{H}_2\text{O}(\text{g})$   
 3.24.  $\text{Pb}(\text{NO}_3)_2(\text{aq}) + 2 \text{KCl}(\text{aq}) \longrightarrow$   
 $\text{PbCl}_2(\text{s}) + 2 \text{KNO}_3(\text{aq})$

## Chapter 4

- 4.1. 4.08 g HCl  
 4.2. 22 kg  $\text{HNO}_3$   
 4.3.  $\text{H}_2$  is the limiting reagent, since it produces the least amount of  $\text{NH}_3$ . Therefore, 29.4 kg  $\text{NH}_3$  is the theoretical yield.  
 4.4. CO is the limiting reagent, since it only produces 114 g Fe. Therefore, 114 g Fe is the theoretical yield: percentage yield = 63.4% yield.  
 4.5. 0.214 M  $\text{NaNO}_3$   
 4.5. For More Practice 44.6 g KBr  
 4.6. 402 g  $\text{C}_{12}\text{H}_{22}\text{O}_{11}$   
 4.6. For More Practice 221 mL of KCl solution  
 4.7. 667 mL  
 4.7. For More Practice 0.105 L  
 4.8. 51.4 mL  $\text{HNO}_3$  solution  
 4.8. For More Practice 0.170 g  $\text{CO}_2$   
 4.9. a. insoluble  
       b. insoluble  
       c. soluble  
       d. soluble  
 4.10.  $\text{NH}_4\text{Cl}(\text{aq}) + \text{Fe}(\text{NO}_3)_3(\text{aq}) \longrightarrow \text{NO REACTION}$   
 4.11.  $2 \text{NaOH}(\text{aq}) + \text{CuBr}_2(\text{aq}) \longrightarrow$   
 $\text{Cu}(\text{OH})_2(\text{s}) + 2 \text{NaBr}(\text{aq})$   
 4.12.  $2 \text{H}^+(\text{aq}) + 2 \text{I}^-(\text{aq}) + \text{Ba}^{2+}(\text{aq}) + 2 \text{OH}^-(\text{aq}) \longrightarrow$   
 $2 \text{H}_2\text{O}(\text{l}) + \text{Ba}^{2+}(\text{aq}) + 2 \text{I}^-(\text{aq})$   
 $\text{H}^+(\text{aq}) + \text{OH}^-(\text{aq}) \longrightarrow \text{H}_2\text{O}(\text{l})$

- 4.13. Molecular equation:  
 $\text{HBr}(\text{aq}) + \text{LiOH}(\text{aq}) \longrightarrow \text{H}_2\text{O}(\text{l}) + \text{LiBr}(\text{aq})$   
 Net ionic equation:  
 $\text{H}^+(\text{aq}) + \text{OH}^-(\text{aq}) \longrightarrow \text{H}_2\text{O}(\text{l})$   
 4.14.  $\text{HCHO}_2(\text{aq}) + \text{OH}^-(\text{aq}) \longrightarrow \text{H}_2\text{O}(\text{l}) + \text{CHO}_2^-(\text{aq})$   
 4.15.  $9.03 \times 10^{-2} \text{ M H}_2\text{SO}_4$   
 4.15. For More Practice 24.5 mL NaOH solution  
 4.16.  $2 \text{HBr}(\text{aq}) + \text{K}_2\text{SO}_3(\text{aq}) \longrightarrow$   
 $\text{H}_2\text{O}(\text{l}) + \text{SO}_2(\text{g}) + 2 \text{KBr}(\text{aq})$   
 4.16. For More Practice  $2 \text{H}^+(\text{aq}) + \text{S}^{2-}(\text{aq}) \longrightarrow \text{H}_2\text{S}(\text{g})$   
 4.17. a. Cr = 0  
       b.  $\text{Cr}^{3+} = +3$   
       c.  $\text{Cl}^- = -1$ , C = +4  
       d. Br = -1, Sr = +2  
       e. O = -2, S = +6  
       f. O = -2, N = +5  
 4.18. Sn is oxidized and N is reduced.  
 4.18. For More Practice b. Reaction b is the only redox reaction. Al is oxidized and O is reduced.  
 4.19. a. This is a redox reaction in which Li is the reducing agent (it is oxidized) and  $\text{Cl}_2$  is the oxidizing reagent (it is reduced).  
       b. This is a redox reaction in which Al is the reducing agent and  $\text{Sn}^{2+}$  is the oxidizing agent.  
       c. This is not a redox reaction because no oxidation states change.  
       d. This is a redox reaction in which C is the reducing agent and  $\text{O}_2$  is the oxidizing agent.  
 4.20.  $2 \text{C}_2\text{H}_5\text{SH}(\text{l}) + 9 \text{O}_2(\text{g}) \longrightarrow$   
 $4 \text{CO}_2(\text{g}) + 2 \text{SO}_2(\text{g}) + 6 \text{H}_2\text{O}(\text{g})$

## Chapter 5

- 5.1. 15.0 psi  
 5.1. For More Practice 80.6 kPa  
 5.2. 2.1 atm at a depth of approximately 11 m  
 5.3. 123 mL  
 5.4. 11.3 L  
 5.5. 1.63 atm, 23.9 psi  
 5.6. 16.1 L  
 5.6. For More Practice 976 mmHg  
 5.7.  $d = 4.91 \text{ g/L}$   
 5.7. For More Practice 44.0 g/mol  
 5.8. 70.7 g/mol  
 5.9. 0.0610 mol  $\text{H}_2$   
 5.10. 4.2 atm  
 5.11. 12.0 mg  $\text{H}_2$   
 5.12. 82.3 g  $\text{Ag}_2\text{O}$   
 5.12. For More Practice 7.10 g  $\text{Ag}_2\text{O}$   
 5.13. 6.53 L  $\text{O}_2$   
 5.14.  $u_{\text{rms}} = 238 \text{ m/s}$   
 5.15.  $\frac{\text{rate}_{\text{H}_2}}{\text{rate}_{\text{Kr}}} = 6.447$

## Chapter 6

- 6.1.  $\Delta E = 71 \text{ J}$
- 6.2.  $C_s = 0.38 \frac{\text{J}}{\text{g} \cdot ^\circ\text{C}}$   
The specific heat capacity of gold is  $0.128 \text{ J/g} \cdot ^\circ\text{C}$ ; therefore, the rock cannot be pure gold.
- 6.2. *For More Practice*  $T_f = 42.1^\circ\text{C}$
- 6.3. 37.8 grams Cu
- 6.4.  $-122 \text{ J}$
- 6.4. *For More Practice*  $\Delta E = -998 \text{ J}$
- 6.5.  $\Delta E_{\text{reaction}} = -3.91 \times 10^3 \text{ kJ/mol C}_6\text{H}_{14}$
- 6.5. *For More Practice*  $C_{\text{cal}} = 4.55 \frac{\text{kJ}}{^\circ\text{C}}$
- 6.6. a. endothermic, positive  $\Delta H$   
b. endothermic, positive  $\Delta H$   
c. exothermic, negative  $\Delta H$
- 6.7.  $-2.06 \times 10^3 \text{ kJ}$
- 6.7. *For More Practice* 33 g  $\text{C}_4\text{H}_{10}$   
99 g  $\text{CO}_2$
- 6.8.  $\Delta H_{\text{rxn}} = -68 \text{ kJ}$
- 6.9.  $\text{N}_2\text{O(g)} + \text{NO}_2\text{(g)} \longrightarrow 3 \text{ NO(g)}, \Delta H_{\text{rxn}} = +157.6 \text{ kJ}$
- 6.9. *For More Practice*  
 $3 \text{ H}_2\text{(g)} + \text{O}_3\text{(g)} \longrightarrow 3 \text{ H}_2\text{O(g)}, \Delta H_{\text{rxn}} = -868.1 \text{ kJ}$
- 6.10. a.  $\text{Na(s)} + \frac{1}{2} \text{ Cl}_2\text{(g)} \longrightarrow \text{NaCl(s)}, \Delta H_f^\circ = -411.2 \text{ kJ/mol}$   
b.  $\text{Pb(s)} + \text{N}_2\text{(g)} + 3 \text{ O}_2\text{(g)} \longrightarrow \text{Pb(NO}_3)_2\text{(s)}, \Delta H_f^\circ = -451.9 \text{ kJ/mol}$
- 6.11.  $\Delta H_{\text{rxn}}^\circ = -851.5 \text{ kJ}$
- 6.12.  $\Delta H_{\text{rxn}}^\circ = -1648.4 \text{ kJ}$   
111 kJ emitted ( $-111 \text{ kJ}$ )
- 6.13.  $1.2 \times 10^2 \text{ kg CO}_2$

## Chapter 7

- 7.1.  $5.83 \times 10^{14} \text{ s}^{-1}$
- 7.2.  $2.64 \times 10^{20} \text{ photons}$
- 7.2. *For More Practice* 435 nm
- 7.3. a. blue < green < red  
b. red < green < blue  
c. red < green < blue
- 7.4.  $6.1 \times 10^6 \text{ m/s}$
- 7.5. *For the 5d orbitals:*  
 $n = 5$   
 $l = 2$   
 $m_l = -2, -1, 0, 1, 2$   
The 5 integer values for  $m_l$  signify that there are five 5d orbitals.
- 7.6. a.  $l$  cannot equal 3 if  $n = 3, l = 2$   
b.  $m_l$  cannot equal  $-2$  if  $l = -1$ . Possible values for  $m_l = -1, 0, \text{ or } 1$   
c.  $l$  cannot be 1 if  $n = 1, l = 0$
- 7.7. 397 nm
- 7.7. *For More Practice*  $n = 1$

## Chapter 8

- 8.1. a.  $\text{Cl } 1s^2 2s^2 2p^6 3s^2 3p^5$  or  $[\text{Ne}] 3s^2 3p^5$   
b.  $\text{Si } 1s^2 2s^2 2p^6 3s^2 3p^2$  or  $[\text{Ne}] 3s^2 3p^2$   
c.  $\text{Sr } 1s^2 2s^2 2p^6 3s^2 3p^6 4s^2 3d^{10} 4p^6 5s^2$  or  $[\text{Kr}] 5s^2$   
d.  $\text{O } 1s^2 2s^2 2p^4$  or  $[\text{He}] 2s^2 2p^4$
- 8.2. There are no unpaired electrons.

- 8.3.  $1s^2 2s^2 2p^6 3s^2 3p^3$  or  $[\text{Ne}] 3s^2 3p^3$ . The 5 electrons in the  $3s^2 3p^3$  orbitals are the valence electrons, while the 10 electrons in the  $1s^2 2s^2 2p^6$  orbitals belong to the core.
- 8.4.  $[\text{Xe}] 6s^2 4f^{14} 5d^{10} 6p^3$
- 8.4. *For More Practice*  $[\text{Kr}] 5s^2 4d^{10} 5p^5$
- 8.5. a. Sn  
b. cannot predict  
c. W  
d. Se
- 8.5. *For More Practice*  $\text{Rb} > \text{Ca} > \text{Si} > \text{S} > \text{F}$
- 8.6. a.  $[\text{Ar}] 4s^0 3d^7$ .  $\text{Co}^{2+}$  is paramagnetic.

- b.  $[\text{He}] 2s^2 2p^6$ .  $\text{N}^{3-}$  is diamagnetic.

- c.  $[\text{Ne}] 3s^2 3p^6$ .  $\text{Ca}^{2+}$  is diamagnetic.

- 8.7. a. K                      b.  $\text{F}^-$                       c.  $\text{Cl}^-$
- 8.8. a. I                      b. Ca  
c. cannot predict                      d. F
- 8.8. *For More Practice*  $\text{F} > \text{S} > \text{Si} > \text{Ca} > \text{Rb}$
- 8.9. a. Sn  
b. cannot predict based on simple trends (Po is larger)  
c. Bi  
d. B
- 8.9. *For More Practice*  $\text{Cl} < \text{Si} < \text{Na} < \text{Rb}$
- 8.10. a.  $2 \text{ Al(s)} + 3 \text{ Cl}_2\text{(g)} \longrightarrow 2 \text{ AlCl}_3\text{(s)}$   
b.  $2 \text{ Li(s)} + 2 \text{ H}_2\text{O(l)} \longrightarrow 2 \text{ Li}^+\text{(aq)} + 2 \text{ OH}^-\text{(aq)} + \text{H}_2\text{(g)}$   
c.  $\text{H}_2\text{(g)} + \text{Br}_2\text{(l)} \longrightarrow 2 \text{ HBr(g)}$

## Chapter 9

- 9.1.  $\text{Mg}_3\text{N}_2$
- 9.2.  $\text{KI} < \text{LiBr} < \text{CaO}$
- 9.2. *For More Practice*  $\text{MgCl}_2$
- 9.3. a. pure covalent  
b. ionic  
c. polar covalent

9.8.

Structure	A			B			C		
	$\text{:}\ddot{\text{N}}=\text{N}=\ddot{\text{O}}\text{:}$			$\text{:}\text{N}\equiv\text{N}-\ddot{\text{O}}\text{:}$			$\text{:}\ddot{\text{N}}-\text{N}\equiv\text{O:}$		
number of valence $e^-$	5	5	6	5	5	6	5	5	6
number of nonbonding $e^-$	-4	-0	-4	-2	-0	-6	-6	-0	-2
$\frac{1}{2}(\text{number of bonding } e^-)$	-2	-4	-2	-3	-4	-1	-1	-4	-3
Formal charge	-1	-1	0	0	+1	-1	-2	+1	+1
Structure B contributes the most to the correct overall structure of $\text{N}_2\text{O}$ .									

9.8. *For More Practice* The nitrogen is +1, the singly bonded oxygen atoms are -1, and the double-bonded oxygen atom has no formal charge.

9.10. *For More Practice*

## Chapter 10

10.1. tetrahedral

10.2. bent

10.3. linear

10.4.

Atom	Number of Electron Groups	Number of Lone Pairs	Molecular Geometry
Carbon (left)	4	0	Tetrahedral
Carbon (right)	3	0	Trigonal planar
Oxygen	4	2	Bent

10.5. The molecule is nonpolar.

10.6. The xenon atom has six electron groups and therefore has an octahedral electron geometry. An octahedral electron geometry corresponds to  $sp^3d^2$  hybridization (refer to Table 10.3).

10.7. Since there are only two electron groups around the central atom (C), the electron geometry is linear. According to Table 10.3, the corresponding hybridization on the carbon atom is  $sp$ .

10.8. Since there are only two electron groups about the central atom (C), the electron geometry is linear. The hybridization on C is  $sp$  (refer to Table 10.3).

10.8. *For More Practice* There are five electron groups about the central atom (I); therefore, the electron geometry is trigonal bipyramidal and the corresponding hybridization of I is  $sp^3d$  (refer to Table 10.3).

10.9.  $\text{H}_2^+$  bond order  $= +\frac{1}{2}$

Since the bond order is positive, the  $\text{H}_2^+$  ion should be stable; however, the bond order of  $\text{H}_2^+$  is lower than the bond order of  $\text{H}_2$  (bond order = 1). Therefore, the bond in  $\text{H}_2^+$  is weaker than in  $\text{H}_2$ .

10.10. The bond order of  $\text{N}_2^+$  is 2.5, which is lower than that of the  $\text{N}_2$  molecule (bond order = 3); therefore, the bond is weaker. The MO diagram shows that the  $\text{N}_2^+$  ion has one unpaired electron and is therefore paramagnetic.

10.10. *For More Practice* The bond order of  $\text{Ne}_2$  is 0, which indicates that dineon does not exist.

10.11. The bond order of NO is +2.5. The MO diagram shows that the ion has one unpaired electron and is therefore paramagnetic.

## Chapter 11

11.1. **b, c**

11.2. HF has a higher boiling point than HCl because, unlike HCl, HF is able to form hydrogen bonds. The hydrogen bond is the strongest of the intermolecular forces and requires more energy to break.

11.3.  $5.83 \times 10^3 \text{ kJ}$

11.3. *For More Practice*  $49^\circ\text{C}$

11.4.  $33.8 \text{ kJ/mol}$

11.5.  $7.04 \times 10^3 \text{ torr}$

## Chapter 12

12.1.  $29.4^\circ$

12.2. 78.5%

12.3.  $3.24 \times 10^{-23} \text{ cm}^3$

12.4.  $7.18 \frac{\text{g}}{\text{cm}^3}$

12.5. Metallic

## Chapter 13

13.1. **a.** not soluble

**b.** soluble

**c.** not soluble

**d.** not soluble

13.2.  $2.7 \times 10^{-4} \text{ M}$

13.3.  $42.5 \text{ g C}_{12}\text{H}_{22}\text{O}_{11}$

13.3. *For More Practice*  $3.3 \times 10^4 \text{ L}$

13.4. **a.**  $M = 0.415 \text{ M}$

**b.**  $m = 0.443 \text{ m}$

**c.** % by mass = 13.2%

**d.**  $\chi_{\text{C}_{12}\text{H}_{22}\text{O}_{11}} = 0.00793$

**e.** mole percent = 0.793%

13.5.  $0.600 \text{ M}$

13.5. *For More Practice*  $0.651 \text{ m}$

13.6. 22.5 torr

13.6. *For More Practice* 0.144

13.7. **a.**  $P_{\text{benzene}} = 26.6 \text{ torr}$

$P_{\text{toluene}} = 20.4 \text{ torr}$

**b.** 47.0 torr

**c.** 52.5% benzene; 47.5% toluene

The vapor will be richer in the more volatile component, which in this case is benzene.

13.8.  $T_f = -4.8^\circ\text{C}$

13.9.  $101.84^\circ\text{C}$

13.10. 11.8 atm

13.11.  $-0.60^\circ\text{C}$

13.12.  $0.014 \text{ mol NaCl}$

## Chapter 14

14.1.  $\frac{\Delta[\text{H}_2\text{O}_2]}{\Delta t} = -4.40 \times 10^{-3} \text{ M/s}$

$\frac{\Delta[\text{I}_3^-]}{\Delta t} = 4.40 \times 10^{-3} \text{ M/s}$

14.2. **a.** Rate  $= k[\text{CHCl}_3][\text{Cl}_2]^{1/2}$ . (Fractional-order reactions are not common but are occasionally observed.)

**b.**  $3.5 \text{ M}^{-1/2} \cdot \text{s}^{-1}$

14.3.  $5.78 \times 10^{-2} \text{ M}$

14.4.  $0.0277 \text{ M}$

14.5.  $1.64 \times 10^{-3} \text{ M}$

14.6. 79.2 s

14.7.  $2.07 \times 10^{-5} \frac{\text{L}}{\text{mol} \cdot \text{s}}$

14.8.  $6.13 \times 10^{-4} \frac{\text{L}}{\text{mol} \cdot \text{s}}$

## Chapter 15

15.1.  $K = \frac{[\text{CO}_2]^3[\text{H}_2\text{O}]^4}{[\text{C}_3\text{H}_8][\text{O}_2]^5}$

15.2.  $2.1 \times 10^{-13}$

15.2. *For More Practice*  $1.4 \times 10^2$

15.3.  $6.2 \times 10^2$

15.4.  $K_c = \frac{[\text{Cl}_2]^2}{[\text{HCl}]^4[\text{O}_2]}$

- 15.5.** 9.4  
**15.6.**  $1.1 \times 10^{-6}$   
**15.7.**  $Q_c = 0.0196$   
 Reaction proceeds to the left.  
**15.8.** 0.033 M  
**15.9.**  $[N_2] = 4.45 \times 10^{-3} \text{ M}$   
 $[O_2] = 4.45 \times 10^{-3} \text{ M}$   
 $[NO] = 1.1 \times 10^{-3} \text{ M}$   
**15.10.**  $[N_2O_4] = 0.005 \text{ M}$   
 $[NO_2] = 0.041 \text{ M}$   
**15.11.**  $P_{I_2} = 0.0027 \text{ atm}$   
 $P_{Cl_2} = 0.0027 \text{ atm}$   
 $P_{ICl_2} = 0.246 \text{ atm}$   
**15.12.**  $1.67 \times 10^{-7} \text{ M}$   
**15.13.**  $6.78 \times 10^{-6} \text{ M}$   
**15.14.** Adding  $Br_2$  increases the concentration of  $Br_2$ , causing a shift to the left (away from the  $Br_2$ ). Adding  $BrNO$  increases the concentration of  $BrNO$ , causing a shift to the right.  
**15.15.** Decreasing the volume causes the reaction to shift right. Increasing the volume causes the reaction to shift left.  
**15.16.** If we increase the temperature, the reaction shifts to the left. If we decrease the temperature, the reaction shifts to the right.

## Chapter 16

- 16.1. a.**  $H_2O$  donates a proton to  $C_5H_5N$ , making it the acid. The conjugate base is therefore  $OH^-$ . Since  $C_5H_5N$  accepts the proton, it is the base and becomes the conjugate acid  $C_5H_5NH^+$ .  
**b.** Since  $HNO_3$  donates a proton to  $H_2O$ , it is the acid, making  $NO_3^-$  the conjugate base. Since  $H_2O$  is the proton acceptor, it is the base and becomes the conjugate acid,  $H_3O^+$ .  
**16.2. a.** Since  $[H_3O^+] < [OH^-]$  the solution is basic.  
**b.**  $[H_3O^+] = 1.0 \times 10^{-7} \text{ M}$   
 Neutral solution.  
**c.**  $[H_3O^+] = 1.2 \times 10^{-5} \text{ M}$   
 Since  $[H_3O^+] > [OH^-]$  the solution is acidic.  
**16.3. a.** 8.02 (basic)  
**b.** 11.85 (basic)  
**16.4.**  $4.3 \times 10^{-9} \text{ M}$   
**16.5.**  $9.4 \times 10^{-3} \text{ M}$   
**16.6.** 3.28  
**16.7.** 2.72  
**16.8.**  $1.8 \times 10^{-6}$   
**16.9.** 0.85%  
**16.10.**  $2.0 \times 10^{-7} \text{ M}$   
**16.11.**  $[OH^-] = 0.020 \text{ M}$  pH = 12.30  
**16.12.**  $[OH^-] = 1.2 \times 10^{-2} \text{ M}$  pH = 12.08  
**16.13. a.** weak base **b.** pH-neutral  
**16.14.** 9.07  
**16.15. a.** pH-neutral  
**b.** weak acid  
**c.** weak acid

- 16.16. a.** basic  
**b.** acidic  
**c.** pH-neutral  
**d.** acidic  
**16.17.** 3.83  
**16.18.**  $[SO_4^{2-}] = 0.00386 \text{ M}$   
 pH = 1.945  
**16.19.**  $5.6 \times 10^{-11} \text{ M}$

## Chapter 17

- 17.1.** 4.44  
**17.1.** For More Practice 3.44  
**17.2.** 9.14  
**17.3.** 4.87  
**17.3.** For More Practice 4.65  
**17.4.** 9.68  
**17.4.** For More Practice 9.56  
**17.5.** hypochlorous acid ( $HClO$ ); 2.4 g  $NaClO$   
**17.6.** 1.74  
**17.7.** 18.08  
**17.8.**  $2.30 \times 10^{-6} \text{ M}$   
**17.9.**  $5.3 \times 10^{-13}$   
**17.10.**  $1.21 \times 10^{-5} \text{ M}$   
**17.11.**  $FeCO_3$  will be more soluble in an acidic solution than  $PbBr_2$  because the  $CO_3^{2-}$  ion is a basic anion, whereas  $Br^-$  is the conjugate base of a strong acid ( $HBr$ ) and is therefore pH-neutral.  
**17.12.**  $Q > K_{sp}$ ; therefore, a precipitate forms.  
**17.13.**  $2.9 \times 10^{-6} \text{ M}$   
**17.14. a.**  $AgCl$  precipitates first;  $[NaCl] = 7.1 \times 10^{-9} \text{ M}$   
**b.**  $[Ag^+]$  is  $1.5 \times 10^{-8} \text{ M}$  when  $PbCl_2$  begins to precipitate, and  $[Pb^{2+}]$  is 0.085 M.  
**17.15.**  $9.6 \times 10^{-6} \text{ M}$

## Chapter 18

- 18.1. a.** positive  
**b.** negative  
**c.** positive  
**18.2.** 15.2 J/K  
**18.3. a.**  $-548 \text{ J/K}$   
**b.**  $\Delta S_{sys}$  is negative.  
**c.**  $\Delta S_{univ}$  is negative, and the reaction is not spontaneous.  
**18.3.** For More Practice 375 K  
**18.4.**  $\Delta G = -101.6 \times 10^3 \text{ J}$   
 Therefore, the reaction is spontaneous. Since both  $\Delta H$  and  $\Delta S$  are negative, as the temperature increases  $\Delta G$  will become more positive.  
**18.5.**  $-153.2 \text{ J/K}$   
**18.6.**  $\Delta G_{rxn}^\circ = -36.3 \text{ kJ}$   
 Since  $\Delta G_{rxn}^\circ$  is negative, the reaction is spontaneous at this temperature.  
**18.7.**  $\Delta G_{rxn}^\circ = -42.1 \text{ kJ}$   
 Since the value of  $\Delta G_{rxn}^\circ$  at the lowered temperature is more negative (or less positive) (which is  $-36.3 \text{ kJ}$ ), the reaction is more spontaneous.

18.8.  $\Delta G_{\text{rxn}}^{\circ} = -689.6 \text{ kJ}$

Since  $\Delta G_{\text{rxn}}^{\circ}$  is negative, the reaction is spontaneous at this temperature.

18.8. *For More Practice*  $\Delta G_{\text{rxn}}^{\circ} = -689.7 \text{ kJ}$  (at 25°)

The value calculated for  $\Delta G_{\text{rxn}}^{\circ}$  from the tabulated values ( $-689.6 \text{ kJ}$ ) is the same, to within 1 in the least significant digit, as the value calculated using the equation for  $\Delta G_{\text{rxn}}^{\circ}$ .

$\Delta G_{\text{rxn}}^{\circ} = -649.7 \text{ kJ}$  (at 500.0 K)

You could not calculate  $\Delta G_{\text{rxn}}^{\circ}$  at 500.0 K using tabulated  $\Delta G_{\text{f}}^{\circ}$  values because the tabulated values of free energy are calculated at a standard temperature of 298 K, much lower than 500 K.

18.9.  $+107.1 \text{ kJ}$

18.10.  $\Delta G_{\text{rxn}}^{\circ} = -129 \text{ kJ}$

The reaction is more spontaneous under these conditions than under standard conditions because  $\Delta G_{\text{rxn}}^{\circ}$  is more negative than  $\Delta G_{\text{rxn}}^{\circ}$ .

18.11.  $-10.9 \text{ kJ}$

## Chapter 19

19.4.  $+0.60 \text{ V}$

19.5. **a.** The reaction *will* be spontaneous as written.

**b.** The reaction *will not* be spontaneous as written.

19.6.  $\Delta G^{\circ} = -3.63 \times 10^5 \text{ J}$

Since  $\Delta G^{\circ}$  is negative, the reaction is spontaneous.

19.7.  $4.5 \times 10^3$

19.8.  $1.08 \text{ V}$

19.10.  $6.0 \times 10^1 \text{ min}$

## Chapter 20

20.2. *For More Practice* Positron emission

20.3. **a.** positron emission

**b.** beta decay

**c.** positron emission

20.4.  $10.7 \text{ yr}$

20.5.  $t = 964 \text{ yr}$

No, the C-14 content suggests that the scroll is from about A.D. 1000, not 500 B.C.

20.6.  $1.0 \times 10^9 \text{ yr}$

20.7. Mass defect =  $1.934 \text{ amu}$

Nuclear binding energy =  $7.569 \text{ MeV/nucleon}$

## Chapter 21

21.1.

21.2. 3-methylhexane

21.3. 3,5-dimethylheptane

21.4. 2,3,5-trimethylhexane

21.5. **a.** 4,4-dimethyl-2-pentyne

**b.** 3-ethyl-4,6-dimethyl-1-heptene

21.6. **a.** 2-methylbutane

**b.** 2-chloro-3-methylbutane

21.7. **a.** Alcohol reacting with an active metal.

**b.** dehydration reaction

## Chapter 22

22.1. Fructose exhibits optical isomerism. It contains three chiral carbons.

22.2.

## Chapter 23

- 23.1.**  $\text{KAlSi}_3\text{O}_8$   
**23.2.**  $x = 2$   
**23.3.** Orthosilicate (or neosilicate): each of the two Be ions has a charge of  $2+$  for a total of  $4+$ , and the  $\text{SiO}_4$  unit has a charge of  $4-$ .  
**23.4.** Inosilicate (or pyroxene): Ca and Mg each have a charge of  $2+$  for a total of  $4+$ , and the  $\text{Si}_2\text{O}_6$  unit has a charge of  $4-$  (two  $\text{SiO}_3^{2-}$  units).  
**23.5.**  $2 \text{H}_2\text{S}(g) + 3 \text{O}_2(g) \longrightarrow 2 \text{H}_2\text{O}(g) + \text{SO}_2(g)$   
 S changes from the  $-2$  to  $+4$  oxidation state.  
**23.6.** The oxidation state for Cl is  $+7$  in  $\text{ClO}_4^-$  and  $-1$  in  $\text{Cl}^-$ .  
**23.7.**  $\text{I}_2(s) + 5 \text{F}_2(g) \longrightarrow 2 \text{IF}_5(g)$   
**23.8.** The electron geometry is tetrahedral and the shape is bent for  $\text{ICl}_2^+$ .  
**23.9.** The electron geometry is octahedral for  $\text{BrF}_5$ , and the molecular geometry is square pyramidal.  
**23.10.** The oxidation number changes from  $-1$  to  $0$  for the oxidation of the Cl in  $\text{HCl}$  to  $\text{Cl}_2$  and from  $+5$  to  $+4$  for the reduction of the Cl in  $\text{NaClO}_3$  to  $\text{ClO}_2$ . The oxidizing agent is  $\text{NaClO}_3$ , and the reducing agent is  $\text{HCl}$ .

## Chapter 24

- 24.1.** At 50 mol% Ni and  $1000^\circ\text{C}$ , this is a solid phase with half of the atoms each Ni and Cu.  
**24.2.** At 50 mol% Ni and  $1400^\circ\text{C}$ , this is a liquid phase with half of the atoms each Ni and Cu.  
**24.3.** At  $900^\circ\text{C}$  and 60 mol% Cr, this is a two-phase region with more Ni-rich face-centered cubic crystals than Cr-rich body-centered cubic crystals. The Ni-rich phase is about 42 mol% Cr and 58 mol% Ni. The Cr-rich phase is about 94 mol% Cr and 6 mol% Ni.  
**24.4.** At  $900^\circ\text{C}$  and 98 mol% Cr, this is a single-phase region with 100 mol% of the Cr-rich body-centered cubic crystals that contains 2% Ni.

## Chapter 25

- 25.1.**  $[\text{Xe}]6s^2 4f^{14} 5d^6$   
**25.2.**  $[\text{Kr}]5s^0 4d^3$  or  $[\text{Kr}]4d^3$

- 25.3.** pentaamminecarbonylmanganese(II) sulfate  
**25.4.** sodium tetrachloroplatinate(II)  
**25.5.** The complex ion  $[\text{Cr}(\text{H}_2\text{O})_3\text{Cl}_3]^+$  fits the general formula  $\text{MA}_3\text{B}_3$ , which results in fac and mer isomers.

- 25.6.** The oxalate ligand is a small bidentate ligand, so it will have to occupy two adjacent (cis) positions of the octahedron. There are three ways to arrange the two  $\text{NH}_3$  and two  $\text{Cl}^-$  ligands in the four remaining positions. One has both  $\text{NH}_3$  and both  $\text{Cl}^-$  in cis positions (cis isomer). Another has the  $\text{NH}_3$  ligands in a trans arrangement with both  $\text{Cl}^-$  in cis positions (*trans*-ammine isomer). The third has both  $\text{NH}_3$  ligands cis and the  $\text{Cl}^-$  ligands trans (*trans*-chloro isomer).

- 25.7.** Both the fac and mer isomers are superimposable (by rotating  $180^\circ$ ) on their mirror images, so neither one is optically active.  
**25.8.**  $288 \text{ kJ/mol}$   
**25.9.** five unpaired electrons  
**25.10.** one unpaired electron

*This page intentionally left blank*

## GLOSSARY

**accuracy** A term that refers to how close a measured value is to the actual value. (1.7)

**acid** A molecular compound that is able to donate an  $\text{H}^+$  ion (proton) when dissolved in water, thereby increasing the concentration of  $\text{H}_3\text{O}^+$ . (3.6)

**acid ionization constant ( $K_a$ )** The equilibrium constant for the ionization reaction of a weak acid; used to compare the relative strengths of weak acids. (16.4)

### acid-base reaction

**(neutralization reaction)** A reaction in which an acid reacts with a base and the two neutralize each other, producing water. (4.8)

**acid-base titration** A laboratory procedure in which a basic (or acidic) solution of unknown concentration is reacted with an acidic (or basic) solution of known concentration, in order to determine the concentration of the unknown. (17.4)

**acidic solution** A solution containing an acid that creates additional  $\text{H}_3\text{O}^+$  ions, causing  $[\text{H}_3\text{O}^+]$  to increase. (16.5)

**activated carbon** Very fine carbon particles with high surface area. (23.5)

**activated complex (transition state)** A high-energy intermediate state between reactant and product. (14.5)

**activation energy** An energy barrier in a chemical reaction that must be overcome for the reactants to be converted into products. (14.5)

**active site** The specific area of an enzyme at which catalysis occurs. (14.7)

**actual yield** The amount of product actually produced by a chemical reaction. (4.3)

**addition polymer** A polymer in which the monomers link together without the elimination of any atoms. (12.9)

**addition reaction** A type of organic reaction in which two substituents are added across a double bond. (21.10)

**alcohol** A member of the family of organic compounds that contain a hydroxyl functional group ( $-\text{OH}$ ). (3.12, 21.9)

**aldehyde** A member of the family of organic compounds that contain a carbonyl functional group ( $\text{C}=\text{O}$ ) bonded to two R groups, one of which is a hydrogen atom. (21.10)

**aldose** A sugar that is an aldehyde. (22.3)

**aliphatic hydrocarbon** A hydrocarbon—including alkanes, alkenes, and alkynes—that does not contain an aromatic ring. (21.3)

**alkali metals** Highly reactive metals in group 1A of the periodic table. (2.7)

**alkaline battery** A dry-cell battery that employs slightly different half-reactions in a basic medium. (19.7)

**alkaline earth metals** Fairly reactive metals in group 2A of the periodic table. (2.7)

**alkaloid** Organic bases found in plants; they are often poisonous. (16.2)

**alkane** A hydrocarbon containing only single bonds. (3.12, 21.3)

**alkene** A hydrocarbon containing one or more carbon-carbon double bonds. (3.12, 21.3)

**alkyne** A hydrocarbon containing one or more carbon-carbon triple bonds. (3.12, 21.3)

**alloy** A metallic material that contains more than one element. (24.4)

**alpha ( $\alpha$ ) decay** The form of radioactive decay that occurs when an unstable nucleus emits a particle composed of two protons and two neutrons. (20.3)

**alpha ( $\alpha$ ) particle** A particle released during alpha decay; equivalent to a helium-4 nucleus. (20.3)

**$\alpha$ -helix** A pattern in the secondary structure of a protein that occurs when the amino acid chain is wrapped tightly in a coil with the side chains extending outward. (22.5)

**aluminosilicates** Members of a family of compounds in which aluminum atoms substitute for silicon atoms in some of the silicon lattice sites of the silica structure. (23.3)

**amine** An organic compound containing nitrogen and derived from ammonia by replacing one or more hydrogen atoms on ammonia with an alkyl group. (21.3)

**amino acid** An organic compound that contains a carbon atom, called the  $\alpha$ -carbon, bonded to four different groups: an amine group, an R group, a carboxylic acid group, and a hydrogen atom. (22.4)

**ammonia**  $\text{NH}_3$ , the strong smelling compound in which nitrogen displays its lowest oxidation state ( $-3$ ). (23.6)

**amorphous** Describes a solid in which atoms or molecules do not have any long-range order. (1.3, 11.2)

**ampere (A)** The SI unit for electrical current;  $1 \text{ A} = 1 \text{ C/s}$ . (19.3)

**amphoteric** Able to act as either an acid or a base. (16.3)

**amplitude** The vertical height of a crest (or depth of a trough) of a wave; a measure of wave intensity. (7.2)

**angular momentum quantum number ( $l$ )** An integer that determines the shape of an orbital. (7.5)

**anion** A negatively charged ion. (2.6)

**anode** The electrode in an electrochemical cell at which oxidation occurs; electrons flow away from the anode. (19.3)

**antibonding orbital** A molecular orbital that is higher in energy than any of the atomic orbitals from which it was formed. (10.8)

**aqueous solution** A solution in which water acts as the solvent. (4.4, 13.2)

**arachno-boranes** Boranes with the formula  $\text{B}_n\text{H}_{n+6}$ , consisting of a cage of boron atoms that is missing two or three corners. (23.4)

**arc-melting** A method in which a solid metal is melted with an arc from a high-voltage electric source in a controlled atmosphere to prevent oxidation. (24.5)

**aromatic hydrocarbon** Any hydrocarbon containing a stabilized planar ring of carbon atoms, most commonly a benzene ring. (21.3)

**Arrhenius definitions (of acids and bases)** According to these definitions, an acid is defined as a substance that produces  $H^+$  ions in aqueous solution and a base is defined as a substance that produces  $OH^-$  ions in aqueous solution. (4.8, 16.3)

**Arrhenius equation** An equation that relates the rate constant of a reaction to the temperature, the activation energy, and the frequency factor;  $k = Ae^{\frac{-E_a}{RT}}$ . (14.5)

**Arrhenius plot** A plot of the natural log of the rate constant ( $\ln k$ ) versus the inverse of the temperature in kelvins ( $1/T$ ) that yields a straight line with a slope of  $-E_a/R$  and a y-intercept of  $\ln A$ . (14.5)

**atmosphere (atm)** A unit of pressure based on the average pressure of air at sea level; 1 atm = 101,325 Pa. (5.2)

**atom** A submicroscopic particle that constitutes the fundamental building block of ordinary matter; the smallest identifiable unit of an element. (1.1)

**atomic element** Elements that exist in nature with single atoms as their basic units. (3.4)

**atomic mass (atomic weight)** The average mass in amu of the atoms of a particular element based on the relative abundance of the various isotopes; numerically equivalent to the mass in grams of one mole of the element. (2.8)

**atomic mass unit (amu)** A unit used to express the masses of atoms and subatomic particles, defined as  $1/12$  the mass of a carbon atom containing 6 protons and 6 neutrons. (2.6)

**atomic number (Z)** The number of protons in an atom; the atomic number defines the element. (2.6)

**atomic radius** The average bonding radius of an atom determined from measurements on a large number of elements and compounds. (8.6)

**atomic solids** Solids whose composite units are atoms; they include nonbonding atomic solids, metallic atomic solids, and network covalent solids. (12.4)

**atomic theory** The theory that each element is composed of tiny indestructible particles called atoms, that all atoms of a given element have the same mass and other properties, and that atoms combine in simple, whole-number ratios to form compounds. (1.2, 2.3)

**aufbau principle** The principle that indicates the pattern of orbital filling in an atom. (8.3)

**autoionization** The process by which water acts as an acid and a base with itself. (16.5)

**Avogadro's law** The law that states that the volume of a gas is directly proportional to its amount in moles ( $V \propto n$ ). (5.3)

**Avogadro's number** The number of  $^{12}C$  atoms in exactly 12 g of  $^{12}C$ ; equal to  $6.0221421 \times 10^{23}$ . (2.9)

**balanced chemical equation** A symbolic representation of a chemical reaction; a balanced equation contains equal numbers of the atoms of each element on both sides of the equation. (3.11)

**ball-and-stick molecular model** A representation of the arrangement of atoms in a molecule that shows how the atoms are bonded to each other and the overall shape of the molecule. (3.3)

**band gap** An energy gap that exists between the valence band and conduction band of semiconductors and insulators. (12.8)

**band theory** A model for bonding in atomic solids based on molecular orbital theory in which atomic orbitals combine and become delocalized over the entire crystal. (12.8)

**barometer** An instrument used to measure atmospheric pressure. (5.2)

**base ionization constant ( $K_b$ )** The equilibrium constant for the ionization reaction of a weak base; used to compare the relative strengths of weak bases. (16.7)

**basic solution** A solution containing a base that creates additional  $OH^-$  ions, causing the  $[OH^-]$  to increase. (16.5)

**bent geometry** A molecular geometry in which the angle between three bonded atoms is approximately  $109^\circ$  (but could be less). (10.3)

**beta ( $\beta$ ) decay** The form of radioactive decay that occurs when an unstable nucleus emits an electron. (20.3)

**beta ( $\beta$ ) particle** A medium-energy particle released during beta decay; equivalent to an electron. (20.3)

**$\beta$ -pleated sheet** A pattern in the secondary structure of a protein that occurs when the amino acid chain is extended and forms a zigzag pattern. (22.5)

**bidentate** Describes ligands that donate two electron pairs to the central metal. (25.3)

**bimolecular** An elementary step in a reaction that involves two particles, either the same species or different, that collide and go on to form products. (14.6)

**binary acid** An acid composed of hydrogen and a nonmetal. (3.6)

**binary compound** A compound that contains only two different elements. (3.5)

**biochemistry** The study of the chemistry occurring in living organisms. (22.1)

**biological effectiveness factor (RBE)** A correction factor multiplied by the dose of radiation exposure in rad to obtain the dose in rem. (20.11)

**black phosphorus** An allotrope of phosphorus with a structure similar to that of graphite; the most thermodynamically stable form. (23.6)

**body-centered cubic** A unit cell that consists of a cube with one atom at each corner and one atom at the center of the cube. (12.3)

**boiling point** The temperature at which the vapor pressure of a liquid equals the external pressure. (11.5)

**boiling point elevation** The effect of a solute that causes a solution to have a higher boiling point than the pure solvent. (13.6)

**bomb calorimeter** A piece of equipment designed to measure  $\Delta E_{\text{rxn}}$  for combustion reactions at constant volume. (6.5)

**bond energy** The energy required to break 1 mol of the bond in the gas phase. (9.10)

**bond length** The average length of a bond between two particular atoms in a variety of compounds. (9.10)

**bond order** For a molecule, the number of electrons in bonding orbitals minus the number of electrons in nonbonding orbitals divided by two; a positive bond order implies that the molecule is stable. (10.8)

**bonding orbital** A molecular orbital that is lower in energy than any of the atomic orbitals from which it was formed. (10.8)

**bonding pair** A pair of electrons shared between two atoms. (9.5)

**boranes** Compounds composed of boron and hydrogen. (23.4)

**Born-Haber cycle** A hypothetical series of steps based on Hess's law that represents the formation of an ionic compound from its constituent elements. (9.4)

**borosilicate glass (Pyrex®)** A type of glass containing boric oxide ( $\text{B}_2\text{O}_3$ ). Borosilicate glass expands less when heated and can withstand heating and cooling cycles without shattering. (12.7)

**Boyle's law** The law that states that volume of a gas is inversely proportional to its pressure  $\left(V \propto \frac{1}{P}\right)$ . (5.3)

**brass** A widely used alloy that contains copper and zinc. (24.5)

**Brønsted-Lowry definitions (of acids and bases)** According to these definitions, an acid is defined as a proton ( $\text{H}^+$  ion) donor and a base is defined as a proton acceptor. (16.3)

**bronze** An alloy of copper and tin that has been used for thousands of years. (24.5)

**buffer** A solution containing significant amounts of both a weak acid and its conjugate base (or a weak base and its conjugate acid) that resists pH change by neutralizing added acid or added base. (17.2)

**buffer capacity** The amount of acid or base that can be added to a buffer without destroying its effectiveness. (17.3)

**calcination** Heating an ore in order to decompose it and drive off a volatile product. (24.3)

**calorie (cal)** A unit of energy defined as the amount of energy required to raise 1 g of water  $1^\circ\text{C}$ ; equal to 4.184 J. (6.2)

**Calorie (Cal)** Shorthand notation for the kilocalorie (kcal), or 1000 calories; also called the nutritional calorie, the unit of energy used on nutritional labels. (6.2)

**calorimetry** The experimental procedure used to measure the heat evolved in a chemical reaction. (6.5)

**capillary action** The ability of a liquid to flow against gravity up a narrow tube due to adhesive and cohesive forces. (11.4)

**carbides** Binary compounds composed of carbon and a low-electronegativity element. (23.5)

**carbohydrate** A polyhydroxyl aldehyde or ketone. (22.3)

**carbon black** A fine powdered form of carbon. (23.5)

**carbonyl group** A functional group consisting of a carbon atom double-bonded to an oxygen atom ( $\text{C}=\text{O}$ ). (21.10)

**carboxylic acid** An organic acid containing the functional group  $-\text{COOH}$ . (16.2, 21.11)

**catalyst** A substance that is not consumed in a chemical reaction that increases the rate of the reaction by providing an alternate mechanism in which the rate-determining step has a smaller activation energy. (14.7)

**cathode** The electrode in an electrochemical cell at which reduction

occurs; electrons flow toward the cathode. (19.3)

**cathode ray** A stream of electrons produced when a high electrical voltage is applied between two electrodes within a partially evacuated tube. (2.4)

**cathode ray tube** An evacuated tube containing charged plates to accelerate and view electron beams. (2.4)

**cation** A positively charged ion. (2.6)

**cell potential (cell emf) ( $E_{\text{cell}}$ )** The potential difference between the cathode and the anode in an electrochemical cell. (19.3)

**cellulose** A polysaccharide that consists of glucose units bonded together by  $\beta$ -glycosidic linkages; the main structural component of plants, and the most abundant organic substance on Earth. (22.3)

**Celsius ( $^\circ\text{C}$ ) scale** The temperature scale most often used by scientists (and by most countries other than the United States), on which pure water freezes at  $0^\circ\text{C}$  and boils at  $100^\circ\text{C}$  (at 1 atm pressure). (1.6)

**ceramics** Inorganic metallic solids that are prepared from powders usually mixed with water, formed into the desired shape, and then heated. (12.7)

**chain reaction** A series of reactions in which previous reactions cause future ones; in a fission bomb, neutrons produced by the fission of one uranium nucleus induce fission in other uranium nuclei. (20.7)

**charcoal** A fuel similar to coal that is made by heating wood in the absence of air. (23.5)

**Charles's law** The law that states that the volume of a gas is directly proportional to its temperature ( $V \propto T$ ). (5.3)

**chelate** A complex ion that contains either a bi- or polydentate ligand. (25.3)

**chelating agent** The coordinating ligand of a chelate. (25.3)

**chemical bond** The sharing or transfer of electrons to attain stable electron configurations for the bonding atoms. (9.3)

**chemical change** A change that alters the molecular composition of a substance; see also *chemical reaction*. (1.4)

**chemical energy** The energy associated with the relative positions of electrons and nuclei in atoms and molecules. (6.2)

**chemical equation** A symbolic representation of a chemical reaction; a balanced equation contains equal numbers of the atoms of each element on both sides of the equation. (3.11)

**chemical formula** A symbolic representation of a compound that indicates the elements present in the compound and the relative number of atoms of each. (3.3)

**chemical property** A property that a substance displays only by changing its composition via a chemical change. (1.4)

**chemical reaction** A process by which one or more substances convert to one or more different substances; see also *chemical change*. (3.11)

**chemical symbol** A one- or two-letter abbreviation for an element; listed directly below an element's atomic number on the periodic table. (2.6)

**chemistry** The science that seeks to understand the behavior of matter by studying the behavior of atoms and molecules. (1.1)

**chiral** Describes an environment or a molecule that is not superimposable on its mirror image; chiral molecules exhibit optical isomerism. (21.3)

**chromosome** The DNA-containing structures that occur in the nuclei of living cells. (22.6)

**cis-trans (geometric) isomerism** Cis-isomers have two functional groups (or R groups) on the same side of a bond and trans-isomers have them on opposite sides of a bond. (21.5)

**Claus process** An industrial process for obtaining sulfur through the oxidation of hydrogen sulfide. (23.8)

**Clausius-Clapeyron equation** An equation that displays the exponential relationship between

vapor pressure and temperature;

$$\ln(P_{\text{vap}}) = \frac{-\Delta H_{\text{vap}}}{R} \left( \frac{1}{T} \right) + \ln \beta. \quad (11.5)$$

**clay** A powdered form of a mineral (such as an aluminosilicate) mixed with water. (12.7)

**closo-boranes** Boranes that have the formula  $B_{12}H_{12}^{2-}$  and form the full icosahedral shape. (23.4)

**coal** A solid, black fuel with high carbon content that is the product of the decomposition of ancient plant material. (23.5)

**codon** A sequence of three bases in a nucleic acid that codes for one amino acid. (22.6)

**coffee-cup calorimeter** A piece of equipment designed to measure  $\Delta H_{\text{rxn}}$  for reactions at constant pressure. (6.7)

**coke** A solid formed by heating coal in the absence of air that consists primarily of carbon and ash. (23.5)

**colligative property** A property that depends on the amount of a solute but not on the type. (13.6)

**collision frequency** A factor in collision theory that represents the number of collisions that occur per unit time. (14.5)

**collision model** A model of chemical reactions in which a reaction occurs after a sufficiently energetic collision between two reactant molecules. (14.5)

**colloidal dispersion (colloid)** A mixture in which a dispersed substance is finely divided but not truly dissolved in a dispersing medium. (13.8)

**combustion analysis** A method of obtaining empirical formulas for unknown compounds, especially those containing carbon and hydrogen, by burning a sample of the compound in pure oxygen and analyzing the products of the combustion reaction. (3.10)

**combustion reaction** A type of chemical reaction in which a substance combines with oxygen to form one or more oxygen-containing compounds; the reaction often causes the evolution of heat and light in the form of a flame. (3.11)

**common ion effect** The tendency for a common ion to decrease the solubility of an ionic compound or

to decrease the ionization of a weak acid or weak base. (17.2)

**common name** A traditional name of a compound that gives little or no information about its chemical structure; for example, the common name of  $\text{NaHCO}_3$  is "baking soda." (3.5)

**complementary** Capable of precise pairing; in particular, the bases of nucleic acids. (22.6)

**complementary properties** Properties that exclude one another, that is, the more you know about one, the less you know about the other; for example, the wave nature and particle nature of the electron are complementary. (7.4)

**complete ionic equation** An equation that lists individually all of the ions present as either reactants or products in a chemical reaction. (4.7)

**complex carbohydrate** Another term for a polysaccharide based on the fact that it is made up of many simple sugars. (22.3)

**complex ion** An ion that contains a central metal ion that is bound to one or more ligands. (17.8, 25.3)

**composition** The basic components that make up a substance. (1.3)

**compound** A substance composed of two or more elements in fixed, definite proportions. (1.3)

**concentrated solution** A solution that contains a large amount of solute relative to the amount of solvent. (4.4, 13.5)

**concrete** A mixture of Portland cement combined with sand and pebbles. (12.7)

**condensation** The phase transition from gas to liquid. (11.5)

**condensation polymer** A polymer formed by elimination of an atom or small group of atoms (usually water) between pairs of monomers during polymerization. (12.9)

**condensation reaction** A reaction in which two or more organic compounds are joined, often with the loss of water or some other small molecule. (21.11)

**conduction band** In band theory, the band of energy levels that forms from antibonding molecular orbitals. (12.8)

**conjugate acid** Any base to which a proton has been added. (16.3)

**conjugate acid-base pair** Two substances related to each other by the transfer of a proton. (16.3)

**conjugate base** Any acid from which a proton has been removed. (16.3)

**constructive interference** The interaction of waves from two sources that align with overlapping crests, resulting in a wave of greater amplitude. (7.2)

**contact process** An industrial method for the production of sulfuric acid. (23.8)

**conversion factor** A factor used to convert between two different units; a conversion factor can be constructed from any two quantities known to be equivalent. (1.8)

**coordinate covalent bond** The bond formed when a ligand donates electrons to an empty orbital of a metal in a complex ion. (25.3)

**coordination compound** A neutral compound made when a complex ion combines with one or more counterions. (25.3)

**coordination isomers** Isomers of complex ions that occur when a coordinated ligand exchanges places with the uncoordinated counter-ion. (25.4)

**coordination number (secondary valence)** The number of molecules or ions directly bound to the metal atom in a complex ion. (25.3)

**coordination number (in a crystal structure)** The number of atoms with which each atom in a crystal lattice is in direct contact. (12.3)

**core electrons** Those electrons in a complete principal energy level and those in complete *d* and *f* sublevels. (8.4)

**corrosion** The gradual, nearly always undesired, oxidation of metals that occurs when they are exposed to oxidizing agents in the environment. (19.9)

**Coulomb's law** A scientific law that states the potential energy between

two charged particles is proportional to the product of the charges divided by the distance that separates the charges. (8.3)

**covalent bond** A chemical bond in which two atoms share electrons that interact with the nuclei of both atoms, lowering the potential energy of each through electrostatic interactions. (3.2, 9.2)

**covalent carbides** Binary compounds composed of carbon combined with low-electronegativity nonmetals or metalloids. (23.5)

**covalent radius (bonding atomic radius)** Defined in nonmetals as one-half the distance between two atoms bonded together, and in metals as one-half the distance between two adjacent atoms in a crystal of the metal. (8.6)

**critical mass** The necessary amount of a radioactive isotope required to produce a self-sustaining fission reaction. (20.7)

**critical point** The temperature and pressure above which a supercritical fluid exists. (11.8)

**critical pressure** The pressure required to bring about a transition to a liquid at the critical temperature. (11.5)

**critical temperature** The temperature above which a liquid cannot exist, regardless of pressure. (11.5)

**crystal field theory** A bonding model for coordination compounds that focuses on the interactions between ligands and the central metal ion. (25.1)

**crystalline** Describes a solid in which atoms, molecules, or ions are arranged in patterns with long-range, repeating order. (1.3, 11.2)

**crystalline lattice** The regular arrangement of atoms in a crystalline solid. (12.3)

**cubic closest packing** A closest-packed arrangement in which the third layer of atoms is offset from the first; the same structure as the face-centered cubic. (12.3)

**cyclotron** A particle accelerator in which a charged particle is accelerated in an evacuated ring-shaped tube

by an alternating voltage applied to each semi-circular half of the ring. (20.10)

**Dalton's law of partial pressures**

The law stating that the sum of the partial pressures of the components in a gas mixture must equal the total pressure. (5.6)

**de Broglie relation** The observation that the wavelength of a particle is inversely proportional to its momentum;  $\lambda = \frac{h}{mv}$ . (7.4)

**decanting** A method of separating immiscible liquids by pouring the top layer into another container. (1.3)

**degenerate** A term describing two or more electron orbitals with the same value of *n* that have the same energy. (8.3)

**density (*d*)** The ratio of an object's mass to its volume. (1.6)

**deposition** The phase transition from gas to solid. (11.6)

**derived unit** A unit that is a combination of other base units. For example, the SI unit for speed is meters per second (m/s), a derived unit. (1.6)

**destructive interference** The interaction of waves from two sources that are aligned so the crest of one overlaps the trough of the other, resulting in cancellation. (7.2)

**deterministic** A characteristic of the classical laws of motion, which imply that present circumstances determine future events. (7.4)

**dextrorotatory** Capable of rotating the plane of polarization of light clockwise. (21.3)

**diamagnetic** The state of an atom or ion that contains only paired electrons and is, therefore, slightly repelled by an external magnetic field. (8.7)

**diamond** An elemental form of carbon with a crystal structure that consists of carbon atoms connected to four other carbon atoms at the corners of a tetrahedron, creating a strong network covalent solid. (12.6)

- diffraction** The phenomena by which a wave emerging from an aperture spreads out to form a new wave front. (7.2)
- diffusion** The process by which a gas spreads through a space occupied by another gas. (5.9)
- dilute solution** A solution that contains a very small amount of solute relative to the amount of solvent. (4.4, 13.5)
- dimensional analysis** The use of units as a guide to solving problems. (1.8)
- dimer** The product that forms from the reaction of two monomers. (12.9)
- diode** A device that allows the flow of electrical current in only one direction. (12.8)
- dipeptide** Two amino acids linked together. (22.4)
- dipole moment ( $\mu$ )** A measure of the separation of positive and negative charge in a molecule. (9.6)
- dipole-dipole force** An intermolecular force exhibited by polar molecules that results from the uneven charge distribution. (11.3)
- diprotic acid** An acid that contains two ionizable protons. (4.8, 16.4)
- disaccharide** A carbohydrate composed of two monosaccharides. (22.3)
- dispersion force** An intermolecular force (also referred to as London force) exhibited by all atoms and molecules that results from fluctuations in the electron distribution. (11.3)
- distillation** The process by which mixtures of miscible liquids are separated by heating the mixture to boil off the more volatile liquid. The vaporized component is then recondensed and collected in a separate flask. (1.3)
- disubstituted benzene** A benzene in which two hydrogen atoms have been replaced by other atoms. (21.7)
- dose** The amount of energy absorbed by bodily tissues as a result of exposure to radiation. (20.11)
- double bond** The bond that forms when two electrons are shared between two atoms. (9.5)
- dry-cell battery** A battery that does not contain a large amount of liquid water, often using the oxidation of zinc and the reduction of  $\text{MnO}_2$  to provide the electrical current. (19.7)
- duet** A Lewis symbol with two dots, signifying a filled outer electron shell for the elements H and He. (9.3)
- dynamic equilibrium** The point at which the rate of the reverse reaction or process equals the rate of the forward reaction or process. (11.5, 13.4, 15.2)
- effective nuclear charge ( $Z_{\text{eff}}$ )** The actual nuclear charge experienced by an electron, defined as the charge of the nucleus plus the charge of the shielding electrons. (8.3)
- effusion** The process by which a gas escapes from a container into a vacuum through a small hole. (5.9)
- electrical charge** A fundamental property of certain particles that causes them to experience a force in the presence of electric fields. (2.4)
- electrical current** The flow of electric charge. (19.3)
- electrochemical cell** A device in which a chemical reaction either produces or is carried out by an electrical current. (19.3)
- electrode** A conductive surface through which electrons can enter or leave a half-cell in an electrochemical cell. (19.3)
- electrolysis** The process in which electrical current drives an otherwise nonspontaneous redox reaction. (19.8)
- electrolyte** A substance that dissolves in water to form solutions that conduct electricity. (4.5)
- electrolytic cell** An electrochemical cell that uses electrical current to drive a nonspontaneous chemical reaction. (19.3)
- electromagnetic radiation** A form of energy embodied in oscillating electric and magnetic fields. (7.2)
- electromagnetic spectrum** The range of the wavelengths of all possible electromagnetic radiation. (7.2)
- electrometallurgy** The use of electrolysis to produce metals from their compounds. (24.3)
- electromotive force (emf)** The force that results in the motion of electrons due to a difference in potential. (19.3)
- electron** A negatively charged, low-mass particle found outside the nucleus of all atoms that occupies most of the atom's volume but contributes almost none of its mass. (2.4)
- electron affinity (EA)** The energy change associated with the gaining of an electron by an atom in its gaseous state. (8.8)
- electron capture** The form of radioactive decay that occurs when a nucleus assimilates an electron from an inner orbital. (20.3)
- electron configuration** A notation that shows the particular orbitals that are occupied by electrons in an atom. (8.3)
- electron geometry** The geometrical arrangement of electron groups in a molecule. (10.3)
- electron groups** A general term for lone pairs, single bonds, multiple bonds, or lone electrons in a molecule. (10.2)
- electronegativity** An atom's ability to attract electrons to itself in a covalent bond. (9.6)
- element** A substance that cannot be chemically broken down into simpler substances. (1.3)
- elementary step** An individual step in a reaction mechanism. (14.6)
- emission spectrum** The range of wavelengths emitted by a particular element; used to identify the element. (7.3)
- empirical formula** A chemical formula that shows the simplest whole number ratio of atoms in the compound. (3.3)
- empirical formula molar mass** The sum of the masses of all the atoms in an empirical formula. (3.10)
- enantiomers (optical isomers)** Two molecules that are nonsuperimposable mirror images of one another. (21.3, 25.4)
- endothermic reaction** A chemical reaction that absorbs heat from its surroundings; for an endothermic reaction,  $\Delta H > 0$ . (6.6)

**endpoint** The point of pH change where an indicator changes color. (17.4)

**energy** The capacity to do work. (1.5, 6.2)

**English system** The system of units used in the United States and various other countries in which the inch is the unit of length, the pound is the unit of force, and the ounce is the unit of mass. (1.6)

**enthalpy (*H*)** The sum of the internal energy of a system and the product of its pressure and volume; the energy associated with the breaking and forming of bonds in a chemical reaction. (6.6)

**enthalpy (heat) of reaction ( $\Delta H_{\text{rxn}}$ )** The enthalpy change for a chemical reaction. (6.5)

**enthalpy of solution ( $\Delta H_{\text{soln}}$ )** The enthalpy change associated with the formation of a solution. (13.3)

**entropy** A thermodynamic function that is proportional to the number of energetically equivalent ways to arrange the components of a system to achieve a particular state; a measure of the energy randomization or energy dispersal in a system. (13.2, 18.3)

**enzyme** A biochemical catalyst made of protein that increases the rates of biochemical reactions. (14.7, 22.4)

**equilibrium constant (*K*)** The ratio, at equilibrium, of the concentrations of the products of a reaction raised to their stoichiometric coefficients to the concentrations of the reactants raised to their stoichiometric coefficients. (15.3)

**equivalence point** The point in a titration at which the added solute completely reacts with the solute present in the solution; for acid-base titrations, the point at which the amount of acid is stoichiometrically equal to the amount of base in solution. (4.8, 17.4)

**ester** A family of organic compounds with the general structure  $\text{R}-\text{COO}-\text{R}$ . (21.11)

**ester linkage** The bonds that form between a carboxylic acid and an alcohol to form an ester, such as those in triglycerides. (22.2)

**ether** A member of the family of organic compounds of the form  $\text{R}-\text{O}-\text{R}'$ . (21.12)

**exact numbers** Numbers that have no uncertainty and thus do not limit the number of significant figures in any calculation. (1.7)

**exothermic reaction** A chemical reaction that releases heat to its surroundings; for an exothermic reaction,  $\Delta H < 0$ . (6.6)

**experiment** A highly controlled procedure designed to generate observations that may support a hypothesis or prove it wrong. (1.2)

**exponential factor** A number between zero and one that represents the fraction of molecules that have enough energy to make it over the activation barrier on a given approach. (14.5)

**exposure** The number of radioactive decay events to which a person is exposed. (20.11)

**extensive property** A property that depends on the amount of a given substance, such as mass. (1.6)

**extractive metallurgy** The process by which an elemental metal is extracted from the compounds in which it is found. (24.3)

**face-centered cubic** A crystal structure that has a unit cell that consists of a cube with one atom at each corner and one atom in the center of every face. (12.3)

**Fahrenheit ( $^{\circ}\text{F}$ ) scale** The temperature scale that is most familiar in the United States, on which pure water freezes at  $32^{\circ}\text{F}$  and boils at  $212^{\circ}\text{F}$  at 1 atm of pressure. (1.6)

**family** A group of organic compounds with the same functional group. (3.12)

**family (group)** Columns within the main group elements in the periodic table that contain elements that exhibit similar chemical properties. (2.7)

**Faraday's constant (*F*)** The charge in coulombs of 1 mol of electrons;  $F = \frac{96,485 \text{ C}}{\text{mol e}^{-}}$ . (19.5)

**fatty acid** A carboxylic acid with a long hydrocarbon tail. (22.2)

**ferromagnetic** The state of an atom or ion that is very strongly attracted by an external magnetic field. (24.5)

**fibrous protein** A protein with a relatively linear structure; fibrous proteins tend to be insoluble in aqueous solutions. (22.5)

**filtration** A procedure used to separate a mixture composed of an insoluble solid and a liquid by pouring the mixture through filter paper or some other porous membrane or layer. (1.3)

**first law of thermodynamics** The law stating that the total energy of the universe is constant. (6.3)

**flux** In pyrometallurgy, material that reacts with the gangue to form a substance with a low melting point. (24.3)

**formal charge** The charge that an atom in a Lewis structure would have if all the bonding electrons were shared equally between the bonded atoms. (9.8)

**formation constant ( $K_f$ )** The equilibrium constant associated with reactions for the formation of complex ions. (17.8)

**formula mass** The average mass of a molecule of a compound in amu. (3.8)

**formula unit** The smallest, electrically neutral collection of ions in an ionic compound. (3.4)

**Frasch process** An industrial process for the recovery of sulfur that uses superheated water to liquefy sulfur deposits in Earth's crust and bring the molten sulfur to the surface. (23.8)

**free energy of formation ( $\Delta G_f^{\circ}$ )** The change in free energy when 1 mol of a compound forms from its constituent elements in their standard states. (18.8)

**free radical** A molecule or ion with an odd number of electrons in its Lewis structure. (9.9)

**freezing** The phase transition from liquid to solid. (11.6)

**freezing point depression** The effect of a solute that causes a solution to have a lower melting point than the pure solvent. (13.6)

**frequency ( $\nu$ )** For waves, the number of cycles (or complete wavelengths) that pass through a stationary point in one second. (7.2)

**frequency factor** The number of times that reactants approach the activation energy per unit time. (14.5)

**fuel cell** A voltaic cell that uses the oxidation of hydrogen and the reduction of oxygen, forming water, to provide electrical current. (19.7)

**fullerenes** Carbon clusters, such as  $C_{60}$ , bonded in roughly spherical shapes containing from 36 to over 100 carbon atoms. (12.6)

**functional group** A characteristic atom or group of atoms that imparts certain chemical properties to an organic compound. (3.12)

**gamma ( $\gamma$ ) ray** The form of electromagnetic radiation with the shortest wavelength and highest energy. (7.2, 20.3)

**gamma ( $\gamma$ ) ray emission** The form of radioactive decay that occurs when an unstable nucleus emits extremely high frequency electromagnetic radiation. (20.3)

**gangue** The undesirable minerals that are separated from specific ores. (24.3)

**gas** A state of matter in which atoms or molecules have a great deal of space between them and are free to move relative to one another; lacking a definite shape or volume, a gas conforms to those of its container. (1.3)

**gas-evolution reaction** A reaction in which two aqueous solutions are mixed and a gas forms, resulting in bubbling. (4.8)

**Geiger-Müller counter** A device used to detect radioactivity, which uses argon atoms that become ionized in the presence of energetic particles to produce an electrical signal. (20.5)

**gene** A sequence of codons within a DNA molecule that codes for a single protein. (22.6)

**geometric (cis-trans) isomerism** A form of stereoisomerism involving the orientation of functional groups in a molecule that contains bonds incapable of rotating. (21.5)

**geometric isomers** For complex ions, isomers that result when the ligands bonded to the metal have a different spatial arrangement. (25.4)

**Gibbs free energy ( $G$ )** A thermodynamic state function related to enthalpy and entropy by the equation  $G = H - TS$ ; chemical systems tend toward lower Gibbs free energy, also called the *chemical potential*. (18.6)

**glass** An amorphous form of silica. (12.7)

**globular protein** A protein that folds into a roughly spherical shape so that its polar side chains are oriented outward and its nonpolar side chains toward the interior; globular proteins tend to be soluble in water. (22.5)

**glycogen** A highly branched form of starch. (22.3)

**glycolipid** A triglyceride composed of a fatty acid, a hydrocarbon chain, and a sugar molecule as the polar section. (22.2)

**glycosidic linkage** A bond between carbohydrates that results from a dehydration reaction. (22.3)

**graphene** A new material that consists of a single sheet of carbon atoms (similar to a sheet from graphite) one atom thick. (12.1)

**graphite** An elemental form of carbon consisting of flat sheets of carbon atoms, bonded together as interconnected hexagonal rings held together by intermolecular forces, that can easily slide past each other. (12.6)

**Graham's law of effusion** A scientific law that states the ratio of effusion rates of two gases is equal to the square root of the inverse of their molar masses. (5.9)

**ground state** The lowest energy state in an atom, ion, or molecule. (8.3)

**Haber-Bosch process** The industrial process for producing ammonia from nitrogen gas and hydrogen gas. (23.6)

**half-cell** One half of an electrochemical cell where either oxidation or reduction occurs. (19.3)

**half-life ( $t_{1/2}$ )** The time required for the concentration of a reactant or the amount of a radioactive isotope to fall to one-half of its initial value. (14.4)

**halogens** Highly reactive nonmetals in group 7A of the periodic table. (2.7)

**heat ( $q$ )** The flow of energy caused by a temperature difference. (6.2)

**heat capacity ( $C$ )** The quantity of heat required to change a system's temperature by  $1^\circ\text{C}$ . (6.4)

**heat of fusion ( $\Delta H_{\text{fus}}$ )** The amount of heat required to melt 1 mole of a solid. (11.6)

**heat of hydration ( $\Delta H_{\text{hydration}}$ )** The enthalpy change that occurs when 1 mol of gaseous solute ions is dissolved in water. (13.3)

**heat (or enthalpy) of sublimation ( $\Delta H_{\text{sub}}$ )** The enthalpy change associated with the sublimation of a substance. (6.6)

**heat (or enthalpy) of vaporization ( $\Delta H_{\text{vap}}$ )** The amount of heat required to vaporize one mole of a liquid to a gas. (11.5)

### Heisenberg's uncertainty

**principle** The principle stating that due to the wave-particle duality, it is fundamentally impossible to precisely determine both the position and velocity of a particle at a given moment in time. (7.4)

**Henderson-Hasselbalch equation** An equation used to easily calculate the pH of a buffer solution from the initial concentrations of the buffer components, assuming that the "*x* is small" approximation is valid;  $\text{pH} = \text{p}K_{\text{a}} + \log \frac{[\text{base}]}{[\text{acid}]}$ . (17.2)

**Henry's law** An equation that expresses the relationship between solubility of a gas and pressure;  $S_{\text{gas}} = k_{\text{H}}P_{\text{gas}}$ . (13.4)

**Hess's law** The law stating that if a chemical equation can be expressed as the sum of a series of steps, then  $\Delta H_{\text{rxn}}$  for the overall equation is the sum of the heats of reactions for each step. (6.8)

**heterogeneous catalysis** Catalysis in which the catalyst and the reactants exist in different phases. (14.7)

**heterogeneous mixture** A mixture in which the composition varies from one region to another. (1.3)

**hexagonal closest packing** A closest-packed arrangement in which the atoms of the third layer align exactly over those in the first layer. (12.3)

**hexose** A six-carbon sugar. (22.3)

**high-spin complex** A complex ion with weak field ligands that have the same number of unpaired electrons as the free metal ion. (25.5)

**homogeneous catalysis** Catalysis in which the catalyst exists in the same phase as the reactants. (14.7)

**homogeneous mixture** A mixture with the same composition throughout. (1.3)

**Hund's rule** The principle stating that when electrons fill degenerate orbitals, they first fill them singly with parallel spins. (8.3)

**hybrid orbitals** Orbitals formed from the combination of standard atomic orbitals that correspond more closely to the actual distribution of electrons in a chemically bonded atom. (10.7)

**hybridization** A mathematical procedure in which standard atomic orbitals are combined to form new, hybrid orbitals. (10.7)

**hydrate** An ionic compound that contains a specific number of water molecules associated with each formula unit. (3.5)

**hydrazine**  $\text{N}_2\text{H}_4$ , a nitrogen and hydrogen compound in which nitrogen has a negative oxidation state ( $-2$ ). (23.6)

**hydrocarbon** An organic compound that contains only carbon and hydrogen. (3.12)

**hydrogen azide ( $\text{HN}_3$ )** A nitrogen and hydrogen compound with a higher hydrogen-to-nitrogen ratio than ammonia or hydrazine. (23.6)

**hydrogen bond** A strong dipole-dipole attractive force between a

hydrogen bonded to O, N, or F and one of these electronegative atoms on a neighboring molecule. (11.3)

**hydrogen bonding** The forming of a hydrogen bond. (11.3)

**hydrogenation** The catalyzed addition of hydrogen to alkene double bonds to make single bonds. (14.7)

**hydrolysis** The splitting of a chemical bond with water, resulting in the addition of H and OH to the products. (22.3)

**hydrometallurgy** The use of an aqueous solution to extract metals from their ores. (24.3)

**hydronium ion**  $\text{H}_3\text{O}^+$ ; the ion formed from the association of a water molecule with an  $\text{H}^+$  ion donated by an acid. (4.8, 16.3)

**hydroxyl group** An  $-\text{OH}$  group. (21.9)

**hypothesis** A tentative interpretation or explanation of an observation. A good hypothesis is *falsifiable*. (1.2)

**hypoxia** A physiological condition caused by low levels of oxygen, marked by dizziness, headache, shortness of breath, and eventually unconsciousness or even death in severe cases. (5.6)

**ideal gas** A theoretical gas that follows the ideal gas law under all conditions. (5.4)

**ideal gas constant** The proportionality constant of the ideal gas law,  $R$ , equal to  $8.314 \text{ J/mol} \cdot \text{K}$  or  $0.08206 \text{ L} \cdot \text{atm/mol} \cdot \text{K}$ . (5.4)

**ideal gas law** The law that combines the relationships of Boyle's, Charles's, and Avogadro's laws into one comprehensive equation of state with the proportionality constant  $R$  in the form  $PV = nRT$ . (5.4)

**ideal solution** A solution that follows Raoult's law at all concentrations for both solute and solvent. (13.6)

**indeterminacy** The principle asserting that present circumstances do not necessarily determine future events in the quantum-mechanical realm. (7.4)

**indicator** A dye whose color depends on the pH of the solution it is dissolved

in; often used to detect the endpoint of a titration. (4.8, 17.4)

**infrared (IR) radiation** Electromagnetic radiation emitted from warm objects, with wavelengths slightly larger than those of visible light. (7.2)

**insoluble** Incapable of dissolving in water or being extremely difficult of solution. (4.5)

**integrated rate law** A relationship between the concentrations of the reactants in a chemical reaction and time. (14.4)

**intensive property** A property such as density that is independent of the amount of a given substance. (1.6)

**interference** The superposition of two or more waves overlapping in space, resulting in either an increase in amplitude (constructive interference) or a decrease in amplitude (destructive interference). (7.2)

**interhalogen compounds** A class of covalent compounds that contain two different halogens. (23.9)

**internal energy ( $E$ )** The sum of the kinetic and potential energies of all of the particles that compose a system. (6.3)

**International System of Units (SI)** The standard unit system used by scientists, based on the metric system. (1.6)

**interstitial alloy** An alloy in which small, usually nonmetallic atoms fit between the metallic atoms of a crystal. (24.4)

**ion** An atom or molecule with a net charge caused by the loss or gain of electrons. (2.6)

**ion product constant for water ( $K_w$ )** The equilibrium constant for the autoionization of water. (16.5)

**ion-dipole force** An intermolecular force between an ion and the oppositely charged end of a polar molecule. (11.3)

**ionic bond** A chemical bond formed between two oppositely charged ions, generally a metallic cation and a nonmetallic anion, that are attracted to each other by electrostatic forces. (3.2, 9.2)

**ionic carbides** Binary compounds composed of carbon combined with low-electronegativity metals. (23.5)

**ionic compound** A compound composed of cations and anions bound together by electrostatic attraction. (3.2)

**ionic solids** Solids whose composite units are ions; they generally have high melting points. (12.4)

**ionization energy (IE)** The energy required to remove an electron from an atom or ion in its gaseous state. (8.7)

**ionizing power** The ability of radiation to ionize other molecules and atoms. (20.3)

**isotopes** Atoms of the same element with the same number of protons but different numbers of neutrons and consequently different masses. (2.6)

**joule (J)** The SI unit for energy: equal to  $1 \text{ kg} \cdot \text{m}^2/\text{s}^2$ . (6.2)

**kelvin (K)** The SI standard unit of temperature. (1.6)

**Kelvin scale** The temperature scale that assigns 0 K ( $-273^\circ\text{C}$  or  $-459^\circ\text{F}$ ) to the coldest temperature possible, absolute zero, which is the temperature at which molecular motion virtually stops. (1.6)

**ketone** A member of the family of organic compounds that contain a carbonyl functional group ( $\text{C}=\text{O}$ ) bonded to two R groups, neither of which is a hydrogen atom. (21.10)

**ketose** A sugar that is a ketone. (22.3)

**kilogram (kg)** The SI standard unit of mass defined as the mass of a block of metal kept at the International Bureau of Weights and Measures at Sèvres, France. (1.6)

**kilowatt-hour (kWh)** An energy unit used primarily to express large amounts of energy produced by the flow of electricity; equal to  $3.60 \times 10^6 \text{ J}$ . (6.2)

**kinetic energy** The energy associated with motion of an object. (1.5, 6.2)

**kinetic molecular theory** A model of an ideal gas as a collection of point particles in constant motion

undergoing completely elastic collisions. (5.8)

**lanthanide contraction** The trend toward leveling off in size of the atoms in the third and fourth transition rows due to the ineffective shielding of the *f* sublevel electrons. (25.2)

**lattice energy** The energy associated with forming a crystalline lattice from gaseous ions. (9.4)

**law** see *scientific law*. (1.2)

**law of conservation of energy** A law stating that energy can neither be created nor destroyed, only converted from one form to another. (1.5, 6.2)

**law of conservation of mass** A law stating that matter is neither created nor destroyed in a chemical reaction. (1.2, 2.3)

**law of definite proportions** A law stating that all samples of a given compound have the same proportions of their constituent elements. (2.3)

**law of mass action** A law regarding the relationship between the balanced chemical equation and the expression of the equilibrium constant. (15.3)

**law of multiple proportions** A law stating that when two elements (A and B) form two different compounds, the masses of element B that combine with one gram of element A can be expressed as a ratio of small whole numbers. (2.3)

**Le Châtelier's principle** The principle stating that when a chemical system at equilibrium is disturbed, the system shifts in a direction that minimizes the disturbance. (15.9)

**leaching** The process by which a metal is separated out of a mixture by selectively dissolving the metal into solution. (24.3)

**lead glass** A type of glass (often called *crystal*) that contains  $\text{PbO}$ . This type of glass has a higher index of refraction (it bends light more than ordinary glass), which results in more brilliant-looking glassware. (12.7)

**lead-acid storage battery** A battery that uses the oxidation of lead and the reduction of lead(IV) oxide

in sulfuric acid to provide electrical current. (19.7)

**lever rule** The rule that states that in a two-phase region, whichever phase is closer to the composition of the alloy is the more abundant phase. (24.4)

**levorotatory** Capable of rotating the polarization of light counterclockwise. (21.3)

**Lewis acid** An atom, ion, or molecule that is an electron pair acceptor. (16.11)

**Lewis base** An atom, ion, or molecule that is an electron pair donor. (16.11)

**Lewis electron-dot structures (Lewis structures)** A drawing that represents chemical bonds between atoms in molecules as shared or transferred electrons; the valence electrons of atoms are represented as dots in a Lewis structure. (9.1)

**Lewis model** A simple model of chemical bonding using diagrams that represent bonds between atoms as lines or pairs of dots. According to this model, atoms bond together to obtain stable octets (eight valence electrons). (9.1)

**Lewis symbol** The symbol of an element surrounded with dots representing the element's valence electrons. (9.3)

**ligand** A neutral molecule or an ion that acts as a Lewis base with the central metal ion in a complex ion. (17.8, 25.3)

**limiting reactant** The reactant that has the smallest stoichiometric amount in a reactant mixture and consequently limits the amount of product in a chemical reaction. (4.3)

**linear accelerator** A particle accelerator in which a charged particle is accelerated in an evacuated tube by a potential difference between the ends of the tube or by alternating charges in sections of the tube. (20.10)

**linear geometry** The molecular geometry of three atoms with a  $180^\circ$  bond angle due to the repulsion of two electron groups. (10.2)

**linkage isomers** Isomers of complex ions that occur when some ligands coordinate to the metal in different ways. (25.4)

**lipid** A member of the class of biochemical compounds that are insoluble in water but soluble in nonpolar solvents, including fatty acids, triglycerides, and steroids. (22.2)

**lipid bilayer** A double-layered structure made of phospholipids or glycolipids, in which the polar heads of the molecules interact with the environment and the nonpolar tails interact with each other; a component of many cellular membranes. (22.2)

**liquid** A state of matter in which atoms or molecules pack about as closely as they do in solid matter but are free to move relative to each other; liquids have a fixed volume but not a fixed shape. (1.3)

**liter (L)** A unit of volume equal to 1000 cm<sup>3</sup> or 1.057 qt. (1.6)

**lithium ion battery** A battery that produces electrical current in the form of motion of lithium ions from the anode to the cathode. (19.7)

**lone pair** A pair of electrons associated with only one atom. (9.5)

**low-spin complex** A complex ion with strong field ligands that have fewer unpaired electrons than the free metal ion. (25.5)

**magic numbers** Certain numbers of nucleons ( $N$  or  $Z = 2, 8, 20, 28, 50, 82$ , and  $N = 126$ ) that confer unique stability. (20.4)

**magnetic quantum number ( $m_l$ )** An integer that specifies the orientation of an orbital. (7.5)

**main-group elements** Those elements found in the  $s$  or  $p$  blocks of the periodic table, whose properties tend to be predictable based on their position in the table. (2.7, 23.2)

**manometer** An instrument used to determine the pressure of a gaseous sample, consisting of a liquid-filled U-shaped tube with one end exposed to the ambient pressure and the other end connected to the sample. (5.2)

**mass** A measure of the quantity of matter making up an object. (1.6)

**mass defect** The difference in mass between the nucleus of an atom and

the sum of the separated particles that make up that nucleus. (20.8)

**mass number ( $A$ )** The sum of the number of protons and neutrons in an atom. (2.6)

**mass percent composition (mass percent)** An element's percentage of the total mass of a compound containing the element. (3.9)

**mass spectrometry** An experimental method of determining the precise mass and relative abundance of isotopes in a given sample using an instrument called a *mass spectrometer*. (2.8)

**matter** Anything that occupies space and has mass. (1.3)

**mean free path** The average distance that a molecule in a gas travels between collisions. (5.9)

**melting (fusion)** The phase transition from solid to liquid. (11.6)

**melting point** The temperature at which the molecules of a solid have enough thermal energy to overcome intermolecular forces and become a liquid. (11.6)

**metal** A member of the class of elements that are generally good conductors of heat and electricity, malleable, ductile, lustrous, and tend to lose electrons during chemical changes. (2.7)

**metallic atomic solids** Atomic solids held together by metallic bonds; they have variable melting points. (12.4)

**metallic bonding** The type of bonding that occurs in metal crystals, in which metal atoms donate their electrons to an electron sea, delocalized over the entire crystal lattice. (9.2)

**metallic carbides** Binary compounds composed of carbon combined with metals that have a metallic lattice with holes small enough to fit carbon atoms. (23.5)

**metalloid** A member of the class of elements found on the boundary between the metals and nonmetals of the periodic table, with properties intermediate between those of both groups; also called *semimetals*. (2.7)

**metallurgy** The part of chemistry that includes all the processes associated with mining, separating, and refining metals and the subsequent production of pure metals and mixtures of metals called alloys. (24.1)

**meter (m)** The SI standard unit of length; equivalent to 39.37 inches. (1.6)

**metric system** The system of measurements used in most countries in which the meter is the unit of length, the kilogram is the unit of mass, and the second is the unit of time. (1.6)

**microwaves** Electromagnetic radiation with wavelengths slightly longer than those of infrared radiation; used for radar and in microwave ovens. (7.2)

**milliliter (mL)** A unit of volume equal to 10<sup>-3</sup> L or 1 cm<sup>3</sup>. (1.6)

**millimeter of mercury (mmHg)** A common unit of pressure referring to the air pressure required to push a column of mercury to a height of 1 mm in a barometer; 760 mmHg = 1 atm. (5.2)

**mineral** A homogeneous, naturally occurring, crystalline inorganic solid. (23.3, 24.2)

**miscibility** The ability to mix without separating into two phases. (11.3)

**miscible** The ability of two or more substances to be soluble in each other in all proportions. (13.2)

**mixture** A substance composed of two or more different types of atoms or molecules that can be combined in variable proportions. (1.3)

**molality ( $m$ )** A means of expressing solution concentration as the number of moles of solute per kilogram of solvent. (13.5)

**molar heat capacity** The amount of heat required to raise the temperature of one mole of a substance by 1 °C. (6.4)

**molar mass** The mass in grams of one mole of atoms of an element; numerically equivalent to the atomic mass of the element in amu. (2.9)

**molar solubility** The solubility of a compound in units of moles per liter. (17.5)

**molar volume** The volume occupied by one mole of a gas; the molar volume of an ideal gas at STP is 22.4 L. (5.5)

**molarity (M)** A means of expressing solution concentration as the number of moles of solute per liter of solution. (4.4, 13.5)

**mole (mol)** A unit defined as the amount of material containing  $6.0221421 \times 10^{23}$  (Avogadro's number) particles. (2.9)

**mole fraction ( $\chi_A$ )** The number of moles of a component in a mixture divided by the total number of moles in the mixture. (5.6)

**mole fraction ( $\chi_{\text{solute}}$ )** A means of expressing solution concentration as the number of moles of solute per moles of solution. (13.5)

**mole percent** A means of expressing solution concentration as the mole fraction multiplied by 100%. (13.5)

**molecular compound** Compounds composed of two or more covalently bonded nonmetals. (3.2)

**molecular element** Those elements that exist in nature with diatomic or polyatomic molecules as their basic unit. (3.4)

**molecular equation** An equation showing the complete neutral formula for each compound in a reaction. (4.7)

**molecular formula** A chemical formula that shows the actual number of atoms of each element in a molecule of a compound. (3.3)

**molecular geometry** The geometrical arrangement of atoms in a molecule. (10.3)

**molecular orbital theory** An advanced model of chemical bonding in which electrons reside in molecular orbitals delocalized over the entire molecule. In the simplest version, the molecular orbitals are simply linear combinations of atomic orbitals. (10.8)

**molecular solids** Solids whose composite units are molecules; they generally have low melting points. (12.4)

**molecularity** The number of reactant particles involved in an elementary step. (14.6)

**molecule** Two or more atoms joined chemically in a specific geometrical arrangement. (1.1)

**monodentate** Describes ligands that donate only one electron pair to the central metal. (25.3)

**monomer** A repeating unit in a polymer. (12.9)

**monoprotic acid** An acid that contains only one ionizable proton. (16.4)

**monosaccharide** The simplest carbohydrates, with three to eight carbon atoms and only one aldehyde or ketone group. (22.3)

**nanotubes** Long, tubular structures consisting of interconnected  $C_6$  rings. (12.6)

**natural abundance** The relative percentage of a particular isotope in a naturally occurring sample with respect to other isotopes of the same element. (2.6)

**Nernst equation** The equation relating the cell potential of an electrochemical cell to the standard cell potential and the reaction quotient;  

$$E_{\text{cell}} = E_{\text{cell}}^{\circ} - \frac{0.0592 \text{ V}}{n} \log Q. \quad (19.6)$$

**net ionic equation** An equation that shows only the species that actually change during the reaction. (4.7)

**network covalent atomic solids** Atomic solids held together by covalent bonds; they have high melting points. (12.4)

**neutral** The state of a solution where the concentrations of  $H_3O^+$  and  $OH^-$  are equal. (16.5)

**neutron** An electrically neutral subatomic particle found in the nucleus of an atom, with a mass almost equal to that of a proton. (2.5)

**nickel-cadmium (NiCad) battery** A battery that consists of an anode composed of solid cadmium and a cathode composed of  $NiO(OH)(s)$  in a KOH solution. (19.7)

**nickel-metal hydride (NiMH) battery** A battery that uses the same cathode reaction as the NiCad battery but a different anode reaction, the oxidation of hydrogens in a metal alloy. (19.7)

**nido-boranes** Boranes that have the formula  $B_nH_{n+4}$  and consist of a cage of boron atoms missing one corner. (23.4)

**nitrogen narcosis** A physiological condition caused by an increased partial pressure of nitrogen, resulting in symptoms similar to those of intoxication. (5.6)

**noble gases** The group 8A elements, which are largely unreactive (inert) due to their stable filled  $p$  orbitals. (2.7)

**node** A point where the wave function ( $\psi$ ), and therefore the probability density ( $\psi^2$ ) and radial distribution function, all go through zero (7.6)

**nonbonding atomic solids** Atomic solids held together by dispersion forces; they have low melting points. (12.4)

**nonbonding electrons** Electrons in a Lewis structure that are not in a chemical bond; also called lone pair electrons. (9.5)

**nonbonding orbital** An orbital whose electrons remain localized on an atom. (10.8)

**nonelectrolyte** A compound that does not dissociate into ions when dissolved in water. (4.5)

**nonmetal** A member of the class of elements that tend to be poor conductors of heat and electricity and usually gain electrons during chemical reactions. (2.7)

**nonvolatile** Not easily vaporized. (11.5)

**normal boiling point** The temperature at which the vapor pressure of a liquid equals 1 atm. (11.5)

**n-type semiconductor** A semiconductor that employs negatively charged electrons in the conduction band as the charge carriers. (12.8)

**nuclear binding energy** The amount of energy that would be required to break apart the nucleus into its component nucleons. (20.8)

**nuclear equation** An equation that represents nuclear processes such as radioactivity. (20.3)

**nuclear fission** The splitting of the nucleus of an atom, resulting in a tremendous release of energy. (20.7)

**nuclear fusion** The combination of two light nuclei to form a heavier one. (20.9)

**nuclear theory** The theory that most of the atom's mass and all of its positive charge is contained in a small, dense nucleus. (2.5)

**nucleic acid** A biological polymer composed of nucleotide units that carries genetic information. (22.6)

**nucleons** The particles that compose the nucleus and that are protons and neutrons. (20.4)

**nucleotides** The individual units composing nucleic acids; each consists of a phosphate group, a sugar, and a nitrogenous base. (22.6)

**nucleus** The very small, dense core of the atom that contains most of the atom's mass and all of its positive charge; composed of protons and neutrons. (2.5)

**nuclide** A particular isotope of an atom. (20.3)

**octahedral geometry** The molecular geometry of seven atoms with 90° bond angles. (10.2)

**octahedral hole** A space that exists in the middle of six atoms on two adjacent close-packed sheets of atoms in a crystal lattice. (24.4)

**octet** The eight dots around atoms in a Lewis structure that signify a filled outer electron shell for *s* and *p* block elements. (9.3)

**octet rule** The tendency for most bonded atoms to possess or share eight electrons in their outer shell to obtain stable electron configurations and lower their potential energy. (9.3)

**optical isomers (enantiomers)** Two molecules that are nonsuperimposable mirror images of one another. (21.3, 25.4)

**orbital** A probability distribution map, based on the quantum-mechanical model of the atom, used to describe the likely position of an electron in an atom; also an allowed energy state for an electron. (7.5)

**orbital diagram** A diagram that gives information similar to an electron configuration but symbolizes an

electron as an arrow in a box representing an orbital, with the arrow's direction denoting the electron's spin. (8.3)

**ore** A rock that contains a high concentration of a specific mineral. (24.2)

**organic chemistry** The study of carbon-based compounds. (21.1)

**organic compound** A compound composed of carbon and hydrogen and possibly a few other elements, including nitrogen, oxygen, and sulfur. (3.12)

**organic molecule** A molecule containing carbon combined with several other elements including hydrogen, nitrogen, oxygen, or sulfur. (21.1)

**orientation factor** A factor in collision theory (usually between 0 and 1) that represents the fraction of collisions having an orientation that can allow the reaction to occur. (14.5)

**orthosilicates** Silicates in which tetrahedral  $\text{SO}_4^{4-}$  ions stand alone. (23.3)

**osmosis** The flow of solvent from a solution of lower solute concentration to one of higher solute concentration. (13.6)

**osmotic pressure** The pressure required to stop osmotic flow. (13.6)

**Ostwald process** An industrial process used for commercial preparation of nitric acid. (23.6)

**overall order** The sum of the orders of all reactants in a chemical reaction. (14.3)

**oxidation** The loss of one or more electrons; also the gaining of oxygen or the loss of hydrogen. (4.9)

**oxidation state (oxidation number)** A positive or negative whole number that represents the "charge" an atom in a compound would have if all shared electrons were assigned to the atom with a greater attraction for those electrons. (4.9)

**oxidation-reduction (redox) reaction** Reactions in which electrons are transferred from one reactant to another and the oxidation states of certain atoms are changed. (4.9)

**oxidizing agent** A substance that causes the oxidation of another substance; an oxidizing agent gains electrons and is reduced. (4.9)

**oxyacid** An acid composed of hydrogen and an oxyanion. (3.6)

**oxyanion** A polyatomic anion containing a nonmetal covalently bonded to one or more oxygen atoms. (3.5)

**oxygen toxicity** A physiological condition caused by an increased level of oxygen in the blood, resulting in muscle twitching, tunnel vision, and convulsions. (5.6)

**ozone**  $\text{O}_3$ , an allotrope of oxygen that is a toxic blue diamagnetic gas with a strong odor. (23.7)

**packing efficiency** The percentage of volume of a unit cell occupied by the atoms, assumed to be spherical. (12.3)

**paramagnetic** The state of an atom or ion that contains unpaired electrons and is, therefore, attracted by an external magnetic field. (8.7)

**partial pressure ( $P_n$ )** The pressure due to any individual component in a gas mixture. (5.6)

**parts by mass** A unit for expressing solution concentration as the mass of the solute divided by the mass of the solution multiplied by a multiplication factor. (13.5)

**parts by volume** A unit for expressing solution concentration as the volume of the solute divided by the volume of the solution multiplied by a multiplication factor. (13.5)

**parts per billion (ppb)** A unit for expressing solution concentration in parts by mass in which the multiplication factor is  $10^9$ . (13.5)

**parts per million (ppm)** A unit for expressing solution concentration in parts by mass in which the multiplication factor is  $10^6$ . (13.5)

**pascal (Pa)** The SI unit of pressure, defined as  $1 \text{ N/m}^2$ . (5.2)

**Pauli exclusion principle** The principle that no two electrons in an atom can have the same four quantum numbers. (8.3)

**penetrating power** The ability of radiation to penetrate matter. (20.3)

**penetration** The phenomenon of some higher-level atomic orbitals having significant amounts of probability within the space occupied by orbitals of lower energy level. For example, the 2s orbital penetrates into the 1s orbital. (8.3)

**peptide bond** The bond that forms between the amine end of one amino acid and the carboxylic end of another. (22.4)

**percent by mass** A unit for expressing solution concentration in parts by mass with a multiplication factor of 100%. (13.5)

**percent ionic character** The ratio of a bond's actual dipole moment to the dipole moment it would have if the electron were transferred completely from one atom to the other, multiplied by 100%. (9.6)

**percent ionization** The concentration of ionized acid in a solution divided by the initial concentration of acid multiplied by 100%. (16.6)

**percent yield** The percentage of the theoretical yield of a chemical reaction that is actually produced; the ratio of the actual yield to the theoretical yield multiplied by 100%. (4.3)

**periodic law** A law based on the observation that when the elements are arranged in order of increasing mass, certain sets of properties recur periodically. (2.7)

**periodic property** A property of an element that is predictable based on an element's position in the periodic table. (8.1)

**permanent dipole** A permanent separation of charge; a molecule with a permanent dipole always has a slightly negative charge at one end and a slightly positive charge at the other. (11.3)

**pH** The negative log of the concentration of  $\text{H}_3\text{O}^+$  in a solution; the pH scale is a compact way to specify the acidity of a solution. (16.5)

**phase** With regard to waves and orbitals, the phase is the sign of the amplitude of the wave, which can be positive or negative. (7.6)

**phase diagram** A map of the phase of a substance as a function of pressure and temperature. (11.8)

**phenyl group** A benzene ring treated as a substituent. (21.7)

**phosphine**  $\text{PH}_3$ ; a colorless, poisonous gas that smells like decaying fish and has an oxidation state of  $-3$  for phosphorus. (23.6)

**phospholipid** Compound similar in structure to a triglyceride but in which one fatty acid is replaced by a phosphate group. (22.2)

**phosphorescence** The long-lived emission of light that sometimes follows the absorption of light by certain atoms and molecules. (20.2)

**photoelectric effect** The observation that many metals emit electrons when light falls upon them. (7.2)

**photon (quantum)** The smallest possible packet of electromagnetic radiation with an energy equal to  $h\nu$ . (7.2)

**physical change** A change that alters only the state or appearance of a substance but not its chemical composition. (1.4)

**physical property** A property that a substance displays without changing its chemical composition. (1.4)

**pi ( $\pi$ ) bond** The bond that forms between two p orbitals that overlap side to side. (10.7)

**p-n junctions** Tiny areas in electronic circuits that have p-type semiconductors on one side and n-type on the other. (12.8)

**polar covalent bond** A covalent bond between two atoms with significantly different electronegativities, resulting in an uneven distribution of electron density. (9.6)

**polyatomic ion** An ion composed of two or more atoms. (3.4)

**polydentate** Describes ligands that donate more than one electron pair to the central metal. (25.3)

**polymer** A long chain-like molecule composed of repeating units called monomers. (12.9)

**polymorphs** The different crystal structures that can sometimes exist for the same compound. (12.4)

**polypeptide** A chain of amino acids joined together by peptide bonds. (22.4)

**polyprotic acid** An acid that contains more than one ionizable proton and releases them sequentially. (4.8, 16.9)

**polysaccharide** A long, chainlike molecule composed of many monosaccharide units bonded together. (22.3)

**Portland cement** A powdered mixture consisting mostly of limestone ( $\text{CaCO}_3$ ) and silica ( $\text{SiO}_2$ ), with smaller amounts of alumina ( $\text{Al}_2\text{O}_3$ ), iron(III) oxide ( $\text{Fe}_2\text{O}_3$ ), and gypsum ( $\text{CaSO}_4 \cdot 2\text{H}_2\text{O}$ ). (12.7)

**positron** The particle released in positron emission; equal in mass to an electron but opposite in charge. (20.3)

**positron emission** The form of radioactive decay that occurs when an unstable nucleus emits a positron. (20.3)

**positron emission tomography (PET)** A specialized imaging technique that employs positron-emitting nuclides, such as fluorine-18, as a radiotracer. (20.12)

**potential difference** A measure of the difference in potential energy (usually in joules) per unit of charge (coulombs). (19.3)

**potential energy** The energy associated with the position or composition of an object. (1.5, 6.2)

**powder metallurgy** A process by which metallic components are made from powdered metal. (24.3)

**precipitate** A solid, insoluble ionic compound that forms in, and separates from, a solution. (4.6)

**precipitation reaction** A reaction in which a solid, insoluble product forms when two solutions are mixed. (4.6)

**precision** A term that refers to how close a series of measurements are to one another or how reproducible they are. (1.7)

**prefix multipliers** Multipliers that change the value of the unit by powers of ten. (1.6)

**pressure** A measure of force exerted per unit area; in chemistry, most commonly the force exerted by gas molecules as they strike the surfaces around them. (5.1)

**pressure-volume work** The work that occurs when a volume change takes place against an external pressure. (6.4)

**primary structure** The sequence of amino acids in a protein chain. (22.5)

**primary valence** The oxidation state on the central metal atom in a complex ion. (25.3)

**principal level (shell)** The group of orbitals with the same value of  $n$ . (7.5)

**principal quantum number ( $n$ )** An integer that specifies the overall size and energy of an orbital. The higher the quantum number  $n$ , the greater the average distance between the electron and the nucleus and the higher its energy. (7.5)

**probability density** The probability (per unit volume) of finding the electron at a point in space as expressed by a three-dimensional plot of the wave function squared ( $\psi^2$ ). (7.6)

**products** The substances produced in a chemical reaction; they appear on the right-hand side of a chemical equation. (3.10)

**proton** A positively charged subatomic particle found in the nucleus of an atom. (2.5)

**p-type semiconductor** A semiconductor that employs positively charged “holes” in the valence band as the charge carriers. (12.8)

**pure substance** A substance composed of only one type of atom or molecule. (1.3)

**pyrometallurgy** A technique of extractive metallurgy in which heat is used to extract a metal from its mineral. (24.3)

**pyrosilicates** Silicates in which two  $\text{SO}_4^{4-}$  tetrahedral ions share a corner. (23.3)

**pyroxenes** Silicates in which  $\text{SO}_4^{4-}$  tetrahedral ions bond together to form chains. (23.3)

**qualitative analysis** A systematic way to determine the ions present in an unknown solution. (17.7)

**quantitative analysis** A systematic way to determine the amounts of substances in a solution or mixture. (17.7)

**quantum number** One of four interrelated numbers that determine the shape and energy of orbitals, as specified by a solution of the Schrödinger equation. (7.5)

**quantum-mechanical model** A model that explains the behavior of absolutely small particles such as electrons and photons. (7.1)

**quartz** A silicate crystal that has a formula unit of  $\text{SiO}_2$ . (12.6, 23.3)

**quaternary structure** The way that subunits fit together in a multi-meric protein. (22.5)

**racemic mixture** An equimolar mixture of two optical isomers that does not rotate the plane of polarization of light at all. (21.3)

**radial distribution function** A mathematical function (corresponding to a specific orbital) that represents the total probability of finding an electron within a thin spherical shell at a distance  $r$  from the nucleus. (7.6)

**radio waves** The form of electromagnetic radiation with the longest wavelengths and smallest energy. (7.2)

**radioactive** The state of those unstable atoms that emit subatomic particles or high-energy electromagnetic radiation. (20.1)

**radioactivity** The emission of subatomic particles or high-energy electromagnetic radiation by the unstable nuclei of certain atoms. (2.5, 20.1)

**radiocarbon dating** A form of radiometric dating based on the C-14 isotope. (20.6)

**radiometric dating** A technique used to estimate the age of rocks, fossils, or artifacts that depends on the presence of radioactive isotopes and their predictable decay with time. (20.6)

**radiotracer** A radioactive nuclide that has been attached to a compound or introduced into a mixture

in order to track the movement of the compound or mixture within the body. (20.12)

**random coil** A section of a protein's secondary structure that has less-regular patterns than  $\alpha$ -helices or  $\beta$ -pleated sheets. (22.5)

**random error** Error that has equal probability of being too high or too low. (1.7)

**Raoult's law** An equation used to determine the vapor pressure of a solution;  $P_{\text{soln}} = X_{\text{soln}} P_{\text{soln}}^{\circ}$ . (13.6)

**rate constant ( $k$ )** A constant of proportionality in the rate law. (14.3)

**rate law** A relationship between the rate of a reaction and the concentration of the reactants. (14.3)

**rate-determining step** The step in a reaction mechanism that occurs much more slowly than any of the other steps. (14.6)

**reactants** The starting substances of a chemical reaction; they appear on the left-hand side of a chemical equation. (3.11)

**reaction intermediates** Species that form in one step of a reaction mechanism and are consumed in another. (14.6)

**reaction mechanism** A series of individual chemical steps by which an overall chemical reaction occurs. (14.6)

**reaction order ( $n$ )** A value in the rate law that determines how the rate depends on the concentration of the reactants. (14.3)

**reaction quotient ( $Q_c$ )** The ratio, at any point in the reaction, of the concentrations of the products of a reaction raised to their stoichiometric coefficients to the concentrations of the reactants raised to their stoichiometric coefficients. (15.7)

**recrystallization** A technique used to purify solids in which the solid is put into hot solvent until the solution is saturated; when the solution cools, the purified solute comes out of solution. (13.4)

**red phosphorus** An allotrope of phosphorus similar in structure to white phosphorus but in which one of the bonds between two phosphorus atoms in the tetrahedron is broken; red phosphorus is more stable than white. (23.6)

**reducing agent** A substance that causes the reduction of another substance; a reducing agent loses electrons and is oxidized. (4.9)

**reduction** The gaining of one or more electrons; also the gaining of hydrogen or the loss of oxygen. (4.9)

**refining** A process in which the crude material is purified. (24.3)

**rem** A unit of the dose of radiation exposure that stands for roentgen equivalent man, where a roentgen is defined as the amount of radiation that produces  $2.58 \times 10^{-4}$  C of charge per kg of air. (20.11)

**resonance hybrid** The actual structure of a molecule that is intermediate between two or more resonance structures. (9.8)

**resonance structures** Two or more valid Lewis structures that are shown with double-headed arrows between them to indicate that the actual structure of the molecule is intermediate between them. (9.8)

**reversible** As applied to a reaction, the ability to proceed in either the forward or the reverse direction. (15.2)

**reversible process** A process that reverses direction upon an infinitesimally small change in some property (such as temperature or pressure) related to the reaction. (18.7)

**roasting** Heating that causes a chemical reaction between a furnace atmosphere and a mineral in order to process ores. (24.3)

**salt** An ionic compound formed in a neutralization reaction by the replacement of an  $H^+$  ion from the acid with a cation from the base. (4.8)

**salt bridge** An inverted, U-shaped tube containing a strong electrolyte (such as  $KNO_3$ ) that connects two half-cells, allowing a flow of ions that neutralizes charge buildup. (19.3)

**saturated fat** A triglyceride with no double bonds in the hydrocarbon chain; saturated fats tend to be solid at room temperature. (22.2)

**saturated hydrocarbon** A hydrocarbon containing no double bonds in the carbon chain. (21.4)

**saturated solution** A solution in which the dissolved solute is in dynamic equilibrium with any undissolved solute; any added solute will not dissolve in a saturated solution. (13.4)

**scientific law** A brief statement or equation that summarizes past observations and predicts future ones. (1.2)

**scintillation counter** A device that detects radioactivity using a material that emits ultraviolet or visible light in response to excitation by energetic particles. (20.5)

**second (s)** The SI standard unit of time, defined as the duration of 9,192,631,770 periods of the radiation emitted from a certain transition in a cesium-133 atom. (1.6)

**second law of thermodynamics** A law stating that for any spontaneous process, the entropy of the universe increases ( $\Delta S_{\text{univ}} > 0$ ). (18.3)

**secondary structure** The regular periodic or repeating patterns in the arrangement of protein chains. (22.5)

**secondary valence** The number of molecules or ions directly bound to the metal atom in a complex ion; also called the *coordination number*. (25.3)

**seesaw geometry** The molecular geometry of a molecule with trigonal bipyramidal electron geometry and one lone pair in an axial position. (10.3)

**selective precipitation** A process involving the addition of a reagent to a solution that forms a precipitate with one of the dissolved ions but not the others. (17.6)

**semiconductor** A material with intermediate electrical conductivity that can be changed and controlled. (2.7)

**semipermeable membrane** A membrane that selectively allows some substances to pass through but not others. (13.6)

**shielding** The effect on an electron of repulsion by electrons in lower-energy orbitals that screen it from the full effects of nuclear charge. (8.3)

**sigma ( $\sigma$ ) bond** The resulting bond that forms between a combination of any two *s*, *p*, or hybridized orbitals that overlap end to end. (10.7)

**significant figures (significant digits)** In any reported measurement, the non-place-holding digits that indicate the precision of the measured quantity. (1.7)

**silica** A silicate crystal that has a formula unit of  $SiO_2$ ; also called *quartz*. (12.6, 23.3)

**silicates** Covalent atomic solids that contain silicon, oxygen, and various metal atoms. (12.6, 23.3)

**simple cubic** A unit cell that consists of a cube with one atom at each corner. (12.3)

**slag** In pyrometallurgy, the waste liquid solution that is formed between the flux and gangue; usually a silicate material. (24.3)

**smelting** A form of roasting in which the product is liquefied, which aids in separation. (24.3)

**soda-lime glass** A type of glass that is about 70%  $SiO_2$  with the balance being mostly  $Na_2O$  and  $CaO$ . This type of glass is transparent to visible light (not ultraviolet) and has a high thermal expansion, but it is less expensive to make and form into desired shapes than vitreous silica. (12.7)

**solid** A state of matter in which atoms or molecules are packed close to one another in fixed locations with definite volume. (1.3)

**solubility** The amount of a substance that will dissolve in a given amount of solvent. (13.2)

**solubility product constant ( $K_{sp}$ )** The equilibrium expression for a chemical equation representing the dissolution of a slightly to moderately soluble ionic compound. (17.5)

**soluble** Able to dissolve to a significant extent, usually in water. (4.5)

**solute** The minority component of a solution. (4.4, 13.1)

**solution** A homogenous mixture of two substances. (4.4, 13.1)

**solvent** The majority component of a solution. (4.4, 13.1)

**soot** An amorphous form of carbon that forms during the incomplete combustion of hydrocarbons. (23.5)

**space-filling molecular model** A representation of a molecule that shows how the atoms fill the spaces between them. (3.3)

**specific heat capacity ( $C_p$ )** The amount of heat required to raise the temperature of 1 g of a substance by 1 °C. (6.4)

**spectator ion** Ions in a complete ionic equation that do not participate in the reaction and therefore remain in solution. (4.7)

**spin quantum number ( $m_s$ )** The fourth quantum number, which denotes the electron's spin as either  $1/2$  (up arrow) or  $-1/2$  (down arrow). (7.5)

**spontaneous process** A process that occurs without ongoing outside intervention. (18.2)

**square planar geometry** The molecular geometry of a molecule with octahedral electron geometry and two lone pairs. (10.3)

**square pyramidal geometry** The molecular geometry of a molecule with octahedral electron geometry and one lone pair. (10.3)

**standard cell potential (standard emf) ( $E^\circ_{\text{cell}}$ )** The cell potential for a system in standard states (solute concentration of 1 M and gaseous reactant partial pressure of 1 atm). (19.3)

**standard electrode potential** The potential of a half-cell in an electrochemical cell. (19.4)

**standard enthalpy change ( $\Delta H^\circ$ )** The change in enthalpy for a process when all reactants and products are in their standard states. (6.9)

**standard enthalpy (heat) of formation ( $\Delta H^\circ_f$ )** The change in

enthalpy when 1 mol of a compound forms from its constituent elements in their standard states. (6.9)

**standard entropy change for a reaction ( $\Delta S^\circ_{\text{rxn}}$ )** The change in entropy for a process in which all reactants and products are in their standard states. (18.7)

**standard free energy change ( $\Delta G^\circ_{\text{rxn}}$ )** The change in free energy for a process when all reactants and products are in their standard states. (18.8)

**Standard Hydrogen Electrode (SHE)** The half-cell consisting of an inert platinum electrode immersed in 1 M HCl with hydrogen gas at 1 atm bubbling through the solution; used as the standard of a cell potential of zero. (19.4)

**standard molar entropy ( $S^\circ$ )** A measure of the energy dispersed into 1 mol of a substance at a particular temperature. (18.7)

**standard state** For a gas the standard state is the pure gas at a pressure of exactly 1 atm; for a liquid or solid the standard state is the pure substance in its most stable form at a pressure of 1 atm and the temperature of interest (often taken to be 25 °C); for a substance in solution the standard state is a concentration of exactly 1 M. (6.9)

**standard temperature and pressure (STP)** The conditions of  $T = 0^\circ\text{C}$  (273 K) and  $P = 1$  atm; used primarily in reference to a gas. (5.5)

**starch** A polysaccharide that consists of glucose units bonded together by  $\alpha$ -glycosidic linkages; the main energy storage medium for plants. (22.3)

**state** A classification of the form of matter as a solid, liquid, or gas. (1.3)

**state function** A function whose value depends only on the state of the system, not on how the system got to that state. (6.3)

**stereoisomers** Molecules in which the atoms are bonded in the same order but have a different spatial arrangement. (21.3, 25.4)

**steroid** A lipid composed of four fused hydrocarbon rings. (22.2)

**stock solution** A highly concentrated form of a solution used

in laboratories to make less concentrated solutions via dilution. (4.4)

**stoichiometry** The numerical relationships between amounts of reactants and products in a balanced chemical equation. (4.2)

**strong acid** An acid that completely ionizes in solution. (4.5, 16.4)

**strong base** A base that completely dissociates in solution. (16.7)

**strong electrolyte** A substance that completely dissociates into ions when dissolved in water. (4.5)

**strong force** Of the four fundamental forces of physics, the one that is the strongest but acts over the shortest distance; the strong force is responsible for holding the protons and neutrons together in the nucleus of an atom. (20.4)

**strong-field complex** A complex ion in which the crystal field splitting is large. (25.5)

**structural formula** A molecular formula that shows how the atoms in a molecule are connected or bonded to each other. (3.3, 21.3)

**structural isomers** Molecules with the same molecular formula but different structures. (21.3, 25.4)

**sublevel (subshell)** Those orbitals in the same principle level with the same value of  $n$  and  $l$ . (7.5)

**sublimation** The phase transition from solid to gas. (11.6)

**substance** A specific instance of matter. (1.3)

**substitutional alloy** An alloy in which one metal atom substitutes for another in the crystal structure. (24.4)

**substrate** The reactant molecule of a biochemical reaction that binds to an enzyme at the active site. (14.7)

**supersaturated solution** An unstable solution in which more than the equilibrium amount of solute is dissolved. (13.4)

**surface tension** The energy required to increase the surface area of a liquid by a unit amount; responsible for the tendency of liquids to minimize their surface area, giving rise to a membrane-like surface. (11.4)

**surroundings** In thermodynamics, everything in the universe that exists outside the system under investigation. (6.2)

**system** In thermodynamics, the portion of the universe that is singled out for investigation. (6.2)

**systematic error** Error that tends toward being consistently either too high or too low. (1.7)

**systematic name** An official name for a compound, based on well-established rules, that can be determined by examining its chemical structure. (3.5)

**temperature** A measure of the average kinetic energy of the atoms or molecules that compose a sample of matter. (1.6)

**termolecular** An elementary step of a reaction in which three particles collide and go on to form products. (14.6)

**tertiary structure** The large-scale bends and folds produced by interactions between the R groups of amino acids that are separated by large distances in the linear sequence of a protein chain. (22.5)

**tetrahedral geometry** The molecular geometry of five atoms with  $109.5^\circ$  bond angles. (10.2)

**tetrahedral hole** A space that exists directly above the center point of three closest-packed metal atoms in one plane and a fourth metal located directly above the center point in the adjacent plane in a crystal lattice. (24.4)

**theoretical yield** The greatest possible amount of product that can be made in a chemical reaction based on the amount of limiting reactant. (4.3)

**theory** A proposed explanation for observations and laws, based on well-established and tested hypotheses, that presents a model of the way nature works and predicts behavior beyond the observations and laws on which it was based. (1.2)

**thermal energy** A type of kinetic energy associated with the temperature of an object, arising from the motion

of individual atoms or molecules in the object; see also *heat*. (1.5, 6.2)

**thermal equilibrium** The point at which there is no additional net transfer of heat between a system and its surroundings. (6.4)

**thermochemistry** The study of the relationship between chemistry and energy. (6.1)

**thermodynamics** The general study of energy and its interconversions. (6.3)

**thermoluminescent dosimeter** A device used to measure the dose of radiation to which a person is exposed. (20.5)

**third law of thermodynamics** The law stating that the entropy of a perfect crystal at absolute zero (0 K) is zero. (18.7)

**titration** A laboratory procedure in which a substance in a solution of known concentration is reacted with another substance in a solution of unknown concentration in order to determine the unknown concentration; see also *acid-base titration*. (4.8)

**torr** A unit of pressure named after Evangelista Torricelli and equivalent to  $1/760$  of an atmosphere (atm). (5.2)

**transition elements (transition metals)** Those elements found in the *d* block of the periodic table whose properties tend to be less predictable based simply on their position in the table. (2.7)

**transmutation** The transformation of one element into another as a result of nuclear reactions. (20.10)

**triglyceride** Triesters composed of glycerol with three fatty acids attached. (21.2)

**trigonal bipyramidal geometry** The molecular geometry of six atoms with  $120^\circ$  bond angles between the three equatorial electron groups and  $90^\circ$  bond angles between the two axial electron groups and the trigonal plane. (10.2)

**trigonal planar geometry** The molecular geometry of four atoms with  $120^\circ$  bond angles in a plane. (10.2)

**trigonal pyramidal geometry**

The molecular geometry of a molecule with tetrahedral electron geometry and one lone pair. (10.3)

**triple bond** The bond that forms when three electron pairs are shared between two atoms. (9.5)

**triple point** The unique set of conditions at which all three phases of a substance are equally stable and in equilibrium. (11.8)

**triprotic acid** An acid that contains three ionizable protons. (16.4)

**T-shaped geometry** The molecular geometry of a molecule with trigonal bipyramidal electron geometry and two lone pairs in axial positions. (10.3)

**two-phase region** The region between the two phases in a metal alloy phase diagram, where the amount of each phase depends upon the composition of the alloy. (24.4)

**Tyndall effect** The scattering of light by a colloidal dispersion. (13.8)

**ultraviolet (UV) radiation**

Electromagnetic radiation with slightly smaller wavelengths than visible light. (7.2)

**unimolecular** Describes a reaction that involves only one particle that goes on to form products. (14.6)

**unit cell** The smallest divisible unit of a crystal that, when repeated in three dimensions, reproduces the entire crystal lattice. (12.3)

**units** Standard quantities used to specify measurements. (1.6)

**unsaturated fat** A triglyceride with one or more double bonds in the hydrocarbon chain; unsaturated fats tend to be liquid at room temperature. (22.2)

**unsaturated hydrocarbon** A hydrocarbon that includes one or more double or triple bonds. (21.5)

**unsaturated solution** A solution containing less than the equilibrium amount of solute; any added solute will dissolve until equilibrium is reached. (13.4)

**valence band** In band theory, the band of energy levels that forms from bonding molecular orbitals. (12.8)

**valence bond theory** An advanced model of chemical bonding in which electrons reside in quantum-mechanical orbitals localized on individual atoms that are a hybridized blend of standard atomic orbitals; chemical bonds result from an overlap of these orbitals. (10.6)

**valence electrons** Those electrons that are important in chemical bonding. For main-group elements, the valence electrons are those in the outermost principal energy level. (8.4)

**valence shell electron pair repulsion (VSEPR) theory** A theory that allows prediction of the shapes of molecules based on the idea that electrons—either as lone pairs or as bonding pairs—repel one another. (10.2)

**van der Waals equation** The extrapolation of the ideal gas law that considers the effects of intermolecular forces and particle volume in a nonideal gas;

$$P + a\left(\frac{n}{V}\right)^2 \times (V - nb) = nRT. (5.10)$$

**van der Waals radius (nonbonding atomic radius)** Defined as one-half the distance between the centers of adjacent, nonbonding atoms in a crystal. (8.6)

**van't Hoff factor (*i*)** The ratio of moles of particles in a solution to

moles of formula units dissolved. (13.7)

**vapor pressure** The partial pressure of a vapor in dynamic equilibrium with its liquid. (5.6, 11.5)

**vapor pressure lowering ( $\Delta P$ )** The change in vapor pressure that occurs in pure substance upon addition of a solute. (13.6)

**vaporization** The phase transition from liquid to gas. (11.5)

**viscosity** A measure of the resistance of a liquid to flow. (11.4)

**visible light** Those frequencies of electromagnetic radiation that can be detected by the human eye. (7.2)

**vitreous (or fused) silica** A type of glass that is hard, resists high temperatures, has a low thermal expansion, and is transparent to both visible light and ultraviolet light. (12.7)

**volatile** Tending to vaporize easily. (1.3, 11.5)

**volt** A unit of potential difference defined as 1 J/C. (19.3)

**voltaic (galvanic) cell** An electrochemical cell that produces electrical current from a spontaneous chemical reaction. (19.3)

**volume (*V*)** A measure of space. Any unit of length, when cubed (raised to the third power), becomes a unit of volume. (1.6)

**washing soda** The hydrated crystal of sodium carbonate,  $\text{Na}_2\text{CO}_3 \cdot 10\text{H}_2\text{O}$ . (23.5)

**wave function ( $\psi$ )** A mathematical function that describes the wavelike nature of the electron. (7.5)

**wavelength ( $\lambda$ )** The distance between adjacent crests of a wave. (7.2)

**weak acid** An acid that does not completely ionize in water. (4.5, 16.4)

**weak base** A base that only partially ionizes in water. (16.7)

**weak electrolyte** A substance that does not completely ionize in water and only weakly conducts electricity in solution. (4.5)

**weak-field complex** A complex ion in which the crystal field splitting is small. (25.5)

**white phosphorus** An unstable allotrope of phosphorus consisting of  $\text{P}_4$  molecules in a tetrahedral shape, with the phosphorus atoms at the corners of the tetrahedron. (23.6)

**work (*w*)** The result of a force acting through a distance. (1.5, 6.2)

**X-ray crystallography** The process of using X-ray diffraction to determine the structure of a crystal. (12.2)

**X-ray diffraction** A powerful laboratory technique that allows for the determination of the arrangement of atoms in a crystal and the measuring of the distance between them. (12.2)

**X-ray** Electromagnetic radiation with wavelengths slightly longer than those of gamma rays; used to image bones and internal organs. (7.2)

## A

- A. *See* Ampere; Mass number
- A. *See* Frequency factor
- A. O. Smith Company, 1107
- Absolute concentration, 792, 794
- Absolute temperature scale (Kelvin scale), 15–16, 206
- Absolute zero, 205, 860
- Absorption spectra, 310–311
- Accuracy, 25–26
- Acetaldehyde (ethanal), 126, 1007–1009
- Acetate, 100
- Acetic acid
  - acid ionization constant for, 731
  - buffering by, 781, 782
  - as carboxylic acid, 126
  - double bonds in, 124
  - formula and uses of, 1009
  - reaction between salicylic acid and, 1011
  - strength of, 160, 169, 730
  - structure of, 725
  - uses of, 724
- Acetone, 39, 126
  - boiling point of, 504
  - charge density plot for, 1009
  - dipole–dipole force in, 492–493
  - formation of, 1008
  - heat of fusion of, 514
  - heat of vaporization of, 504
  - intermolecular forces in, 575
  - as solvent, 576
  - structure of, 1007
  - volatility of, 503
- Acetonitrile, 643–644
- Acetylene (ethyne)
  - from calcium carbide, 1074
  - formula of, 125, 994
  - hybrid orbitals of, 455–456
  - Lewis structure of, 980
  - representations of, 93
  - structure and properties of, 993
  - triple bonds in, 124
- Acetylde ion, 1073
- Acetylsalicylic acid, 479, 1011
- Acid(s). *See also* Acid–base chemistry;

<sup>a</sup>The labels on top (1A, 2A, etc.) are common American usage. The labels below these (1, 2, etc.) are those recommended by the International Union of Pure and Applied Chemistry.

Atomic masses in brackets are the masses of the longest-lived or most important isotope of radioactive elements.

\*The names of elements 113, 115, 117, and 118 are currently under review by IUPAC.

## List of Elements with Their Symbols and Atomic Masses

Element	Symbol	Atomic Number	Atomic Mass
Actinium	Ac	89	227.03 <sup>a</sup>
Aluminum	Al	13	26.98
Americium	Am	95	243.06 <sup>a</sup>
Antimony	Sb	51	121.76
Argon	Ar	18	39.95
Arsenic	As	33	74.92
Astatine	At	85	209.99 <sup>a</sup>
Barium	Ba	56	137.33
Berkelium	Bk	97	247.07 <sup>a</sup>
Beryllium	Be	4	9.012
Bismuth	Bi	83	208.98
Bohrium	Bh	107	264.12 <sup>a</sup>
Boron	B	5	10.81
Bromine	Br	35	79.90
Cadmium	Cd	48	112.41
Calcium	Ca	20	40.08
Californium	Cf	98	251.08 <sup>a</sup>
Carbon	C	6	12.01
Cerium	Ce	58	140.12
Cesium	Cs	55	132.91
Chlorine	Cl	17	35.45
Chromium	Cr	24	52.00
Cobalt	Co	27	58.93
Copernicium	Cn	112	285 <sup>a</sup>
Copper	Cu	29	63.55
Curium	Cm	96	247.07 <sup>a</sup>
Darmstadtium	Ds	110	271 <sup>a</sup>
Dubnium	Db	105	262.11 <sup>a</sup>
Dysprosium	Dy	66	162.50
Einsteinium	Es	99	252.08 <sup>a</sup>
Erbium	Er	68	167.26
Europium	Eu	63	151.96
Fermium	Fm	100	257.10 <sup>a</sup>
Flerovium	Fl	114	289 <sup>a</sup>
Fluorine	F	9	19.00
Francium	Fr	87	223.02 <sup>a</sup>
Gadolinium	Gd	64	157.25
Gallium	Ga	31	69.72
Germanium	Ge	32	72.63
Gold	Au	79	196.97
Hafnium	Hf	72	178.49
Hassium	Hs	108	269.13 <sup>a</sup>
Helium	He	2	4.003
Holmium	Ho	67	164.93
Hydrogen	H	1	1.008
Indium	In	49	114.82
Iodine	I	53	126.90
Iridium	Ir	77	192.22
Iron	Fe	26	55.85
Krypton	Kr	36	83.80
Lanthanum	La	57	138.91
Lawrencium	Lr	103	262.11 <sup>a</sup>
Lead	Pb	82	207.2
Lithium	Li	3	6.94
Livermorium	Lv	116	292 <sup>a</sup>
Lutetium	Lu	71	174.97
Magnesium	Mg	12	24.31
Manganese	Mn	25	54.94

<sup>a</sup>Mass of longest-lived or most important isotope.

<sup>b</sup>The names of these elements have not yet been decided.

Element	Symbol	Atomic Number	Atomic Mass
Meitnerium	Mt	109	268.14 <sup>a</sup>
Mendelevium	Md	101	258.10 <sup>a</sup>
Mercury	Hg	80	200.59
Molybdenum	Mo	42	95.96
Neodymium	Nd	60	144.24
Neon	Ne	10	20.18
Neptunium	Np	93	237.05 <sup>a</sup>
Nickel	Ni	28	58.69
Niobium	Nb	41	92.91
Nitrogen	N	7	14.01
Nobelium	No	102	259.10 <sup>a</sup>
Osmium	Os	76	190.23
Oxygen	O	8	16.00
Palladium	Pd	46	106.42
Phosphorus	P	15	30.97
Platinum	Pt	78	195.08
Plutonium	Pu	94	244.06 <sup>a</sup>
Polonium	Po	84	208.98 <sup>a</sup>
Potassium	K	19	39.10

## Conversion Factors and Relationships

### Length

SI unit: meter (m)

1 m	= 1.0936 yd
1 cm	= 0.39370 in
1 in	= 2.54 cm (exactly)
1 km	= 0.62137 mi
1 mi	= 5280 ft
	= 1.6093 km
1 Å	= $10^{-10}$ m

### Temperature

SI unit: kelvin (K)

0 K	= $-273.15^{\circ}\text{C}$
	= $-459.67^{\circ}\text{F}$
K	= $^{\circ}\text{C} + 273.15$
$^{\circ}\text{C}$	= $\frac{(^{\circ}\text{F} - 32)}{1.8}$
$^{\circ}\text{F}$	= $1.8(^{\circ}\text{C}) + 32$

### Energy (derived)

SI unit: joule (J)

1 J	= $1 \text{ kg} \cdot \text{m}^2/\text{s}^2$
	= 0.23901 cal
	= 1 C · V
	= $9.4781 \times 10^{-4}$ Btu
1 cal	= 4.184 J
1 eV	= $1.6022 \times 10^{-19}$ J

### Pressure (derived)

SI unit: pascal (Pa)

1 Pa	= $1 \text{ N}/\text{m}^2$
	= $1 \text{ kg}/(\text{m} \cdot \text{s}^2)$
1 atm	= 101,325 Pa
	= 760 torr
	= 14.70 lb/in <sup>2</sup>
1 bar	= $10^5$ Pa
1 torr	= 1 mmHg

### Volume (derived)

SI unit: cubic meter (m<sup>3</sup>)

1 L	= $10^{-3} \text{ m}^3$
	= 1 dm <sup>3</sup>
	= $10^3 \text{ cm}^3$
	= 1.0567 qt
1 gal	= 4 qt
	= 3.7854 L
1 cm <sup>3</sup>	= 1 mL
1 in <sup>3</sup>	= 16.39 cm <sup>3</sup>
1 qt	= 32 fluid oz

### Mass

SI unit: kilogram (kg)

1 kg	= 2.2046 lb
1 lb	= 453.59 g
	= 16 oz
1 amu	= $1.66053873 \times 10^{-27}$ kg
1 ton	= 2000 lb
	= 907.185 kg
1 metric ton	= 1000 kg
	= 2204.6 lb

### Geometric Relationships

$$\pi = 3.14159 \dots$$

$$\text{Circumference of a circle} = 2\pi r$$

$$\text{Area of a circle} = \pi r^2$$

$$\text{Surface area of a sphere} = 4\pi r^2$$

$$\text{Volume of a sphere} = \frac{4}{3}\pi r^3$$

$$\text{Volume of a cylinder} = \pi r^2 h$$

### Fundamental Constants

Atomic mass unit	1 amu 1 g	= $1.66053873 \times 10^{-27}$ kg = $6.02214199 \times 10^{23}$ amu
Avogadro's number	$N_A$	= $6.02214179 \times 10^{23}/\text{mol}$
Bohr radius	$a_0$	= $5.29177211 \times 10^{-11}$ m
Boltzmann's constant	$k$	= $1.38065052 \times 10^{-23}$ J/K
Electron charge	$e$	= $1.60217653 \times 10^{-19}$ C
Faraday's constant	$F$	= $9.64853383 \times 10^4$ C/mol
Gas constant	$R$	= 0.08205821 (L · atm)/(mol · K) = 8.31447215 J/(mol · K)
Mass of an electron	$m_e$	= $5.48579909 \times 10^{-4}$ amu = $9.10938262 \times 10^{-31}$ kg
Mass of a neutron	$m_n$	= 1.00866492 amu = $1.67492728 \times 10^{-27}$ kg
Mass of a proton	$m_p$	= 1.00727647 amu = $1.67262171 \times 10^{-27}$ kg
Planck's constant	$h$	= $6.62606931 \times 10^{-34}$ J · s
Speed of light in vacuum	$c$	= $2.99792458 \times 10^8$ m/s (exactly)

### SI Unit Prefixes

a	f	p	n	μ	m	c	d	k	M	G	T	P	E
atto	femto	pico	nano	micro	milli	centi	deci	kilo	mega	giga	tera	peta	exa
$10^{-18}$	$10^{-15}$	$10^{-12}$	$10^{-9}$	$10^{-6}$	$10^{-3}$	$10^{-2}$	$10^{-1}$	$10^3$	$10^6$	$10^9$	$10^{12}$	$10^{15}$	$10^{18}$

## Selected Key Equations

### Density (1.6)

$$d = \frac{m}{V}$$

### Solution Dilution (4.4)

$$M_1 V_1 = M_2 V_2$$

### Ideal Gas Law (5.4)

$$PV = nRT$$

### Dalton's Law (5.6)

$$P_{\text{total}} = P_a + P_b + P_c + \dots$$

### Mole Fraction (5.6)

$$\chi_a = \frac{n_a}{n_{\text{total}}}$$

### Average Kinetic Energy (5.8)

$$KE_{\text{avg}} = \frac{3}{2} RT$$

### Root Mean Square Velocity (5.8)

$$u_{\text{rms}} = \sqrt{\frac{3RT}{M}}$$

### Effusion (5.9)

$$\frac{\text{rate A}}{\text{rate B}} = \sqrt{\frac{M_B}{M_A}}$$

### Van der Waals Equation (5.10)

$$\left[ P + a \left( \frac{n}{V} \right)^2 \right] \times [V - nb] = nRT$$

### Kinetic Energy (6.2)

$$KE = \frac{1}{2} mv^2$$

### Internal Energy (6.3)

$$\Delta E = q + w$$

### Heat Capacity (6.4)

$$q = m \times C_s \times \Delta T$$

### Pressure-Volume Work (6.4)

$$w = -P \Delta V$$

### Change in Enthalpy (6.6)

$$\Delta H = \Delta E + P \Delta V$$

### Standard Enthalpy of Reaction (6.9)

$$\Delta H_{\text{rxn}}^\circ = \sum n_p \Delta H_f^\circ(\text{products}) - \sum n_r \Delta H_f^\circ(\text{reactants})$$

### Frequency and Wavelength (7.2)

$$\nu = \frac{c}{\lambda}$$

### Energy of a Photon (7.2)

$$E = h\nu$$

$$E = \frac{hc}{\lambda}$$

### De Broglie Relation (7.4)

$$\lambda = \frac{h}{mv}$$

### Heisenberg's Uncertainty Principle (7.4)

$$\Delta x \times m \Delta v \geq \frac{h}{4\pi}$$

### Energy of Hydrogen Atom Levels (7.5)

$$E_n = -2.18 \times 10^{-18} \text{ J} \left( \frac{1}{n^2} \right) \quad (n = 1, 2, 3 \dots)$$

### Coulomb's Law (8.3)

$$E = \frac{1}{4\pi\epsilon_0} \frac{q_1 q_2}{r}$$

### Dipole Moment (9.6)

$$\mu = qr$$

### Clausius-Clapeyron Equation (11.5)

$$\ln P_{\text{vap}} = \frac{-\Delta H_{\text{vap}}}{RT} + \ln \beta$$

$$\ln \frac{P_2}{P_1} = \frac{-\Delta H_{\text{vap}}}{R} \left[ \frac{1}{T_2} - \frac{1}{T_1} \right]$$

### Henry's Law (13.4)

$$S_{\text{gas}} = k_H P_{\text{gas}}$$

### Raoult's Law (13.6)

$$P_{\text{solution}} = \chi_{\text{solvent}} P_{\text{solvent}}^\circ$$

### Freezing Point Depression (13.6)

$$\Delta T_f = m \times K_f$$

### Boiling Point Elevation Constant (13.6)

$$\Delta T_b = m \times K_b$$

### Osmotic Pressure (13.6)

$$\Pi = MRT$$

### The Rate Law (14.3)

$$\text{Rate} = k[A]^n \quad (\text{single reactant})$$

$$\text{Rate} = k[A]^m[B]^n \quad (\text{multiple reactants})$$

### Integrated Rate Laws and Half-Life (14.4)

Order	Integrated Rate Law	Half-Life Expression
0	$[A]_t = -kt + [A]_0$	$t_{1/2} = \frac{[A]_0}{2k}$
1	$\ln[A]_t = -kt + \ln[A]_0$	$t_{1/2} = \frac{0.693}{k}$
2	$\frac{1}{[A]_t} = kt + \frac{1}{[A]_0}$	$t_{1/2} = \frac{1}{k[A]_0}$

### Arrhenius Equation (14.5)

$$k = A e^{\frac{-E_a}{RT}}$$

$$\ln k = -\frac{E_a}{R} \left( \frac{1}{T} \right) + \ln A \quad (\text{linearized form})$$

$$k = pz e^{\frac{-E_a}{RT}} \quad (\text{collision theory})$$

### $K_c$ and $K_p$ (15.4)

$$K_p = K_c(RT)^{\Delta n}$$

### pH Scale (16.5)

$$\text{pH} = -\log[\text{H}_3\text{O}^+]$$

### Henderson-Hasselbalch Equation (17.2)

$$\text{pH} = \text{p}K_a + \log \frac{[\text{base}]}{[\text{acid}]}$$

### Entropy (18.3)

$$S = k \ln W$$

### Change in the Entropy of the Surroundings (18.5)

$$\Delta S_{\text{surr}} = \frac{-\Delta H_{\text{sys}}}{T}$$

### Change in Gibbs Free Energy (18.6)

$$\Delta G = \Delta H - T \Delta S$$

### The Change in Free Energy: Nonstandard Conditions (18.9)

$$\Delta G_{\text{rxn}} = \Delta G_{\text{rxn}}^\circ + RT \ln Q$$

### $\Delta G_{\text{rxn}}^\circ$ and $K$ (18.10)

$$\Delta G_{\text{rxn}}^\circ = -RT \ln K$$

### Temperature Dependence of the Equilibrium Constant (18.10)

$$\ln K = -\frac{\Delta H_{\text{rxn}}^\circ}{R} \left( \frac{1}{T} \right) + \frac{\Delta S_{\text{rxn}}^\circ}{R}$$

### $\Delta G^\circ$ and $E_{\text{cell}}^\circ$ (19.5)

$$\Delta G^\circ = -nF E_{\text{cell}}^\circ$$

### $E_{\text{cell}}^\circ$ and $K$ (19.5)

$$E_{\text{cell}}^\circ = \frac{0.0592 \text{ V}}{n} \log K$$

### Nernst Equation (19.6)

$$E_{\text{cell}} = E_{\text{cell}}^\circ - \frac{0.0592 \text{ V}}{n} \log Q$$

### Einstein's Energy-Mass Equation (20.8)

$$E = mc^2$$
